Mean reading F0 increased from 152 Hz preoperatively to 196.4 Hz at 4 weeks ($p < 0.0001$) and 188.5 Hz at 3 months postoperatively ($p < 0.0001$). Similarly, mean free-speaking F0 increased from 149.5 Hz to 190.8 Hz at 4 weeks ($p = 0.0002$) and 184.3 Hz at 3 months ($p < 0.0001$).

Mean VHI-10 scores improved from 18.05 preoperatively to 11.38 postoperatively ($p = 0.0008$). TWVQ scores also demonstrated significant improvement, decreasing from 73.26 to 52.85 ($p = 0.0005$).

Perceived vocal femininity showed significant improvement on visual analogue scale (VAS) assessment for both reading voice ($p = 0.0154$) and free-speaking voice ($p = 0.0068$), as rated by two blinded assessors.

However, there was a small deterioration in perceptual overall grade (Grade, GRBAS scale) for free-speaking voice quality following surgery (1.0 vs 1.3, $p = 0.0312$). A similar trend was observed for reading voice quality ($p = 0.0654$).

CONCLUSIONS

VFMR appears to be an effective second-line intervention for transfeminine patients in whom glottoplasty fails to achieve satisfactory pitch elevation. The procedure demonstrates significant improvements in both objective acoustic measures and patient-reported outcomes, while maintaining acceptable voice quality.

OP-591

The Effectiveness Of Platelet Rich Plasma (PRP) Injection In The Treatment Of Sulcus Vocalis

Akın Şahin[1], **Necati Enver**[2], **Ceren Yılmaz**[2]

[1]*Akın Şahin Private Practice Clinic;* [2]*Necati Enver Private Practice Clinic*

BACKGROUND & AIM

Sulcus vocalis and vocal fold atrophy present significant challenges in phonosurgery due to the loss of lamina propria volume and elasticity. Platelet-Rich Plasma (RPP) has emerged as a regenerative therapy to improve vocal fold vibration and glottal closure. This study aims to evaluate the clinical efficacy of PRP injections using subjective and objective voice parameters.

MATERIAL & METHODS

This clinical study included 20 patients diagnosed with sulcus vocalis. Patients were followed for 6 months using Voice Handicap Index (VHI), Reflux Symptom Index (RSI), Dysphonia Severity Index (DSI), and Maximum Phonation Time (MFS) for vowels /A, S, Z, İ/.

RESULTS

A significant improvement was observed in RSI scores, decreasing from a pre-operative mean of 15.6 to 9.0 post-operatively ($p < 0.05$). Objective phonatory endurance showed marked enhancement; specifically, MFS-A (Maximum Phonation Time for /A/) improved by 67%, increasing from 11.2s to 18.7s by the 6th month. MFS-Z scores also showed a 55% increase (11.3s to 17.5s). VHI scores remained stable, while DSI showed clinical trends toward improvement.

CONCLUSIONS

PRP injection is an effective and safe regenerative treatment for sulcus vocalis, significantly improving reflux-related symptoms and objective vocal endurance over a 6-month period.

Zopapogene Imadenovec-Drba, A Novel Adenovector-Based Immunotherapy, Induces Complete And Durable Responses In Recurrent Respiratory Papillomatosis

Gaetano Bonifacio[2], **Scott M Norberg**[1], **Roshanak Semnani**[2], **Tasha Tan**[2], **David M Dalton**[2], **Premkumar V Giridhar**[2], **Amy Lankford**[2], **Helen Sabzevari**[2], **Clint T Allen**[1,3]

[1]Center for Immuno-Oncology, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, Maryland, USA; [2]Precigen, Inc. Germantown, Maryland, USA; [3]Surgical Oncology Program, Center for Cancer Research, National Cancer Institute, National Institutes of Health, Bethesda, Maryland, USA

BACKGROUND & AIM

Recurrent respiratory papillomatosis (RRP) is a rare, neoplastic disorder caused by chronic human papillomavirus (HPV) type 6 or 11 infection. Repeat surgical debulking has historically been the most common treatment for RRP symptom management. Zopapogene imadenovec-drba (zopa), a novel adenoviral vector-based immunotherapy, is the first and only FDA-approved treatment for adults with RRP. Zopa is now recommended as the first-line treatment for adults with RRP in an RRP Foundation position statement authored by 16 key opinion leaders (Best et al, Laryngoscope 2026.)

MATERIAL & METHODS

The pivotal trial (NCT04724980) evaluated zopa in patients with RRP requiring ≥3 clinically indicated interventions 12 months (m) prior to treatment. 12m follow-up data was reported and demonstrated that 4 subcutaneous injections of zopa (5x1011 particle units per injection; n=35) were well-tolerated, with no serious adverse events, no grade >2 treatment-related adverse events, and no early treatment discontinuations. The most common adverse events were injection-site reaction, fatigue, chills, fever, and myalgia.

Robust efficacy was observed following zopa treatment with 51% (34 to 69; 95% CI) of patients achieving a complete response (CR), defined as no requirement for interventions in the 12m following treatment. Here we present data up to 51m of follow-up.

RESULTS

As of December 15, 2025, with a median duration of follow-up of 36m (range: 30-51m), 83% (15/18) of patients who achieved a CR at 12m remain in CR with no recurrence of papilloma requiring surgical or medical intervention. Out of the 15 patients remaining in CR, 3 patients have reached 4 years of follow-up.

No new safety events were observed during long-term follow-up.

CONCLUSIONS

Zopa treatment demonstrated significant clinical benefit with the vast majority of CR patients experiencing ongoing durable complete responses for up to 4 years with excellent long-term safety. Updated follow-up results for all patients achieving CR will be available at the time of presentation.

Clinical Variation In The Surgical Management Of Idiopathic Subglottic Stenosis: An International Multidisciplinary Quantitative And Qualitative Study

Emilie A.C. Dronkers, MD, MPH, PhD[1], **Jip Y Mulders, MD, MPH**[1], **Dale Ekbom, MD, PhD**[2], **Alexander H Gelbard, MD, PhD**[3], **Karla O'Dell, MD, PhD**[4], **Ricky Thakrar, MD, PhD**[5], **Ad Verhagen, MD, PhD**[6], **Chadwan Al Yaghchi, MD, PhD**[7]

[1]Department of Otolaryngology-Head and Neck Surgery, LUMC Expert Center for Laryngology, Leiden University Medical Center, Leiden, The Netherlands; [2]Alix School of Medicine, Mayo Clinic, Rochester, Minnesota, USA; [3]Department of Otolaryngology-Head & Neck Surgery, Vanderbilt University Medical Center, Nashville, Tennessee, USA.; [4]USC Voice Center, Los Angeles, California, USA; [5]Department of Thoracic Medicine, University College London Hospital, London, UK.; [6]Department of Cardio-thoracic Surgery, Radboud University Medical Center, Nijmegen, the Netherlands.; [7]National Centre for Airway Reconstruction, Imperial College Healthcare NHS Trust, London, United Kingdom

BACKGROUND & AIM

Idiopathic subglottic stenosis (iSGS) is a rare, fibroinflammatory airway disorder with non-standardized management. This study aimed to quantify the global clinical variation in surgical strategies for iSGS and identify barriers and facilitators to the adoption of both established and novel techniques.

MATERIAL & METHODS

An international cross-sectional online survey was responded by 193 clinicians (Otolaryngologists, Thoracic Surgeons, and Interventional Pulmonologists) across 42 countries. Data on demographics, technique execution, treatment algorithms, clinician satisfaction (7-point Likert scale), and adoption barriers were collected. Both statistical analysis and thematic analysis were done.

RESULTS

Otolaryngologists constituted the majority of respondents (84%), predominantly from Europe (52%) and North America (28%). Endoscopic Dilation was nearly universal (95%), but execution was heterogenous (85% used occlusive balloons, 56% CO2 laser). Newer techniques showed varied adoption: In-office Serial Intralesional Steroid Injections were used by 57% of clinicians, and the Maddern Procedure by 17%. Overall satisfaction with current treatment strategies was moderate (mean Likert score 5.07; SD=1.15). Significant variation was found in the definition of treatment failure. Fellowship-trained surgeons managed higher case volumes and were more likely to perform complex open surgery (p=0.019). Key barriers to adoption included lack of experience and insufficient supporting evidence.

CONCLUSIONS

Significant global clinical variation exists in the management of iSGS, affecting surgical technique, adjuvant therapy, and the definition of treatment failure. Standardization of clinical outcomes, continued large-scale comparative effectiveness trials, and newer efforts aimed at implementing emerging evidence are needed to reduce variability, establish evidence-based guidelines, and improve global patient care for this complex disease.

Tissue Expression Of IL-6/LIF/LIFR And CXCL9 Is Associated With High-Risk NBI Patterns And Squamous Cell Carcinoma In Vocal Fold Lesions

Magda Barańska[1], **Katarzyna Taran**[2], **Wioletta Pietruszewska**[1]

[1]Medical University of Lodz, Department of Otolaryngology, Head and Neck Oncology; [2]Medical University of Lodz, Department of Pathomorphology, Chair of Oncology

BACKGROUND & AIM

Laryngeal squamous cell carcinoma (LSCC) carries substantial mortality, and preoperative risk stratification remains imperfect. Narrow-Band Imaging (NBI) visualizes mucosal microvascular remodelling, yet the molecular correlates of high-risk vascular phenotypes are incompletely defined. We hypothesized that epithelial expression of interleukin-6 (IL-6), leukaemia inhibitory factor (LIF), its receptor (LIFR) and C-X-C motif chemokine ligand 9 (CXCL9) tracks NBI-defined microvascular patterns and histopathological severity, and that combining tissue markers with NBI refines discrimination of squamous cell carcinoma (SCC).

MATERIAL & METHODS

In a prospective single-centre cohort of 145 patients with vocal fold lesions (2020–2023), NBI patterns were graded with the Ni classification and dichotomized at Ni ≥ 4. Histopathology followed WHO 2017. Epithelial IL-6, LIF, LIFR and CXCL9 were quantified by immunohistochemistry using the immunoreactive score (IRS). Inter- and intra-observer reliability was assessed (Cohen's κ, intraclass correlation coefficient). Group differences were analyzed with non-parametric tests; predictors of SCC were evaluated by univariable and multivariable logistic regression, with discrimination quantified by area under the ROC curve (AUC).

RESULTS

SCC was diagnosed in 63/145 (43.4%) lesions. Ni category showed a stepwise association with histopathology (Cramér's V = 0.56; trend $p = 2.1 \times 10^{-17}$). The Ni ≥ 4 threshold yielded sensitivity 82.5%, specificity 82.9%, accuracy 82.8%. Epithelial LIF and LIFR decreased with histological severity and with higher NBI grade (Spearman ρ = −0.56 and −0.48, both $p < 10^{-9}$); CXCL9 increased modestly (ρ = +0.23, p = 0.006); epithelial IL-6 did not differ across categories. In multivariable logistic regression, Ni ≥ 4 was the strongest independent predictor of SCC (adjusted odds ratio [OR] 8.90, 95% CI 2.97–26.62), while LIF (adjusted OR 0.73) and LIFR (adjusted OR 0.78) were independently inversely associated with SCC (model AUC 0.943).

CONCLUSIONS

NBI Ni ≥ 4 grading is the dominant single discriminator of vocal fold SCC. Tissue LIF/LIFR and CXCL9 show distinct, biologically plausible associations with NBI risk phenotypes—LIF/LIFR consistent with loss of differentiation-associated signalling, CXCL9 with immune–vascular activation and may complement NBI. Absence of an epithelial IL-6 signal supports microenvironmental trans-signalling rather than epithelial abundance as the operative IL-6 mechanism in LSCC.

CELLULAR ATLAS OF HUMAN VOCAL FOLD EPITHELIUM ACROSS THE LIFESPAN AND VOCAL FOLD ORGANOID BIOLOGY

Vlasta Lungova[1], **Elliot Xie**[2], **Jie Cai**[1], **Christina Kendziorski**[2], **Susan L Thibeault**[1]

[1]Department of Otolaryngology, University of Wisconsin Madison, Madison WI, USA; [2]Department of Biostatistics and Medical Informatics, University of Wisconsin Madison. Madison, WI, USA

BACKGROUND & AIM

The vocal fold (VF) epithelium is a critical barrier required for maintaining healthy VF function, and its disruption can lead to changes in the lamina propria and impaired phonation. Defining cell types that constitute VF epithelium—and how they develop across the lifespan—is therefore essential for understanding their roles in VF diseases. In this study, we performed histological evaluation and single-cell RNA sequencing to characterize epithelial cell development during fetal stages and adulthood. We also cultured these cells in vitro, generating VF organoids that recapitulated epithelial stratification.

MATERIAL & METHODS

Human larynges and VFs were collected at multiple stages of fetal development and adulthood. Collected tissues were enzymatically dissociated and processed for single-cell RNA sequencing to generate transcriptional profiles across developmental time points. In parallel, tissue samples were fixed and processed for histological analysis to assess tissue architecture and cellular organization, while additional specimens were used to establish three-dimensional organoid cell cultures for functional studies.

RESULTS

Our data show that early fetal VF epithelium is a two-layered structure composed of basal (BEC) and immature suprabasal cells (SBEC) that are highly enriched for cell adhesion and migration pathways. This is consistent with early morphogenetic events, such as epithelial invagination and cavitation required for laryngeal tube recanalization and separation of false and true VFs. In later fetal stages, VF epithelium becomes multilayered and functionally specialized, forming respiratory-lineage cell types along the superior VF margin and subglottis, and stratified squamous epithelium in VF contact region. Notably, many of the cell types that first emerge in early VF development persist into adulthood—including highly specialized BEC and SBEC linked to innate immunity and enriched for macrophage-related genes.

When harvested and cultured in vitro, epithelial cells assemble into organoids that reestablish the full epithelial architecture, including basal, suprabasal, and terminally differentiated superficial layers.

CONCLUSIONS

Together, these findings advance our understanding of VF epithelial development and biology and offer new models for investigating mechanisms underlying VF diseases.

Impact Of COVID-19 On Tracheostomy Training Of Indian Otorhinolaryngology–Head And Neck Surgery (ORLHNS) Residents

Roopsa Saha[2], **Amrita Bhattacharya**[3], **Parichay Panda**[4], **Ranjan Raychowdhury**[1]

[1]Ramakrishna Mission Seva Pratishthan Vivekananda Institute of Medical Sciences; [2]Dr. B. C. Roy Post Graduate Institute of Pediatric Sciences, Kolkata, India; [3]Sarat Chandra Chattopadhyay Government Medical College & Hospital, Howrah, West Bengal, India; [4]Ghatal Subdivisional Hospital & Superspecilty Hospital, Paschim Medinipur, West Bengal, India

BACKGROUND & AIM

The COVID-19 pandemic reshaped surgical training worldwide. This study compares tracheostomy training among Indian ORLHNS residents before and after the pandemic, using a 2020 national survey as a baseline.

MATERIAL & METHODS

A structured survey was conducted in 2024 among ORLHNS residents and senior residents across India. Responses were compared with the 2020 national survey to evaluate changes in clinical exposure, procedural responsibility, operative technique, and trainee confidence.

RESULTS

Post-pandemic, residents reported substantially greater hands-on tracheostomy experience. More procedures were performed by second- and third-year trainees, including in emergencies. A shift toward faster incision techniques in acute scenarios was noted. Trainee confidence improved significantly, with more residents feeling prepared to perform the procedure independently. However, exposure to advanced methods such as percutaneous tracheostomy remained limited.

CONCLUSIONS

Tracheostomy training in the post-pandemic era shows earlier engagement, increased autonomy, and higher self-assurance among trainees. Despite progress, variability in exposure and technique highlights the need for a unified, competency-based national curriculum to standardize training across programs.

Chatgpt Hallucination Frequency In Clinical Text Mining And Comparative Performance With ENT Residents In Laryngeal Cancer Risk Classification

Ozgur Kemal[1], **Nurlan Majidov**[1], **Kadir Emre Kiliç**[1], **Erkin Koray Teke**[1], **İrem Nur Kabakçı**[1], **Esra Demir**[1]

[1]Samsun Ondokuz Mayıs University

BACKGROUND & AIM

The increasing use of large language models (LLMs) in clinical text analysis has introduced new opportunities for clinical decision support systems. However, hallucination—defined as the generation of information not supported by source data—remains a major limitation for clinical reliability. In otorhinolaryngology, evidence regarding the reliability of artificial intelligence in malignancy risk assessment from clinical texts is limited. This study aimed to evaluate the hallucination frequency of ChatGPT during clinical text mining and to compare its performance with ENT resident physicians in laryngeal cancer risk classification using histopathological diagnosis as the reference standard.

MATERIAL & METHODS

Materials & MethodsThis single-center retrospective study included clinical records of patients who underwent direct laryngoscopy at the Department of Otorhinolaryngology, Ondokuz Mayıs University. Approximately 350 patients were analyzed.The study has three sequential phases:Calibration phase: adaptation of the AI system to clinical terminology using 50 patient files.Hallucination assessment phase: evaluation of hallucination frequency in 200 patients by comparing AI-generated outputs with original clinical records.Blind risk classification phase: independent malignancy risk classification of 100 patients by ChatGPT and five ENT residents using only clinical texts.Histopathological diagnosis was accepted as the gold standard. Sensitivity, specificity, overall accuracy, and Spearman correlation coefficients were calculated using SPSS software.

RESULTS

At least one hallucination was detected in 46% of evaluated patients, while major hallucinations occurred in 13%.

In malignancy risk classification, ChatGPT demonstrated a sensitivity of 59.4% and specificity of 80.9%, showing performance comparable to several ENT residents. Statistically significant correlations between risk classification and histopathological diagnosis were observed for all evaluators ($p < 0.001$). ChatGPT demonstrated moderate ordinal agreement with pathology results (Spearman $\rho = 0.478$).

CONCLUSIONS

ChatGPT demonstrated clinically comparable performance to ENT residents in laryngeal cancer risk classification based on clinical texts. However, the presence of hallucinations represents an important limitation affecting reliability. Artificial intelligence systems may serve as supportive tools in clinical decision-making processes but should be used under physician supervision rather than as independent diagnostic systems.

OP-598

Correlation Between Vocal Tract Dimensions And Patient Tolerance In Office-Based Laryngeal Surgery

Abdul-Latif Hamdan[1], **Elie Alam**[1], **Patrick Abou Raji Feghali**[1], **Anthony Nasr**[2], **Lana Ghzayel**[1], **Jonathan Abou Chaar**[1], **Omar Aboul Hosn**[1], **Rami Saade**[3]

[1]*Department of Otolaryngology-Head and Neck Surgery, American University of Beirut Medical Center, Beirut, Lebanon.*; [2]*Department of Radiology, American University of Beirut Medical Center, Beirut, Lebanon.*; [3]*Department of Otolaryngology-Head and Neck Surgery, Lebanese American University, Byblos, Lebanon.*

BACKGROUND & AIM
Office-based laryngeal surgery (OBLS) using the transnasal approach has become an effective alternative to procedures under general anesthesia. Although generally well tolerated, patient discomfort remains a limiting factor and may affect procedural success. While psychological and anesthetic factors have been studied, the impact of upper airway anatomy on tolerance has not been clearly established. Variations in vocal tract dimensions may influence endoscope passage and sensory stimulation during surgery. This study aimed to evaluate the correlation between radiologically measured vocal tract dimensions and patient tolerance to transnasal OBLS using the IOWA Satisfaction with Anesthesia Scale.

MATERIAL & METHODS
The medical records and video-recordings of all patients who underwent OBLS between September 2024 and May 2025 were reviewed. Only patients who had a pre-operative computed tomography (CT) scan of the neck and had filled out the IOWA tolerance questionnaire were included in this study. A total of 11 anatomical measurements of the upper airway were evaluated. These included: Velum Length, vertical position of the larynx, distance from nostril to the vocal folds, distance from nostril to hard/Soft palate junction, distance from nostril to posterior nasopharyngeal mucosa, nasopharyngeal width, length of the oral component of the vocal tract, velopharyngeal width, oropharyngeal width, opening of the Hypopharynx, hypopharyngeal width. Patient tolerance to the procedure was assessed using the IOWA Satisfaction with Anesthesia Scale, which ranges between -3 and +3 (completely satisfied).

RESULTS
Twenty patients, with a mean age of 62.55 ± 14.93 years, were included. The most common voice diagnosis was unilateral vocal fold paralysis (60%), followed by laryngeal squamous cell carcinoma (25%). The most commonly performed procedures were injection laryngoplasty (65%) and laryngeal biopsy (15%). There was a moderate negative correlation between velum length and IOWA scores ($r = -0.568$, $p = 0.009$). There was no statistically significant correlation between any other vocal tract measurements and IOWA scores.

CONCLUSIONS
This investigation showed that the longer the velum, the lower the tolerance score for office-based laryngeal surgery.

OP-599

Botulinum Toxin Dosing Trends For Vocal Tremor At A Single Tertiary Centre

Roanna Norman[1], **Chang Woo Lee**[2], **Ivor Kwame**[2], **Sindhuja Bhanwala**[2], **Martin Birchall**[2], **Jonathan Fishman**[2], **John Rubin**[2]

[1]*Torbay and South Devon NHS Foundation Trust*; [2]*Royal National ENT and Eastman Dental Hospitals*

BACKGROUND & AIM
Botulinum toxin injection dosing trends for vocal tremor (VT) remain poorly understood. This study aimed to identify longitudinal dosing patterns, to assess changes between initial and final doses, associations with treatment duration and adverse event frequency.

MATERIAL & METHODS
A retrospective analysis of adult VT patients undergoing laryngeal botulinum toxin injection at a single tertiary centre (01/01/2024-31/12/2024) was performed. All injections used Dysport® (abobotulinumtoxinA) under electromyographic guidance. Dosing trend analysis included only patients receiving three or more injections. Longitudinal dose changes were analysed using linear mixed-effects models: model fit was compared using likelihood ratio testing. First and last doses were compared using the Wilcoxon signed-rank test ($p<0.05$).

RESULTS
547 injections across 39 patients were analysed (median 14 injections/patient, IQR 6-18). A small dose reduction per injection was observed in the random-intercept model ($\beta = -0.010$ units/injection, SE = 0.003, $t = -3.33$) but not in the random-slope specification ($\beta = -0.003$ units/injection, SE = 0.005, $t = -0.50$), which showed superior fit ($p<0.001$). Longer treatment duration

was independently associated with higher doses (β = 0.010 units/month, SE = 0.003, t = 3.29). No statistically significant difference was observed between first and last doses (p=0.64). At the individual level, 92.3% of patients (36/39) demonstrated stable dosing within the predefined ± 0.5 unit threshold; dose reduction occurred in two patients (5.1%) and escalation in one (2.6%). No patient developed tolerance. The adverse event rate was 1.6% (9/547 injections).

CONCLUSIONS

Botulinum toxin dosing remained stable in most VT patients. Apparent dose reductions are better explained by inter-individual variability rather than a true trend. Longer treatment duration was associated with higher doses, though this may reflect confounding rather than true dose escalation. These findings support an individualised dosing approach, with no clear evidence for systematic dose escalation over time. The absence of tolerance development and low adverse event rate support the long-term safety of laryngeal botulinum toxin injection in VT.

AI-Based Frame-Level Classification Of Vocal Cord Lesions Using Endoscopic Images: A Three-Class Pilot Study

Kadir Emre Kılıç[1], **İdris Sancaktar**[2], **Özgür KEMAL**[1], **Efkan Yiğit Karagülle**[2], **Mohsen Lorghaba**[3]

[1]*Ondokuz Mayis University, Department of Otorhinolaryngology – Head and Neck Surgery, Samsun, Turkey;* [2]*Ondokuz Mayis University , Department of Electrical and Electronics Engineeri, Samsun, Turkey;* [3]*Ondokuz Mayıs University, Department of Computational Sciences, Samsun, Turkey*

BACKGROUND & AIM

Differentiating malignant from benign vocal cord lesions during routine endoscopic examination remains challenging and frequently requires histopathological confirmation. Artificial intelligence (AI)-based image analysis has the potential to support clinical decision-making by providing objective real-time assessment. This study aimed to evaluate the performance of a deep learning model for frame-level classification of vocal cord endoscopic images into malignant, benign, and normal categories.

MATERIAL & METHODS

This clinical translational study included endoscopic recordings obtained from patients aged 18–65 years undergoing vocal cord evaluation. Final diagnoses were confirmed histopathologically following planned biopsy. A total of 96 cases were included (38 malignant, 38 benign, and 20 normal). Eighteen videos (5 normal, 7 benign, 6 malignant) were isolated as an independent test set. A YOLOv11s-based deep learning model was trained for three-class classification. Performance analysis was performed at a confidence threshold of 0.79 using frame-based evaluation on detected frames only. Accuracy, precision, recall, and F1 scores were calculated from confusion matrix analysis.

RESULTS

The test set included 18 videos comprising 4561 frames, processed at a mean speed of 21.66 frames per second. Frame-level overall accuracy for detected frames was 85.7%. Malignant lesion detection demonstrated high performance with 100% precision, 93.3% recall, and an F1 score of 96.6%, indicating strong capability in recognizing clinically critical lesions. Normal frames showed a precision of 75.2%, recall of 93.4%, and F1 score of 83.3%. Benign lesion classification was comparatively lower (precision 70.5%, recall 56.4%, F1 score 62.6%). Macro F1 score was approximately 80.8%. The overall dataset detection rate was 6.52%.

CONCLUSIONS

AI-based analysis of vocal cord endoscopic frames demonstrated strong performance in identifying malignant lesions, highlighting its potential clinical value in supporting early recognition during endoscopic examination. Although benign lesion differentiation remains more challenging, the model achieved robust three-class performance with real-time processing capability. These findings suggest that AI-assisted endoscopic assessment may serve as a clinically relevant decision-support tool, potentially reducing diagnostic uncertainty and supporting clinician performance. Further large-scale, patient-level validation studies are warranted before clinical integration.

OP-601

Standardized Office-Based Injection Laryngoplasty For Unilateral Vocal Fold Paralysis: Early Multimodal Outcomes

Rafael Pires[1], **Lília Ferraria**[1], **Aldora Quintal**[1], **Ana Miguel Couto**[1], **Joana Dias**[1], **Jorge Dentinho**[1], **Luís Antunes**[1]

[1]*Hospital Garcia de Orta, Almada, Portugal*

BACKGROUND & AIM

Office-based injection laryngoplasty is an established minimally invasive treatment for unilateral vocal fold paralysis (UVFP), enabling early restoration of glottic competence and functional voice improvement. Although widely studied, variability persists in the application of standardized multimodal voice assessment protocols in clinical practice. This study aimed to

evaluate early outcomes of a structured office-based injection laryngoplasty protocol using subjective, perceptual, acoustic, aerodynamic, and endoscopic measures.

MATERIAL & METHODS

A retrospective analysis included 6 patients with UVFP. Injection laryngoplasty was performed under local anesthesia using hyaluronic acid (n=5) or calcium hydroxyapatite (n=1), via percutaneous thyrohyoid or transoral approaches.

Pre- and post-procedure assessment included the Voice Handicap Index-10 (VHI-10), Reflux Symptom Index (RSI), Eating Assessment Tool-10 (EAT-10), acoustic parameters (fundamental frequency, jitter, shimmer, harmonic-to-noise ratio [HNR], vocal intensity), aerodynamic measures (maximum phonation time [MPT], s/z ratio), and perceptual voice evaluation (GRBAS scale). Glottic closure was assessed using nasofibrolaryngoscopy according to the modified Södersten and Lindestad classification. Statistical analysis was performed using the Wilcoxon signed-rank test.

RESULTS

The cohort was predominantly female (83.3%) with a mean age of 55.7±17.7 years. Most vocal folds were in paramedian position (83.3%), with left-sided paralysis in 83.3% of cases; etiology was heterogeneous. Significant improvement was observed in VHI-10 (median 18.0 to 7.5; p=0.028) and RSI scores (18.5 to 10.5; p=0.027). Aerodynamic assessment demonstrated increased MPT (5.9 to 8.4 seconds; p=0.046) and reduced s/z ratio (1.48 to 1.05; p=0.046), indicating improved glottic efficiency. Perceptual voice quality improved significantly in GRBAS grade (p=0.014). Glottic closure improved in all patients. Acoustic parameters showed reductions in jitter and shimmer and increased HNR and vocal intensity; however, these changes did not reach statistical significance. No procedure-related complications were observed.

CONCLUSIONS

A standardized office-based injection laryngoplasty protocol is a safe and effective approach for early management of UVFP. Multimodal assessment demonstrates consistent improvement in subjective, perceptual, aerodynamic, and endoscopic outcomes, supporting its role as a reliable outpatient intervention. Larger studies are required to confirm acoustic parameter trends.

Accuracy Of Chatgpt Responses On Questions Related Tp Tracheostomy Care

Muneera Al-Khalifah[2], **Aishah AlGhuneem**[1], **Saleh Alwasil**[1], **Danah Alrusayyis**[1], **Mohamed Alshehabi**[2]

[1]*Saudi Commission for Health Specialties, KSA;* [2]*Barhain Defence Force - Royal Medical Servises, Kingdom of Bahrain*

BACKGROUND & AIM

The emergence of artificial intelligence-powered language, such as Chatbot Generative Pre-Trained Trans- former (ChatGPT) is evolving in medicine. ChatGPT-5.2 is one of the most used chatbots by patients and practitioners, leading to an increase in the number of studies dedicated to the evaluation of the accuracy of information provided by ChatGPT-5.2. This paper aims to evaluate the accuracy of ChatGPT-5.2 Responses for tracheostomy care related questions by six experienced otorhinolaryngologists.

MATERIAL & METHODS

A total of thirty-three questions related to tracheostomy indication, procedure details, weaning, care and maintenance and psychosocial care. Using the Quality Analysis of Medical Artificial Intelligence (QAMAI) tool which is a validated and standardized tool dedicated to the evaluation of Chatbot accuracy, answered were graded. It includes six domains (Accuracy, Clarity, Relevance, Completeness, Provision of sources and references, usefulness) and each item is assessed with a 5-point Likert scale (Strongly disagree, disagree, neutral, agree, strongly agree). The interrater reliability and the stability of the ChatGPT-5.2 responses were evaluated with intraclass correlation coefficient (ICC) and Pearson correlation analysis.

RESULTS

A total of 33 answers were evaluated by 6 expert otolaryngologists, and a total of 1,188 ratings were analyzed. ChatGPT-5.2 demonstrated high relevance (4.10 ± 0.12) and accuracy (4.03 ± 0.13), though it scored significantly lower in completeness (3.37 ± 0.19) and provision of sources (2.37 ± 0.20). Inter-rater reliability for the group consensus was moderate (ICC = 0.59), reflecting varying expert thresholds for AI-generated medical content.

CONCLUSIONS

The accuracy of ChatGPT-5.2 response is moderate-to-high in providing information related to the tracheotomy care related questions. However, patients or caregivers need to be cautious about the information related to tracheotomy care, steps, and the differences between temporary and permanent tracheotomies.

Management Of Globus Pharyngeus: A Review Of Current UK-Wide Practice

Jacob Rapier[1], **Stephen Bennett**[2], **Kate Heathcote**[4], **Niamh Gibson**[1], **Elly Wood**[3], **Lima Gharbawi**[2], **Darcy Farthing**[3], **Miles Eason**[1], **Sachi Sahi**[1]

[1]University Hospitals Southampton NHS Foundation Trust; [2]Portsmouth Hospitals University NHS Trust; [3]Salisbury NHS Foundation Trust; [4]University Hospitals Dorset NHS Foundation Trust

BACKGROUND & AIM

Globus Pharyngeus is a common reason for referral to Ear, Nose and Throat outpatient clinics. Its aetiology continues to be an area of much debate and may be multifactorial in a significant proportion of patients. This has led to wide variation in its management by clinicians. The last published survey of UK practice was completed over 25 years ago. With improving knowledge and development of better investigational technologies, we have sought to gain insight into the current management of patients presenting with globus symptoms in the UK.

MATERIAL & METHODS

Through the Robert White Centre for Airway, Voice and Swallowing at University Hospitals Dorset, we have conducted a UK-wide survey of practising Ear, Nose and Throat consultants. We aimed to identify how they would triage, investigate a manage a patient presenting with classical Globus Pharyngeus symptoms. We look at regional variations in the availability of investigative technologies, and approaches to management.

RESULTS

We see significant variation in the management of Globus Pharyngeus across the UK. This occurs at all stages of the patient's journey from the triage of referral to management. We find that the majority of clinicians would initially manage with re-assurance and lifestyle advice, after a normal examination and flexible nasoendoscopic examination. However, the routine use of transnasal oesophagoscopy, manometry, and pH monitoring varies more widely across regions.

CONCLUSIONS

Globus Pharyngeus remains an area for debate, with no clear guidelines for investigation and management in the UK. Due to the variation in responses to our survey, we believe there is a role for a more comprehensive consensus document on this condition.

Clinical Outcomes And Safety Of Novel Portable Device For Real-Time Light-Guided Vocal Fold Injection: A Prospective Study

Seo Young Kim[1], **Jeong-Yeon Ji**[2], **Woo-Jin Jeong**[2], **Wonjae Cha**[2]

[1]Department of Otorhinolaryngology-Head & Neck Surgery, Chung-Ang University Hospital, Chung-Ang University College of Medicine, Seoul, Republic of Korea; [2]Department of Otorhinolaryngology-Head & Neck Surgery, Seoul National University Bundang Hospital, Seoul National University College of Medicine, Seongnam-si, Gyeonggi-do, Republic of Korea

BACKGROUND & AIM

Accurate needle placement is difficult in the cricothyroid (CT) approach to vocal fold injection (VFI) due to the invisibility of the needle tip. While the initial 'Real-time light-guided VFI (RL-VFI) device' helped mitigate this issue by providing real-time light guidance, its clinical utility was constrained by the need for external hardware and connecting cables. Recently, a novel second-generation portable device was developed to eliminate external connections. The purpose of this study was to assess the safety and feasibility of office-based RL-VFI using this advanced, wireless system.

MATERIAL & METHODS

This single-center, prospective clinical trial enrolled patients with unilateral vocal fold paralysis (UVFP) aged 20–85 years. All procedures were performed via a cricothyroid approach in an outpatient setting by a single experienced laryngologist using cross-linked hyaluronic acid (HA) fillers. Intraoperative parameters (injection volume and procedure times) were measured. Subjective and objective voice assessments, including the Voice Handicap Index (VHI-10), GRBAS scale, aerodynamic studies, and acoustic analyses, were performed preoperatively and 1 month postoperatively.

RESULTS

A total of 36 patients completed the 1-month follow-up. Left-sided paralysis was predominant, and the primary etiologies were surgical interventions (75.0%) followed by idiopathic causes (13.9%). The mean administered filler volume was 0.9 ± 0.4 mL, and the mean total procedure time for initial injections was 103.9 ± 59.8 seconds. Following RL-VFI, the mean VHI-10 score significantly improved from 37.6 ± 5.4 to 21.6 ± 14.3 ($P < 0.001$). Significant improvements were also observed in the GRBAS scale, aerodynamic parameters (maximum phonation time, mean expiratory airflow, and mean sound pressure level), and acoustic parameters (jitter, shimmer, and noise-to-harmonic ratio etc.) (all $P < 0.05$). No acute or delayed complications occurred.

CONCLUSIONS

RL-VFI using the novel portable device is a safe, swift, and effective outpatient procedure for patients with UVFP, demonstrating excellent safety profiles and significant subjective and objective voice improvements.

Understanding Tracheostomy: A Systematic Review Of Knowledge Among Healthcare Workers

Farah Saleh Allabun[1]

[1]*King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia*

BACKGROUND & AIM

Background: Tracheostomy is a surgical procedure used to create a stoma in the neck to provide an alternate airway for people who are having difficulty breathing. It used to be the only feasible method for releasing upper airway obstruction. In an emergency, tracheostomy is typically the primary line of treatment, even if there are now alternative options.

Objective: This study aimed to assess the healthcare professionals' level of tracheostomy knowledge.

MATERIAL & METHODS

Method: The study used Preferred Reporting Items for Systematic Reviews and Meta-Analyses PRISMA guidelines to search five medical databases for relevant scholarly publications published between 2015 and 2024, focusing on terms like "tracheostomy", "stoma", "knowledge", and "health personnel". The study includes publications based on pre-defined criteria, such as peer-reviewed journals, papers focused healthcare worker with validated knowledge levels, English publication with full-text available from 2005 onward. The quality and item risk of bias of RCT studies were assessed using RevMan software version 5.1.4, and the risk of publication bias was shown using a funnel plot. In contrast, the risk of bias in the observational, cross-sectional, retrospective, and descriptive studies was evaluated using the Newcastle Ottawa Quality Assessment Scale.

RESULTS

Results: The results of the study indicate that healthcare providers have considerable knowledge gaps in tracheostomy care, with just 17% completing the essential care criteria. Many practitioners are unfamiliar with tracheostomy management, emergency interventions, and the prevention of ventilator-associated pneumonia. Training increases self-efficacy, but there are no long-term improvements in suctioning skills after training.

CONCLUSIONS

Conclusion: This study highlights the need for improved training and education for medical personnel about tracheostomy care. To fill in knowledge gaps, hone skills, and improve patient outcomes, it recommends creating extensive programs, conducting frequent assessments, creating customized content, using simulation-based learning, and fostering interdisciplinary teamwork.

INVESTIGATION OF THE VALUE OF CERTAIN MORPHOMETRIC MEASUREMENTS AND CLASSIFICATIONS IN THE PREDICTABILITY OF DIFFICULT LARYNGEAL EXPOSURE DURING DIRECT LARYNGOSCOPY WITH RIGID LARYNGOSCOPE

Büşra Nur Coşan Seçgin[1], **Ruçhan Seçgin**[1], **Mehmet Salih Parça**[1], **Yalçın Alimoğlu**[1], **Özgür Yiğit**[1]

[1]*Basaksehir Cam and Sakura City Hospital, Department of Otolaryngology - Head and Neck Surgery, Istanbul*

BACKGROUND & AIM

This study aims to investigate the value of preoperative morphometric measurements and clinical classifications in predicting difficult laryngeal exposure (DLE) during direct laryngoscopy performed with a rigid laryngoscope. Furthermore, we aimed to analyze the effects of different patient positions and laryngoscope sizes on glottic visibility.

MATERIAL & METHODS

Eighty-two patients scheduled for direct laryngoscopy at Başakşehir Çam and Sakura City Hospital were prospectively included. Preoperative demographic data, BMI, Modified Mallampati Score, Delilkan score, and various linear/angular morphometric measurements were recorded. Intraoperative glottic visibility was comparatively evaluated using four methods: narrow-lumen (IA) and wide-lumen (IB) laryngoscopes in a shoulder-supported position, and narrow-lumen (IIA) and wide-lumen (IIB) laryngoscopes in a neutral position without shoulder support.

RESULTS

The highest full view rate was achieved with method IIA at 84.1%, while the lowest was method IB at 20.7%. In method IB, advanced age (OR: 1.060) and an increase in thyromental distance in full extension (TMD-FE) (OR: 2.386) were independent predictors. Threshold values were 56.5 years for age, 8.50 cm for TMD-FE, and 6.50 cm for mentohyoid distance. Paradoxically, increased body weight and BMI improved visibility in method IIA ($p<0.05$), while mouth opening decreased the likelihood of a full view (OR: 0.378). In method IIB, MMS and TMD-NP showed significant differences.

CONCLUSIONS

Dynamic measurements such as thyromental distance in full extension (TMD-FE) are superior to static measurements in predicting difficult laryngeal exposure. Furthermore, our findings suggest that glottic visibility is significantly influenced by the choice of laryngoscope size and patient positioning. Utilizing a wide-lumen laryngoscope in a neutral position may optimize the view in challenging cases, providing clinicians with more reliable preoperative predictors for surgical planning.

Voice as a Digital Biomarker: Preliminary Comparison of Classical Acoustic Analysis and Self-Supervised Learning Models

Maria Stella Di Modica[1], **Mario Lentini**[1], **Antonino Maniaci**[1], **Andy Bertolin**[2]

[1]*Università degli Studi di Enna Kore;* [2]*Azienda ULSS 2 Marca Trevigiana UOC Otorinolaringoiatria – Ospedale di Vittorio Veneto*

BACKGROUND & AIM

Laryngeal diseases, with a clinical presentation ranging from functional dysphonia to malignant neoplasms, pose a significant challenge in terms of early diagnosis. In this context, the vocal signal emerges as a promising non-invasive clinical biomarker, capable of reflecting the structural integrity and efficiency of the vocal cords. However, many pathological acoustic alterations manifest as sub-acoustic patterns imperceptible to traditional clinical auscultation or before becoming visible on endoscopy. The objective of this study is to validate a system based on Artificial Intelligence (AI) aimed at the automatic identification of vocal pathologies through advanced machine learning models.

MATERIAL & METHODS

This prospective, controlled observational study included 200 adults, equally divided into healthy controls (n=100) and patients with laryngeal pathology (n=100), recruited from three clinical centers. Participants performed three standardized voice tasks via smartphone: sustained /a/, repetition of /pa/, and reading of phonetically balanced sentences. After pre-processing, acoustic features such as F0, jitter, shimmer, and HNR were extracted. Classical approaches based on Praat features and machine learning classifiers were compared with self-supervised learning models, including wav2vec2, HuBERT, and Voc2Vec, evaluated both with fixed weights and end-to-end fine-tuning. Finally, predictions from individual recordings were combined through majority voting to obtain a single classification for each subject.

RESULTS

Evaluations performed on the independent test set (40 unrelated speakers) highlighted the clear superiority of end-to-end (E2E) trained models over fixed-weight configurations and classical acoustic analysis. The best overall system was the E2E approach based on the Voc2Vec (HuBERT) model, specialized in nonverbal vocalizations, which achieved 95.0% accuracy, sensitivity, and specificity at the patient level, with an AUC of 0.992 (correctly identifying 19 out of 20 pathological patients and 19 out of 20 healthy subjects). Among traditional approaches, the Praat + SVM combination showed solid sensitivity (95.0%), but lower specificity (75.0%).

CONCLUSIONS

Self-supervised learning (SSL) models that have been appropriately optimized end-to-end demonstrate excellent performance in the automated and non-invasive screening of laryngeal pathologies. The specialization of these models for specific vocalization tasks (Voc2Vec) offers a clear competitive advantage over generic language models. Despite the promising results supporting clinical triage, external validations on larger, more balanced cohorts will be necessary to confirm their reliability and applicability in heterogeneous clinical settings.

Procedure-Specific Phonatory Outcomes In Unilateral Vocal Fold Paralysis

Takashi Kurita, MD, PhD[1], **Hirohito Umeno, MD, PhD**[1], **Shun-ichi Chitose, MD, PhD**[1], **Mioko Fukahori, MD, PhD**[2], **Fumihiko Sato, MD, PhD**[1], **Takeharu Ono, MD, PhD**[1], **Hisaichiro Tanaka, MD**[1]

[1]*Department of Otolaryngology-Head and Neck Surgery, Kurume University School of Medicine, Kurume, Fukuoka, Japan;* [2]*Department of Otolaryngology, Aso Iizuka Hospital, Iizuka, Fukuoka, Japan*

BACKGROUND & AIM

Unilateral vocal fold paralysis (UVFP) is a common cause of dysphonia and can be treated with type I thyroplasty (TP1), arytenoid adduction (AA), combined TP1+AA, or fat injection laryngoplasty (FIL), depending on the glottal gap and the presence of vertical level difference. While TP1 and FIL primarily address horizontal glottal insufficiency with closely approximated vocal processes during phonation, AA is indicated for a posterior glottal gap at the vocal processes, often with a vertical level difference. We hypothesized that procedure selection based on these pathophysiologic features would yield favorable postoperative phonatory outcomes.

MATERIAL & METHODS

We retrospectively reviewed 309 consecutive patients with UVFP who underwent TP1, AA, TP1+AA, or FIL at a single institution between 1996 and 2024. Patients lacking preoperative data or any postoperative phonatory assessment were excluded, leaving 293 patients for analysis: AA alone, 20; TP1 alone, 77; TP1+AA, 68; and FIL, 128. Postoperative values at 3-6 months were preferentially analyzed; when unavailable, the nearest later postoperative value or the 1-month value was adopted. Maximum phonation time (MPT), mean flow rate (MFR), pitch perturbation quotient (PPQ), and amplitude perturbation quotient (APQ) were compared before and after surgery and across procedure groups.

RESULTS

All procedures showed significant postoperative improvement in aerodynamic and acoustic parameters overall ($p<0.0001$). Because AA alone was uncommon and accounted for few cases, between-group interpretation mainly focused on TP1 alone, TP1+AA, and FIL. Preoperatively, TP1 showed significantly shorter MPT and higher MFR, PPQ, and APQ than FIL, despite both procedures generally being indicated for patients without marked vertical level difference. Postoperatively, FIL and TP1+AA showed significantly longer MPT than TP1 alone. FIL and TP1+AA also demonstrated significantly lower postoperative MFR than TP1 alone. In addition, FIL showed significantly lower postoperative PPQ and APQ than either TP1 alone or TP1+AA.

CONCLUSIONS

Procedure-specific surgical management for UVFP was associated with favorable postoperative phonatory outcomes. TP1+AA provided better postoperative aerodynamic outcomes than TP1 alone, while FIL was associated with more favorable postoperative acoustic outcomes than TP1 alone or TP1+AA. Although TP1 alone improved voice function, FIL and TP1+AA appeared more advantageous in postoperative phonatory performance when appropriately selected.

Disease Regression Of Contralateral Reactive Lesions Following Office-Based Laryngeal Surgery

Abdul-Latif Hamdan[1], **Lana Ghzayel**[1], **Lucien Khalil**[1], **Valerie Sarkis**[1], **Ghena Lababidi**[1], **Jad Hosri**[1], **Ibana Carapiperis**[1], **Patrick Abou Raji Feghali**[1]

[1]*Department of Otolaryngology – Head and Neck Surgery, American University of Beirut Medical Center, Beirut, Lebanon*

BACKGROUND & AIM

Contralateral reactive lesions (CRLs) have been described in patients with benign vocal fold lesions but their treatment have rarely been described. The aim of this study is to describe the prevalence and morphology of vocal fold contralateral reactive lesions in patients with vocal fold polyps or cysts, and to report disease regression following office-based laryngeal surgery (OBLS).

MATERIAL & METHODS

Medical records and video recordings of patients with vocal fold polyps or cysts who underwent OBLS between November 2023 and September 2025 were reviewed. Demographic data included age, gender, history of smoking, history of reflux disease, type of vocal fold pathology, and type of office-based laryngeal procedure. Prevalence, morphology, and disease regression of CRLs were assessed by two otolaryngologists who independently reviewed the video recordings of patients included in this study.

RESULTS

Twenty-six males and 19 females were included in the study. The mean age was 48.9 ± 14.9 years. The prevalence of CRLs was 60%. Most of these lesions were fibrous. Eighteen lesions were treated with ILSI, and 8 lesions were treated with the blue laser and steroid injection. Five patients were lost to follow-up. Analysis of 21 CRLs showed complete disease regression in 52.4% of cases, and partial disease regression in 47.6% of cases. There was no statistically significant difference in disease regression between the two treatment subgroups ($p = 0.284$). There was a statistically significant difference in total disease regression of the primary lesion between those who had partial vs. complete disease regression of their CRL ($p < 0.001$).

CONCLUSIONS

CRLs are common in patients with vocal fold polyps and cysts. All lesions regressed partially or completely following OBLS using the blue laser and/or steroid injection.

contralateral reactive lesion; office-based; vocal fold cysts; vocal fold polyps.

OP-610

Biomechanical Voice Analysis As A Screening Tool For Reinke's Edema Identification In Women

Isabel Cardoso[1,2], **Walter Tenesaca**[3], **Ángel Rodríguez-Paramás**[1,3], **Roberto Fernández-Baíllo**[3], **Sandra Corvo-Macarro**[4]

[1]*Vithas Arturo Soria University Hospital;* [2]*Universidad Europea;* [3]*University of Alcalá de Henares;* [4]*University of Salamanca*

BACKGROUND & AIM
Reinke's edema is a benign disease of the vocal fold caused by smoking and excessive vocal effort, that usually leads to chronic dysphonia, especially in women. Diagnosis requires direct evaluation of the vocal folds using videolaryngoscopy. The biomechanical analysis of the voice makes it possible to obtain from a sound sample a set of parameters that describe the pattern of voice production associated with the specific architecture of each vocal fold. The objective is to identify the characteristic vocal production pattern in Reinke's edema, as well as analyzing the validity of this methodology for screening the pathology.

MATERIAL & METHODS
The study was performed with a sample of 188 women from 26 to 74 years old separated in 3 groups: Control group, 52 participants; Reinke's edema Group, 39 patients; Vocal Fold Pathology-no Reinke's edema, 97 patients. All the patients were evaluated by biomechanical analysis tool App Online Lab VCS® by Voice Clinical Systems®.

RESULTS
It is observed that a decrease in F0 (Pr01), an increase in the mucosal wave in the opening phase (Pr20), a shortened closure phase (Pr04) and the presence of mass effect (Pr22) are the main features that characterize Reinke's edema compared to the control group with broad statistical significance (p<0,001). These results establish that the screening based on the joint presence of the decrease in F0 (Pr01) and the increase in the mucosal wave effect (Pr19/Pr20) presents high sensitivity and specificity indices: Group control vs. Reinke's edema, Specificity: 0.85, Sensitivity: 0.85; Reinke's edema vs. Vocal Fold Pathology-no Reinke's edema, Specificity: 0.93, Sensitivity: 0.85.

CONCLUSIONS
Biomechanical voice analysis objectively identifies voice patterns in women with Reinke's edema, aiding in effective screening.

KEYWORDS
Laryngeal cancer; Reinke's edema; Voice pathology; Biomechanical Analysis; Mucosal wave; Laryngeal Anatomy.

OP-611

Presbylarynx And Laryngeal Asymmetry As Predictors Of Dysphonia In Patients 65 And Over

Priya Krishna, MD MS[2], **Ivan Vegar, MPH MS**[2], **Alden Smith, MD**[2], **Salem Dehom, PhD**[2]

[1]*University of California, Davis;* [2]*Loma Linda University*

BACKGROUND & AIM
Objectives/Hypothesis: Presbyphonia and presbylarynx are both common and readily observed in an aging population. Presbylarynx and laryngeal asymmetry increase in incidence with age and are visible on videostroboscopy. However, neither presbylarynx nor laryngeal asymmetry have been definitively connected with patient-reported dysphonia related to the aging voice. The purpose of this study was to determine if videostroboscopy could be used to link presbylarynx or laryngeal asymmetry with patient-reported dysphonia (pathologic presbyphonia) in the absence of additional laryngeal pathology.

MATERIAL & METHODS
Methods: This was a retrospective chart review of consecutive patients 65 and over presenting to an academic voice and swallowing center. 200 patients were included: 100 with voice complaints and 100 without voice complaints. Their videostroboscopic exams were reviewed during concurrent sessions by three fellowship-trained laryngologists for findings of presbylarynx and laryngeal asymmetry.

RESULTS
Results: Of 200 patients, the median age was 72 (65-95) and 127 (63.5%) were female. 146 (73%) had all 3 measured findings of presbylarynx (vocal fold bowing, vocal process prominence in abduction, and vocal process contact preceding midfold contact at initial adduction). 171 (85.5%) patients had overall laryngeal asymmetry, 166 (83%) had phase asymmetry, and 131 (65.5%) had asymmetric speed or range of motion of the vocal folds on videostroboscopy. Only 24 had all 3 asymmetric findings of increased ventricular show, contralateral false vocal fold contraction, and interarytenoid cleft tilt. The dysphonia group had a significantly higher VHI-10 (13 vs 2) and lower BMI (26.5 vs 28.3) than the non-dysphonia group but did not differ in age, gender, nor height. No videostroboscopic exam features differed

between those two groups. Gender, age, and height were associated with findings of presbylarynx but not with dysphonia.

CONCLUSIONS

Conclusions: In this study, standard clinical videostroboscopy could not be used to associate laryngeal asymmetry nor findings of presbylarynx with dysphonia in patients 65 and over. The complaint of dysphonia was consistent with VHI-10 scores. Pathologic presbyphonia remains a complaint without a universal distinguishing group of predictive features, complicating patient care and treatment.

presbylarynx, vocal fold paresis, laryngeal asymmetry, pathologic presbyphonia

OP-612

Objective Voice Outcomes Following Thyroid Surgery: Prospective Assessment Using Acoustic Analysis, Videolaryngostroboscopy, And VHI-10

Mobin Hemmati[1], **Şerife Nur Biçen**[2]

[1]*Bakırçay University Faculty of Medicine, Department of Otorhinolaryngology, İzmir, Türkiye;* [2]*Bakırçay University Faculty of Health Sciences, Department of Speech and Language Therapy, İzmir, Türkiye*

BACKGROUND & AIM

Thyroid surgery is widely performed for benign and malignant thyroid diseases. Although preservation of the recurrent laryngeal nerve is a primary surgical goal, patients may still experience postoperative voice alterations even in the absence of overt nerve injury. These changes are thought to arise from surgical manipulation, intubation-related trauma, or transient neuromuscular dysfunction. This study aimed to comprehensively evaluate early and mid-term voice outcomes following thyroid surgery using objective acoustic analysis, videolaryngostroboscopy (VLS), and patient-reported voice handicap.

MATERIAL & METHODS

All patients underwent standardized preoperative, postoperative 1-month, and postoperative 3-month assessments including acoustic voice analysis (F0, jitter, shimmer, harmonicity), VLS examination, and Voice Handicap Index-10 (VHI-10).

Paired comparisons were performed between time points using appropriate statistical methods. Continuous variables were analyzed using paired tests, while categorical VLS findings were evaluated using McNemar analysis. Statistical significance was defined as $p<0.05$.

RESULTS

Sixteen patients were prospectively included.The mean age was 51.4 ± 11.4 years; 68.8% were female and 31.2% were male.Surgical procedures included lobectomy (87.5%) and total thyroidectomy (12.5%).

Preoperatively,all patients demonstrated normal VLS findings.

At postoperative 1 month, jitter increased significantly from 0.543 ± 0.181 to 0.578 ± 0.394 (p=0.031), accompanied by a significant rise in VHI-10 scores from 4.81 ± 9.44 to 7.63 ± 9.37 (p=0.012), indicating early subjective voice deterioration. No significant changes were observed in F0 or shimmer.

VLS evaluation at 1 month revealed significant deterioration in glottic closure (p=0.039), mucosal wave (p=0.021), amplitude (p=0.021), and periodicity (p=0.021).

At postoperative 3 months, shimmer decreased significantly from 3.33 ± 1.26 to 2.01 ± 0.59 (p=0.041), while VHI-10 scores improved significantly to 1.81 ± 3.27 (p=0.018).

Direct comparison between postoperative 1-month and 3-month findings demonstrated significant recovery in jitter (p=0.027), shimmer (p=0.018), VHI-10 scores (p=0.006), and VLS parameters including mucosal wave, amplitude, and periodicity (p=0.046).

CONCLUSIONS

Thyroid surgery is associated with early postoperative voice alterations detectable both objectively and subjectively. However, significant functional recovery occurs by the third postoperative month, suggesting that most voice changes are transient rather than permanent.

Development And Validation Of A Transformer Electronic Laryngoscope Deep Learning Model For Diagnosis Of Vocal Cord Lesions

Xu Chenyang[1], **Song Wenhua**[1], **Li Changling**[1], **Yu Zhenbin**[1], **Yan Jiaxuan**[1], **Lei Dapeng**[1]

[1]*Department of Otorhinolaryngology, Qilu Hospital of Shandong University, National Health Commission Key Laboratory of Otorhinolaryngology (Shandong University), Jinan 250012, China*

BACKGROUND & AIM

Vocal fold lesions have diverse morphology, making accurate diagnosis challenging. Artificial intelligence (AI) can aid laryngoscopic analysis, but robust multi-modal and multi-center models remain limited. This study developed and validated a

Pyramid Transformer model for simultaneous classification and segmentation of vocal fold lesions using white light imaging (WLI) and narrow-band imaging (NBI), aiming to improve diagnostic accuracy and support clinical decision-making.

MATERIAL & METHODS

A total of 3,543 WLI and 1,906 NBI images from three medical centers were retrospectively analyzed. Lesions were categorized into six types. A Pyramid Transformer model integrating feature pyramid and reverse attention modules was developed. Ten-fold cross-validation was used for internal validation, with two independent cohorts for external validation. Model performance was assessed via AUC, accuracy, mIoU, and clinical utility metrics including Grad-CAM and DCA.

RESULTS

The model achieved high AUCs in internal (WLI: 0.9956; NBI: 0.9881) and external validation cohorts (WLI: 0.9616–0.9799; NBI: 0.9736–0.9852). Mean mIoU reached 0.7429 internally and 0.7287–0.7231 externally. It accurately localized lesions. Model assistance significantly improved junior and senior surgeons' diagnostic accuracy and efficiency.

CONCLUSIONS

The Pyramid Transformer model enables accurate, simultaneous classification and segmentation of vocal fold lesions on WLI/NBI images with robust multi-center generalizability. It enhances diagnostic performance and efficiency for clinicians, especially juniors. This AI tool holds promise as a real-time auxiliary system for precise laryngeal lesion diagnosis in clinical practice.

OP-614

Clinical And Radiological Predictors Of Retropharyngeal Abscesses In Deep Neck Infections

Funda Kutay[1], **Mehmet İhsan Gülmez**[1], **Ali Kimiaei**[1], **Gül Soylu Özler**[1]

[1]*Hatay Mustafa Kemal University, Faculty of Medicine, Department of Otorhinolaryngology, Hatay, Türkiye*

BACKGROUND & AIM

Retropharyngeal abscesses (RPAs) are severe deep neck infections that require rapid intervention to prevent life-threatening complications. This study aimed to evaluate the clinical, laboratory, and radiological risk factors that predict the need for intensive care unit (ICU) admission and surgical drainage in adult patients with RPAs.

MATERIAL & METHODS

A retrospective review was conducted on patients treated for RPAs at our center between January 2013 and December 2023. Of the 64 initial cases, 57 adults were included in the final analysis after excluding pediatric patients and incomplete records. We analyzed the impact of demographics, diabetes mellitus (DM) status, admission laboratory markers (C-reactive protein [CRP], white blood cell [WBC] count), and radiological abscess size on the necessity for ICU admission and surgical intervention. Additionally, Receiver Operating Characteristic (ROC) curves were generated to assess the predictive value of these variables for ICU admission.

RESULTS

The cohort's mean age was 37.7 ± 16.7 years, with 9 patients (15.8%) requiring ICU care. Multivariate logistic regression identified DM (OR=3.61, 95% CI: 1.31–9.92, p=0.01), admission CRP level (OR=1.01, 95% CI: 1.00–1.02, p=0.03), and abscess size (OR=1.09, 95% CI: 1.02–1.18, p=0.02) as independent predictors of ICU admission. ROC analysis for CRP yielded an area under the curve (AUC) of 0.87; a 200 mg/L cut-off achieved 100% sensitivity and 80.9% specificity. Abscess size demonstrated an AUC of 0.81, with a 30 mm cut-off providing 88.9% sensitivity and 71.4% specificity. None of the evaluated parameters significantly correlated with the need for surgical drainage.

CONCLUSIONS

Comorbid DM, elevated CRP levels, and larger abscess dimensions independently predict the need for intensive care in adults with RPAs. The strong discriminative capacity of admission CRP and radiological abscess size highlights their critical utility in early clinical risk stratification and guiding targeted treatment strategies.

OP-615

Type III Thyroplasty For Refractory Puberphonia: A Step-By-Step Surgical And Anaesthetic Guide

Shaden Zakariya Yahya Al Riyami[1], **Rabaa Al Kalbani**[1]

[1]*ministry of Health , Sultanate of Oman , The Directorate of Khoula Hospitals , Al Nahda Hospital*

BACKGROUND & AIM

Background

Puberphonia, or mutational falsetto, is a functional voice disorder characterized by the failure of the male voice to transition to a lower pitch during puberty. Despite a morphologically normal larynx, the persistence of a high-pitched voice can lead to profound psychosocial distress, social withdrawal, and professional limitations. While voice therapy remains the gold standard for initial management, a cohort of patients exhibits resistance to vocal exercises, necessitating surgical intervention to achieve a lower pitch.

Aim

To describe the surgical technique of Type III Thyroplasty, evaluate its efficacy in long-term pitch reduction, and discuss intraoperative strategies to optimize vocal outcomes in refractory puberphonia.

MATERIAL & METHODS

Methods & Surgical Technique

This presentation outlines a standardized approach to Type III Thyroplasty performed under local anesthesia with conscious sedation. Key surgical steps include:

· Anaesthesia explaining the details of an Ultrasound-Guided Cervical Plexus Block.

· Positioning & Exposure,

· Detailed surgical steps,

· Intraoperative voice monitoring Utilizing real-time patient phonation,

· Stabilization and securement of the thyroid framework.

RESULTS

Results

Postoperative analysis demonstrates a significant reduction in the fundamental frequency (F0), typically shifting from a pre-operative range of 200–250 Hz to a gender-appropriate 100–120 Hz. Beyond objective acoustics, patients report marked improvements in the Voice Handicap Index (VHI-10). We address common challenges such as local anaesthetic over dose and avoiding endolaryngeal mucosal penetration.

CONCLUSIONS

Conclusion

Type III Thyroplasty is a robust and predictable corrective procedure for patients with puberphonia who fail conservative therapy. By physically shortening the vocal folds, this "relaxation" technique provides immediate and permanent pitch lowering. Success hinges on precise chondrotomies and intraoperative vocal feedback to ensure the patient's "new" voice aligns with their physical identity.

OP-616

Visual Diagnostic Performance Of Untrained Generic Llms In Benign-Malignant Differentiation Of Laryngeal Lesions: Comparison With ENT Specialist And Resident

Veli Yiğit Berçin[1], **Derya Kusun Özer**[1]

[1]*Bakırçay University Çiğli Training and Research Hospital*

BACKGROUND & AIM

The objective of this study is to determine the inherent diagnostic tendencies toward benign or malignant classifications of non-fine-tuned, generic Large Language Models (LLMs) when evaluating endoscopic photographs of laryngeal lesions. Furthermore, by comparing their diagnostic performance with an otolaryngology specialist and a resident using a visual-only approach—without any clinical patient history—this study aims to investigate the suitability and reliability of these artificial intelligence tools for daily use (for preliminary evaluation or consultation purposes) by resident physicians or individuals without medical expertise.

MATERIAL & METHODS

This retrospective study included 65 patients who underwent laryngeal biopsy between August 2025 and January 2026. Based on histopathology, lesions were categorized as benign (n=38; including low-grade dysplasia) or malignant (n=27; including moderate/high-grade dysplasia and carcinoma). A single physician extracted standardized high-resolution JPEG frames from laryngostroboscopy recordings. An otolaryngologist, a resident, and two non-fine-tuned LLMs (Gemini, ChatGPT) evaluated these single static images, completely blinded to clinical history. To prevent context contamination, images were uploaded to LLMs in independent chat sessions (zero-shot approach) using a standardized prompt forcing binary classification. Diagnostic metrics (Sensitivity, Specificity, PPV, NPV, Accuracy) and inter-rater agreement (Cohen's/Fleiss' Kappa) were calculated. Cochran's Q and McNemar tests were used for comparisons. Post-hoc power analysis via G*Power (v3.1) for the Exact McNemar test confirmed 87.6% statistical power (>80% threshold) at $p < 0.05$.

RESULTS

In the conducted analyses, while the correct classification rate of laryngeal lesions as benign or malignant by the otolaryngologist was 76.9%, the overall accuracy of the generic LLMs (Gemini and ChatGPT) was determined to be 55.4%, revealing a statistically significant difference in favor of the specialist physician ($p < 0.05$). Although the accuracy of the resident (67.7%) was higher than that of the artificial intelligence models, no statistically significant difference was detected between them ($p > 0.05$). Even though the artificial intelligence models demonstrated high sensitivity in detecting malignant cases (Gemini 82.8%, ChatGPT 69.0%), their specificity rates (33.3% and 44.4%, respectively) remained considerably low compared to the otolaryngologist (77.8%). Fleiss' Kappa analysis indicated that the diagnostic agreement between the two artificial intelligence models was poor ($\kappa=0.156$). The tendency of the models to label benign lesions as malignant (false positivity) was found to be markedly higher compared to the specialist physician.

CONCLUSIONS

While generic LLMs show potential in detecting laryngeal malignancies, their overly defensive nature and low specificity lead to high false-positive rates. An expert physician's visual discriminative ability on two-dimensional images remains vastly superior. Currently, using these models as clinical decision support risks increasing unnecessary biopsies, while layperson use for preliminary triage may trigger unwarranted anxiety. Ultimately, AI is not a standalone diagnostic tool for laryngeal cancer based solely on visual data; it functions only as an adjunct requiring integration with comprehensive clinical history and expert physical examination to achieve true clinical value

OP-617

Chronic Laryngopharyngeal Reflux And Associated Benign, Premalignant, And Malignant Laryngeal Lesions

Gulnur Nukusbekova[1], **Taukeleva Saule**[1]

[1]*Kazakhstan-Russian Medical University (KRMU), Almaty, Kazakhsta*

BACKGROUND & AIM

To evaluate the prevalence of benign, premalignant, and malignant laryngeal lesions among adult patients diagnosed with chronic laryngopharyngeal reflux.

MATERIAL & METHODS

A retrospective observational study was conducted at a tertiary otorhinolaryngology center. Medical records of 46 adult patients diagnosed with chronic laryngopharyngeal reflux (LPR) between January 2026 and May 2026 were retrospectively reviewed. The study population consisted of 28 males and 18 females aged 18–65 years. Clinical characteristics, reflux-related symptoms, smoking status, videolaryngoscopic findings, and associated laryngeal lesions were analyzed.

RESULTS

A total of 46 patients with chronic LPR were included in the study. Thirty-six patients (78.3%) were active smokers. Videolaryngoscopic examination revealed a spectrum of laryngeal lesions. Vocal fold leukoplakia was identified in 3 patients (6.5%), vocal fold polyps in 3 patients (6.5%), Reinke's edema in 2 patients (4.3%), and a vocal fold cyst in 1 patient (2.2%). Histologically confirmed laryngeal squamous cell carcinoma was diagnosed in 2 patients (4.3%). Chronic inflammatory laryngeal findings, including erythema, edema, pachydermia, and posterior commissure hypertrophy, were observed in the majority of patients. Premalignant and malignant lesions were predominantly identified among smokers with persistent reflux-related symptoms.

CONCLUSIONS

The presence of premalignant and malignant laryngeal lesions among patients with chronic laryngopharyngeal reflux suggests a potential association between long-term reflux exposure and laryngeal mucosal pathology. Although tobacco smoking remains the principal established risk factor for laryngeal carcinogenesis, chronic reflux-related inflammation may act as an additional contributing factor. Early recognition and management of LPR, particularly in smokers, may help reduce chronic mucosal injury and facilitate earlier detection of laryngeal lesions. Larger prospective studies are needed to clarify the independent role of LPR in laryngeal carcinogenesis.

OP-618

Embryonal Rhabdomyosarcoma Of The Larynx In An Adult: A Systematic Review And Case Report

Magdalena Pietrzak[1], **Wioletta Pietruszewska**[1], **Wiktoria Balińska**[1]

[1]*Department of Otolaryngology, Head and Neck Oncology, Medical University of Lodz*

BACKGROUND & AIM

Embryonal rhabdomyosarcoma (ERMS) of the larynx in adults is an

exceptionally rare and aggressive malignancy, accounting for less than 1% of laryngeal tumors. Its tendency to mimic benign laryngeal pathology frequently results in delayed or missed diagnosis. Furthermore, the extreme scarcity of documented cases has precluded the establishment of standardized, evidence-based treatment protocols.
The study aims to systematically evaluate the clinical characteristics, diagnostic challenges, and therapeutic strategies for adult laryngeal ERMS, synthesizing current evidence alongside a novel case report to guide multidisciplinary clinical management.

MATERIAL & METHODS

A systematic review was conducted searching PubMed, Embase, Scopus, Web of Science, Google Scholar, and ClinicalTrials.gov (updated through February 5, 2026). The inclusion criteria encompassed case reports and case series detailing adult patients (≥18 years) with histopathologically confirmed laryngeal ERMS. Risk of bias was evaluated independently using the Joanna Briggs Institute (JBI) Critical Appraisal Checklist for Case Reports.

RESULTS

The review identified 15 eligible literature studies, which, alongside the present case, yielded a total cohort of 16 patients. The population was predominantly male (n=12; 75.0%), with a mean age of 39.8 years. The primary clinical presentations were hoarseness (n=12; 75.0%) and dyspnea (n=8; 50.0%), frequently masquerading as benign exophytic lesions. Distant metastasis at initial diagnosis was extremely rare (n=1; 6.3%). Surgical resection served as the primary therapeutic modality in 81.3% (n=13) of cases. Among the 14 patients with available follow-up data (median follow-up, 32 months; range, 6–216 months), local recurrence was observed in two cases (12.5%). Adjuvant therapy was highly individualized; 50.0% of patients received no further oncological treatment following primary surgery. The newly reported case details a 69-year-old female successfully managed with organ-preserving transoral laser microsurgery after an initial misdiagnosis of a benign polyp.

CONCLUSIONS

Adult laryngeal ERMS presents a profound diagnostic challenge due to its benign macroscopic appearance. Clinicians must maintain a high index of suspicion for atypical or rapidly recurring laryngeal lesions. Definitive diagnosis relies strictly on immunohistochemical profiling (desmin, myogenin, MyoD1). Complete surgical excision with negative margins, often attainable via organ-preserving approaches, constitutes the optimal primary intervention for the disease.

OP-619

Tracheal Stoma: A Classification Proposal For Tracheostomy

Rouda Almaazmi[1], **Anastasios Hantzakos**[1], **Maryam Al Jawi**[1]

[1]*Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates*

BACKGROUND & AIM

Tracheostomy is a critical airway procedure performed across diverse acute and chronic conditions. While tracheal stoma complications including stenosis, dehiscence, and peristomal infection significantly impact ventilation, phonation, and quality of life, no standardized classification system currently exists. This paper proposes a structured, morphology-based classification of tracheal stoma complications to improve interdisciplinary communication, guide individualized management decisions, and provide an educational and research framework applicable to both temporary and permanent tracheostomies.

MATERIAL & METHODS

A structured classification system was developed through systematic review of the literature and expert clinical experience in tracheostomy management. Complications were categorized based on three parameters: tracheal lumen patency, directionality of tissue breakdown, and presence of inflammatory or physiological markers. Four primary types were defined, each with two subtypes, yielding a tiered eight-subtype framework. The system was designed for practical application across ICU, surgical, and outpatient settings by multidisciplinary teams.

RESULTS

Four types of tracheal stoma complications were identified. Type 1 (Stenotic Stoma) involves fibrotic concentric narrowing, subdivided by degree: subtype a (<50% lumen narrowing) and subtype b (>50% lumen narrowing). Type 2 (Lateral Dehiscence without Lumen Change) describes lateral peristomal tissue breakdown, subdivided by presence or absence of erythema. Type 3 (Superior-Inferior Dehiscence without Lumen Change) represents vertical tissue separation without lumen compromise, similarly subdivided by erythema. Type 4 (Dehiscence with Lumen Change) describes severe structural disruption with tracheal distortion, subdivided by the presence or absence of air leak, indicating the degree of physiological compromise.

CONCLUSIONS

This novel classification system provides a clinically grounded, actionable framework for evaluating tracheal stoma complications. By integrating anatomical and functional parameters, it standardizes documentation, facilitates interdisciplinary communication, and supports both clinical education and research. Applicable to temporary and permanent tracheostomies, it has the potential to improve patient outcomes. Prospective validation studies assessing interobserver reliability and clinical correlation are warranted.

OP-620

Sociodemographic And Diagnostic Characteristics Of Patients With Dysphonia At A Tertiary Voice Unit In Chile

Carla Napolitano[1], **Antonia Lagos-Villaseca**[1], **Adrian Castillo-Allendes**[1], **Karen Nazal**[1], **Macarena Viñuela**[1], **Norma León**[1]

[1]*Hospital Clinico Universidad Catolica*

BACKGROUND & AIM

Dysphonia is a prevalent health condition that affects communication, quality of life, and work productivity. Globally, prevalence estimates vary widely and are influenced by age, occupational voice demands, lifestyle factors, and comorbidities. Dysphonia is associated with multiple etiologies, including benign vocal fold lesions, inflammatory conditions, functional disorders, laryngopharyngeal reflux, neurologic diseases, and age-related changes. In Chile, there is a lack of comprehensive data regarding sociodemographic and diagnostic characteristics of this population. This study aims to characterize the sociodemographic profile and describe the diagnoses of patients who consult for dysphonia at a voice unit in a University healthcare network in Chile.

MATERIAL & METHODS

A total of 1,079 patients with dysphonia were assessed at the Voice Unit of a university hospital. The variables analyzed included age, sex assigned at birth, occupation, smoking status, laryngeal diagnoses, patient-reported outcome measures (PROMs), and GRBASI perceptual voice ratings.

RESULTS

Of the 1079 patients with dysphonia who were included in this study, 418 were male(38.7%) and 661 were female(61.3%). The age groups were as follows: under 18 years(n=68); 19–40 years(n=353); 41–60 years(n=383); and >60 years(n=162). The predominant professions of the patients were teachers, retired individuals and students. Smoking was reported by 17.7% patients. With regard to the etiology of dysphonia, in children(1–17 years old), cyst(n=23;33,8%), nodules(n=20;29,4%). In adults (18–60 years old), polyps(n=142;19.3%), muscle tension dysphonia(n=107;14.5%) and vocal paralysis(n=67;9.1%) predominated. In patients >60 years, vocal paralysis(n=47;17%), presbylarynx(n=30;10.9%), and vocal fold neoplasm(n=22;8%) predominated. Based on videolaryngoscopic findings, the sample group was divided into functional dysphonia(n=174), organic dysphonia(n=679) and movement disorders(n=226). The most frequently laryngeal pathologies were polyps, muscle tension dysphonia and vocal fold paralysis. Organic dysphonia was more common in all age groups and movement disorders dysphonia presented a worse voice quality and voice-related quality of life.

CONCLUSIONS

Among the 1,079 patients evaluated for dysphonia, adults and women represented the majority. The underlying causes varied according to age group: cysts and nodules were more frequent in children, polyps and muscle tension dysphonia predominated in adults, and vocal fold paralysis was more common in older individuals. This is the first study in Chile to report the prevalence and diagnostic distribution of dysphonia across a large, age-diverse cohort attending a Voice Unit within an Otolaryngology Department.

Standards Of Care In Gender-Affirming Laryngeal Surgery For Transfeminine Individuals: An International Delphi Consensus Study

Laura-Elisabeth Gosselin[1,2], **Ahmed Geneid**[3], **Markus Hess**[4], **Hyung-Tae Kim**[5], **Juan Carlos Casado Morente**[6], **Nupur Nerurkar**[7], **Chadwan Al Yaghchi**[1]

[1]National Center for Airway Reconstruction, Imperial College Healthcare NHS Trust, Charing Cross Hospital, London, UK; [2]CHU de Québec - Université Laval, Quebec, Canada; [3]Department of Otolaryngology and Phoniatrics—Head and Neck Surgery, Helsinki University Hospital and University of Helsinki, Helsinki; [4]Medical Voice Center, Hamburg, Germany; [5]Yeson Voice Center, Institute of Performing Art Medicine, Seoul, South Korea; [6]Department of Otorhinolaryngology. Hospital Quiron Salud Marbella & Hospital Quiron Salud Campo de Gibraltar. Spain; [7]Bombay Hospital Voice and Swallowing Centre, Bombay Hospital and Medical Research Centre, Mumbai, India

BACKGROUND & AIM

Gender-affirming voice interventions are a recognized and valued aspect of gender-affirming care, yet standardized clinical guidelines remain limited, highlighting the need for evidence-based directives. This study aims to establish consensus-based recommendations for standards of care in gender-affirming laryngeal surgery (GALS) for transfeminine individuals.

MATERIAL & METHODS

A modified Delphi consensus methodology was designed to achieve agreement among expert clinicians who demonstrated experience in performing or managing GALS. A consensus committee was established, and a panel of experts, including laryngologists and speech-language therapists were chosen. The panel consisted of full and associate members of the IATVS (International Association of Transvoice Surgeons), supplemented by select non-member physicians and speech-language therapists with recognized academic and clinical expertise. Statements were derived from current clinical practices, published literature, and expert input, and rated by panelists using a Likert scale across three anonymized online survey rounds. Essentiality items were additionally incorporated, to prioritize perioperative management recommendations. Consensus was defined as more than 70% agreement.

RESULTS

The consensus process was conducted over a 5-month period, with three iterative voting rounds. The expert panel comprised 33 experts. Twenty-three initial statements were included in the first voting iteration. After the initial round, 10 statements were modified, 8 statements were not accepted and 1 new statement was added. All new statements were accepted in round 2 and 2 new statements were added and subsequently accepted in round 3. A total of 18 statements have been included in the final consensus. Final statements are covering all aspects surrounding GALS, including preoperative evaluation, indication for surgery, surgical consent and postoperative management.

CONCLUSIONS

This study represents the first standard of care recommendations for gender-affirming laryngeal surgery, using a modified Delphi design. We believe this consensus will allow standardized perioperative management and overall better quality of care in GALS for transfeminine individuals. Further research is still needed to refine voice therapy protocols, surgical techniques, and the socioeconomic impact of GALS.

OP-622

Risk Factors Predicating Desaturation And Complications During Jet Ventilation In Endoscopic Airway Surgery

Andrew Kinshuck[2], **Worood Husain**[1], **Bisanth Batuwinage**[2]

[1]Salmaniya Medical Complex, Bahrain; [2]Liverpool foundation trust, UK

BACKGROUND & AIM

Endoscopic airway surgery is a shared a sahred field between anaesthesia and surgeons to address this challenge. Jet ventilation is used in these procedures to maitain surgical access. However, it does not come without complications. The imapct of patient characteristics regarding intraoperative complications remains unclear, highlighting the need to identify risk factors for jet ventilation failure.

MATERIAL & METHODS

502 patients between May 2015 and November 2024 were reviewed. complications were recorded. Types of endoscopic surgery were recorded. The patients who destaureated beloiw 89% were identified.

RESULTS

of 52 cases who desaturated, 23/52 (44.2%) were males and 29/52 (55.8%) were females.

the average age is 52.6 years and jetting time was 32.1 minutes.

obesity was present in 33/52 (63.5%)

26.9% was ex-smoker.

CONCLUSIONS

Jet ventilation is well tolerated . Smoking and obesity are risk factors for desaturation and they need to be taking with extra precuation.

OP-623

Impact Of HPV Vaccination On Surgical Burden In Recurrent Respiratory Papillomatosis: Preliminary Multi-Centre Hong Kong Data

Aurora Ka Yue Tam[2], **Alex Kam Fung Lee**[2], **Nikie Ho Yee Sun**[1], **Jason Ying Kuen Chan**[2]

[1]*The University of Hong Kong, Hong Kong;* [2]*The Chinese University of Hong Kong, Hong Kong;* [3]*Prince of Wales Hospital, Hospital Authority, Hong Kong*

BACKGROUND & AIM

Recurrent respiratory papillomatosis (RRP) is a chronic HPV-driven disease requiring repeated surgeries. The intersurgical interval (ISI) reflects disease control, but real-world data on adjuvant HPV vaccination and other modifiers in Asian populations remain scarce. This multi-centre study evaluated RRP burden in Hong Kong and whether adjuvant HPV vaccination increases ISI independent of baseline disease severity and other therapies.

MATERIAL & METHODS

This ongoing multi-centre review includes all patients with clinically diagnosed RRP treated at three tertiary hospitals in Hong Kong from January 2000 to December 2026. Demographic, clinical, and operative data were collected. The primary outcome was ISI; for patients without recurrence, ISI equalled the time from last surgery to latest follow-up. Key variables included juvenile- versus adult-onset RRP, initial and highest Derkay scores, adjuvant therapies (e.g. cidofovir), and HPV vaccination status. For patients receiving adjuvant treatment, pre- and post- treatment ISI were compared. Statistical analyses were performed using SPSS version 27.0.

RESULTS

At interim analysis, 23 patients (16 male, 7 female) were included, with mean age at diagnosis 42.4 years old (95%CI 35.0-49.8) and mean follow-up 146.9 months (95%CI 92.1-201.6). Most (91.3%) had adult-onset RRP. Hoarseness of voice was the most common presenting symptom, with the true vocal folds the predominant site. The mean number of operations per patient was 9.48 (95%CI 3.1-15.9). The median ISI was 20.2 months (1-125.5), corresponding to 0.05 (0-0.33) surgeries per month. Nine patients received HPV vaccination a mean of 57.4 months (95%CI 6.2-108.7) after diagnosis. In these patients, median ISI increased significantly from 10 months (2.4-18.2) pre-vaccination to 29 months (4.8-73) post-vaccination ($p < 0.05$). ISI did not differ significantly with cidofovir use, Derkay scores, or age of onset. Six patients (27.3%) experienced surgical complications, most commonly anterior glottic webbing. HPV genotyping and serological response data are being collected.

CONCLUSIONS

Preliminary data from this Hong Kong multi-centre study suggest that adjuvant HPV vaccination is associated with longer ISI in RRP, independent of baseline severity or adjuvant therapy. Ongoing recruitment and HPV subtype may clarify predictors of vaccine response and refine adjuvant treatment strategies.

KEYWORDS

Recurrent respiratory papillomatosis, RRP, HPV vaccine

OP-624

Office-Based Steroid Injection For Benign Vocal Fold Lesions

Yu-Hsiang Hung[1], **Chien-Jen Chiu**[1], **Yung-An Tsou**[1]

[1]*China Medical University Hospital*

BACKGROUND & AIM

Hoarseness is a common complaint in laryngology outpatient clinics and can be classified into organic and functional causes. Among organic causes, benign vocal fold lesions—such as nodules, polyps, and cysts—are the most frequently observed. In recent years, office-based steroid injection under endoscopic guidance has become a new treatment option for patients with mild lesions. The aim of this study is to evaluate pre- and post-treatment voice quality and change of lesion size in patients diagnosed with benign vocal fold lesions and treated with office-based steroid injections by two physicians at a single medical center.

MATERIAL & METHODS

This study retrospectively reviewed patients diagnosed with benign vocal fold lesions who received outpatient steroid injections between 2018 and 2024 at a single medical center by two practitioners via cricothyroid approach. Pre- and post-treatment voice analyses were conducted, including VHI-10, GRBAS, MPT, intensity, F0, highest/lowest frequency, NHR, jitter, shimmer. Size of lesions were also measured. Statistical analysis was performed using paired t-tests with SPSS.

RESULTS

Out of 120 patients, 37 with complete data were included. Results showed significant improvements in VHI-10 and GRBAS after treatment ($p<0.05$). The mean lesion size decreased by 43.84%, which was statistically significant.

CONCLUSIONS

Outpatient endoscopic steroid injection is an effective alternative for patients unable or unwilling to undergo general anesthesia or microlaryngoscopic surgery, and it can significantly improve voice quality and lesion size.

KEYWORDS

Benign vocal fold lesions, office-based steroid injection

OP-625

Inhaled Methoxyflurane – A Novel Adjunct For Office-Based Laryngeal Procedures

R, Jun Lin[1]

[1]*University of Toronto*

BACKGROUND & AIM

Methoxyflurane, an inhaled anesthetic introduced in the 1960s, has been repurposed at low doses as an emergency analgesic and is delivered via a handheld inhaler (Penthrox®). Its analgesic and anxiolytic properties may benefit patients undergoing awake laryngeal interventions. This study evaluated the safety and effectiveness of adding inhaled methoxyflurane to standard local anesthesia protocols for office-based laryngeal procedures.

MATERIAL & METHODS

A retrospective chart review was conducted on patients who self-administered Penthrox® prior to and during elective awake laryngeal procedures. Standard local anesthesia included nasal and topical laryngeal lidocaine application. Collected data included demographics, procedure type, and peri-procedural vital signs (HR, RR, O_2 saturation, SBP, DBP). Pain was rated on a 0–10 visual analogue scale. Descriptive analyses were performed, and the Wilcoxon Signed Rank test compared paired vitals.

RESULTS

Thirty-eight patients [22 men, median age 57 years (range 32–91), mean weight 78.2±14.1 kg] were included. Most underwent in-office laser ablation (32/38, 84.2%), with 6/38 (15.8%) receiving subglottic steroid injections. Average lidocaine use was 328.6±57.9 mg. Procedural completion was achieved in 37/38 cases (97.4%). Median intraoperative pain was 3/10 (range 0–10). Post-procedure O_2 saturation was slightly lower than baseline (96.1±2.0% vs 97.7±1.8%, $p<0.05$), while DBP increased modestly (87.6±11.6 vs 84.8±10.8, $p<0.05$). HR, RR, and SBP showed no significant changes. Reported side effects included drowsiness (23.7%), vomiting (10.5%), and dizziness (7.9%), with no major adverse events.

CONCLUSIONS

Inhaled methoxyflurane provides a safe and well-tolerated adjunct to local anesthesia for awake laryngeal procedures, supporting its role in optimizing patient comfort.

Is Voice Rest Necessary After Vocal Fold Surgery?

Dalia Gustaityte Larsen[1]

[1]*Aarhus University Hospital*

BACKGROUND & AIM

After vocal fold surgery it is common to recommend total voice rest for some days. A few latest studies reveal that it does not show significant differences in voice outcomes. Therefor this study may bring a new insight for future perspectives.

MATERIAL & METHODS

To perform a current literature review regarding latest knowledge of voice restrictions after vocal fold microsurgery and obtain suggestions for future voice use guidance.

RESULTS

The results of reviewed studies and collected data will be presented later.

CONCLUSIONS

The conclusions of this study with future proposals will be presented later.

OP-627

Laryngeal Diadochokinesis As A Potential Marker Of Vocal Stability Following Vocal Loading

Göksu Tarakçı[1], **Büşra Çınar**[1], **Ayşe Buse Saraç**[1], **Maral Yeşilyurt**[1], **Emine Beyza Karaboğa**[1]

[1]*Uskudar University*

BACKGROUND & AIM

Acoustic and electroglottographic (EGG) measurements are commonly used to assess phonatory changes that occur following vocal loading tasks, which are used to determine the physiological limits and endurance of the voice. However, the sensitivity of laryngeal motor performance measures, such as laryngeal diadochokinesis (LDDK), regarding vocal stability remains unclear. This study investigated changes in EGG-jitter, cepstral peak prominence (CPP), and LDDK following vocal loading and evaluated whether LDDK can serve as a marker of vocal stability.

MATERIAL & METHODS

Vocal loading was induced by asking participants to read a text for 1 hour at approximately 80 dBA. Measurements were obtained at three time points: before vocal loading (T0), immediately after vocal loading (T1), and after a 15-minute rest period (T2). EGG and acoustic recordings were collected simultaneously. The data were derived from adductor LDDK (rate of /a/ syllable repetitions) and sustained vowel /a/ phonation tasks. LDDK-rate was analyzed using Motor Speech Profile software, while CPP was analyzed using the Analysis of Dysphonia in Speech and Voice software. Repeated measures ANOVA was conducted to examine changes over time, and Bonferroni correction was applied for pairwise comparisons.

RESULTS

EGG-jitter values showed a significant effect of time. A significant increase in jitter was observed following vocal loading (T0: 0.880±0.310; T1: 1.058±0.438; $p < .001$). After the rest period,EGG-jitter significantly decreased (T1–T2: $p < .001$); however, T2 values remained significantly different from baseline (T2: 0.987±0.343; T0–T2: $p = .043$). LDDK-rate values significantly decreased following vocal loading (T0: 4.373±0.945; T1: 3.887±0.743; $p < .001$) and increased again after rest (T2: 4.239±1.016; T1–T2: $p = .004$). CPP values significantly increased following vocal loading (T0: 10.73±1.33; T1: 11.90±1.42; $p = .001$) and significantly decreased after rest (T2: 10.98±1.54; T1–T2: $p = .016$).

CONCLUSIONS

The findings indicate that vocal loading leads to significant changes in both acoustic and electroglottographic voice parameters. The decrease in LDDK performance following vocal loading and its subsequent recovery after rest suggest that laryngeal motor performance may be sensitive to changes in vocal stability. These results support the potential use of laryngeal diadochokinesis as a marker for assessing functional changes associated with vocal loading.

Vocal loading; Laryngeal diadochokinesis (LDDK); Vocal stability

OP-628

AIRWAY MANAGEMENT IN THE PRESENCE OF CERVICAL CEREBROSPINAL FLUID FISTULA: A RARE AND HIGH-RISK CLINICAL DILEMMA

Bárbara Rodrigues[1], **Gonçalo Quadros**[1], **Márcia Mourão**[1], **Joana Silva**[1], **André Gonçalves**[1], **Inês Pereira**[1], **António Alves**[1]

[1]*Department of Otorhinolaryngology, Unidade Local de Saúde de Viseu Dão-Lafões, Viseu, Portugal.*

BACKGROUND & AIM

Airway management in patients with complex cervical trauma is challenging. Prolonged mechanical ventilation in the presence of a cervical cerebrospinal fluid (CSF) fistula complicates tracheostomy due to the risk of CNS contamination, fistula worsening, and impaired tissue healing. Such cases are rare, and guidance for ventilator-dependent patients with active CSF fistula is limited. A literature review was performed to identify reported strategies and outcomes, highlighting the scarcity of data and reinforcing the clinical relevance of this scenario.

MATERIAL & METHODS

A 59-year-old male patient with traumatic tetraplegia underwent C7–T1 microdiscectomy, posterior fixation from C4 to C6, and C3–C7 laminectomy. By postoperative day 32, he remained ventilator-dependent via orotracheal intubation, exceeding conventional thresholds for prolonged intubation. Imaging revealed a right parathyroid hypodense collection (7.8 × 3 × 3.5 cm) extending into the superior mediastinum, with MRI confirming a cervical CSF fistula. The fistula's proximity to the tracheostomy site posed a high-risk clinical dilemma. A multidisciplinary team, including neurosurgery, otolaryngology, and intensive care specialists, conducted detailed anatomical assessment and coordinated surgical planning.

RESULTS

A stepwise airway management strategy was developed, prioritizing CSF fistula preservation while addressing the need for definitive airway access. Planning focused on minimizing intracranial contamination and tissue disruption. Airway management was executed according to this coordinated plan, emphasizing careful anatomical and procedural considerations throughout.

CONCLUSIONS

Cervical CSF fistula in ventilator-dependent patients represents a rare and complex airway challenge. Prolonged intubation requiring tracheostomy necessitates meticulous anatomical evaluation and multidisciplinary coordination. Integrating evidence from the literature can guide decision-making, while structured risk assessment and individualized planning are essential to ensure safe airway management in similarly high-risk cases.

Malignancy Rate Among Patients Presenting With Dysphonia

NEVRESTE DİDEM SONBAY YILMAZ[1], **MUHAMMET YILDIZ**[1], **ÖZER ERDEM GÜR**[1], **BEHÇET GÜNSOY**[2]

[1]Department of Otorhinolaryngology–Head and Neck Surgery, Antalya Training and Research Hospital, Antalya, Türkiye; [2]Department of Otorhinolaryngology–Head and Neck Surgery,Gaziantep University Türkiye

BACKGROUND & AIM

The aim of this study was to determine the frequency of laryngeal malignancy among patients presenting with dysphonia and to evaluate malignancy rates according to age, sex, and accompanying clinical findings. Additionally, we aimed to analyze the association between symptom duration, risk factors, and malignancy in order to identify potential predictive parameters that may facilitate early diagnosis in clinical practice.

MATERIAL & METHODS

The patients included in the study were divided into six age groups: 30–40, 40–50, 50–60, 60–70, 70–80, and ≥80 years. The rate of malignancy was analyzed separately for each age group, and the distribution between groups was compared.

RESULTS

While dysphonia in the 30–40 age group was primarily attributable to vocal cord paralysis secondary to thyroid malignancy, primary laryngeal malignancies constituted the leading cause of dysphonia in patients over 40 years of age.

CONCLUSIONS

Dysphonia should be regarded as a potential warning symptom for underlying malignancy, especially in older adults. The age-dependent shift in etiology underscores the need for an age-stratified diagnostic approach in patients presenting with voice complaints.

Surgical Treatment And Voice Therapy In Benign Vocal Fold Lesions: Evaluation Of Voice Quality With Objective And Subjective Voice Analysis

Muhammed Talha Yiğit[1], **Doç. Dr. Mehmet Akif Alan**[2], **Asude Beyza Savaş**[1]

[1]Konya City Hospital; [2]Istanbul Medipol University

BACKGROUND & AIM

This study aimed to evaluate the effects of postoperative voice therapy on voice quality in patients who underwent surgery for benign vocal fold polyps. The comparison was based on objective (PRAAT-based acoustic measures: fundamental frequency [F0], jitter, shimmer, noise-to-harmonics ratio [NHR], and maximum phonation time [MPT]) and subjective (GRBAS, Voice Handicap Index-10 [VHI-10], Voice-Related Quality of Life [V-RQOL]) voice assessment methods.

MATERIAL & METHODS

Twenty-seven patients aged between 18 and 65 years who were diagnosed with vocal fold polyp and underwent phonomicrosurgery were included. Patients were divided into two groups based on their treatment preferences: surgery only (n=14) and surgery combined with voice therapy (n=13). Voice analyses were performed preoperatively and at 3 months postoperatively. Objective parameters were measured using PRAAT software, and subjective evaluations were conducted using the GRBAS scale, Voice Handicap Index-10 (VHI-10), and Voice-Related Quality of Life (V-RQOL) questionnaire.

RESULTS

Both groups showed a general trend of improvement in voice parameters after surgery. However, a statistically significant difference was found only in the MPT parameter, which improved more prominently in the surgery+therapy group (p=0,014). No statistically significant differences were observed in other acoustic or subjective measures between groups.

CONCLUSIONS

Surgical treatment effectively improves phonatory efficiency in patients with vocal fold polyps. Postoperative voice therapy appears to provide an additional advantage, particularly by further enhancing phonation time, and contributes to overall functional recovery. The subtle changes in acoustic and perceptual measures may require longer follow-up periods to become

more pronounced. These findings support the integration of voice therapy as a complementary component of postoperative care to achieve optimal vocal rehabilitation.

OP-631

Impact Of Endotracheal Intubation Duration On Voice Quality: Objective Acoustic Analysis And Subjective Outcomes

Burcu Vural Çamalan[1], **Ebru Karakaya Gojayev**[1], **Hasan Söker**[1], **Elif Su Yaşar**[1], **Muharrem Dağlı**[1]

[1]*Ankara Etlik Hospital*

BACKGROUND & AIM
Endotracheal intubation (ETI) is recognized as a potential source of mechanical trauma to laryngeal structures, resulting in postoperative hoarseness in up to 50% of patients undergoing general anesthesia. Among the variables associated with postoperative voice changes, operative duration has received comparatively little attention, particularly when assessed through both objective and subjective outcome measures. Studies simultaneously incorporating objective acoustic analysis and validated patient-reported outcome measures across different intubation durations remain scarce. This study aimed to evaluate the effect of intubation duration on voice quality using both modalities across the preoperative and postoperative periods.

MATERIAL & METHODS
This prospective observational study included 105 patients undergoing elective surgery under general anesthesia (51 female, 54 male; mean age 47.21±15.89 years), stratified by operative duration: <60 minutes (n=39), 60–120 minutes (n=24), and >120 minutes (n=42). Voice quality was assessed preoperatively and on postoperative days one and five using the Voice Handicap Index (VHI), Voice-Related Quality of Life scale (V-RQOL), fundamental frequency (F0), jitter (%), shimmer (%), and harmonics-to-noise ratio (NHR). Statistical analyses were performed using IBM SPSS Statistics 23.0. Generalized Estimating Equations were applied for repeated measures analysis, with age and comorbidities as covariates. Statistical significance was set at p<0.05.

RESULTS
No significant differences were observed between operative duration groups in any voice parameter, and no group-by-time interaction reached statistical significance. VHI scores transiently increased on postoperative day one and returned to baseline by day five (p=0.007). V-RQOL improved significantly by postoperative day five compared to day one (p<0.001). Jitter (%) peaked on postoperative day one and showed significant improvement by day five (p=0.009). NHR reached its highest value on postoperative day five (p<0.001). Shimmer (%) and F0 showed no significant temporal variation.

CONCLUSIONS
ETI causes transient, self-limiting voice changes independent of operative duration, with objective and subjective outcomes returning to preoperative levels by postoperative day five. To our knowledge, this is one of the few studies integrating both acoustic parameters and patient-reported voice outcomes across varying intubation durations, addressing a meaningful gap in the literature. These findings provide an evidence-based framework for preoperative counseling, particularly for professional voice users undergoing elective surgery.

Effectiveness Of Supraglottoplasty In Supraglottic Exercise Induced Laryngeal Obstruction

Lorentz Sandvik[11], **Ola Drange Røksund**[1464,6,1], **Ole Gamlemshaug**[11], **Hans Jørgen Aarstad**[1313,], **Sivert Veseth Helland**[4664,6], **Haakon Kristian Kvidaland**[4664,6], **Hege H. Clemm**[4774,7], **Maria Vollsæter**[4554,5], **Thomas Halvorsen**[4554,5], **Petrine Veierød Solli**[4664,6], **John Helge Heimdal**[1231,2,3], **Camilla Martens1**[1]

[1]Department of Otolaryngology / Head and Neck Surgery, Haukeland University Hospital, Bergen, Norway; [2]Department of Surgery, Haukeland University Hospital, Bergen, Norway; [3]Institute of Clinical Medicine, University of Bergen, Bergen, Norway; [4]Department of Pediatrics, Haukeland University Hospital, Bergen, Norway; [5]Department of Clinical Science, University of Bergen, Bergen, Norway; [6]Faculty of Health and Social Sciences, Western Norway University of Applied Sciences, Bergen, Norway; [7]Department of Sports Medicine, Norwegian School of Sport Sciences, Oslo, Norway

BACKGROUND & AIM

Background: Exercise-induced laryngeal obstruction (EILO), is a transient inspiratory narrowing of the laryngeal airway during exercise, causing exertional dyspnoea and limiting physical performance. When conservative therapy fails, supraglottoplasty may be considered as treatment for patients with severe supraglottic EILO.

Aims: To elaborate the effects of supraglottoplasty on laryngeal obstruction and respiratory symptoms in EILO patients compared to not treated controls.

MATERIAL & METHODS

Material & Methods: In a randomized controlled clinical trial patients with verified EILO who remained symptomatic after conservative management were by consent randomized to surgical intervention or a wait-and-see control group. Conservative treatment included respiratory advice to all patients before randomization to either inspiratory muscle strength training, speech therapy or a combination of both. Supraglottoplasty was performed by bilateral aryepiglottic fold incisions with excision of the cuneiform tubercle tip. Continuous laryngoscopy during exercise (CLE) (Heimdal, 2006) was performed at baseline and at follow-up, 3-6 months after either surgery or the waiting period for controls. Laryngeal obstruction was graded using a validated CLE-score (Maat, 2009). Subjective breathing difficulties were assessed with symptom rating scales (SRS). Analyses compared within-group and between-group differences using appropriate statistical tests; significance was defined as $p < 0.05$.

RESULTS

Results: Twenty-six patients were randomized (13 in each group). Baseline CLE-scores did not differ between groups. CLE scores improved from pre- to post-surgery, by showing reduced obstruction mainly at the supraglottic level, both at moderate and maximal exercise intensity. Of the 13 surgically treated patients, six normalized their supraglottic CLE sub-score. Residual supraglottic adduction was within normal limits in six others, while one patient exhibited persistent marked supraglottic obstruction, indicating limited surgical effect. The control group showed no changes in CLE scores after waiting period. The SRS showed reduced overall symptom-score for respiratory distress in patients treated with supraglottoplasty compared to controls.

CONCLUSIONS

Conclusions: In patients with severe supraglottic EILO who did not respond to conservative management, supraglottoplasty proved superior to wait-and-see control.

OP-633

Effect Of Serial Intra-Lesional Steroid InjectionsOn Risk Of Recurrence In Idiopathic Subglottic Stenosis (Isgs)

R. Jun Lin[1]

[1]University of Toronto

BACKGROUND & AIM

Serial intralesional steroid injections (ILSIs) have been suggested to be an effective adjunct treatment for idiopathic subglottic stenosis (iSGS) by maintaining airway patency and extending inter-surgical intervals. However, evidence for the effectiveness of serial ILSIs remains inconclusive. The current study aimed to assess whether ILSIs reduce the risk of subsequent surgical dilation (i.e., recurrence) in a cohort of patients with iSGS.

MATERIAL & METHODS

Prospectively collected clinical data for 75 female iSGS patients with 1-4 years of follow-up were analyzed. To assess the effect of ILSI use on the risk of recurrence, we assessed both the time-to-first recurrence using a standard Cox proportional hazards model and all recurrences per patient using a recurrent-events model. Overall, there were 36 patients who had received ILSIs at any point in the follow-up period and 39 patients who had not.

RESULTS

ILSI use was associated with a significantly reduced risk of recurrence in both time-to-first event (hazard ratio (HR) = 0.20, 95% confidence interval (CI) 0.08-0.49) and recurrent events (HR = 0.44, 95% CI 0.26-0.75) multivariate Cox proportional hazard models, along with older age at diagnosis and longer time since diagnosis (all $p < 0.05$). In the time-to-first event analysis, the median time to recurrence among those who had received ILSIs was 2.5 years compared to 1.4 years among those who had not. The number needed to treat with ILSIs to avoid one recurrence by 2 years follow-up was two.

CONCLUSIONS

Serial ILSIs were associated with reduced risk of recurrence, along with older age at diagnosis and longer time since diagnosis.

Proactive Therapy For Treated Head And Neck Cancer

Yung An Tsou[1]

[1]*Department of Otolaryngology, China Medical University, Taiwan*

BACKGROUND & AIM

Dysphagia is a significant and persistent side effect following treatment for head and neck cancer (HNC), severely impacting patients' nutritional status, overall health, and quality of life. Surgical resection and chemoradiotherapy frequently damage swallowing-related structures, resulting in impairments in both the oral and pharyngeal phases. In clinical practice, early intervention through proactive swallowing therapy based on the "use it or lose it" principle has been increasingly emphasized.

MATERIAL & METHODS

This study synthesizes findings from two retrospective analyses involving patients with advanced HNC, including cancers of the oral cavity, oropharynx, and hypopharynx. Participants underwent tailored proactive swallowing rehabilitation programs targeting specific physiological deficits. Interventions included range-of-motion exercises, strengthening exercises, and compensatory swallowing maneuvers (e.g., Mendelsohn and Masako maneuvers), administered before, during, and after cancer treatment. Swallowing function was assessed using subjective measures (EAT-10, Reflux Symptom Index [RSI], MD Anderson Dysphagia Inventory [MDADI]) and objective evaluations (Functional Oral Intake Scale [FOIS], Penetration-Aspiration Scale [PAS], and Modified Barium Swallow Impairment Profile [MBSImP]). Assessments were conducted at baseline and at 1, 3, and 6 months post-treatment.

RESULTS

In both cohorts, swallowing function significantly deteriorated at 1 month post-treatment, reflecting the acute effects of cancer therapy. However, patients who participated in proactive rehabilitation demonstrated significant recovery over time. In a cohort of 90 advanced HNC patients, three months of rehabilitation resulted in significant improvements in FOIS, EAT-10, PAS, RSI, and pharyngeal delay time (PDT), outperforming non-rehabilitation controls. Similarly, among 118 oral cancer patients, substantial improvements in EAT-10, FOIS, and MBSImP scores were observed at 6 months post-surgery. Tube-feeding dependency decreased from 11.5% at 1 month to 5.4% at 6 months.

CONCLUSIONS

Early and continuous proactive swallowing therapy is essential in survivorship care for patients with head and neck cancer. Initiating rehabilitation prior to or during treatment and maintaining individualized programs for at least 3–6 months can effectively reverse acute swallowing dysfunction, reduce aspiration risk, and restore functional oral intake and quality of life. Regular, comprehensive swallowing assessments are critical for guiding treatment and monitoring long-term recovery.

OP-635

Risk Factors Predicting Open Surgical Tracheotomy Complications: A Retrospective Analysis

Atilay Yaylaci[1], **Bekir Cem Ozcan**[1], **Dogukaan Ruhi Akturk**[1], **Murat Ozturk**[1]

[1]*Kocaeli University Faculty of Medicine, Department of Otorhinolaryngology and Head and Neck Surgery, Kocaeli, Türkiye*

BACKGROUND & AIM

Tracheotomy is a life-saving surgical procedure performed to secure the airway (1). However, as with all surgical interventions, it carries potential risks that may increase morbidity, prolong hospitalization, and burden healthcare resources. (2,3) This study aimed to identify risk factors associated with postoperative complications, morbidity, and mortality following open surgical tracheotomy.

MATERIAL & METHODS

Medical records of patients who underwent open surgical tracheotomy between 2018 and 2024 at Kocaeli University Hospital were retrospectively reviewed. Demographic characteristics, comorbidities, surgical indications, urgency of the procedure, anesthesia type, history of chemoradiotherapy, and postoperative complications were analyzed.

RESULTS

A total of 315 patients (201 males, 114 females; median age: 64 years) were included. The most common indication for tracheotomy was prolonged intubation (62.5%). Complications occurred in 34.3% of patients, including 10.2% intraoperative, 22.5% early postoperative, and 4.1% late postoperative complications. Pneumonia was the most common complication (11.1%), while minor bleeding was the most frequent surgical complication (8.3%). Overall complication rates differed

significantly according to tracheotomy timing, being highest in emergency and lowest in elective procedures (61.1%, 42.0%, and 30.8%; p=0.015). Surgical complications showed a similar distribution (50.0%, 24.0%, and 15.8%; p=0.001). Patients with prior radiotherapy had higher surgical complication rates than those without radiotherapy (31.8% vs. 17.0%; p=0.020). Surgical complications were more frequent under local than general anesthesia, but this was not statistically significant (25.8% vs. 17.4%; p=0.130).

CONCLUSIONS

Open surgical tracheotomy is associated with a considerable rate of complications, particularly in emergency settings and in patients with prior neck radiotherapy. Elective procedures performed under general anesthesia demonstrated lower complication rates. Identifying and addressing modifiable risk factors, careful preoperative planning, and multidisciplinary management may help reduce morbidity and improve overall patient outcomes.

Early Effects Of Nebulized Ciprofloxacin/Dexamethasone In An In Vivo Tracheal Stenosis Rabbit Model

Travis Peng[1,2,3], **Pooja Swami**[1,2,4], **Rachel Kaye**[5], **Seth Kaplan**[1,3], **Daniel A. Grande**[1,2], **Patrick Scheffler**[1,3,6], **Lee P. Smith**[1,3,6]

[1]Northwell Health; [2]Feinstein Institute for Medical Research; [3]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell; [4]Department of Biotechnology, Shoolini University; [5]Department of Otolaryngology-Head and Neck Surgery, Rutgers New Jersey Medical School; [6]Division of Pediatric Otolaryngology, Steven and Alexandra Cohen Children's Medical Center of New York

BACKGROUND & AIM

Acquired tracheal stenosis often develops through a sustained fibroinflammatory response following mucosal insult. Ciprofloxacin/dexamethasone has shown promise as an adjunctive therapy for airway stenosis, with prior work from our group demonstrating reduced mucosal thickening and inflammation in a rabbit model following 3 weeks of treatment. However, the early effects of treatment during the acute post-injury phase remain incompletely characterized. This study evaluated whether nebulized ciprofloxacin/dexamethasone attenuates early mucosal thickening 24 hours after tracheal injury.

MATERIAL & METHODS

New Zealand White rabbits (n=4) underwent open tracheal injury using our previously established model in which the trachea was exposed through a midline cervical incision and mucosal injury was created using a nylon brush. Following injury, animals were randomized to receive either nebulized ciprofloxacin/dexamethasone (1mL of 0.3% ciprofloxacin / 0.1% dexamethasone diluted in 3mL saline) or no treatment. Rabbits were sacrificed 24 hours after injury, and tracheas were harvested for analysis. Specimens were imaged using microCT, and cross-sectional airway area was measured using ImageJ.

RESULTS

Untreated tracheas demonstrated increased mucosal thickness in injured regions compared with uninjured control regions (mean difference = 2.53 ± 0.17 mm2), consistent with an acute inflammatory response following mucosal disruption. We found that nebulized ciprofloxacin/dexamethasone significantly reduced the injury-associated change in mucosal thickness compared with untreated controls (p = 0.0309).

CONCLUSIONS

Nebulized ciprofloxacin/dexamethasone significantly attenuated early mucosal thickening 24 hours after tracheal injury in a rabbit model of acquired airway stenosis. Our previously published work demonstrated that nebulized ciprofloxacin/dexamethasone reduced subsequent stenosis development in this model. These findings suggest that treatment may act during the acute inflammatory phase of airway injury, even prior to the development of mature scar formation.

OP-637

A Retrospective Analysis Of 113 Cases With Deep Neck Space Infections: Mediastinal Progression And Prognostic Factors

Özlem Özdemir[1], **Aleyna Şivetoğlu**[1], **Deniz Baklacı**[1]

[1]Department of Otolaryngology, Zonguldak Bulent Ecevit University Faculty of Medicine

BACKGROUND & AIM

Deep neck infections (DNIs) represent a life-threatening clinical entity that can culminate in sepsis and multi-organ failure, particularly when progressing to mediastinitis. Literature indicates that the mortality rate rises to 16–40% upon the development of mediastinitis, exceeding 60% in certain cohorts. This study aims to retrospectively evaluate the clinical characteristics and predictors of poor prognosis/mortality among 113 patients followed for DNIs in our clinic, with a specific emphasis on cases complicated by mediastinitis.

MATERIAL & METHODS

In this single-center retrospective study, a total of 113 patients diagnosed and treated for DNIs between January 2023 and May 2026 were evaluated. Patient data regarding age and sex distribution, primary infectious focus, duration of symptoms, length of hospital stay, intensive care unit (ICU) admission, and duration of mechanical ventilation/intubation, white blood cell (WBC) count and C-reactive protein (CRP) levels at admission, involved anatomical neck compartments, and therapeutic interventions (antibiotic therapy alone, drainage, or surgical intervention) were analyzed. Cases that developed secondary mediastinitis due to DNI were subjected to a detailed subgroup analysis.

RESULTS

The mean age of 113 patients was 38.3±21 years (71.6% male). Pain and swelling were the most common complaints, with a median symptom duration of 5 days (IQR 3–7). The median length of hospital stay was 5 days (IQR 3–7; range: 1–55 days). Multi-compartment involvement occurred in 43.4% of cases. All patients received intravenous antibiotics. Regarding management, medical therapy alone was administered in 56.6% (n=64), needle aspiration or local/spontaneous drainage in 39.8% (n=45), and surgical exploration in 3.54% (n=4). Mediastinitis developed in 5 patients; 4 had a fatal outcome, resulting in a 3.54% overall mortality rate. For these critical cases, the median ICU stay was 4 days (IQR 2–15.75) and the median intubation duration was 4 days (IQR 3–10.5). Prolonged symptoms, multi-compartment involvement, and elevated baseline CRP/WBC levels emerged as prominent risk factors associated with mediastinitis and mortality.

CONCLUSIONS

Deep neck infections are poor-prognosis clinical entities that can rapidly progress to mediastinitis and death, particularly in the presence of delayed presentation, elevated CRP levels, and multi-compartment or retropharyngeal–anterior visceral space involvement. Early diagnosis, close clinical monitoring, aggressive medical therapy, and prompt surgical drainage/exploration when indicated are of critical importance in reducing mortality. Our findings underscore that this disease group must never be overlooked and that high-risk cases should be managed under intensive care conditions using a multidisciplinary approach.

Basic Research On Recurrent Laryngeal Nerve Regenerative Therapy Aimed At Restoration Of Vocal Fold Mobility

Koji Araki, M.D., Ph.D.[1], **Masahiko Seki, M.D.**[1], **Hiroshi Suzuki, M.D., Ph.D.**[1], **Naoya Yamazaki, M.D.**[1], **Takahiro Hirano, M.D.**[1], **Tatsuya Takenaka, M.D.**[1], **Kosuke Uno, M.D., Ph.D.**[1], **Akihiro Shiotani, M.D., Ph.D.**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, National Defense Medical College*

BACKGROUND & AIM

Functional recovery after recurrent laryngeal nerve (RLN) injury is impeded by motor neuron loss in the nucleus ambiguus, degeneration and insufficient regeneration of neuro-musclar junctions, laryngeal muscle atrophy, and misdirected reinnervation. We have previously demonstrated beneficial effects of gene- and pharmacological therapies using neurotrophic factors, including GDNF, BDNF and IGF-I, on neuronal survival, neuro-musclar regeneration, and nerve regeneration. However, misdirected reinnervation remains the most challenging obstacle. We hypothesized that selective inhibition of reinnervation to the posterior cricoarytenoid (PCA) muscle—the sole vocal fold abductor—would relatively enhance reinnervation of the adductor muscles and thereby improve glottal closure.

MATERIAL & METHODS

Sprague–Dawley rats underwent transection of the left RLN main trunk followed by bridging with a nerve regeneration tube (Nerbridge®). In the experimental group, the PCA branch was additionally transected (PCA branch transection group). Animals receiving RLN transection and tube bridging alone served as controls. At 15 weeks postoperatively, glottal movements were endoscopically recorded and quantitatively analyzed. Electrophysiological and histological evaluations of the regenerated RLN were subsequently performed.

RESULTS

Distinct glottal closure was observed more frequently in the PCA branch transection group. In contrast, little to no glottal closure was observed in the control group, although synkinetic movements were noted in a subset of animals. The glottal closure angle was significantly greater in the PCA branch transection group (2.3 ± 0.5° vs 0.8 ± 0.4°, $p < 0.05$). The compound muscle action potential of the adductor muscles was significantly higher in the experimental group (2.60 ± 0.54 V vs 0.76 ± 0.14 V, $p < 0.05$). No significant difference in nerve conduction velocity was observed between groups. The number of axonal fibers was significantly greater in the PCA branch transection group (172 ± 18 vs 120 ± 21, $p < 0.05$), whereas axonal diameter did not differ significantly between groups.

CONCLUSIONS

Selective suppression of reinnervation to the PCA branch of the RLN induced preferential reinnervation of the glottal adductor muscles and resulted in dynamic recovery of glottal closure. This approach may represent a potential therapeutic strategy for RLN injury.

OP-639

A Noble Combined Otoneurolological And Middle Fossa Approach For Post Mastoidectomy Meningoencephalocele

Dr Abhishek Bahadur Singh[1], **Dr Anupam Mishra**[1], **Dr Chitij Srivastava**[1]

[1]*King George Medical University Lucknow*

BACKGROUND & AIM

The post-mastoidectomy meningoencephaloceles are not suspected early at times. They are usually referred to a neurosurgeon.

MATERIAL & METHODS

Two cases of large post-mastoidectomy herniations were treated using a combined middle fossa and otological approach. A posterior-based post-aural incision allowed for the elevation of a periosteal flap towards the external auditory canal herniation site. Drill holes were created to breach the skull and enlarge for dura exposure. The skull cap was removed to access the dura, revealing herniated meninges and brain. Nonfunctional brain tissue was resected, followed by dural suturing. A split calvarial bone graft reinforced the tegmen defect, and surgical glue secured the assembly. A lumbar drain was used postoperatively for three days, along with antibiotics and acetazolamide to manage cerebrospinal fluid production.

RESULTS

Both patients successfully underwent repair of large post-mastoidectomy meningoencephaloceles using a combined neuro-otological middle fossa approach, with no major intraoperative complications. The procedure allowed for adequate exposure, excision of herniated tissue, and effective dural closure. Reconstruction utilized split calvarial bone graft, preventing recurrent herniation. Postoperative recovery was smooth, with no cerebrospinal fluid leaks or infections. Lumbar drainage and acetazolamide therapy minimized intracranial pressure, aiding healing. Hearing function was maintained, and follow-up indicated good wound healing and stable outcomes, showcasing the technique's safety and effectiveness.

CONCLUSIONS

The combined neuro-otological middle fossa approach is a safe and effective technique for managing large post-mastoidectomy meningoencephaloceles. It provides excellent exposure for dural repair and reconstruction while minimizing brain retraction and preserving hearing function. Simultaneous management of associated middle ear pathology can also be achieved. The use of split calvarial bone grafts, lumbar drainage, and adjunctive medical therapy contributes to successful healing and prevention of recurrence. This multidisciplinary approach offers favorable immediate and long-term outcomes with minimal postoperative complications.

OP-640

Neither Wave Nor Vibration: Harmonic Hydromechanical Motion As A New Theory Of Auditory Physiology

Tieso Maria Fernanda, Md.[1], **Marcovecchio Remo, Eng.**[1], **Tieso Santos, Md.**[1]

[1]*Sound Engineering University, Universidad de Tres De Febrero, Buenos Aires, Argentina*

BACKGROUND & AIM

The aim of this study is to demonstrate that the traveling wave does not exist. Von Békésy's theory was based on observations of an inert cochlea stimulated at high sound pressure levels, where he described basilar membrane movement and phase differences between basal segments and the resonance site. By extrapolating existing mathematical models, he predicted basilar membrane displacement at threshold levels; however, these values were implausible and later contradicted by Khana and Leonard. Because the classical wave equation cannot be directly applied to cochlear fluids, Békésy proposed a "slow wave", a concept that still lacks a defining algebraic expression.

MATERIAL & METHODS

In this primary investigation in auditory physiology, we developed a theoretical model termed the Harmonic Hydromechanical System. This model strictly adheres to established principles of fluid dynamics, electromagnetism, acoustics, Newtonian mechanics, and Pascal's law, among others. It provides a mathematical framework for analyzing cochlear behavior under various acoustic stimuli without introducing hypothetical physical entities inconsistent with known laws.

RESULTS

We developed a set of coupled equations enabling both Lagrangian and Eulerian analyses of cochlear fluid motion through hydromechanical and particular impedances. These formulations demonstrate that Békésy's interpretations are physically insufficient and that cochlear physiology requires a more comprehensive framework—one that, while conceptually novel, remains fully consistent with established physical and mathematical principles.

CONCLUSIONS

The proposed equations offer a coherent explanation of cochlear physiology and account for phenomena such as the auditory threshold curve, the Fletcher–Munson equal-loudness contours, the Tullio phenomenon, and the predominance of higher-frequency loss in auditory fatigue testing. Although in vivo measurements are still required, experimental validation in artificial models is currently underway to further substantiate this theory.

OP-641

Role Of MRI Diffusion-Weighted Imaging (DWI) In Cholesteatoma Diagnosis And Surgical Planning

Azfar Javed[1], **Atilla Dezso**[2], **Harpreet Chohan**[2]

[1]*Royal Stoke University Hospital, U.K.*; [2]*Walsall Manor Healthcare Trust, U.K.*

BACKGROUND & AIM

Magnetic resonance imaging with diffusion-weighted sequences (MRI-DWI) is increasingly used to detect and monitor cholesteatoma. This study evaluates its diagnostic accuracy and impact on surgical decision-making over five years.

MATERIAL & METHODS

A retrospective analysis was conducted of MRI-DWI scans performed between April 2020 and June 2025 for suspected primary or recurrent cholesteatoma. Radiology, operative, and follow-up data were reviewed to determine diagnostic accuracy, surgical outcomes, and recurrence.

RESULTS

A total of 391 MRI-DWI scans were identified. Of these, 56 were positive in 52 patients, including 28 first-time diagnoses and 28 recurrence assessments. MRI-DWI demonstrated 48 true positives, 8 false positives, and 1 false negative, with a sensitivity of 98% and specificity of 97.6%. Diagnostic errors were more common in scans reported by non–head and neck radiologists.

Of the positive cases, 45 patients underwent surgery, including limited attico-antrostomy (n=10), combined approach tympanoplasty (n=13), canal wall down (CWD) mastoidectomy (n=13), and CWD with obliteration (n=5). MRI-DWI informed operative planning by defining disease extent, although three cases required intraoperative conversion to more extensive surgery due to underestimated disease. Postoperative follow-up identified 9 cases of recurrence or residual disease.

CONCLUSIONS

MRI-DWI demonstrates high diagnostic accuracy for both primary and recurrent cholesteatoma. It plays a key role in confirming diagnosis, guiding surgical approach, and supporting postoperative surveillance.

OP-642

Development Of An Innovative App For The Diagnosis And Treatment Of Tinnitus Using Sound Therapy And Nutritional Supplements

Sergio A Mora Camargo PhD Acoustic Neuroengineering Researcher Sound Engineer[1], **Israel de la Cruz MD**[1]

[1]*Hospital Zambrano Hellion Tec Salud*

BACKGROUND & AIM

Tinnitus is the perception of sound—such as ringing, buzzing, or hissing—in the absence of an external auditory stimulus. It affects approximately 10–15% of the adult population worldwide and can significantly impair quality of life by causing sleep disturbance, concentration problems, anxiety, and depression.Tinnitus is often associated with hearing loss, noise exposure, ototoxic medications, or neurological and psychological factors. However, its exact pathophysiology remains complex, involving abnormal neural activity and maladaptive plasticity in the auditory pathways and brain networks responsible for sound perception and attention.

MATERIAL & METHODS

Current tinnitus management is largely symptomatic, emphasizing psychological adaptation and sound-based therapies. Nowdays, emerging digital and neuromodulation technologies offer new possibilities for personalized, accessible, and effective care. The integration of AI-driven tools like mobile apps, represents a significant step toward individualized tinnitus management and potentially better clinical outcomes.

RESULTS

Since the sound is unlikely to disappear entirely, the focus is on reducing intrusiveness and impact on life: improving sleep, concentration, reducing annoyance, emotional distress. Not everyone responds the same. Some predictors of better response include relatively recent onset of tinnitus, better hearing, less severe hearing loss, positive attitude toward therapy. By Logging daily experiences allows users (and clinicians) to identify factors that make tinnitus better or worse we can monitor patterns, triggers, and symptom severity. Also tthrough the app we encourages personalized management and empowers self-awareness.

CONCLUSIONS

the App offers significant benefits for patients. These tool enable real-time tracking of symptoms, medication adherence, and lifestyle habits, leading to early detection of health issues and more effective tinnitus management. It also promotse patient engagement and self-awareness. Overall, disease monitoring apps enhance accessibility, improve health outcomes, and support a more proactive approach to healthcare.

Symptomatic Vs. Asymptomatic Semicircular Canal Dehiscence: Evaluating The Clinical Correlation Between Radiological Findings And Symptomatology

Muhammed Sefa UYAR[1], **Melih AKGÜL**[1], **Mehmet Özgür PINARBAŞLI**[1], **Ercan KAYA**[1], **Şaziye Armağan İNCESULU**[1]

[1]*Department of Otorhinolaryngology - Head and Neck Surgery, Eskişehir Osmangazi University Faculty of Medicine, Eskişehir, Turkey*

BACKGROUND & AIM

Since its 1998 identification, semicircular canal dehiscence (SCD) has emerged as the pathognomonic 'third window' pathology. Although its pathophysiology is well-defined, the ubiquity of high-resolution CT (HRCT) has precipitated a surge in incidental findings among asymptomatic cohorts, complicating the clinical interpretation of radiological defects. This study is predicated on the hypothesis that anatomical dehiscence does not inherently dictate clinical manifestation. The objective is to delineate the correlation between HRCT evidence and actual symptomatology. It is contended that clinical presentation, rather than isolated imaging, must remain the primary diagnostic determinant to mitigate overdiagnosis and unwarranted interventions.

MATERIAL & METHODS

A retrospective cohort study was conducted using temporal bone high-resolution computed tomography (HRCT) reports from a tertiary university hospital over a ten-year period (2015–2025). A total of 405 patients with radiologically confirmed semicircular canal dehiscence (SCD) were initially identified. To minimize potential confounding factors, 53 patients with a history of chronic otitis media, otosclerosis, or prior otologic surgery were excluded. The final cohort comprised 352 patients, who were categorized into ‘symptomatic’ and ‘asymptomatic’ groups based on clinical records. Statistical analyses were performed using IBM SPSS Statistics v26.0 (IBM Corp., Armonk, NY, USA). Categorical variables were analyzed using Pearson’s chi-square test, and continuous variables were compared using the independent samples t-test or Mann–Whitney U test, as appropriate. Normality was assessed using the Shapiro–Wilk test. A p-value <0.05 was considered statistically significant.

RESULTS

Among 352 evaluated cases, 57 (16.2%) were classified as symptomatic, while 295 (83.8%) were asymptomatic. No statistically significant difference was observed in gender distribution between the groups. The symptomatic group had a significantly higher mean age (50.6 ± 15.5 years) compared to the asymptomatic group (45.0 ± 16.0 years) (p = 0.031). Imbalance was the most frequently reported clinical complaint, observed in 44 patients (12.5%). Characteristic physical findings, including sound- or pressure-induced nystagmus (Tullio phenomenon and Hennebert sign), were present in 11 symptomatic patients (19.3%). Among the subgroup that underwent cervical Vestibular Evoked Myogenic Potential (cVEMP) testing (n = 40), pathological thresholds were detected in 25 cases (62.5%). Bilateral dehiscence was identified in 63 patients (17.9%), with no significant association between bilaterality and symptom presence (p = 0.939).

CONCLUSIONS

The findings demonstrate that a significant proportion of individuals with radiological dehiscence remain asymptomatic. Consequently, diagnostic evaluation should prioritize clinical presentation over isolated imaging findings. The detection of radiological dehiscence in younger asymptomatic patients, followed by symptomatic manifestation in older cohorts, suggests a dynamic disease progression influenced by aging. While objective markers such as nystagmus and cVEMP are valuable diagnostic adjuncts, treatment decisions should be primarily guided by complaints that impair quality of life. To prevent unwarranted surgical interventions, clinical practice should focus on addressing the patient's symptomatic status rather than isolated radiological abnormalities.

Dynamic Endoscopic Assessment Of Tympanic Membrane Mobility In Eustachian Tube Disorders

Saleh Alamry[1]

[1]*Prince Sultan Military Medical City (PSMMC)*

BACKGROUND & AIM

Assessment of Eustachian tube (ET) function remains challenging, as most available tools provide indirect or static evaluation. Endoscopic visualization of tympanic membrane (TM) mobility offers a dynamic and real-time method to assess ET patency. This study aims to propose a practical endoscopic classification system for TM mobility and evaluate its clinical utility in diagnosing and monitoring Eustachian tube disorders, including obstructive dysfunction and patulous Eustachian tube (PET).

MATERIAL & METHODS

Endoscopic ear examination was performed to assess TM mobility under controlled conditions, including modified Valsalva maneuver and nasal breathing. TM motion patterns were categorized into six types based on mobility and recoil characteristics:

- Type I–II: Reduced or absent mobility
- Type III: Normal mobility
- Type IV–VI: Increasing hypermobility associated with PET

The classification was applied in routine clinical assessment and follow-up of patients with suspected ET dysfunction.

RESULTS

The proposed classification allowed clear differentiation between obstructive ET dysfunction, normal ET function, and varying degrees of patulous ET. Dynamic TM behavior demonstrated consistent correlation with clinical presentation and provided a practical framework for bedside evaluation and follow-up.

CONCLUSIONS

Endoscopic dynamic assessment of TM mobility represents a simple, reproducible, and clinically applicable tool for functional evaluation of the Eustachian tube. The proposed classification system facilitates diagnosis, grading, and longitudinal monitoring of both obstructive and patulous ET disorders.

OP-645

A Retrospective Review Of Revision Cochlear Implant Surgery

Özgür Yiğit[1], **Selin Üstün Bezgin**[1], **Ozan Özdemir**[2], **Nursena Nair Polat**[1]

[1]*Health Sciences University, Istanbul Basaksehir Cam and Sakura City Hospital, Department of Otorhinolaryngology;* [2]*Istanbul Training and Research Hospital, Department of Otorhinolaryngology*

BACKGROUND & AIM

Cochlear implantation (CI) is a safe and effective surgical procedure for the rehabilitation of hearing in patients with severe sensorineural hearing loss. However, some patients may require revision surgery during follow-up.

To evaluate the clinical and surgical characteristics of patients who underwent revision cochlear implant surgery.

MATERIAL & METHODS

In this retrospective study, patients who underwent CI between 2008 and 2026 were reviewed. Patients who underwent revision surgery were included in the analysis. Demographic datas, implant characteristics, revision ages, intervals between revisions, causes of revisions, and surgical procedures performed were analyzed.

RESULTS

Among 1,375 patients, revision surgery was required in 83 patients (6.04%), with a total of 121 revision procedures performed. Patients had a mean age of 6.1 ± 11.6 years; 53.1% were female and 46.9% male. Most patients undergoing revision required only one procedure (73.4%), while smaller proportions underwent multiple revisions.

The leading cause of revision surgery was device failure (40.6%), predominantly hard failure (96.2%). Other common causes included skin defects (19.5%), electrode migration (7%), device migration (6.3%), and electrode tip fold-over (3.9%).

Among the 121 procedures, the most frequently performed intervention was explantation with ipsilateral reimplantation during the same session (42.1%). Other common procedures included electrode repositioning (11.6%) and isolated skin defect repair (9.1%). Explantation with contralateral implantation combined with flap repair of the skin defect during the same session accounted for 6.6% of procedures. Ipsilateral reimplantation of the existing device was performed in 5.8% of procedures.

CONCLUSIONS

Revision CI was observed more frequently in young children and was most often performed due to device hard failure problems and skin defects. Explantation and ipsilateral reimplantation during the same session and skin defect repair were among the most frequently performed surgical procedures.

OP-646

Modified Canal Wall Up Facial Recess Approach In Cholesteatoma: Anatomical And Hearing Outcomes Versus Canal Wall Down

Dr Davit Gevorgyan[1]

[1]*Erebuni Medical Center, Yerevan, Armenia • Vagharshapat (Ejmiatsin) Medical Center, Armenia • Artashat Medical Center, Armenia*

BACKGROUND & AIM

Cholesteatoma surgery requires complete disease removal while preserving hearing and middle ear anatomy. Canal wall down techniques provide reliable disease control but sacrifice normal anatomy, whereas canal wall up techniques with facial recess approach aim to preserve anatomy but may risk residual disease. This study compares anatomical preservation, residual cholesteatoma rates, and hearing outcomes between canal wall up (facial recess) and canal wall down techniques in a single-surgeon series.

MATERIAL & METHODS

A retrospective single-surgeon study was conducted on 20 patients with middle ear cholesteatoma. Patients were divided into two groups: 10 underwent canal wall up surgery using a facial recess approach, and 10 underwent canal wall down mastoidectomy. Outcomes assessed included anatomical preservation, residual disease, and postoperative hearing improvement. Follow-up evaluations were performed clinically and audiologically to compare surgical results between the two techniques.

RESULTS

All patients were successfully operated without major intraoperative complications. In the canal wall up group, normal middle ear anatomy was preserved in all cases, with one case of residual cholesteatoma. Hearing improvement was observed postoperatively in most patients. In the canal wall down group, one case of residual disease was also identified; however, anatomical disruption of the middle ear and mastoid cavity was present in all cases, with comparatively less favorable hearing outcomes.

CONCLUSIONS

Canal wall up cholesteatoma surgery using the facial recess approach provides superior anatomical preservation with comparable residual disease rates to canal wall down surgery in this single-surgeon series. Additionally, canal wall up technique demonstrated better postoperative hearing outcomes, supporting its role as a preferred approach in selected patients when complete disease removal is achievable while preserving middle ear function.

OP-647

Serum Paraoxonase-1 And Carbonic Anhydrase IX Levels In Patients With Chronic Otitis Media With And Without Cholesteatoma:A Case-Control Study

Ülke Direybatoğulları[1], **Kazım Bozdemir**[1]

[1]*Ankara Yıldırım Beyazıt University, Department of Otolaryngology Head and Neck Surgery, Ankara, Türkiye*

BACKGROUND & AIM

To evaluate serum levels of the antioxidant enzymes Paraoxonase-1 (PON1) and Carbonic Anhydrase IX (CA-IX) in patients with chronic otitis media (COM), with and without cholesteatoma, and to assess the influence of systemic comorbidities and nasal septum deviation on these enzyme levels.

MATERIAL & METHODS

This single-center case–control study was conducted at the Department of Otorhinolaryngology, Ankara Bilkent City Hospital, between September and December 2022. Written informed consent was obtained from all participants.This study included 41 patients aged 18–65 years diagnosed with COM and 39 healthy controls. Patients with a history of previous ear surgery were excluded. Based on high-resolution computed tomography (HRCT) findings, patients were classified into two subgroups: COM without cholesteatoma (simple COM) (n=27) and COM with cholesteatoma (n=14).Clinical and demographic data were collected, and venous blood samples were obtained from all participants. Serum PON1 and CA-IX levels were measured using spectrophotometric methods. Statistical analyses were performed to compare enzyme levels between groups and to evaluate the effects of cholesteatoma, comorbidities, and nasal septum deviation.

RESULTS

Serum PON1 levels were significantly lower in patients with COM compared with healthy controls ($p < 0.001$). Although CA-IX levels were lower in the COM group, this difference did not reach statistical significance. Among COM patients, those with nasal septum deviation showed significantly reduced PON1 levels ($p = 0.001$), whereas higher PON1 levels were observed in patients with systemic comorbidities ($p = 0.033$). Both PON1 and CA-IX levels were significantly decreased in patients with COM and cholesteatoma compared with those without cholesteatoma ($p < 0.001$ and $p = 0.021$, respectively).

CONCLUSIONS

Reduced serum levels of PON1 and CA-IX may be associated with chronic inflammatory processes in COM, particularly in patients with cholesteatoma. These enzymes may serve as potential biomarkers for disease severity and progression, although further prospective studies are needed.

Artificial Intelligence-Based Prognostic Prediction In Sudden Sensorineural Hearing Loss

Muhammed Sefa UYAR[1], **Yigit AKCI**[1], **Mehmet Ozgur PINARBASLI**[1], **Melek Kezban GURBUZ**[1], **Hamdi CAKLI**[1], **Saziye Armagan INCESULU**[1]

[1]*Department of Otorhinolaryngology, Faculty of Medicine, Eskişehir Osmangazi University, Eskişehir, Turkey.*

BACKGROUND & AIM

Sudden sensorineural hearing loss (SSNHL) is an otologic emergency defined as a hearing loss of at least 30 dB across three consecutive frequencies within 72 hours, most often of idiopathic origin. Its prognosis varies widely depending on factors such as time to treatment initiation, baseline hearing thresholds, and accompanying vertigo, making individualized prediction difficult. Although recent studies have applied nomograms and deep learning models to analyze these complex data, prognostic research has largely focused on deep learning approaches. The role of non–deep learning artificial intelligence methods in clinical decision-making remains limited.This study evaluates their predictive value in SSNHL prognosis.

MATERIAL & METHODS

Adult patients diagnosed with SSNHL between 2015 and 2026 at the Department of Otorhinolaryngology, Eskişehir Osmangazi University, were included in the study. Patients with insufficient follow-up, history of trauma, or incomplete data were excluded. Demographic characteristics, symptom duration, audiometric patterns, accompanying symptoms, comorbidities, and treatment protocols were transformed into a standardized dataset. These data were processed using non–deep learning machine learning algorithms that leverage artificial intelligence's ability to analyze past clinical experiences and complex relationships between variables. Individual hearing prognoses were predicted using systems trained on existing clinical data.

RESULTS

A total of 208 patients were included in the study. Preliminary analyses demonstrated that initial hearing thresholds, time to treatment initiation, and audiometric patterns were key determinants of prognosis. Non–deep learning machine learning

models successfully captured nonlinear relationships among clinical variables and achieved high accuracy in predicting hearing recovery. Particularly in cases with complex symptomatology, these models provided more comprehensive predictive insights compared to traditional statistical methods.

CONCLUSIONS

This study demonstrates that non–deep learning artificial intelligence approaches can serve as reliable and interpretable tools for predicting SSNHL prognosis. The developed models have the potential to provide clinicians with an objective decision-support mechanism for individualized treatment planning and patient counseling.

OP-649

Retrospective Evaluation Of Our Primary Stapedotomy Outcomes

Can Apaydın[1], **Yüksel Olgun**[1], **Enis Alpin Güneri**[1]

[1]*Dokuz Eylul University, Faculty of Medicine, Department of Otorhinolaryngology and Head and Neck Surgery, Izmir, Türkiye*

BACKGROUND & AIM

Stapedotomy is the standard surgical treatment for otosclerosis-related conductive hearing loss. Although it is a well-established procedure, debate continues regarding the influence of surgical approach, piston diameter, and laterality on hearing outcomes. The aim of this study was to evaluate the postoperative hearing results of patients who underwent primary stapedotomy in our clinic over the past decade and to assess potential factors affecting these outcomes in light of the current literature. We hypothesized that surgical approach, piston diameter, and operated side would not significantly influence hearing gain.

MATERIAL & METHODS

Demographic data, surgical characteristics, and pre- and postoperative audiological assessments of patients who underwent stapedotomy at Dokuz Eylul University, Department of Otorhinolaryngology, between January 2014 and May 2024 were retrospectively reviewed. Patients with at least 6 months of postoperative audiological follow-up were included; revision surgeries were excluded. Pure-tone audiometry results obtained preoperatively and at the postoperative 6th month were analyzed. Air and bone conduction thresholds at 0.5, 1, 2, and 4 kHz were used for evaluation. Surgical approach (microscopic/endoscopic), piston diameter, and operated side (right/left) were assessed as independent variables.

RESULTS

Of 177 stapedotomies performed, 118 ears of 107 patients met inclusion criteria. Mean air-bone gap (ABG) decreased from 29.88 ± 8.30 dB preoperatively to 7.62 ± 6.99 dB at 6 months, with a mean gain of 22.26 ± 8.85 dB ($p<0.001$). Postoperative ABG was <10 dB in 76 ears (64.4%), 10–20 dB in 39 (33.1%), and 21–30 dB in 3 (2.5%). A 0.6 mm piston was used in 95 ears (80.5%) and 0.4 mm in 23 (19.5%). Microscopic endaural approach was applied in 86 ears (72.9%) and endoscopic transcanal in 32 (27.1%); 67 (56.8%) were right-sided. No significant differences in hearing gain were found by piston diameter, approach, or side ($p=0.1218$, 0.8547, 0.2063). Bone conduction deterioration >10 dB occurred in 5 ears (4.25%). Transient vertigo/nystagmus occurred in 10 patients (8.5%), all resolving conservatively. Intraoperative tympanomeatal perforations in 10 patients (8.5%) were repaired in the same session without sequelae.

CONCLUSIONS

Primary stapedotomy provides reliable and significant hearing improvement in otosclerosis. Hearing outcomes were not significantly affected by piston diameter, surgical approach, or operated side, supporting the surgeon's preference-based selection of these parameters.

OP-650

Is Galvanic VEMP A Prediction Of The Nerve Origin And Damage In Patients Of Vestibular Schwannoma

Zhang Yan[1], **Chen Zichen**[1], **Zhang Yuzhong**[1], **Chen Feiyun**[1], **Hu Juan**[1], **Wang Junli**[1], **Zhang Qing**[1]

[1]*Department of Otolaryngology Head & Neck Surgery, Second Affiliated Hospital of Xi'an Jiaotong University, School of Medicine, Xi'an, Shaanxi, China*

BACKGROUND & AIM

Recent studies proved that certain proportions of vestibular schwannoma (VS) originated other than vestibular nerve of the eighth cranial nerve.Unlike air-conducted sounds (ACS) and bone-conducted vibration (BCV), galvanic vestibular stimulation (GVS) evokes vestibular evoked myogenic potentials (VEMPs) from the vestibular nerve.

MATERIAL & METHODS

Case-control study was conducted in unilateral VSpatients pre-operatively. Healthy ears were controls. Patients examined ACS, BCV and GVSocular VEMP (oVEMP) and cervical VEMP (cVEMP), caloric test, video head impulse test (vHIT), suppression head impulse paradigm (SHIMP) and pure tone audiometry (PTA).

RESULTS

Seven (26.9%) tumors affected left ear and 19 (73.1%) on the right($p < .05$). Response rates in VSgroup were statistically lower than control except for ACS-cVEMP ($p < .05$). Response rates of VEMPs in VSpatients decreased with the tumor size grows. But not all BCV and GVSVEMPs disappeared in the largest tumor group. Abnormal rates of caloric test, vHITgains and SHIMP were found.

CONCLUSIONS

Response rates of GVSVEMPs decreased with the residual functional nerve fibers. GVSVEMPs help to differentiating labyrinthine and retro-labyrinthine lesions. GVScombined with BCV VEMPs probably reflex the tumor origin from the eighth cranial nerve and/or the remaining vestibular function

KEYWORDS

Vestibular schwannoma; vestibular evoked myogenic potentials; caloric test; video head impulse test; suppression head impulse paradigm

OP-651

Beyond Graft Take: Determinants Of Post-Myringoplasty Infection And Myringitis In A Retrospective Cohort Study

Dr. Teh Hui Mon[1], **Dr. Natalie Pang Yan-Lin**[1], **Dr. Raymond Ngo Yeow Seng**[1]

[1]*Department of Otolaryngology – Head & Neck Surgery, Ng Teng Fong General Hospital & National University Hospital, Singapore.*

BACKGROUND & AIM

Myringoplasty is performed to achieve a dry, stable tympanic membrane (TM), yet a proportion of patients remain troubled by a persistent “wet ear” due to post-operative infection or myringitis despite closure of TM. The incidence and determinants of these complications, particularly late-onset myringitis, are not well defined. This study aimed to determine the incidence of post-myringoplasty infection and myringitis and to identify clinical predictors. We hypothesized that host and middle-ear factors would outweigh surgical variables in driving these outcomes.

MATERIAL & METHODS

We conducted a retrospective clinical study of 152 consecutive myringoplasties for chronic TM perforation in adults in a single institution. Collected variables were smoking, diabetes, atopy, immunocompromised status, middle-ear (ME) mucosa, perforation site, graft type, surgical technique, and use of post-operative prophylactic topical or oral antibiotics. Outcomes were post-operative infection and post-operative myringitis, defined as persistent erythema or granulation of the TM with otorrhoea beyond the expected healing period. Myringitis was categorized as early onset (<6 weeks) or late onset (>6 weeks). Associations were examined using χ^2 or Fisher’s exact tests and multivariable logistic regression, reported as odds ratios (OR) with 95% confidence intervals (CI).

RESULTS

Post-operative infection occurred in 19/152 patients (12.5%). Infection was more common in smokers than non-smokers (25.7% vs 8.5%; p=0.007), with smoking independently associated with a higher infection risk (adjusted OR 4.23; 95% CI 1.13–15.82; p=0.032). Post-operative myringitis developed in 23/152 patients (15.1%). On multivariable analysis, atopy (adjusted OR 4.68; 95% CI 1.16–18.86; p=0.03) and abnormal ME mucosa (adjusted OR 9.24; 95% CI 2.22–38.47; p=0.002) were strong independent predictors of myringitis, while anterior perforations were protective compared with central perforations (adjusted OR 0.19; 95% CI 0.04–0.80; p=0.024). A history of atopy was significantly associated with late-onset myringitis: 75.0% of atopic patients had late onset versus 26.7% of non-atopic patients (OR for late vs early onset 8.25; 95% CI 1.15–59.00; p=0.039). Surgical technique, graft material, and prophylactic antibiotics were not significantly associated with infection or myringitis.

CONCLUSIONS

After myringoplasty, clinically relevant rates of post-operative infection (12.5%) and myringitis (15.1%) contribute to persistent wet ear. Smoking is a key modifiable risk factor for infection, whereas atopy and abnormal ME mucosa strongly predispose to myringitis, with atopic patients particularly vulnerable to late-onset disease. In contrast, surgical technique, graft choice, and prophylactic antibiotics appear to have limited impact on these complications. Pre-operative optimization of ME status, smoking cessation, and extended surveillance plus targeted counselling for atopic patients may help reduce persistent wet ear following myringoplasty.

CT-Like Images Of The Temporal Bone From MRI Using Machine Learning: Development, Validation And Usefulness

P. (Paul) Merkus, MD PhD[1], **M.D. (Marlise) van der Veen, MSc**[1], **M.M.S. (Bas) Jasperse, MD PhD**[1], **P. (Pim) de Graaf, MD PhD**[1], **J.P.A. (Joost) Kuijer, PhD**[1], **T. (Thadé) Goderie, MD PhD**[1]

[1]*Amsterdam UMC*

BACKGROUND & AIM

For otological diagnostics and pre-surgical planning both MRI and CT are frequently wanted to visualise soft tissues and bone structures. A single, radiation-free imaging modality generating both soft and bony tissue information would be ideal.

Aim: To train and evaluate a machine-learning algorithm for generating synthetic-CT images (sCT) from MRI of the head.

MATERIAL & METHODS

Paired MRI and CT scans have been obtained from 73 patients. Sixty-seven paired scans were used to train a machine-learning algorithm to generate sCT images from MRI data. Fifteen MRI scans were used to create sCT images for evaluation purposes (technical accuracy, clinical accurateness and clinical suitability.)

RESULTS

Geometry and radiodensity on sCT were sufficiently accurate. Conspicuity of 12 clinically relevant landmarks was independently rated by two otologists and two radiologists on a 4-point Likert scale ranging from poor to excellent. The conspicuity was generally deemed comparable. However, the thickness of the tegmen bone was sometimes overestimated, while on the other hand, the ossicles were often not depicted by the algorithm. The four raters assessed most sCT scans (>80%) as been suitable for localisation, not for diagnostic purposes.

CONCLUSIONS

CT-like images of the temporal bone can be successfully generated from MR images of the head using a machine learned algorithm. This is making visualisation of bony next to soft tissues, using a single, radiation-free imaging modality possible. Synthetic CT-images are considered suitable for localisation in otologic procedures.

OP-653

Management Of Petrous Apex Cholesterol Granuloma

Alessia Rubini[1], **Daniele Marchioni**[1], **Nicola Bisi**[1]

[1]*Modena University Hospital*

BACKGROUND & AIM

Petrous apex cholesterol granulomas are benign inflammatory cystic lesions of the temporal bone. Although many patients are asymptomatic, symptoms may develop as the lesion enlarges. Diagnosis relies on a combination of CT and MRI findings, and management options include a “wait-and-scan” strategy or surgical intervention.

MATERIAL & METHODS

Patients with petrous apex choelsterol granuloma who underwent surgical treatment between 2014 and 2024 were included. Clinical presentation, imaging findings, surgical approach, and postoperative complications were analyzed. CT scans were classified into Type A (preserved petrous apex cellularity), Type B (erosion of the petrous apex cellularity), and Type C (involvement of the bony boundaries of critical neurovascular structures). The presence of potential connections between the lesion and the infracochlear, perilabyrinthine, and sphenoidal air cell tracts was also evaluated.

RESULTS

Nineteen symptomatic patients presenting with diplopia, headache, and sensorineural hearing loss were included. According to the proposed classification, 1/19 patients were classified as Type A, 4/19 as Type B, and 14/19 as Type C. Five patients underwent total resection, seven subtotal resection, and seven surgical drainage. Only two postoperative complications were observed, and 17/19 patients demonstrated symptom regression and disease stability during follow-up.

CONCLUSIONS

Although the management of petrous apex cholesterol granulomas remains controversial, our classification and surgical outcomes suggest a tailored approach. Type A lesions, which are usually asymptomatic, should be managed with a “wait-and-scan” strategy. Type B lesions should be surgically treated when symptomatic, whereas Type C lesions warrant surgical intervention in all cases because of their invasive nature and potential for serious complications. When feasible, surgical drainage should be preferred; otherwise, resection is indicated, with the extent of removal guided by the patient’s preoperative general condition and hearing status.

Vestibular Organ Surgery: A Piezo Of Cake? Using A Piezoelectric Drill To Fenestrate Semicircular Canals

Raymond van de Berg[1], **Stan van Boxel**[1], **Angelo Immordino**[2], **Nils Guinand**[3], **Joost Stultiens**[1]

[1]*Department of Otorhinolaryngology and Head & Neck Surgery, Maastricht University Medical Center, The Netherlands;* [2]*Department of Otorhinolaryngology, Palermo University Hospital, Palermo, Italy;* [3]*Department of Otorhinolaryngology, University Hospital Geneva, Geneva, Switzerland*

BACKGROUND & AIM

To investigate the effects of piezoelectric drill use for semicircular canal fenestration on the endolymphatic membrane, hearing, and vestibular function.

MATERIAL & METHODS

The piezoelectric drill was used to fenestrate semicircular canals in five patients undergoing surgical plugging of a semicircular canal. This involved posterior canal plugging (n=4) for intractable BPPV and superior semicircular canal plugging (n=1) for superior canal dehiscence syndrome. Primary outcome measures included: Preservation of endolymphatic membrane intraoperatively; Bone conduction Pure Tone Average of 1, 2 and 4 kHz (PTA1,2,4); Air conduction 8 kHz threshold; Lateral semicircular canal VHIT vestibulo-ocular reflex gain (VOR gain) and asymmetry; 4) cVEMP and oVEMP thresholds. Secondary outcome measures included VHIT VOR gain and asymmetry of the plugged and non-plugged vertical canals of the operated ear. Audiovestibular testing was performed preoperatively, and at 1 week and 2 months postoperatively (VEMPs only at 2 months postoperatively).

RESULTS

The membranous labyrinth was preserved in all cases following fenestration of the canals using the piezoelectric drill. No endolymphatic leakage was observed.

No significant sensorineural hearing loss was found in PTA1,2,4 at one week and two months postoperatively. Two out of five patients demonstrated a high-frequency hearing loss of >10dB at 8 kHz, assessed two months postoperatively (both 15 dB increase).

Nu unintended loss of vestibular function was found at 1 week and 2 months postoperatively.

CONCLUSIONS

The piezoelectric drill appears safe for semicircular canal fenestration. Findings of this study should be validated in a larger cohort of patients. If replicated, vestibular surgery might become a ‘piezo of cake’.

Composite Patient-Specific 3D Printed Models For Complex Temporal Bone Pathology: A Case Series

Adam Omari[1,2,3], **Obinna I. Nwosu**[3], **Dunia E. Abdul-Aziz**[3], **Steven A. W. Andersen**[1,4], **Alicia M. Quesnel**[3], **Alicia M. Quesnel**[3]

[1]*Department of Otolaryngology–Head & Neck Surgery, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark;* [2]*Institute for Cellular and Molecular Medicine (ICMM), Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark;* [3]*Department of Otolaryngology-Head and Neck Surgery, Massachusetts Eye and Ear, Boston, Massachusetts, USA;* [4]*Dept. of Clinical Medicine (ICM), Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark*

BACKGROUND & AIM

Temporal bone surgery involves navigating complex anatomy with a narrow margin for error. Patient-specific 3D printed temporal bone (PS-TB) models facilitate surgical planning, but traditional methods are costly, resource-intensive, and typically limited to bony anatomy, omitting critical soft tissues and pathology. This study introduces a rapid, cost-effective workflow utilizing consumer-grade 3D printing to create composite PS-TB models and evaluates their clinical utility in four unique complex cases.

MATERIAL & METHODS

We conducted a prospective case series of four complex temporal bone surgeries at the Massachusetts Eye and Ear Infirmary, Boston, USA. Clinical CT and MRI data were semi-automatically segmented to generate 3D models incorporating bony matrix, neurovascular structures, and target pathology. Models were manufactured using consumer-grade multi-material FDM and resin 3D printers as either drillable preoperative rehearsal models or pre-drilled intraoperative inspection models. Model utility was assessed postoperatively by surgeons using the Schlegel questionnaire.

RESULTS

Composite patient-specific 3D printed models were successfully produced for four distinct challenging cases: revision translabyrinthine resection of a vestibular schwannoma, congenital external auditory canal duplication with an aberrant facial nerve, petrous apex chondrosarcoma, and complex cholesteatoma with a labyrinthine fistula. All four surgeries were performed safely with no postoperative complications.

Surgeons rated the models excellent in user experience, reporting increased confidence and ease of use across all cases. The semi-automated workflow required approximately 1-2 hours of processing time. Material costs were vastly reduced compared to industrial methods, ranging from USD 2 for inspection models to USD 15 for drillable rehearsal models. Break-even analysis indicated the models become cost-effective if they save just 4 minutes of operative time.

CONCLUSIONS

Composite patient-specific 3D printed models, integrating soft tissues and pathology, can be rapidly and affordably manufactured using consumer-grade technology. These accessible models provide surgical confidence and spatial awareness, offering a practical and cost-effective tool for preoperative rehearsal and intraoperative navigation in complex temporal bone surgery.

Pediatric Endoscopic Cholesteatoma Surgery

Georgy Polev[2], **Ilya Zyabkin**[1], **Aina Magomedova**[1]

[1]*Federal Scientific and Clinical Center for Children and Adolescents of the Federal Medical-Biological Agency of Russia;* [2]*Ilyinskaya hospital*

BACKGROUND & AIM

The aim of this study was to evaluate the effectiveness of an endoscopic approach in the surgical treatment of chronic suppurative otitis media (CSOM) with cholesteatoma in children.

MATERIAL & METHODS

Between 2021 and 2025, 85 endoscopic surgeries were performed on children with chronic suppurative otitis media andconfirmed cholesteatoma. Patients age ranged from 2 to 17 years. The follow-up period ranged from 3 to 39 months. The study included patients with CSOM and cholesteatoma without signs of spreading into the mastoid cells. Surgical technique involved a transcanal approach, creation of a meato-tympanic flap, and sequential removal of the cholesteatoma under the control of 0°, 45° and 70° Karl Storz rigid endoscopes. All patients underwent not only the debridement but also a reconstructive stage of the surgery using a chondro-perichondrial tragal graft. Treatment effectiveness was assessed based on the integrity and vascularization of the neotympanic membrane, as well as the absence of signs of residual cholesteatomaor its recurrence, using control studies (CT and MRI fusion imaging) at 6 and 12 months postoperatively.

RESULTS

All patients in the postoperative period showed satisfactory vascularization of the neotympanic membrane, with no signs of lateralization or deformation of the cartilage graft. During the follow-up, no signs of residual or recurrent cholesteatoma were detected based on postoperative examinations. The only intraoperative complication was injury to the jugular bulb in one patient; the bleeding was stopped intraoperatively with local packing, and the surgery was completed.

CONCLUSIONS

The endoscopic approach provides optimal visualization of hard-to-reach areas of the middle ear that are inaccessible without additional bone removal when using a microscope. The ability to look around the corner allows for the precise removal of residual cholesteatoma tissue, thereby preventing further interventions. Furthermore, the endoscopic approach is associated with less surgical trauma and less postoperative pain, which is particularly important in pediatric practice. However, the isolated endoscopic approach is not universal and has limitations, primarily related to anatomical features or the spread of cholesteatoma into the mastoid process.

Facial Tumors: Symptoms, Diagnosis And Management

Mario Sanna[1]

[1]*VITTORIA DI RUBBO Gruppo Otologico Piacenza*

BACKGROUND & AIM

Study the characteristics and surgical approaches of the Facial tumors, including the long-term outcomes of the grafts used after surgical sacrifice of the nerve itself.

MATERIAL & METHODS

The retrospective study involved all cases of the Facial tumors between July 1989 and July 2025 treated at our Quaternary Reference Center for Skull Base Surgery. The characteristics, treatment strategies, and results in terms of improvement of facial paralysis at 1 and 3 years after intraoperative sural nerve grafting were studied.

RESULTS

The patients showed improvement of facial paresis up to grade III according to House-Brackmann at the last postoperative follow-up. A low-grade preoperative facial paresis according to HB is an important predictive factor for postoperative improvement.

CONCLUSIONS

The facial tumors can affect multiple segments of the nerve itself. A low-grade preoperative facial paresis according to HB shows a greater improvement compared to a high-grade preoperative facial paresis. The greatest improvement that can be achieved in the long term is a grade III according to HB.

A Case Of Otitis Media With ANCA-Associated Vasculitis Comorbid With Asthma And Chronic Rhinosinusitis Treated With Tezepelmab, An Anti-TSLP Antibody

Tomoaki Shirakawa[1], **Marie Yamada**[1], **Koichi Hirose**[1], **Kengo Kanai**[1], **Ryo Takagi**[1], **Maki Akamatsu**[1], **Ihsan Gunduz**[1], **Akiho Shibata**[1], **Masahiro Takahashi**[2], **Mitsuhiro Okano**[1]

[1]*International University of Health and Welfare Narita Hospital;* [2]*International University of Health and Welfare Mita Hospital*

BACKGROUND & AIM

Otitis media with anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (OMAAV) is a disease that produces refractory otitis media and/or progressive sensorineural hearing loss in association with ANCA-associated vasculitis.

MATERIAL & METHODS

The patient was a 42-year-old man with severe asthma and peripheral blood eosinophilia. Dupilumab, an anti-interleukin-4 (IL-4) receptor alpha antibody, was first used to treat his asthma. Thereafter, he developed myeloperoxidase specific (MPO)-ANCA positive EGPA. Hence, glucocorticoid (GC) administration was commenced, and mepolizumab, an anti-IL-5 antibody, was introduced, leading to sustained remission for 15 months.

RESULTS

After gradually tapering off the GC, he developed bilateral CRS, for which endoscopic sinus surgery (ESS) was performed. After mepolizumab was tapered, the respiratory symptoms flared up again, along with left-sided hearing loss, earache, and otorrhea, which was diagnosed as OMAAV. The treatment was switched to benralizumab, an anti-IL-5 receptor antibody. However, as the GC was gradually tapered, serum MPO-ANCA levels increased again, with relapse of coughing and shortness of breath. Hence, the treatment was switched to tezepelumab. Immediately thereafter, his MPO-ANCA level became negative, and the various symptoms, including OMAAV, CRS, and respiratory symptoms, improved, with sustained remission despite tapering of GC.

CONCLUSIONS

This is the first reported case of the efficacy of tezepelumab for treating OMAAV comorbid with CRS and asthma due to EGPA.

Audiological And Histopathological Investigation Of The Ototoxic Effects Of Bee Venom: An Experimental Study

Murat Erinç[3], **Emirhan Çeviken**[1,2], **Serdal Çelik**[1,2], **Erdoğan Bulut**[4,5], **Ahmet Mutlu**[1,2], **Ali Murati**[1,2], **M. Tayyar Kalcıoğlu**[1,2]

[1]*Istanbul Medeniyet University, Faculty of Medicine, Department of Otorhinolaryngology, Istanbul, Türkiye;* [2]*Göztepe Prof. Dr. Süleyman Yalçın City Hospital, ENT Clinic, Istanbul, Türkiye;* [3]*Istanbul Medeniyet University, Faculty of Health Sciences, Department of Audiology, Istanbul, Türkiye;* [4]*Trakya University, Faculty of Health Sciences, Department of Audiology, Mirko Tos Ear and Hearing Research Center, Edirne, Türkiye;* [5]*Trakya University, Mirko Tos Ear and Hearing Research Center, Edirne, Türkiye*

BACKGROUND & AIM

Due to its anti-inflammatory, antibacterial, antioxidant and antineoplastic properties, bee venom is being used increasingly in various fields of medicine. There are also some publications regarding its potential use in treating ear diseases. However, while the neurotoxic side effects of bee venom are well known, its ototoxic effects have not yet been clearly determined.This study aims to evaluate potential ototoxic effects of bee venom using audiological and histopathological methods.

MATERIAL & METHODS

A total of 40 Wistar albino rats were included in the study. The animals were divided into five groups for intratympanic injection: Group A received 0.5 mg/mL of bee venom; Group B received 1 mg/mL of bee venom; Group C received 0.1 mg/mL of bee venom; Group D received an isotonic solution, and Group E received a solution of 70% isopropyl alcohol and 2%

chlorhexidine. Baseline hearing thresholds were measured using an auditory brainstem response (ABR) test. Each rat subsequently received three intratympanic injections of 0.03 ml administered every two days. ABR measurements were repeated on days 7 and 21. Following the final measurements, the rats were sacrificed and their temporal bones underwent histopathological examination.

RESULTS

The baseline hearing thresholds of all groups were within normal limits. Administering increasing doses of bee venom was associated with dose-dependent ototoxicity. This effect was more pronounced at higher frequencies (e.g. 32 kHz). This was particularly evident in Group B, which received the highest dose of bee venom, and in the alcohol group. Significant changes were also observed in Group A, which received a moderate dose. In contrast, Group C, which received the lowest dose, showed limited changes in ABR measurements, and no significant ototoxic effect compared to the isotonic solution group. Histopathological examinations revealed progressively more pronounced degenerative changes with increasing doses, consistent with the audiological findings.

CONCLUSIONS

This study is the first to demonstrate the ototoxic effects of bee venom using audiological and histopathological methods. The findings suggest that bee venom poses an ototoxic risk, especially at high doses, although the impact may be more limited at lower doses. These results suggest that the potential ototoxic effects of bee venom must be carefully considered when it is used in clinical practice.

Early Taste Disturbance After Middle Ear Surgery, The Role Of Chorda Tympani Manipulation

László Székely[1], **Anita Gáborján**[1], **László Tamás**[1], **Gábor Polony**[1]

[1]*Semmelweis University*

BACKGROUND & AIM

One of the most common postoperative complication after middle ear surgery is temporary or permanent taste disturbance, which is due to the anatomical location of the chorda tympani nerve. A detailed knowledge of the characteristics of this complication is essential for optimal intraoperative decision-making. Our goal is to investigate taste disturbances in the early postoperative period. We aimed to clarify the consequences of the different types of surgeries and the effects of chorda tympani manipulation during surgery.

MATERIAL & METHODS

A prospective investigation was carried out using questionnaires one day before and on the day after the procedure. 14 patients underwent stapes surgery and 25 patients underwent tympanoplasty. We examined the change using a visual analogue scale (VAS, 0-10) and simple decision questions. The manipulations were divided into 5 categories based on the degree of nerve damage.

RESULTS

There was no significant difference in postoperative taste complaints between tympanoplasty and stapes surgery (VAS score 9 vs. 8.9; (p=0.914)). The mean VAS values in the '0', '1' and '2' groups were 10, 9.23, and 8.5, respectively. A significant difference was found between the 'no manipulation' (0) and the 'significant manipulation without visible injury' (2) groups (VAS 10 vs. 8.5; (p=0.044)). No significant taste-related complications (VAS<5) occurred in the stapes surgery group.

CONCLUSIONS

With appropriate microscopic ear surgery technique, a relatively low complication rate was found, and the type of surgery did not influence the complication rate. Postoperative taste disturbance can be kept to a low level, preservation of the chorda tympani is possible in most cases. The presence of postoperative complaints depend on the degree of nerve manipulation and not on the type of surgery.

Contemporary Surgical Management Of Malignant Tumors Of The External Auditory Canal

Kryukov A.I.[1], **Garov E.V.**[1], **Kravtsov S.A.**[3], **Zelenkova V.N.**[1], **M.M. Radzhabova**[1], **Lapenko E.G.**[1]

[1]*The Sverzhevskiy Otorhinolaryngology Healthcare Research Institute;* [2]*Pirogov Russian National Research Medical University, Moscow, Russia;* [3]*Yudin City Clinical Hospital, Oncology Center No. 1, Moscow, Russia*

BACKGROUND & AIM

Malignant tumors of the external auditory canal (EAC) are rare and aggressive neoplasms, with squamous cell carcinoma (SCC) accounting for approximately 80% of cases. Optimal surgical management, particularly regarding elective neck dissection and

parotid resection in clinically node-negative patients, remains controversial. The aim of this study was to evaluate surgical outcomes and define treatment strategy according to tumor stage.

MATERIAL & METHODS

Between 2021 and 2025, 14 patients (9 men, 5 women; age 45–66 years) with histologically confirmed EAC malignancies were treated. Ten patients were diagnosed with SCC and four with basal cell carcinoma. Tumor staging was as follows: T1N0M0 (n=4), T2N0M0 (n=4), T3N0M0 (n=3), T3N1M0 (n=1), and T4N0M0 (n=2). Surgical management was tailored to tumor stage and included lateral temporal bone resection, subtotal temporal bone resection, parotidectomy, and neck dissection where indicated. Adjuvant radiotherapy was administered in eight patients.

RESULTS

Patients with T1–T2 disease underwent lateral temporal bone resection, with selective soft tissue and auricular reconstruction when required. Advanced-stage tumors (T3–T4) were treated with subtotal temporal bone resection combined with parotidectomy and neck dissection, even in the absence of clinically evident metastasis. Histopathology confirmed SCC in 10 cases and basal cell carcinoma in 4. Positive surgical margins were identified in two advanced-stage cases. During follow-up (3–42 months), local recurrence occurred in one patient (T3N0M0) 1.5 months postoperatively; combined chemoradiotherapy achieved disease stabilization for 12 months. No recurrence was detected in other patients based on serial contrast-enhanced MRI. One patient (T4N0M0) died of unrelated causes.

CONCLUSIONS

Early diagnosis and a multidisciplinary approach are critical for achieving oncologic radicality in EAC malignancies. Combined treatment, including temporal bone resection with adjuvant radiotherapy, improves disease control in T2–T4 stages. Elective neck dissection and parotidectomy should be considered in advanced tumors regardless of clinical nodal status. Positive surgical margins remain an adverse prognostic factor.

Mind The Gap: A Comprehensive Review Of Facial Nerve Dehiscence In Chronic Otitis Media And Its Surgical Challenges

Ouziane Megherbi[1], **Si Belkacem Amar Boulifa**[1], **Mokhtar Hasbellaoui**[1], **Kenza Merwa Chadjaa**[1], **Celia Lina Lamali**[1], **Samira Medkour**[1], **Lilya Oukaour**[2]

[1]*Otorhinolaryngology department of university hospital of Bab El Oued Algiers Algeria;* [2]*Medical imaging and interventional radiology of university hospital of Bab El Oued*

BACKGROUND & AIM

Background: Facial nerve dehiscence (FND) remains a formidable "silent hazard" in middle ear surgery, particularly in the context of chronic otitis media and cholesteatoma. While anatomical literature provides a framework for its prevalence, a significant clinical "gap" persists between preoperative radiological suspicion and intraoperative reality, posing a constant risk of iatrogenic injury.

Aim: To analyze the prevalence, anatomical distribution, and surgical implications of FND by integrating a literature review with a retrospective clinical series, and to propose a standardized "safety-first" management algorithm.

MATERIAL & METHODS

We conducted a hybrid study combining a systematic review of Fallopian canal anatomy with a retrospective analysis of 444 patients undergoing otological surgery at our institution over a 2-year period (January 2024 to December 2025). Preoperative High-Resolution Computed Tomography (HRCT) scans and intraoperative microscopic findings were compared to assess diagnostic accuracy. Surgical modifications and protective maneuvers employed upon FND discovery were recorded.

RESULTS

In our clinical series, FND was identified in 18,24% of cases. The tympanic segment was the most frequent site of exposure 97%, particularly near the oval window. Our data highlights a significant "radiological-surgical mismatch," where HRCT sensitivity for FND was only 21,43%, often failing to distinguish true dehiscence from a thin bony lamella. Intraoperative discovery of FND necessitated a modification of the surgical plan was noted in the majority of our patients. We describe a specific "Step-Back" technique for incidental discovery and the use of cartilage for nerve reinforcement. 8,65% of the patients with FND presented a transitory facial nerve palsy. No cases of permanent postoperative facial palsy occurred.

CONCLUSIONS

Facial nerve dehiscence is a common "trap" for the otologist. "Mind the Gap" is a dual imperative: narrowing the diagnostic gap through critical imaging interpretation and bridging the surgical gap through systematic nerve identification and protective protocols. We advocate for a high index of suspicion and a standardized surgical approach to minimize risks during middle ear procedures, regardless of preoperative imaging results

Readability Analysis Of Online Patient Education Materials In Otology: A Cross-Sectional Study

Abdullah Qureshi[1], **Ayeh Aldulaymi**[1], **Hamza Arshad**[1], **Dr. Katie De Champlain**[1], **Dr. Amiel Dror**[1]

[1]*University of Saskatchewan*

BACKGROUND & AIM

Patients with otologic concerns rely on written information for education; yet, ~60% of adult Canadians lack the minimum health literacy. Therefore, this study evaluates the readability of web-based otology patient education materials. We also seek to answer: Can artificial intelligence reduce the reading level of otology resources to meet health literacy guidelines?

MATERIAL & METHODS

This cross-sectional study, conducted in November 2025, examined online patient education materials on 7 otologic conditions. Four large language models were used to write original text for each otologic condition, allowing direct comparison with the existing materials. The primary outcome measures consisted of extracting validated readability metrics, including Flesch Kincaid Grade Level (FKGL). The independent variables include outcome source (AI vs webpage) and otologic condition. Preliminary analyses obtained descriptive statistics, 95% confidence intervals, t-tests, one-way ANOVA, and Wilson confidence intervals.

RESULTS

70 otology websites were analyzed. Mean FKGL score was 9.94 (SD 2.64; 95% CI 9.31–10.57), significantly exceeding the recommended sixth-grade reading level (95% CI 3.31–4.57; $t(69)=12.50$, $p< 0.001$). Only 10.0% of webpages met a sixth-grade level (95% CI 4.9%–19.2%). Comparing the 28 AI-generated rewrites to webpage content, AI revisions were significantly less readable, with a mean FKGL score of 11.08 ($p=0.0018$).

CONCLUSIONS

Online otology patient education consistently exceeds the recommended readability standards, with uniform complexity across all otology topics. Contrary to expectation, AI revisions significantly worsen readability rather than improving it. Current online otology information remains difficult for most patients to read, underscoring barriers to informed decision-making and equitable care.

OP-664

A Hidden Surgical Risk: Intratympanic Aberrant Internal Carotid Artery

Rafael Pires[1], **Vera Vaz Teixeira**[1], **Jorge Dentinho**[1], **Leonor Oliveira**[1], **David Marcelo**[1], **Filipa Castelão**[1], **Luís Pereira**[1], **Lisete Santos**[1], **Luis Antunes**[1]

[1]*Hospital Garcia de Orta, Almada*

BACKGROUND & AIM

Intratympanic aberrant internal carotid artery (ICA) is a rare congenital vascular anomaly characterized by an abnormal course of the ICA within the middle ear cavity. It may present with pulsatile tinnitus, conductive hearing loss, and a retrotympanic mass, and carries a significant risk of life-threatening hemorrhage if misdiagnosed and surgically manipulated. Carotid–cochlear dehiscence (CCD) has recently been described as a potential “third-window” lesion at the basal turn of the cochlea. We present a case report that aims to highlight the coexistence of these entities and discuss their clinical and radiological implications.

MATERIAL & METHODS

A 51-year-old patient presented with a 15-year history of progressive right-sided hearing loss, ear fullness, and continuous pulsatile tinnitus. Otoscopic examination showed a right white pulsatile retrotympanic mass in the anteroinferior quadrant. Audiological evaluation revealed a right-sided Jerger type B tympanogram and moderate conductive hearing loss, with an air–bone gap of 25 dB and a pure-tone average of 50 dB. Computed tomography and magnetic resonance imaging/angiography demonstrated a right aberrant ICA with an intratympanic course in close contact with the ossicular chain, with focal CCD involving the basal turn of the cochlea, and a left persistent trigeminal artery (Saltzman type I). The patient was proposed for rehabilitation with a bone-anchored hearing aid and is currently awaiting implantation.

RESULTS

Imaging confirmed the diagnosis and excluded other retrotympanic vascular or neoplastic lesions. The conductive hearing loss is best explained by impaired ossicular mobility secondary to contact with the aberrant ICA. Although CCD may theoretically contribute via a third-window mechanism, its clinical relevance in this case appears limited.

CONCLUSIONS

Intratympanic aberrant ICA should be considered in the differential diagnosis of pulsatile retrotympanic masses. Accurate radiological identification is essential to prevent potentially catastrophic hemorrhagic complications during middle ear procedures. Hearing rehabilitation with bone-anchored devices represents a safe and effective management strategy, while surgical intervention is rarely indicated.

KEYWORDS

intratympanic aberrant internal carotid artery, pulsatile tinnitus, conductive hearing loss, retrotympanic mass, carotid–cochlear dehiscence

OP-665

Blue Laser–Assisted Excision Of Glomus Tympanicum: Technical Advantages – A Case Report

Adriana Cunha[1,2,3], **Pedro Barros**[1,2], **Vítor Cardoso**[1,2], **Jorge Spratley**[1,2,5], **Ricardo Vaz**[4,5,6,1]

[1]Department of Otorhinolaryngology, Unidade Local Saúde de São João, Porto, Portugal; [2]Department of Surgery and Physiology, Faculty of Medicine, University of Porto, Porto, Portugal; [3]Department of Otorhinolaryngology, Unidade Local Saúde de Tâmega e Sousa, Porto, Portugal; [4]Unit of Anatomy, Department of Biomedicine, Faculty of Medicine, University of Porto, Porto, Portugal; [5]CINTESIS@RISE, Faculty of Medicine, University of Porto, Porto, Portugal; [6]NeuroGen Research Group, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal

BACKGROUND & AIM

Glomus tympanicum are benign, vascular, primary middle ear neoplasms of neural crest origin, arising from Jacobson's or Arnold's nerve on the cochlear promontory. Only about 4% of paragangliomas secrete catecholamines. Despite their benign and slow-growing nature, tympanic and jugular paragangliomas can be locally destructive, potentially affecting the ossicular chain, cranial nerves and adjacent cranial and vascular structures.

MATERIAL & METHODS

Case report supported by computed tomography (CT) and magnetic resonance imaging (MRI), audiological assessment, and intraoperative video documentation.

RESULTS

A 42-year-old woman presented to the emergency department with left-sided pulsatile tinnitus. She denied headaches, palpitations, or tachycardia. Her medical history was significant for hypertension and HIV infection, which was suppressed under antiretroviral therapy. Otoscopy of the left ear revealed a reddish, pulsatile mass in the inferior quadrants of the tympanic membrane. Brown's sign was positive. Pure tune audiometry revealed mild bilateral sensorineural hearing loss. CT and MRI showed a lobulated lesion measuring 8.5 × 6.5 × 3 mm, occupying the meso- and hypotympanum, adjacent to the ossicular chain and abutting the promontory and tympanic membrane. The lesion was classified as A2 according to the modified Fisch–Mattox classification. The 24-hour urinary metanephrine levels were negative. The patient underwent surgical treatment aided by blue laser to facilitate excision and minimize bleeding. Histopathological examination confirmed the diagnosis of tympanic paraganglioma. One month after surgery, the patient was asymptomatic, with tinnitus resolution.

CONCLUSIONS

Glomus tympanicum is a rare, challenging condition. Complete surgical excision remains the treatment of choice, whereas active surveillance and radiotherapy may be considered in patients who decline surgery or have contraindications to it. The blue laser is a safe and effective surgical tool that reduces intraoperative bleeding, minimizes thermal injury to surrounding tissues, and facilitates excision.

Transmastoid Facial Nerve Decompression In Severe Peripheral Facial Palsy: Our Clinical Results

Selin Ustun Bezgin[1], **Zeliha Kapusuz Gencer**[1], **Sahin Ogreden**[1], **Hasan Uyar**[1], **Ozgur Yigit**[1]

[1]Health Sciences University, Istanbul Basaksehir Cam and Sakura City Hospital, Department of Otorhinolaryngology

BACKGROUND & AIM

Our study aims to retrospectively present the etiologies and prognostic outcomes of patients undergoing transmastoid facial decompression surgery in our clinic.

MATERIAL & METHODS

Medical records of patients undergoing transmastoid facial nerve decompression in our clinic between 2023 and 2026 were retrospectively reviewed. Demographics, etiology, intraoperative procedures, pre- and postoperative House-Brackmann (HB) grades, and follow-up periods were recorded.

RESULTS

Nine patients [5 (56%) male, 4 (44%) female; mean age 28.1, range 2-63 years] underwent transmastoid facial decompression (4 left, 5 right). Decompression involved the geniculate ganglion, tympanic, and mastoid segments in 6 patients, with additional

distal labyrinthine segment decompression in 3. Etiologies included temporal bone trauma in 5 (56%) (two having otic capsule fractures), iatrogenic causes in 2 (22%), Bell's palsy in 1 (11%), and acute otitis media in 1 (11%). At admission, 4 patients presented with HB Grade VI and 5 with Grade V paralysis. During follow-up of the 4 Grade VI patients, 3 improved to Grade II and 1 to Grade I. Postoperatively for the 5 Grade V patients, 1 was Grade I, 2 were Grade II, 1 was Grade III, and 1 was Grade IV. Follow-up ranged from 2 to 30 months (mean: 13.8 months).

CONCLUSIONS

Transmastoid facial nerve decompression is a fast, safe, and highly effective surgical procedure for various etiologies without taking craniotomy risks.

OP-667

"Hidden Effusion In Borderline Cases: Is Tympanometry Enough To Guide Ventilation Tube Decisions"

Elif Güre[1], **Mustafa Aslıer**[1]

[1]*Bursa Uludag University Faculty of Medicine,Otorhinolaryngology and Head and Neck Surgery*

BACKGROUND & AIM

Otitis media with effusion and recurrent acute otitis media are common pediatric diseases that may cause conductive hearing loss and delayed speech and language development. Myringotomy with ventilation tube insertion is the main surgical treatment in refractory cases. However, patients with borderline otoscopic findings and non-Type B tympanograms present a diagnostic challenge, as middle ear effusion cannot be confirmed preoperatively.

This study aimed to determine the frequency of middle ear effusion detected during diagnostic myringotomy in pediatric patients with borderline findings. Additionally, the study evaluated whether tympanometric findings alone are sufficient for guiding decisions regarding ventilation tube insertion.

MATERIAL & METHODS

This retrospective cohort study included 43 pediatric patients (67 ears) who underwent adenoidectomy and diagnostic myringotomy for suspected otitis media with effusion (OME) refractory to medical treatment between 2011 and 2025.

Ears with non-specific otoscopic findings and non–Type B tympanograms were defined as borderline cases. Patients were classified into three groups according to tympanic membrane appearance and tympanogram type (Type A or Type C). Ventilation tubes were inserted when intraoperative middle ear effusion was detected during myringotomy.

Ears without intraoperative effusion were followed for at least one year to evaluate disease recurrence and the subsequent need for VT insertion. Demographic and clinical variables were analyzed to identify potential risk factors associated with effusion and recurrence.

RESULTS

A total of 43 pediatric patients (22 males, 21 females) with 67 borderline ears were included. Diagnostic myringotomy revealed intraoperative middle ear effusion in 23 of 67 ears (34.3%). No statistically significant difference was found in VT insertion rates between the three preoperative groups (Group 1: 47.6%, Group 2: 29.0%, and Group 3: 26.7%; p=0.224). However, a highly significant correlation was identified between adenoid vegetation grade and the presence of effusion, with the rate reaching 48.6% in Grade 4 (totally obstructive) cases (p=0.016). Among the 44 ears followed without an initial tube, 5 (11.4%) experienced disease recurrence requiring VT insertion within one year. While laryngopharyngeal reflux (40.0%) and daycare attendance (80.0%) showed strong clinical trends in the recurrence group, no environmental or clinical risk factors reached statistical significance (p>0.05)

CONCLUSIONS

Preoperative assessments, including non-specific otoscopic findings and non-flat tympanograms, are insufficient to definitively exclude middle ear effusion in clinically suspicious pediatric cases. Since a substantial number of these borderline ears harbor occult effusion, diagnostic myringotomy remains a critical reference standard during adenoidectomy to prevent the undertreatment of middle ear disease. This intervention is particularly vital in patients with advanced obstructive adenoid hypertrophy, who exhibit a significantly higher risk of effusion. For children managed without tubes, close monitoring for recurrence is advised, especially in the presence of clinical trends such as reflux or daycare attendance

Comparison Of Paranasal Sinus Anatomical Variations According To Laterality In Patients With Unilateral Chronic Otitis Media

NECMETTİN CAN EYÜBOĞLU[1], **FATİH TETİK**[1], **FIRAT ONUR**[1], **NEŞE UÇAR**[1], **ÖMER NECATİ DEVELİOĞLU**[1]

[1]*SAĞLIK BİLİMLERİ ÜNİVERSİTESİ GAZİOSMANPAŞA EĞİTİM VE ARAŞTIRMA HASTANESİ*

BACKGROUND & AIM

This study aimed to evaluate the relationship between nasal and paranasal sinus anatomical variations and disease laterality in patients with unilateral chronic otitis media (COM), using a paired (ipsilateral vs. contralateral) analysis model.

MATERIAL & METHODS

This retrospective, single-center study included 77 adult patients who underwent surgery for unilateral COM and had available bilateral temporal bone and paranasal sinus computed tomography (CT) scans between 2020 and 2025. Septal deviation angle and distance, middle and inferior turbinate measurements, paranasal sinus volumes (maxillary, sphenoid, and frontal), and anatomical variations (Agger nasi, Haller, and Onodi cells) were evaluated. Sinus volumes were calculated using semi-automated segmentation with 3D Slicer/ITK-SNAP software. All measurements were compared between ipsilateral (diseased) and contralateral sides within the same patient. Paired statistical tests and McNemar analysis were used as appropriate. Multivariate analysis was performed using matched logistic regression.

RESULTS

Septal deviation direction did not significantly correlate with disease laterality (p=0.24), and no significant differences were found in deviation angle (p=0.68) or distance (p=0.47). Middle turbinate width (p=0.709) and inferior turbinate measurements (anterior p=0.64, posterior p=0.39, length p=0.28) showed no significant differences between sides. Anatomical variations, including Agger nasi (p=0.68), Haller (p=0.73), and Onodi cells (p=0.75), were not associated with COM laterality. In contrast, maxillary sinus volume was significantly lower on the diseased side (11.4±3.5 cm^3 vs. 13.8±3.9 cm^3, p=0.008). No significant differences were observed for sphenoid (p=0.26) or frontal sinus volumes (p=0.19). In multivariate analysis, maxillary sinus volume was identified as the only independent predictor of disease laterality (OR=0.69, 95% CI: 0.55–0.86, p=0.006).

CONCLUSIONS

Among evaluated anatomical and volumetric parameters, only reduced maxillary sinus volume was independently associated with the side of chronic otitis media. These findings suggest that impaired sinus aeration, rather than structural nasal variations, may play a more critical role in the pathophysiology of COM. Future studies incorporating functional assessments of nasal airflow and Eustachian tube function are warranted.

OP-669

Recurrence And Risk Factors Of Attic Cholesteatoma Removed By Transcanal Endoscopic Ear Surgery

Ahmad Alrasheed[1], **Jong Woo Chung**[2]

[1]*Riyadh Third Health Cluster, Riyadh, Saudi Arabia;* [2]*Asan Medical Center, Seoul, South Korea*

BACKGROUND & AIM

Attic cholesteatoma is a common and potentially destructive pathology of the middle ear and often leads to complications. This study aimed to evaluate the long-term outcomes of TEES in attic cholesteatoma, with particular emphasis on recurrence rates and prognostic factors.

MATERIAL & METHODS

This study was a retrospective chart review of patients ≥19 years old conducted between 2014 and 2023 at a tertiary referral center. We reviewed the surgical outcomes, which included: 1) the type of surgery finally conducted; 2) the follow-up duration; 3) the audiologic outcome.

RESULTS

A total of 105 patients were included in this study. Intraoperative ossicular destruction was identified in 79 cases. The recurrence rates by stage were 0% for stage Ia, 9.5% for stage Ib, and 23.1% for stage II. Overall, CT staging tended to underestimate stage Ia disease and overestimate stage II disease.

CONCLUSIONS

The retrospective analysis shows that endoscopic transcanal ear surgery (TEES) serves as an effective method for treating attic cholesteatoma while remaining highly secure and dependable. The audiological results from this method showed outstanding durability while demonstrating substantial hearing gain and minimal disease recurrence.

Traumatic Facial Paralysis: Management Strategies And Factors Associated With Recovery

Ömer Orak[1], **Said Sönmez**[1], **Mehmet Çelik**[1], **Beldan Polat**[1], **Kadir Serkan Orhan**[1], **Yahya Güldiken**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Türkiye.*

BACKGROUND & AIM

Traumatic facial paralysis (FP) after head injury can cause substantial morbidity, and the indications for facial nerve decompression remain debated. We aimed to compare long-term facial nerve function between surgical decompression and conservative follow-up and to identify factors associated with baseline severity and postoperative outcomes.

MATERIAL & METHODS

We retrospectively reviewed FP cases at a single tertiary center between 2010-2024. Of 103 screened patients, 51 met eligibility criteria for traumatic FP and were analyzed: surgical decompression (n=35) versus conservative follow-up (n=16). Facial function was graded at diagnosis and last follow-up using the House–Brackmann (HB) system. Onset was categorized as early (≤48 h), delayed (>48 h), or first detected after intensive care unit (ICU) stay. Otoscopy, audiometry, temporal bone computed tomography (CT), and electromyography (EMG) were reviewed. Non-parametric tests and Spearman's rho were used; two-tailed $p<0.05$ was significant.

RESULTS

Median age was 26 years, and 43/51 (84.3%) were male. Injury mechanisms were road traffic accident (49.0%), blunt head trauma (31.4%), and fall (19.6%); onset was early (45.1%), delayed (19.6%), or first detected after ICU stay (35.3%). Surgical approaches were transmastoid (54.3%), combined transmastoid+MCF (31.4%), and translabyrinthine (14.3%); trauma-to-surgery time was 44 days. Median follow-up was 66.0 vs 19.0 months (surgery vs follow-up). Preoperative HB grade was associated with admission type ($p=0.001$), injury mechanism ($p=0.017$), ICU admission ($p=0.043$), onset category ($p=0.012$), fracture pattern ($p=0.028$), otic capsule status ($p=0.011$), and EMG category ($p<0.001$). Both groups improved significantly from baseline to last follow-up (each $p<0.001$). HB grades differed between groups at baseline and last follow-up ($p<0.001$ and $p=0.001$), whereas among severe presentations (HB V–VI) postoperative HB did not differ ($p=0.759$). In the surgical group, postoperative HB correlated with preoperative HB ($p=0.031$) and abnormal otoscopy ($p=0.009$), not trauma-to-surgery interval ($\rho=0.129$, $p=0.459$).

CONCLUSIONS

In this cohort, both surgical decompression and conservative management were associated with significant improvement in traumatic FP. Baseline severity and otologic examination findings were key determinants of postoperative HB outcome among surgically treated patients, while multiple clinical, radiologic, and EMG factors correlated with initial severity. Importantly, among patients presenting with severe FP (HB V–VI), follow-up HB outcomes were comparable between treatment strategies. These findings support individualized decision-making processes for appropriate treatment strategy.

A Novel Graft Material For Tympanoplasty: Bone Marrow–Derived Mesenchymal Stem Cell Sheet

Ahmet Kara[1], **Aykan Kandemir**[1], **Halil Elden**[1], **Oğuz Kadir Eğilmez**[1], **Yusufhan Yazır**[2], **Gökhan Duruksu**[2], **Büşra Öncel Duman**[2], **Ahmet Öztürk**[2], **Selenay Hümeyra Furat Rençber**[2]

[1]Sakarya University Faculty of Medicine, Department of Otolaryngology, Sakarya, Türkiye; [2]Kocaeli University Stem Cell and Gene Therapies Research and Application Center (KÖGEM), Kocaeli, Türkiye

BACKGROUND & AIM

Chronic tympanic membrane (TM) perforations remain a common clinical problem requiring surgical repair. Conventional graft materials used in tympanoplasty provide structural support but lack biological activity to actively promote regeneration. Although mesenchymal stem cells (MSCs) have shown promise in tissue repair, most previous approaches relied on cell suspension or scaffold-based delivery systems, which may limit cell retention and disrupt cell–cell interactions.

The aim of this study was to evaluate the regenerative potential of a scaffold-free, bone marrow–derived mesenchymal stem cell (MSC) sheet in a chronic TM perforation model and to compare its biological and histological effects with standard paper patch myringoplasty.

MATERIAL & METHODS

A chronic tympanic membrane (TM) perforation model was established in 21 Wistar albino rats. Animals were divided into four groups: untreated chronic perforation, mesenchymal stem cell (MSC)–derived cell sheet (overlay technique), paper patch myringoplasty, and normal TM control. Chronic perforations were induced using mitomycin application followed by standardized myringotomy and dexamethasone exposure.

Bone marrow–derived MSCs were cultured, GFP-labeled, and harvested as contiguous cell sheets using temperature-responsive culture dishes without enzymatic digestion, preserving cell–cell junctions. The MSC sheets were transplanted onto the lateral surface of the perforated TM.

Three months postoperatively, tissues were evaluated by histopathology (H&E, Masson trichrome), immunofluorescence (GFP, CK19, fibronectin, collagen I, TNF-α, caspase), quantitative PCR, and Western blot analysis. Statistical analysis was performed using parametric or non-parametric tests as appropriate

RESULTS

Complete perforation closure was observed in both the MSC cell sheet and paper patch groups; however, the MSC group demonstrated superior structural organization without cholesteatoma formation. Histological analysis revealed improved epithelial integrity and more organized lamina propria architecture in the MSC group compared to surgical controls.

Immunofluorescence showed increased fibronectin expression, enhanced CD31-mediated angiogenesis, reduced TNF-α levels, and decreased caspase activity in the MSC-treated group. Gene expression analysis demonstrated significant upregulation of CK19 (2.6-fold), fibronectin (3.5-fold), collagen type I (4.3-fold), and CD31 (2.6-fold) compared to controls. GFP expression confirmed graft viability at three months.

In contrast, the paper patch group exhibited moderate regeneration with less organized extracellular matrix remodeling and higher inflammatory markers.

CONCLUSIONS

Bone marrow–derived mesenchymal stem cell sheet application promotes biologically active regeneration in chronic tympanic membrane perforations. Compared with conventional paper patch myringoplasty, the scaffold-free MSC sheet enhanced epithelial repair, extracellular matrix remodeling, angiogenesis, and reduced inflammation and apoptosis. Preservation of cell–cell junctions and high cellular density may explain its superior regenerative performance.

This approach represents a promising regenerative graft strategy with potential for clinical translation in tympanoplasty.

Low GNRI Predicts Poor Outcomes In Elder Sudden Hearing Loss Patients

SHU-YU TAI[1,2], **CHEN-YU CHIEN**[3,4]

[1]Department of Family Medicine, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan; [2]Department of Family Medicine, School of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan; [3]Department of Otorhinolaryngology, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan; [4]Department of Otorhinolaryngology, School of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan

BACKGROUND & AIM

Sudden sensorineural hearing loss (SSNHL) is associated with metabolic syndrome, central obesity, and albumin level. This study investigated the associations of the geriatric nutritional risk index (GNRI) with clinical outcomes in older patients (age >65 y) with SSNHL.

MATERIAL & METHODS

We retrospectively investigated 328 older patients with SSNHL, and their clinical variables were compared. GNRI was calculated based on body weight and serum albumin. We analyzed the relationship between GNRI and outcomes in SSNHL. Demographic and clinical characteristics, audiometry results, and clinical outcomes were examined.

RESULTS

Among older patients with SSNHL, 107 (32.62%) and 221 (67.38%) had favorable and unfavorable outcomes, respectively. Vertigo, worse initial level of hearing loss, and low GNRI were mainly associated with unfavorable hearing outcomes in older patients with SSNHL. Furthermore, low GNRI (<99) was linked to unfavorable clinical outcomes (odds ratio [OR] = 1.91, P = .0151). Multivariate logistic regression revealed that vertigo (aOR = 3.45, P = .0002), worse initial level of hearing loss (per 1 unit increase in hearing loss elevates the risk of poor hearing recovery by 2%, P = .0015), and low GNRI (aOR = 1.79, P = .0435) were associated with unfavorable clinical outcomes.

CONCLUSIONS

In summary, evaluation of nutritional status plays a crucial role in improving clinical outcomes in SSNHL. Moreover, GNRI can predict clinical outcomes in older patients with SSNHL treated with steroids. Older patients with SSNHL who have vertigo, worse initial level of hearing loss, and low GNRI exhibit unfavorable outcomes.

OP-673

Dual-Site Rtms Is More Effective Than Single-Site Rtms For Chronic Tinnitus: A Randomized Clinical Trial

Hui Wang[1]

[1]Department of Otolaryngology-Head and Neck Surgery, Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China

BACKGROUND & AIM

Chronic tinnitus is a debilitating condition with limited treatment options. While repetitive transcranial magnetic stimulation (rTMS) has shown promise, its efficacy remains moderate. This study aimed to determine whether a dual-site rTMS protocol

targeting both the temporoparietal junction (TPJ) and dorsolateral prefrontal cortex (DLPFC) is superior to TPJ stimulation alone in improving outcomes in chronic tinnitus.

MATERIAL & METHODS

This randomised, single-blind controlled trial compared dual-site (TPJ+DLPFC) rTMS with TPJ-only rTMS in 110 patients with chronic tinnitus. Patients received daily sessions for five consecutive days. The dual-site group received 1 Hz stimulation over the left TPJ followed by 10 Hz stimulation over the left DLPFC, while the TPJ group received only 1 Hz TPJ stimulation. The primary outcome was tinnitus loudness measured by visual analogue scale (VAS). Secondary outcomes included TMS-EEG measures of local mean field power and source-based connectivity. This study has been registered on chictr.org.cn identifier ChiCTR2400085901.

RESULTS

The dual-site group showed significantly greater reduction in tinnitus loudness VAS scores (adjusted β=-1.17, 95% CI -1.82 to -0.51, P=0.001) and higher response rates (73.3% vs 44.4%) compared to the TPJ-only group. TMS-EEG analysis revealed that dual-site rTMS specifically enhanced prefrontal excitability and decreased current propagation to limbic/default-mode network regions. Machine learning models achieved high predictive accuracy (AUC=0.87) for treatment response using these neural features.

CONCLUSIONS

Dual-site rTMS demonstrates superior efficacy for chronic tinnitus by uniquely modulating prefrontal excitability and limbic/default-mode networks. The identified neural predictors support a precision medicine approach for personalized neuromodulation therapy.

OP-674

Analysis Of Predictive Factors For Resistance To Medical Therapy And Prognosis In Patients With Malignant Otitis Externa

Nadir Yıldırım[1], **Yasin Kalmış**[1], **Nesibe Esra Mutlu**[1]

[1]*Kütahya sağlık bilimleri üniversitesi*

BACKGROUND & AIM

Malignant otitis externa (MOE) can lead to severe morbidity and mortality in cases unresponsive to standard medical therapy. This study aimed to identify the clinical, laboratory, and microbiological predictive factors associated with facial nerve palsy (CN VII), lower cranial nerve involvement, and mortality in patients with MOE.

MATERIAL & METHODS

Twenty consecutive adult patients diagnosed with MOE at a tertiary care center were evaluated retrospectively. All patients presented with diabetes mellitus, otalgia, and inflammation of the external auditory canal. Comorbidity burden was assessed using the Charlson Comorbidity Index (CCI), and glycemic control was evaluated via HbA1c levels. The C-reactive protein-to-albumin ratio (CAR) and neutrophil-to-lymphocyte ratio (NLR) were calculated from available laboratory data as indicators of systemic inflammation. MOE-specific morbidities were defined as facial nerve palsy, lower cranial nerve involvement, and intracranial complications. The associations between a complicated clinical course (cranial/intracranial involvement) and CCI, HbA1c, CAR, and NLR were analyzed, while factors contributing to advanced morbidity and mortality were reported using descriptive statistics.

RESULTS

All 20 patients were diabetic (mean HbA1c: 8.6%). Peripheral facial palsy (PFP) occurred in 30% (n=6). PFP patients had a significantly higher mean CCI (5.8 vs. 4.0) and markedly elevated CAR and NLR values compared to non-PFP patients. HbA1c levels showed no significant intergroup difference. Mortality was 10% (n=2), involving skull base osteomyelitis with lower cranial nerve involvement (n=1) and sigmoid sinus thrombophlebitis (n=1); both had above-average baseline CCIs. Alongside ubiquitous P. aeruginosa, atypical/resistant pathogens (Aspergillus spp., Candida spp., K. pneumoniae) were isolated in 35% of cases. Although atypical pathogens lacked direct association with PFP, multidrug-resistant P. aeruginosa was isolated from the fatal case with lower cranial nerve involvement.

CONCLUSIONS

In MOE, a high Charlson Comorbidity Index, along with elevated CAR and NLR values, is strongly associated with the development of facial nerve palsy. The presence of lower cranial nerve involvement and intracranial complications, in addition to CAR and NLR, serve as critical clinical markers for predicting mortality and evaluating disease progression. The notable frequency of atypical pathogens suggests that the early integration of antifungals or broad-spectrum antibiotics should be carefully considered when planning empirical therapy for high-risk patients.

OP-675

Long-Term Outcomes Of Transmastoid Facial Nerve Decompression Without Incus Removal In Traumatic And Non-Traumatic Facial Paralysis**

Yasin Çetinkaya[1], **Said Sönmez**[1], **Mehmet Çelik**[1], **Beldan Polat**[1], **Yahya Güldiken**[1], **Kadir Serkan Orhan**[1]

[1]*Istanbul University Istanbul Faculty of Medicine*

BACKGROUND & AIM

Facial nerve paralysis is a common cranial neuropathy with idiopathic, traumatic, infectious, or neoplastic causes. Although most Bell's palsy cases recover conservatively, patients with complete paralysis and poor electrophysiological prognosis may require surgical decompression. This procedure aims to relieve nerve compression and promote neural recovery. Transmastoid decompression is commonly preferred because of its technical feasibility and lower morbidity; however, ossicular chain disruption may impair hearing. This study evaluates the long-term facial nerve and audiological outcomes of transmastoid facial nerve decompression performed without incus removal, assessing the effectiveness and safety of this hearing-preserving surgical approach in severe peripheral facial paralysis.

MATERIAL & METHODS

This retrospective study included patients who underwent transmastoid facial nerve decompression without incus removal for traumatic or non-traumatic facial paralysis at the Department of Otorhinolaryngology, Istanbul University Istanbul Faculty of Medicine, between January 2021 and December 2022. Patients with facial paralysis secondary to chronic otitis media, previous ear surgery, congenital facial nerve anomalies, or regular use of ototoxic medications were excluded. Demographic and clinical data were collected, including age, sex, etiology, time from symptom onset to surgery, preoperative and postoperative facial nerve function assessed by House-Brackmann grading, inflammatory markers, and pure-tone audiometry results. Medical treatment history, including steroid and/or antiviral therapy, electromyography findings, postoperative follow-up duration, and intraoperative findings regarding the affected facial nerve segment were also recorded. Long-term functional and audiological outcomes were analyzed to evaluate the safety and effectiveness of the surgical technique.

RESULTS

No statistically significant differences were observed in postoperative audiometric outcomes, including air-conduction thresholds (15 vs. 15 dB HL, p=0.975), bone-conduction thresholds (5 vs. 7.5 dB HL, p=0.083), and air-bone gap (5 vs. 6 dB, p=0.110), indicating preserved hearing in all patients. All 22 patients presented with preoperative House-Brackmann (HB) grade VI facial paralysis. Significant postoperative improvement in facial nerve function was observed over a median follow-up of 35 months (range, 12–60 months). At final evaluation, 6 patients (27.3%) achieved HB grade I, 13 (59.1%) HB grade II, and 3 (13.6%) HB grade III, resulting in a surgical success rate (HB ≤II) of 86.4%. Patients with idiopathic facial paralysis demonstrated significantly better outcomes compared with those with traumatic etiology (p=0.007). Time to decompression was not significantly associated with postoperative outcome. Greater segment involvement was correlated with better postoperative HB grades, although this finding should be interpreted cautiously.

CONCLUSIONS

This study evaluated the long-term outcomes of transmastoid facial nerve decompression without incus removal in 22 patients with traumatic and non-traumatic peripheral facial paralysis. Favorable functional and audiological outcomes were observed, supporting the effectiveness and safety of this surgical approach. Significant improvement in facial nerve function, along with preservation of hearing, suggests that ossicular chain-preserving transmastoid decompression is a reliable treatment option, particularly in patients with severe facial nerve degeneration. These findings indicate that this technique may offer an effective balance between facial nerve recovery and hearing preservation.

OP-676

Recurrence Rate And Predictive Factors In Benign Paroxysmal Positional Vertigo: A Large Single-Center Retrospective Cohort Study

Onur ERDOĞAN[1]

[1]*Olbamed Hospitaly, Turkey, Mersin*

BACKGROUND & AIM

Benign paroxysmal positional vertigo (BPPV) is the most common cause of peripheral vestibular vertigo, accounting for 17–42% of all vertigo presentations. Although canalith repositioning procedures (CRP) demonstrate high short-term efficacy, BPPV is well recognized for its tendency to recur. Published recurrence rates vary widely across studies, highlighting the need for large-

scale, real-world data. The aim of this study was to determine BPPV recurrence rates over a seven-year period in a large all-age single-center cohort and to identify independent clinical predictors of recurrence.

MATERIAL & METHODS

Patients registered with ICD-10 code H81.1 and treated with repositioning maneuvers at our otolaryngology clinic between May 2019 and May 2026 were retrospectively analyzed through the hospital information system (HIS). No age restriction was applied, as BPPV can occur across all age groups including pediatric patients. Inclusion criteria were: confirmed BPPV diagnosis based on clinical history and positive Dix-Hallpike or supine roll test, treatment with at least one CRP, and ≥6 months of follow-up data. Patients with central pathology or insufficient records were excluded. True recurrence was defined as a new BPPV-coded visit ≥30 days after the index visit. Primary outcomes were 1-year and 2-year recurrence rates. Descriptive statistics, Kaplan-Meier analysis, and logistic regression were used.

RESULTS

A total of 2,686 patients were included, generating 6,677 BPPV-coded visits over the study period (mean 2.5 visits per patient). Among 2,015 patients with available age data, mean age was 53.0 years, median 54 years (range: 10–97 years). Pediatric patients (<18 years) constituted 2.7% of the cohort (n=54). The age distribution was predominantly middle-aged and older: 37.6% aged 40–59 years, 26.7% aged 60–74 years, and 12.0% aged ≥75 years. True recurrence was identified in 624 patients (23.2%). Median time to first recurrence was 524 days (~17 months); mean was 686 days. Cumulative recurrence rates were 24.5% at 6 months, 39.1% at 1 year, and 61.2% at 2 years. A total of 496 patients (79.5% of the recurrent group) experienced more than one recurrence, with a mean of 3.7 episodes per patient in this subgroup. Advanced age (≥50 years) and female sex were identified as independent predictive factors ($p<0.05$).

CONCLUSIONS

In this large-series retrospective cohort study, the BPPV recurrence rate was 23.2%, consistent with published literature. The cumulative 2-year recurrence rate of 61.2% and a mean of 3.7 recurrence episodes per patient in the recurrent subgroup indicate that BPPV may follow a chronic, relapsing course in a meaningful subset of patients. Advanced age and female sex are the primary predictors of recurrence. The inclusion of pediatric patients (2.7%) reflects real-world all-age practice. These findings support individualized risk stratification and integration of long-term follow-up protocols into routine BPPV management across all age groups.

Single-Cell Transcriptomes Reveal The Heterogeneity And Microenvironment Of Vestibular Schwannoma

Zirong Huo[1,2,3], **Zhaohui Wang**[1,2,3], **Huahong Luo**[1,2,3], **Tao Yang**[1,2,3], **Huihui Liu**[1,2,3], **Huipeng Li**[1,2,3], **Zhihua Zhang**[1,2,3], **Hao Wu**[1,2,3]

[1]Shanghai Ninth People's Hospital, Affiliated to Shanghai Jiao Tong University School of Medicine; [2]Ear Institute, Shanghai Jiao Tong University School of Medicine; [3]Shanghai Key Laboratory of Translational Medicine on Ear and Nose Diseases

BACKGROUND & AIM

Vestibular schwannoma (VS) is the most common benign tumor in the cerebellopontine angle (CPA) and internal auditory canal. Illustrating the heterogeneous cellular components of VS could provide insights into its various growth patterns.

MATERIAL & METHODS

Single-cell RNA sequencing (scRNA-seq) was used to profile transcriptomes from 7 VS samples and 2 normal nerves. Multiplex immunofluorescence was employed to verify the dataset results. Bulk RNA sequencing was conducted on 5 normal nerves and 44 VS samples to generate a prediction model for VS growth.

RESULTS

A total of 83,611 cells were annotated as 14 distinct cell types. We uncovered the heterogeneity in distinct VS tumors. A subset of the Schwann cells with the VEGFA biomarker was significantly associated with fast VS growth through mRNA catabolism and peptide biosynthesis. The macrophages in the normal nerves were largely composed of the M2 phenotype, while no significant differences in the proportions of M1 and M2 macrophages were found between slow-growing and fast-growing VS. The normal spatial distribution of the fibroblasts and vascular cells was destroyed in VS. The communications between Schwann cells and vascular cells were strengthened in the samples of VS compared with those in the normal nerve. Three cell clusters were significantly associated with fast VS growth and could refine the growth classification in bulk RNA.

CONCLUSIONS

Our findings offer novel insights into the VS microenvironment at the single-cell level. It may enhance our understanding of the different clinical phenotypes of VS and help predict growth characteristics. Molecular subtypes should be included in the treatment considerations.

Transmastoid Facial Nerve Decompression With Intact Ossicular Chain Preservation

R. Abada[1], **M/ MAhtar**[1]

[1]*ENT department, 20 August Hospital, IBN ROCHD University Hospital Casablanca*

BACKGROUND & AIM

the classical approach of the labyrinthine portion of facial nerve remain by middle fossa approach, with possible morbidity. we discuss the feasability and efficiency of transmastoid facial nerve decompression of the three fallopian portions with preservation of intact ossicular chain

MATERIAL & METHODS

We performed this procedure on 25 patients suffering total facial palsy with at least V grade of House and Brakman scale and severe denervation up to 90% at ENOG. The etiologies were post traumatic (19 cases) and Bells Palsy (6 cases). we analysed the post operative facial nerve function , hearing outcomes, and we performed ct scan post operativly to measure the pourcentage of labyrinthine portion decompressed

RESULTS

after 6 months post operativly, All patients reached At least Grade 3 HB, and 85% reached Grade 1 or 2 HB, with no significant hearing deterioration. Ct scan showed a mean decompression OF 65% of the labyrinthin portion

CONCLUSIONS

Transmatsoid approach for labyrynthine portion with hearing preservation is challenging, but effective and feasable. the results on facial nerve recovry are very encouraging. it remains an alternative approach avoiding transcranial approach.

OP-679

Prevalence Of Facial Canal Dehiscence And Ossicular Chain Erosion In Chronic Otitis Media: A Single-Centre Analysis Of 180 Mastoidectomies

Levent Yiğiner[1], **Belgin Tutar**[1]

[1]*University of Health Sciences Prof. Dr. Cemil Taşçıoğlu City Hospital, Department of Otorhinolaryngology, Istanbul, Turkey*

BACKGROUND & AIM

Facial canal dehiscence (FCD) and ossicular chain erosion are two of the most clinically relevant intraoperative findings in chronic otitis media (COM) surgery. FCD increases the risk of iatrogenic facial nerve injury, while ossicular erosion drives postoperative hearing outcome. We aimed to determine the prevalence of these two findings in patients operated for COM at a tertiary referral centre, and to describe their distribution by disease subtype.

MATERIAL & METHODS

We retrospectively reviewed all mastoidectomy procedures performed for COM at our centre between January 2020 and March 2026. After excluding cortical/simple mastoidectomies and non-COM indications, 180 surgeries from 163 unique patients were analysed (16 patients underwent same-ear revisions). Demographics, mastoidectomy subtype, revision status and intraoperative FCD were recorded from operative notes; cholesteatoma status was based on histopathological examination of the surgical specimen. Ossicular chain status was reclassified by structured re-reading of every operative note as eroded, non-eroded or undetermined. Prevalence rates with 95% Wilson confidence intervals were calculated; subgroups were compared with chi-square or Fisher exact test.

RESULTS

Mean age was 35.5 ± 18.8 years (range 3–84); 53.9% were male. Cholesteatoma was present in 147 cases (81.7%) and 51 (28.3%) were revisions. Facial canal dehiscence was identified in 48 cases (26.7%, 95% CI 20.7–33.6). Ossicular chain erosion was documented in 129 cases (71.7%, 95% CI 64.7–77.7), absent in 14 (7.8%) and undetermined in 37 (20.6%). Both findings co-existed in 41 cases (22.8%). Ossicular erosion was markedly more frequent in cholesteatoma cases

(79.6% vs 36.4%; p < 0.001), as was FCD (29.9% vs 12.1%; p = 0.048). Notably, none of the 14 patients without ossicular erosion had FCD (0% vs 31.8%; Fisher p = 0.011). Revision status was not associated with either finding.

CONCLUSIONS

In our COM cohort, FCD was present in over one-quarter and ossicular erosion in nearly three-quarters of cases. Both abnormalities occurred almost exclusively in cholesteatomatous disease, and the absence of ossicular erosion was a strong negative predictor of FCD. Surgeons should anticipate facial nerve exposure when ossicular erosion is encountered, particularly in cholesteatomatous COM.

EVALUATION OF COCHLEAR DAMAGE IN TYMPANOPLASTY THROUGH SERUM PRESTIN LEVELS: A COMPARISON OF OVER-UNDERLAY TYMPANOPLASTY AND BUTTERFLY MYRINGOPLASTY TECHNIQUES

NAZIM EYMEN TURAN[1], AHMET MUTLU[2], ATAKAN AKBULUT[3], FERRUH KEMAL İŞMAN[3], MAHMUT TAYYAR KALCIOĞLU[1],
NAZIM EYMEN TURAN[1], AHMET MUTLU[2], ATAKAN AKBULUT[3], FERRUH KEMAL İŞMAN[3], MAHMUT TAYYAR KALCIOĞLU[1]

[1]Department of Otorhinolaryngology, İstanbul Medeniyet University Göztepe Prof. Dr. Süleyman Yalçın City Hospital, İstanbul, Türkiye; [2]Department of Otorhinolaryngology, Memorial Göztepe Hospital, İstanbul, Türkiye; [3]Department of Medical Biochemistry, İstanbul Medeniyet University Göztepe Prof. Dr. Süleyman Yalçın CitHospital, İstanbul, Türkiye

BACKGROUND & AIM

Middle ear surgery performed for chronic otitis media aims to restore the conductive component of hearing, yet it may transmit mechanical and acoustic energy to the inner ear through suction noise and manipulation of the ossicular chain. The aim of this study was to investigate whether the serum level of prestin, the motor protein of outer hair cells, can serve as an early indicator of cochlear involvement that remains undetectable by conventional audiometric methods. The comparison of two tympanoplasty techniques that differ in their requirement for ossicular manipulation was designed as a model serving this aim.

MATERIAL & METHODS

This prospective study included 29 patients who underwent microscopic postauricular over-underlay type 1 tympanoplasty, 28 patients who underwent endoscopic butterfly inlay myringoplasty, and 26 healthy volunteers. Venous blood samples were obtained from patients preoperatively and on the first, third, and seventh postoperative days, and serum prestin levels were measured by the enzyme-linked immunosorbent assay method. Audiological evaluation was repeated preoperatively and at the third postoperative month.

RESULTS

In age- and sex-comparable groups, preoperative serum prestin was significantly higher in patients than in healthy individuals (p=0.034), a finding confirmed by age-adjusted analysis. Postoperatively, prestin rose on the third day and returned to baseline by the seventh day. The two techniques did not differ in prestin response and were equivalent in bone conduction change within a five-decibel margin. The third-day prestin increase was associated with deterioration of bone conduction thresholds at three months, most strongly at 1000 hertz, whereas it was unrelated to changes in air conduction and in the air-bone gap. For discriminating deterioration of five decibels or more in the bone conduction pure tone average, the area under the curve was 0.783 and the negative predictive value 97.1 percent.

CONCLUSIONS

In the context of chronic otitis media and middle ear surgery, serum prestin behaves as a marker that reflects cochlear stress and yields information at a level where conventional pure tone audiometry remains silent. However, this information can be read not from absolute levels but from the change relative to the patient's own preoperative serum prestin value. Because measurement methods have not yet been standardized, prestin currently represents a research tool suitable for carefully designed studies rather than a clinical test.

EVALUATION OF SURGICAL, AUDIOLOGICAL, AND PATIENT SATISFACTION OUTCOMES OF BONE-ANCHORED HEARING AID (BAHA) APPLICATIONS: A SINGLE-CENTER EXPERIENCE

Mahmut Furkan Beyaz[1], Orhan Asya[1], Nilüfer Bal[2], Ali Cemal Yumuşakhuylu[3], Yavuz Gündoğdu[1], Badel Tereci Oran[1]

[1]Marmara University, Department of Otorhinolaryngology–Head and Neck Surgery; [2]Marmara University, Department of Audiology and Speech-Language Pathology; [3]Memorial Göztepe Hospital

BACKGROUND & AIM

Bone-anchored hearing aids (BAHA) are effective rehabilitation options for patients with conductive or mixed hearing loss and single-sided deafness who cannot benefit from conventional hearing aids. Although BAHA systems provide significant audiological improvement, surgical complications and postoperative skin reactions remain important concerns. This study aimed to evaluate the surgical outcomes, perioperative complications, audiological benefits, and patient satisfaction of patients who underwent BAHA implantation at a tertiary referral center.

MATERIAL & METHODS

A total of 26 patients who underwent BAHA implantation between 2018 and 2025 at the Department of Otorhinolaryngology–Head and Neck Surgery, Marmara University Pendik Training and Research Hospital, were retrospectively included in the study. Ethical approval was obtained (Approval No: 09.2025.25-0437, Date: 23.05.2025). Demographic characteristics, etiology, implant type (Baha Attract / Baha Connect), operative time, intraoperative and postoperative complications, Holgers classification, preoperative and aided hearing thresholds (free-field SRT), and International Outcome Inventory for Hearing Aids (IOI-HA) scores were analyzed.

RESULTS

Eighteen patients were male (69.2%) and 8 were female (30.8%), with a mean age of 26.2 ± 19.9 years. The most common etiologies were chronic otitis media (30.8%) and congenital atresia (23.1%), while 34.6% had an associated syndrome. Baha Attract was used in 17 patients and Baha Connect in 7 patients. Mean operative time was 105.0 ± 27.3 minutes. Intraoperative and postoperative complications occurred in 19.2% and 30.8% of patients, respectively. According to the Holgers classification, 84.6% of patients were grade 0. Mean free-field SRT improved from 62.2 ± 11.3 dB preoperatively to 33.8 ± 9.6 dB with BAHA use, providing an average gain of 28.4 dB. Among 20 patients evaluated with IOI-HA, the mean total score was 28.8 ± 4.7, and 65% achieved good-to-excellent satisfaction levels.

CONCLUSIONS

BAHA implantation provides significant audiological improvement and high patient satisfaction in congenital and acquired conductive hearing loss. Although complication rates were consistent with the literature, the successful osseointegration outcomes achieved without high rates of postoperative skin reactions are noteworthy. BAHA appears to be a safe and effective rehabilitation method in both pediatric and adult populations.

OP-682

Sound-Induced Vertigo In A Child With Suspected Posterior Semicircular Canal Dehiscence Successfully Treated By Capping Surgery

Kanazawa Yuji[1], **Kitani Yoshiharu**[1], **Kiyonobu Taiki**[1], **Torii Hiroko**[1], **Matsubara Aya**[1], **Hattori Norishige**[1], **Goda Riki**[1]

[1]*Department of Otolaryngology-Head and Neck Surgery, Shizuoka General Hospital, Shizuoka, Japan*

BACKGROUND & AIM

Semicircular canal dehiscence syndrome represents a “third mobile window” disorder of the inner ear that can cause sound- or pressure-induced vertigo. While superior semicircular canal dehiscence is well described, posterior semicircular canal dehiscence (PSCD) is rare, particularly in children. Furthermore, some symptomatic cases demonstrate only bone thinning rather than a clear bony defect. We report a pediatric case presenting with the Tullio phenomenon (sound-induced vertigo) suspected to be PSCD and successfully treated with capping surgery, highlighting diagnostic features and surgical considerations.

MATERIAL & METHODS

An 8-year-old boy presented with a 4-month history of vertigo triggered by loud environments such as schools and shopping centers. Pure-tone audiometry showed normal hearing without an air-bone gap (average 3.8 dB bilaterally). No positional nystagmus was observed, and caloric and Schellong tests were normal. Temporal bone computed tomography (CT) reconstructed in Pöschl and Stenvers planes suggested a dehiscence of the right posterior semicircular canal. Cervical vestibular evoked myogenic potential (cVEMP) testing showed a lower threshold on the right side (75 dB) compared with the left (85 dB). Sound stimulation using a 1000-Hz chirp evoked vertigo and an upbeat torsional nystagmus at 90–100 dB in the right ear. Similar nystagmus occurred during the Valsalva maneuver. These findings suggested right PSCD, and surgical intervention was subsequently performed. A mastoid approach with endoscopic assistance was used, and capping of the suspected dehiscence site was performed using calcium phosphate bone paste.

RESULTS

No definite bony defect was identified intraoperatively. However, after capping of the suspected area, sound-induced vertigo completely resolved. Postoperative hearing remained unchanged. At one month, cVEMP thresholds became symmetric (85 dB bilaterally), and sound- or pressure-induced nystagmus was no longer observed. The patient remained symptom-free at 1-year follow-up.

CONCLUSIONS

Even when a definite dehiscence cannot be confirmed intraoperatively, the combination of imaging findings, physiological testing, provoked nystagmus, and postoperative symptom resolution strongly suggests a third mobile window pathology. Surgical capping may be effective in symptomatic pediatric cases with suspected posterior semicircular canal thinning or micro-dehiscence.

High-Resolution Intraoperative Guide For Cochlear Implant Surgery Using Optical Coherence Tomography

Guillaume Gersdorff[1,2], **Phoebe Ramos**[1,2], **Sudanthi Wijewickrema**[1,2], **Stephen O'Leary**[1,2], **Jean-Marc Gerard**[1,2]

[1]*Royal Victorian Eye and Ear Hospital, Melbourne, Australia;* [2]*Department of Surgery (Otolaryngology), University of Melbourne, Melbourne, Australia*

BACKGROUND & AIM

Despite advancements in soft surgery techniques and softer electrodes, intra-cochlear trauma during cochlear implant (CI) electrode insertion still occurs. Such trauma can damage the micro-structures, potentially compromising hearing outcomes and future intra-cochlear treatments. Although the round window membrane (RWM) approach is generally considered less traumatic, the hook region's complex and variable anatomy can still lead to mechanical trauma during electrode insertion. A significant factor contributing to this trauma is the lack of visual guidance.

Pre-operative imaging for surgical planning and intra-operative monitoring using Optical Coherence Tomography (OCT) could minimize trauma by providing a high-resolution, real-time view of cochlear micro-structures.

MATERIAL & METHODS

Eight fresh frozen temporal bones (TB) were micro-scanned to obtain a precise anatomy of the RW region through manual segmentation. Following a conventional CI surgical approach, a microscope equipped with an OCT camera was used to identify intra-cochlear structures behind the RWM. Co-registration of micro-CT anatomy as the ground truth with OCT images was performed.

RESULTS

OCT images were successfully obtained for each TB. Proper exposure of the RWM is crucial for acquiring usable OCT images. The OCT microscope facilitated scanning of the RWM and scala tympani (ST) at a surgical working distance from various axes, depths, and angles, thereby enhancing our ability to assess proximal ST anatomy. Co-registration of preoperative imagery with intra-operative OCT images was achieved. OCT could be considered a reliable tool for evaluating micro-anatomy through the RWM and potentially guiding CI electrode insertion. It may assist in selecting the most suitable electrode and approach and in modifying the proximal course of the electrode array (EA) during insertion. By enabling surgeons to visualize critical structures through the RWM and infer the positions of deeper structures, OCT could facilitate the execution of a preoperative imagery-based surgical plan, reducing the risk of damaging essential intracochlear structures.

CONCLUSIONS

Intra-operative OCT imaging enhances the precision of cochlear opening site and electrode insertion axis. By integrating OCT, CI surgery could shift from a largely blind procedure to one with significant visual guidance, reducing surgical trauma and improving postoperative hearing preservation. Our findings suggest that clinical trials are needed to confirm the clinical feasibility of this approach.

OP-684

Management Of Inner Ear Schwannomas With Cochlear Involvement In A Tertiary Referral Centre

Daniele Bernardeschi[1], **Matteo Di Bari**[1], **Luisa Mattalia**[1], **Hugo Delille**[1]

[1]*Hôpital Pitié Salpétrière, Paris, France*

BACKGROUND & AIM

Inner ear schwannomas represent a distinct clinical entity from vestibular schwannomas of the cerebellopontine angle, with specific anatomical involvement, clinical presentation, and management challenges. The aim of this study is to describe the particular characteristics of inner ear schwannomas with cochlear involvement and to highlight their clinical presentation and therapeutic specificities.

MATERIAL & METHODS

This retrospective observational study was conducted in a tertiary otologic referral center. We included thirty-three consecutive patients diagnosed with inner ear schwannoma with cochlear involvement (intracochlear, intravestibulocochlear,

or transfundal with modiolar extension). Collected data comprised demographic characteristics, presenting symptoms, audiometric findings, radiological tumor features at diagnosis and during follow-up, as well as the treatment modalities applied

RESULTS

Twenty-four patients (73%) had intracochlear, 5 (15%) transfundal with modiolar involvement, 2 (6%) intravestibulocochlear schwannoma. Two (6%) schwannomas involved the cerebellopontine angle. Concerning symptoms all patients presented some degree of hearing loss. Three patients had facial paralysis.

Twenty-eight (85%) underwent wait-and-scan management, during which hearing worsened to AAO-HNS class D for 6 (21%), 15 (54%) showed some degree of tumour growth, 2 (7%) developed spontaneous facial paralysis.

Eleven of 28 patients (39%) underwent surgery after an initial wait-and-scan management (median follow-up of 50 months). Five patients (15%) elected immediate microsurgery tumour removal. Two patients underwent cochlear implantation: one patient did not use the device and had not achieved satisfactory audiometric results The other one exhibited good audiometric results after 3 months (PTA = 30 dB, Speech Discrimination Score = 100% at 70 dB).

Complications were rare and minor. No patients showed residual tumour or recurrence.

CONCLUSIONS

A wait-and-scan policy is the preferred treatment if patients have serviceable hearing. With AAO-HNS class D hearing, microsurgical removal is advised: tumours extending to the internal auditory canal were associated with risk of spontaneous facial paralysis. Surgery is safe and effective.

Objective And Patient-Reported Outcomes After Endoscopic Ear Surgery

Süheyla KANDEMİR[1], **Lütfiye Nisa CANER**[1], **Burak Mustafa TAŞ**[1], **Ziya ŞENCAN**[1], **Ela CÖMERT**[1], **Nuray BAYAR MULUK**[1]

[1]*Kırıkkale University Faculty of Medicine, Department of Otorhinolaryngology*

BACKGROUND & AIM

Chronic otitis media (COM) is a common inflammatory disease and a preventable cause of hearing loss. It presents with persistent or recurrent otorrhea, tympanic membrane perforation, otalgia, and hearing impairment, affecting quality of life. Endoscopic ear surgery offers improved visualization of hidden middle ear areas, preserves critical structures, and provides outcomes comparable to microscopic techniques with less pain and faster recovery. The Zurich Chronic Middle Ear Inventory (ZCMEI-21) assesses patient-reported quality of life in COM. This study evaluates HRQoL, hearing outcomes (air–bone gap), and graft success in patients undergoing endoscopic tympanoplasty.

MATERIAL & METHODS

This retrospective, descriptive study included patients who underwent endoscopic ear surgery at the Department of Otorhinolaryngology, Kırıkkale University Faculty of Medicine Hospital, between November 2021 and December 2025. Demographic data (age, sex), surgical technique, graft type, postoperative graft status, and pre- and postoperative pure-tone audiometry results were obtained from patient records. Hearing outcomes were evaluated using the air–bone gap (ABG), calculated from air- and bone-conduction averages. Patients completed the Turkish version of the Zurich Chronic Middle Ear Inventory (ZCMEI-21), which has established validity and reliability. Health-related quality of life was assessed retrospectively using ZCMEI-21 results. Inclusion criteria were patients aged 18 years and older with chronic otitis media who underwent endoscopic tympanoplasty (± limited ossicular intervention) and had complete pre- and postoperative audiometric data. Exclusion criteria were patients under 18, those who underwent non-endoscopic (microscopic or combined) surgery, open mastoidectomy, revision surgery, or had incomplete audiometric data.

RESULTS

A total of 40 patients were included (mean age: 39.63±13.50 years). Graft success was achieved in 36 patients (90%). The mean duration of surgery was 66.5±18.7 minutes, and mean follow-up was 17.9±8.5 months. Postoperative ABG improved significantly compared to preoperative values (23.35±6.89 dB vs. 15.85±8.05 dB, $p<0.001$). Disease-specific quality of life scores also demonstrated significant improvement (ZCMEI-21: 43.43±12.00 vs. 11.85±11.87, $p<0.001$).

CONCLUSIONS

Endoscopic ear surgery provides high graft success rates and significant improvements in hearing and patient-reported quality of life. These findings support the effectiveness of the endoscopic approach in managing chronic middle ear disease.

Risk Of Middle Ear Cholesteatoma In Patients With Aural And Maxillofacial Malformations

Mikolaj Stachurski[1,2], **Agnes Modée Borgström**[1,3], **Hanna Mogensen**[4,5], **Per Olof Eriksson**[6], **Eva Westman**[7], **Åsa Bonnard**[1,3]

[1]Division of CLINTEC, Department of Ear, Nose and Throat Diseases, Karolinska Institutet, Stockholm, Sweden; [2]Department of Otorhinolaryngology, Östersund Hospital, Östersund, Sweden; [3]Medical Unit of ENT, H&B, Karolinska University Hospital, Stockholm, Sweden; [4]Department of Immunology, Genetics and Pathology, Cancer Precision Medicine, Uppsala University, Sweden; [5]Unit of Epidemiology, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden; [6]Department of Surgical Sciences, Otorhinolaryngology, Uppsala University Hospital, Uppsala, Sweden; [7]Department of Clinical Sciences, Otorhinolaryngology, Umeå University, site Sundsvall, Umeå, Sweden

BACKGROUND & AIM

Aural and maxillofacial malformations is a group of conditions characterized by an abnormal anatomy of the ear and the facial skeleton. These malformations can involve the eustachian tube and may lead to chronic otitis media. Some of these conditions such as Down syndrome and Turner syndrome are associated with middle ear cholesteatoma development. We aim to assess the risk of developing middle ear cholesteatoma in patients with these and other malformations, which have not yet been analyzed.

MATERIAL & METHODS

A nationwide, matched case-control study including all patients surgically treated for cholesteatoma in Sweden between 1987 and 2018 have been identified in the Swedish National Patient Register (cases). Two controls per case, matched on sex, age and place of residency, were randomly selected from the general population. In total, 10618 cases and 21236 controls were included, making up a total of 31854 individuals. Information on aural and maxillofacial malformations was also obtained from the Swedish National Patient Register. Logistic conditional regression was used to estimate odds ratios (ORs) with 95% confidence intervals (CI) for the association between aural and maxillofacial malformations and the risk of developing cholesteatoma.

RESULTS

In patients with cholesteatoma, 277 (2.6%) patients had aural or maxillofacial malformation while in the control group only 78 (0.4%). Fifteen cases (0.1%) of cholesteatoma had multiple malformation diagnoses. Patients with any maxillofacial malformation, regardless of its type, had a significantly higher relative risk for developing cholesteatoma, OR: 7.41 (95%CI [5.73-9.58], p<0.001). Highest relative risk was discovered in Turner syndrome, OR: 14.50 (95%CI [5.10 – 41.24], p<0.001), Down syndrome, OR: 12.8 (95%CI [7.43-22.06], p<0.001) and cleft lip and palate, OR: 10.00 (95%CI [5.75-17.41], p<0.001) while the lowest risk was in malformations of the external ear, OR: 2.16 (95%CI [1.69 – 4.06], p<0.001).

CONCLUSIONS

Maxillofacial malformations are associated with a higher risk of developing middle ear cholesteatoma, with the highest relative risk in patients with Turner and Down syndrome as well as cleft lip and palate. These results indicate the need for a standarized ear follow-up structure for all patients with aural and maxillofacial malformations.

OP-687

The Utility Of Bottom Push Up Method On Intact Canal Wall Up Tympanoplasty For Cholesteatoma Surgery

Nobuhiro Hakuba[1]

[1]Department of otolaryngology, Teikyo University School of medicine, Mizonokuchi Hospital

BACKGROUND & AIM

In the intact canal wall tympanplasty (ICWT) for cholesteatoma, the bottom push up method is available to push out matrix membrane of cholesteatoma through the continuity of the matrix membrane to reduce the residual of cholesteatoma. Depending on this method the scutumplasty and cartilage tympanoplasty could be fixed tightly due to the minimum of the transmeatal atticotomy to prevent the recurrence of cholesteatoma.

MATERIAL & METHODS

In this study, we classified a total 151 cases : 145 cases for one-staged operation, 6 cases for planned two-staged operation of the pars tensa cholesteatoma and 114 cases: 104 cases for one-staged operation, 10 cases for planned two-staged operation cases of the pars flaccida cholesteatoma primary underwent CWUM on Teikyo University School of Medicine, Mizonokuchi Hospital during 2015-2023. We discussed the recurrent rate of the cases with one-staged operation or planned two-staged operation.

RESULTS

The residual recurrent of cholesteatoma of the pars tensa cholesteatoma was 1 case and reforming of cholesteatoma of the pars tensa cholesteatoma were 4 cases for one-staged operation, no recurrent cases for planned two-staged operation of the pars tensa cholesteatoma. And the residual recurrent of cholesteatoma of the pars flaccida cholesteatoma was no cases and reforming of cholesteatoma of the pars flaccida cholesteatoma were 3 cases for one-staged operation, no recurrent cases for planned two-staged operation of the pars flaccida cholesteatoma.

The recurrent rate was 3.3% (5/151) on the pars tensa cholesteatoma and 2.6% (3/114) on the pars flaccida cholesteatoma and the total recurrent rate was 3.0% (8/265).

CONCLUSIONS

During CWUT, the Bottom Push Up method, which pushes out the bottom of the depression from the mastoid side, relieved tension on the cholesteatoma maternal membrane, making it possible to continuously remove the cholesteatoma as one block without braking the membrane, resulting in less residual cholesteatoma. In addition, because the extent of the transmeatal atticotomy was minimized, the cartilage tympanoplasty, which prevents recurrence due to reforming of cholesteatom, became stronger, resulting in less cholesteatoma reformation.

OP-688

Atresia Of The Eustachian Tube: Experience From A Tertiary Referral Center

Saleh Alamry[1]

[1]*Prince Sultan Military Medical City (PSMMC)*

BACKGROUND & AIM

Atresia of the Eustachian tube is rare but can be a serious complication of nasal surgery. It often has a major impact on patients' daily lives, leading to ear pain, tinnitus, dizziness, and conductive hearing loss. We share our experience managing three patients with this condition and highlight the lessons learned from different surgical approaches.

MATERIAL & METHODS

Three patients with complete Eustachian tube atresia were treated surgically. The surgical techniques varied depending on the individual case. In some, scar tissue was released and the tube dilated; in others, laser dissection was used to reopen the blocked segment. To help keep the tube open, balloon dilation and temporary stenting were added when needed.

RESULTS

The results were not identical in every patient, but each approach provided valuable insights. While outcomes varied, all surgeries aimed to restore tube function and improve quality of life. Most patients experienced symptom relief, particularly in ear pain and hearing, though the degree of improvement differed.

CONCLUSIONS

Eustachian tube atresia is an uncommon but challenging condition. Our experience shows that surgery can provide meaningful benefits, especially when techniques are tailored to the individual patient. Combining scar release, laser dissection, balloon dilation, and stenting offers a practical way to restore function and reduce symptoms.

Chronic Otitis Media Due To Mycobacterium Tuberculosis With Mastoid Involvement In A Diabetic Patient: A Case Report

M.D. Christian Eliud Galindo Salazar[1], **M.D. Lizette Montserrat Cabrera Lopez**[2], **M.D. Juan José Reyes Fortanelli**[1], **M.D. Victor Roman Sanchez Balderas**[1], **M.D. Maria Fernandez Olvera**[1]

[1]*Hospital Regional de Alta Especialidad "Dr. Ignacio Morones Prieto"*; [2]*Medical School, Universidad Autonoma de San Luis Potosi*

BACKGROUND & AIM

Tuberculous otitis media (TOM) is a rare form of extrapulmonary tuberculosis, accounting for less than 1% of chronic otitis media cases in developed countries. Its clinical presentation often mimics chronic suppurative otitis media or cholesteatoma, leading to delayed diagnosis and treatment. The aim of this report is to describe a case of tuberculous otitis media with mastoid involvement in a patient with diabetes mellitus and to highlight the importance of considering this diagnosis in refractory chronic otitis media.

MATERIAL & METHODS

We report the case of a 42-year-old male with poorly controlled diabetes mellitus who presented with progressive unilateral hearing loss and persistent purulent otorrhea unresponsive to conventional antibiotic therapy. Otoscopic examination, high-resolution computed tomography (HRCT) of the temporal bone, surgical findings, histopathological analysis, and radiologic evaluation were performed. The patient underwent surgical management followed by standard antituberculous therapy and was monitored with regular clinical follow-up.

RESULTS

Otoscopy revealed a large (60–80%) tympanic membrane perforation on the affected side. HRCT demonstrated opacification of the middle ear and mastoid with partial aeration and sclerotic changes of the mastoid air cells. A canal wall-up mastoidectomy revealed extensive inflammatory tissue occupying the middle ear and mastoid, which was removed and sent for histopathological examination. Histopathology confirmed infection with Mycobacterium tuberculosis. Chest radiography

showed bilateral upper-lobe infiltrates consistent with pulmonary involvement. The patient completed standard antituberculous therapy with favorable clinical evolution. At five months of follow-up, otoscopy showed an intact tympanic membrane and complete resolution of otorrhea.

CONCLUSIONS

Tuberculous otitis media should be considered in cases of chronic otitis media unresponsive to standard antibiotic treatment, particularly in patients with risk factors such as diabetes mellitus or in tuberculosis-endemic regions. Early recognition and combined surgical and medical management are essential to achieve favorable clinical outcomes and prevent complications. This case underscores the importance of maintaining a high index of suspicion for tuberculous involvement of the ear in atypical or refractory presentations.

Digital Therapy For Meniere's Disease

Pa-Chun Wang[1], **Te-Yung Fang**[1]

[1]*Cathay General Hospital*

BACKGROUND & AIM

Life style modification is a crucial part for the treatment of Meniere's disease (MD). In this project we develop a digital therapy assistant (eTxMD) aiming to improve the case management quality for the MD patients and their care professionals.

MATERIAL & METHODS

We develop an iOS-based digital application to monitor and to manage the life style of patients with MD, the targeted dimensions, including: 1. medication compliance 2. diet control 3. sleep and emotion monitoring 4. noise exposure avoidance 5. rehabilitation modules are designed on smartphone. Upon entry to the system, the history, stage and severity of MD are registered as baseline information. In order to understand their expectation and preference with treatment, patients will be asked to complete a share-decision making process with their caring physician.

Eight professionals participated in the validation processes of eTxMD using technology acceptance methodology (TAM, scale 0-5, from not acceptable to fully acceptable).

RESULTS

The TAM evaluation shows high acceptance of eTxMD from "perceived usefulness (4.30.7~4.40,7)", "perceived ease of use (4.30.4~4.50.5)", "attitude toward using(3.82.7~4.00.8)", and 80% of the participant agree that eTxMD might be helpful for MD patients (behavior intention to use).

CONCLUSIONS

The preliminary TAM data shows eTxMD has potential to be used in the clinical setting to assist MD patients for their life style modification.

OP-691

Octyl-2-Cyanoacrylate Tissue Adhesive Closure Versus Subcuticular Suture For Post-Auricular Incisions

Maryam aljohani[1], **Mansoor alshamani**[1], **Marzogi salamah**[1]

[1]*Ohud hospital Madinah Helath cluster*

BACKGROUND & AIM

Skin closure techniques in otolaryngology vary based on surgeon preference and wound site. Octyl-2-Cyanoacrylate may be a safe, rapid, and cost-effective option for post-site closure.

This randomized controlled trial study aimed to compare Octyl-2-Cyanoacrylate and conventional subcuticular sutures in ear surgeries, assessing wound closure results in both case and control groups.

MATERIAL & METHODS

This prospective, randomized, controlled, single-blind study was conducted at Ohud Hospital from May 2021 to May 2022. Ear surgery and cochlear implantation in patients were examined, and each group was randomly assigned to receive Derma-bond TM and deep layer subcuticular sutures closure. Incisions were assessed at various time points, including 3 weeks,6 weeks, 6 months, and 1 year post-surgery. The patient and observer Scar Assessment Scale was used, and two independent ear surgeons used the Stony Brook Scar Evaluation Scale for initial scar assessment.

RESULTS

This study involved 126 ear surgery and cochlear implantation patients randomized to use cyanoacrylate tissue adhesive or subcuticular suture for port site closure. The study found that tissue adhesive (OCA) was faster and more ef cient than standard

sutures, saving an average of 12 min per incision in each ear. Incision cosmesis showed immediate results and significant differences, and patient satisfaction with OCA wound closure was higher than standard sutures.

CONCLUSIONS

The ndings con rmed that cyanoacrylate tissue adhesive signi cantly reduced the time needed for skin clo-sure during ear surgery and showed immediate cosmetic improvements without any documented instances of bleeding, hema-toma, infection, or wound separation.

OP-692

Facial Nerve Decompression In Unusual Clinical Situation - Case Series & Literature Review.

Leila Slade[1], **S Basavaraj**[1]

[1]*St Mary's Hospital, Isle of Wight*

BACKGROUND & AIM

Facial nerve paralysis is uncommon, but very disfiguring condition with serious physical and psychological impact on patients. We present cases series to demonstrate successful outcome by surgical decompression based on location of the disease.

MATERIAL & METHODS

We had series of 4 patients with facial palsy or potential risk of facial nerve paralysis. 3 patients had facial weakness and one patient was in severe risk of facial nerve paralysis without decompression during otological procedure.

RESULTS

Two patients had local cause in temporal bone for their facial nerve paralysis - with decompression they recovered completely. One patient had inflamed nerve due to cholestotoma, without segmental decompression we avoided any weakness post-operatively. One was due to systemic cause - didn't recover.

CONCLUSIONS

Successful decompression of facial nerve is always possible when it is due to local cause., duration may not have any significance.

OP-693

Mild Traumatic Brain Injury -Then, Now, And In The Future

Michael Hoffer[1], **Erin Williams**[1], **Alex Kiderman**, **Carey Balaban**

[1]*University of Miami;* [2]*University of Miami*

BACKGROUND & AIM

Mild traumatic brain injury (mTBI) is an increasingly common global health issue that affects 50-60 Million people worldwide. Thirty to forty percent of those who experience mTBI have subacute or chronic effects of the injury. Optimized diagnosis and treatment modalities for this disorder are urgently needed. Unfortunately, questions remain including how best to diagnose the condition, how to determine the prognosis of the condition, and how to treat the condition to prevent short and long term consequences. The aim of this talk is to discuss novel diagnostic and treatment paradigms in mTBI

MATERIAL & METHODS

A combination of oculomotor, vestibular and reaction time (OVRT) tests were performed in a virtual reality google (Synopsis, Inc, Pittsburgh, PA, USA). The test included pursuit tests, saccade tests, oculomotor control tests, reaction time testes and vergence tests. In a series of several experiments this battery of tests was used to examine performance differences between the following: 1) Controls and mTBI subjects, 2) mTBI subjects and other vestibular disorders, and 3) acute mTBI subjects and more chronic mTBI subjects. Objective test outcomes of each of the 14 tests were compared between groups using standard statical methods to determine differences. In addition, patterns of pupil and eye motion response were evaluated for the vergence tests and compared in controls, acute mTBI, chronic mTBI, and other vestibular conditions.

RESULTS

The experiments in total included over 500 controls, 450 mTBI subjects, and 100 other vestibular condition subjects. Each experiment was had properly matched comparison groups and the power to determine differences between the groups. The results are as follows: 1) A series of six tests could determine the presence of mTBI when comparing acute mTBI to control, (AUC 0.966, Sensitivity 0.929, and Specificity 0.90) Using these tests and the analysis of vergencies acute mTBI could be distinguished from other vestibular disorders and 3) Using vergence alone the state of mTBI (acute (0-7 days), subacute (10-30 days), and chronic (90 days and over) could be determined. Furthermore, using a combination of the tests and vergence results prognosis of the state of mTBI recovery could be determined.

CONCLUSIONS

Mild TBI is a major public health problem. Despite a great deal of study accurate diagnosis, prognostic information, and optimal treatment have not been defined. We discuss the use of a portable device to study mTBI. Using a combination of tests the device can determine the presence of mTBI and has achieved US FDA approval for determining the presence of mTBI. Moreover, using different combinations of tests, the device can determine the difference between mTBI and other vestibular disorders and can determine the status of recovery of an individual with mTBI. We also discuss novel new treatment paradigms.

OP-694

THE FATE TYMPANIC MEMBRANE RETRACTIONS: SEVEN YEARS FOLLOW UP

Guilherme Doehl Knebel[2], **Sady Selaimen da Costa**[1,2], **Maurício Noschang Lopes da Silva**[2], **Fábio André Selaimen**[2]

[1]*Federal University of Rio Grande do Sul;* [2]*Hospital de Clínicas de Porto Alegre*

BACKGROUND & AIM

Tympanic membrane retractions (TMRs) are frequent otologic findings, with a reported risk of progression to cholesteatoma ranging from 1–5% in the literature. Identifying risk factors associated with progression is essential to optimize clinical management and to indicate surgery at an early stage when necessary. This study aimed to analyze the long-term evolution of TMRs over a mean follow-up period of 7 years and to identify risk factors associated with disease progression.

MATERIAL & METHODS

This retrospective cohort study evaluated 61 ears with TMRs followed for a mean period of 7 years at a tertiary referral center. Video-otoscopic and surgical records were reviewed. Outcomes included stability, improvement, worsening of the retraction, tympanic membrane perforation, and development of cholesteatoma. Anatomical and clinical variables were correlated with outcomes through statistical analysis of the collected data.

RESULTS

The rate of progression to cholesteatoma was 19.7% (12/61 ears), higher than most previously reported data. Complete erosion of the long process of the incus was the main risk factor identified (RR 3.34; p = 0.002), whereas a normal malleus and absence of posterior recess involvement were protective factors. Adhesion of the tympanic membrane to the promontory in the posterosuperior quadrant (PSQ) was also identified as a risk factor (RR 2.14 [1.26–3.63]; p = 0.037).

The findings suggest that progression may be more common than classically described, particularly in more severe cases. Complete erosion of the long process of the incus emerged as a robust prognostic marker, indicating retractions with low reversibility and a high risk of cholesteatoma formation. Adhesion of the tympanic membrane to the promontory in the PSQ indicates greater aggressiveness, as this requires erosion of the long process of the incus and the stapes suprastructure.

CONCLUSIONS

Conclusion: Tympanic membrane retractions carry a relevant risk of progression, particularly when associated with ossicular erosion. These findings highlight the importance of individualized follow-up and underscore the need for prospective studies to validate these markers, enabling more precise management protocols.

Comparison Of Endoscopic And Microscopic Management Of Attic Cholesteatoma: A Systematic Review And Meta-Analysis

hasan alawi[2]

[1]*national guard hospital jeddah;* [2]*fake hospital*

BACKGROUND & AIM

Attic cholesteatoma is a common otologic disease that leads to several complications. Endoscopic ear surgery is becoming increasingly more used for its management. The differences in the outcomes between the totally endoscopic approach and the traditional microscopic approach remain unclear for limited attic cholesteatomas. As such, this systematic review and meta-analysis aims to compare the outcomes of the endoscopic approach and the microscopic approach for the management of cholesteatoma limited to the attic.

MATERIAL & METHODS

This review was conducted in accordance with the PRISMA-P 2020 guidelines. Searches were performed using the databases PubMed, Cochrane Library, Web of Science, Clinical Trials, and Google Scholar. Studies were included based on predefined eligibility criteria and assessed for quality using the Revised Cochrane Risk-of-Bias Tool for randomized trials (RoB2) and the Methodological Index for Non-Randomized Studies (MINORS). The primary outcomes for this review were audiological

outcome, healing time, operating time, middle ear structures visibility index (MESVI), post-operative complications, graft success rate, and long term outcomes. Mean difference (MD) and odds ratio (OR) with 95% confidence intervals (CI) were used to represent the outcomes.

RESULTS

7 studies with a total of 539 patients (541 operated ears) were included. The endoscopic group had a statistically significant higher MESVI (Z=23.205, P<0.0001). The overall effectshowed less post-operative pain among patients undergoing the endoscopic technique (Z= -6.942, P=0.000). No statistically significant difference between both groups was found in terms of healing time, operating time, graft success rate, post-operative complications and audiological outcome.

CONCLUSIONS

The endoscopic approach for the management of cholesteatoma limited to the attic region has some advantages compared to the microscopic approach namely in terms of better middle ear structures visibility and less postoperative pain. No significant differences in the operation time, average healing time, graft success rate, and audiological outcome between both approaches were found. Future research conducted with high quality comparative prospective studies is needed to further compare both surgical approaches and confirm the advantages of the endoscopic approach.

OP-696

Congenital Ossicular Malformations: Report On 46 Ears

Nako Okuda[1], **Keizo Fujiwara**[1], **Yasushi Naito**[1], **Masahiro Kikuchi**[1], **Koichiro Yamada**[1], **Tomoko Kubo**[1], **Takuya Yamamoto**[1], **Daichi Miyata**[1], **Kohei Takase**[1], **Kohei Yamamoto**[1], **Norio Yamamoto**[1]

[1]*Department of Otolaryngology-Head and Neck Surgery, Kobe City Medical Center General Hospital, Kobe, Japan*

BACKGROUND & AIM

Congenital ossicular malformations exhibit a wide range of anatomical variations, and multiple classification systems have been proposed. The Teunissen and Cremers classification remains widely used. More recently, classifications have focused on surgical outcome prediction and prosthesis selection, often based on stapes footplate mobility and the presence of stapes anomalies. This study aimed to identify the types of ossicular anomalies within each class, analyze them, and examine their relationship to surgical outcomes.

MATERIAL & METHODS

The subjects were 38 patients (46 ears) who underwent surgery over 14 years, from October 2011 to July 2025. The diagnosis was confirmed intraoperatively. There were 22 male and 16 female patients, with a mean age of 16.2 years (range, 5 to 54 years) at the first surgery. Preoperative and postoperative audiological findings, as well as intraoperative anatomical findings, were analyzed based on the modified Teunissen and Cremers classification. A successful hearing outcome was defined as a postoperative air-bone gap of 20 dB or less.

RESULTS

A total of 28 distinct types of ossicular malformations were identified. According to the classification, seventeen, seventeen, one, nine, and two ears were classified in Class 1, 2, 3, 4, and 5, respectively. Success rates were 88.2% in Class 1 and 82.4% in Class 2, whereas they were lower in Class 4 (62.5%). The mean postoperative air conduction thresholds were 23.5 dB in Class 1 and 26.4 dB in Class 2, compared with 41.3 dB in Class 4, indicating poorer hearing outcomes in Class 4.

CONCLUSIONS

Consistent with previous reports showing decreasing postoperative hearing improvement from Class 1 to Class 5, Class 4 demonstrated inferior outcomes. In Class 4, 7 of 9 cases involved anomalies beyond the stapes, particularly the incus. When confined to the stapes, standard stapes surgery can be performed. However, additional anomalies may prevent incus attachment and necessitate alternative reconstruction, resulting in poorer outcomes. Based on these observations, we propose that stapedial fixation cases may be divided into cases with and without malleus and/or incus anomalies, regardless of stapes anomalies, instead of Class 3 and 4 in the modified Teunissen and Cremers classification.

OP-697

A Study On The Use Of Slow Motion Imaging To Assist In The Diagnosis Of Eustachian Tube Function

Kuei-Ting, Yen[1], **Chia-Der Lin**[1], **Hou-Kuang Chen**[1], **Xuan-Fu,Chang**[1]

[1]*The Department of Otolaryngology Head and Neck Surgery , China Medical University Hospital*

BACKGROUND & AIM

This study investigates the efficacy and reliability of using slow-motion dynamic video endoscopy to evaluate Eustachian tube (ET) function . By standardizing observational procedures, we aim to accurately analyze the dynamic kinetic patterns of the normal ET during swallowing and validate this method as an effective diagnostic tool

MATERIAL & METHODS

Healthy subjects scoring less than 2 on both the ETDQ-7 and PHI-10 questionnaires were recruited for this study . A standardized operation procedure was utilized, involving local anesthesia followed by the insertion of a flexible fiberoptic endoscope to record slow-motion video of the ET orifice during resting, phonation, and swallowing . The recorded imaging data were converted into image series at 30 frames per second for quantitative analysis, which included angle measurements of the medial and lateral laminae . These dynamic findings were then systematically compared and correlated with standard ET function tests to evaluate their clinical reliability .

RESULTS

Slow-motion dynamic video endoscopy (DSVE) revealed that the complete periodic motion of a normal ET during swallowing comprises four distinct phases: resting, soft palate elevation, post-soft palate elevation, and post-wriggling wave phases . Specifically, the sequential movement involves: 1) the soft palate elevates, causing the medial wall and medial cartilaginous lamina to move inward; 2) the lateral wall expands outward; 3) upon maximal expansion, an inward wriggling or peristaltic wave initiates from the medial inferior part towards the ET orifice; and 4) following this wave, the cartilaginous isthmus opens completely before closing . The quantitative angle measurements obtained from these healthy participants correlated consistently with normal ET function test outcomes.

CONCLUSIONS

This study successfully establishes a standardized operation procedure for DSVE to precisely record and evaluate ET kinematics. The proposed quantitative descriptive model provides a new, comprehensive understanding of healthy ET functionality. This standardized imaging-based approach holds significant clinical promise for facilitating more accurate differential diagnoses and targeted treatments for patients with ET dysfunction in the future .

OP-698

Audiologic Outcomes Of Bone Cement And Incus Interposition In Austin-Kartush Type A Ossicular Defects

Kardo Önder[1], **Onur Güder**[1], **Yüksel Olgun**[1], **Enis Alpin Güneri**[1]

[1]*Dokuz Eylul University, School of Medicine, Department of Otolaryngology–Head and Neck Surgery, Izmir, Türkiye*

BACKGROUND & AIM

Long process erosion of the incus is one of the most common ossicular chain pathologies in chronic otitis media and temporal bone trauma. Bone cement reconstruction and incus interposition are two commonly used techniques for repairing this defect. This study aimed to compare the postoperative audiologic outcomes of glass ionomer bone cement and incus interposition in patients with Austin-Kartush Type A ossicular chain pathology.

MATERIAL & METHODS

Patients who underwent ossicular chain reconstruction with either glass ionomer bone cement or incus interposition for Austin-Kartush Type A pathology at Dokuz Eylul University Department of Otorhinolaryngology between January 2015 and September 2024 were retrospectively reviewed. Patients with at least 6 months of audiologic follow-up were included. Demographic characteristics, preoperative and postoperative audiologic findings, and Middle Ear Risk Index (MERI) scores were analyzed. Preoperative and postoperative air-bone gap values and postoperative gain were compared between groups.

RESULTS

A total of 42 patients were included: 27 underwent bone cement reconstruction and 15 underwent incus interposition. Mean age was significantly higher in the bone cement group than in the incus interposition group (45.2±13.8 vs 33.4±16.0 years, p=0.023). Preoperative air-bone gap values were similar between groups (33.0±8.9 vs 32.0±12.2 dB, p=0.654). Both groups showed significant postoperative improvement (p<0.001 for both). Postoperative air-bone gap values (15.6±9.5 vs 13.5±9.1 dB, p=0.674), postoperative gain (17.0±10.0 vs 18.5±8.7 dB, p=0.537), and MERI scores (p=0.873) were not significantly different. No significant correlation was found between MERI score and postoperative gain (p=0.903).

CONCLUSIONS

Both bone cement and incus interposition are effective techniques for reconstruction of Austin-Kartush Type A ossicular defects and provide significant postoperative audiologic improvement. However, no significant difference was found between the two methods in terms of postoperative air-bone gap or hearing gain. Larger studies are needed to better define prognostic factors and optimal technique selection.

OP-699

The Neural Response Properties And Linear-Nonlinear Neural Signal Transformation Of The Semicircular Canal Afferent Neuron Population

Peng Han[1], **Qing Zhang**[2], **Pengyu Ren**[3,4]

[1]*The First Affiliated Hospital of Xi'an Jiaotong University;* [2]*Shanghai Jiaotong University;* [3]*Second Affiliated Hospital of Xi'an Jiaotong University;* [4]*Departments of Otolaryngology-Head and Neck Surgery, School of Medicine, Johns Hopkins University*

BACKGROUND & AIM

Well-explored neural response properties and signal transformation within a sensory system with hierarchical stages are the basis for neuromodulation techniques to treat neurological disorders.Here we tested semicircular canal afferent neurons (SCNs) by sinusoidal rotation to reveal the neural response properties and signal transformation in the first stage of the vestibular system.

MATERIAL & METHODS

A total of 15 adult female chinchillas (C. laniger) with 480-550g body weight were used in the present study.Here we constructed a coordinate system in three-dimensional space and used right hand rule to judge positive directions of stimuli,once a neuron was isolated well, its sensitivities were tested by using combined stimuli consisted with yaw and pitch rotations. Then the corresponding semicircular canal of this neuron could be immediately identified by monitoring neural response activities during stimuli.

RESULTS

Our data indicate that the mean resting-state discharge rate of SCNs is 47.11 ± 18.17 spikes/s, and the distribution of CV* has a peak locating at CV* = 0.029 ± 0.004. The sensitivity and phase lead of the irregular SCN population are significantly higher than those of the regular SCN population. The frequency of stimuli has a positive effect on sensitivities but a negative effect on phase leads. However, the effect of amplitudes of stimuli on the sensitivities and phase leads is negative and ineffective, separately. Furthermore, the regular SCN population transforms linear neural signals based on angular velocity, however, the irregular SCN population transforms nonlinear neural signals based on angular velocity.

CONCLUSIONS

All of these findings improve our understanding about the neural response properties and signal transformation in the first stage of the vestibular system, complementing how sensory pathways encode and transmit neural signals under natural conditions.

Distribution Of Otoscopic Pathologies Associated With Tympanic Membrane Perforation: A Retrospective Analysis Based On Perforated Ear Images

İbrahim Kolukısa[1], **Miyase Orhan**[2], **Fakih Cihat Eravcı**[1]

[1]*Necmettin Erbakan Üniversitesi Tıp Fakültesi;* [2]*Ereğli Devlet Hastanesi*

BACKGROUND & AIM

The aim of this study was to evaluate the distribution of otoscopic pathologies associated with tympanic membrane perforation in perforated ear images and to identify the most frequently observed accompanying findings.

MATERIAL & METHODS

In this retrospective, descriptive, cross-sectional study, otoendoscopic images of patients diagnosed with tympanic membrane perforation who presented to the Necmettin Erbakan University Department of Otorhinolaryngology between March 2023 and March 2026 were evaluated. A total of 1970 perforated ear images from 1550 patients were included in the study. In patients with bilateral perforations, images from both ears were analyzed, while repeated images from the same ear were excluded. Images were obtained using a 0° rigid endoscope. Associated otoscopic pathologies were assessed using a predefined multi-label classification system. Categorical data were presented as counts and percentages.

RESULTS

The most common accompanying pathological finding in perforated ear images was myringosclerosis (n=1035, 52.5%). This was followed by discharge (n=529, 26.9%), attic retraction (n=306, 15.5%), and pars tensa retraction (n=253, 12.8%). Less frequently observed findings included otomycosis (n=124, 6.3%), cholesteatoma (n=93, 4.7%), and pseudomembrane (n=77, 3.9%). Hemorrhage (n=46, 2.3%), granulation tissue (n=34, 1.7%), and scutum erosion (n=27, 1.4%) were observed less commonly. As multiple pathological findings could be present in a single image, the categories were not mutually exclusive.

CONCLUSIONS

Tympanic membrane perforation is not an isolated otoscopic finding in most cases and is frequently accompanied by additional pathologies such as myringosclerosis, discharge, and retraction changes. These findings suggest that perforation should be

evaluated within the broader morphological spectrum of chronic middle ear disease. Systematic identification of associated otoscopic findings in perforated ears may enhance standardized reporting and support future image-based classification approaches.

OP-701

Computational Fluid Dynamics (CFD) Analysis Of Otoconia Behavior In The Inner Ear And Their Role In Benign Paroxysmal Positional Vertigo (BPPV).

Augusto Peñaranda Sanjuan[2], **María Alejandra Hoyos Agudelo**[1], **Carlos Andrés Bravo Vega**[1], **Christian Javier Cifuentes de la Portilla**[1]

[1]*Universidad de los Andes;* [2]*Fundación Santa Fé de Bogotá*

BACKGROUND & AIM

Benign Paroxysmal Positional Vertigo (BPPV) is the leading cause of peripheral vertigo, accounting for approximately 25% of vestibular cases. It results from the displacement of otoconia—calcium carbonate particles—from the utricular macula into the semicircular canals. Although repositioning maneuvers are commonly used, their success rates range from 50% to 80%, depending on particle location. Research on the physical and physiological factors influencing otoconia movement remains limited.

This study aims a three-dimensional inner ear model and Computational Fluid Dynamics (CFD) simulations to analyze the motion of otoconia of varying sizes within the endolymph across the three semicircular canals.

MATERIAL & METHODS

A three-dimensional model of the inner ear was implemented in ANSYS Workbench/Fluent. A pressure-based, transient CFD model with absolute velocity formulation was used, incorporating gravity (−9.8 m/s^2) as the principal force. Navier–Stokes equations governed fluid behavior. Three particle diameters (1 µm, 15 µm, and 30 µm) were simulated to represent variability in otoconia size. Repositioning maneuvers (Epley, Gufoni, and Yacovino) were modeled using rotation matrices (Rx, Ry, Rz) calculated in Python to determine gravity vectors for each step. Velocity magnitude, dynamic pressure contours, pathlines, and particle tracking (DPM) analyses were performed to evaluate particle trajectories and repositioning outcomes.

RESULTS

Pathline analysis showed defined trajectories from the ampulla toward the macula; however, not all particles reached their final destination, with accumulation observed in canal curvature regions.

Smaller particles (1 µm) exhibited higher exit percentages and lower permanence within the canals compared to larger particles (30 µm). Simulations demonstrated that particle size significantly influences repositioning success.

In the horizontal canal, maximum velocity reached 2.02×10^{-2} m/s, the highest among the three canals evaluated. Accumulations were more likely in regions with lower velocities, particularly before reaching the macula

CONCLUSIONS

CFD simulation provides a physiologically approximated model for analyzing otoconia motion in BPPV. Particle size plays a crucial role in displacement behavior and repositioning outcomes, with smaller particles demonstrating greater mobility.

Differences in canal geometry influence velocity distribution and particle accumulation, particularly in the horizontal canal. These findings contribute to a better understanding of the biomechanical factors involved in BPPV treatment and highlight the value of computational modeling for studying vestibular disorders.

OP-702

Comparative Protective Effects Of MESNA And Methylprednisolone Against Radiotherapy-Induced Ototoxicity: An Experimental Animal Study

Selçuk EROL[1], **Ayça ARSLAN**[3], **Gözde Bayramoğlu ÇABUK**[2], **Bekir Eren ÇETİN**[2], **C. Merve SEYMEN**[2], **Çisem YEŞİL KAYABAŞI**[2], **Recep KARAMERT**[2]

[1]*Ankara Atatürk Sanatoryum Training and Research Hospital;* [2]*Gazi University Faculty of Medicine;* [3]*Dr. Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital*

BACKGROUND & AIM

Radiotherapy (RT) is a cornerstone in the management of head and neck malignancies; however, radiation-induced ototoxicity affecting the external, middle, and inner ear remains a significant clinical challenge. Although corticosteroids are widely used for their anti-inflammatory properties, effective pharmacological strategies to prevent RT-induced ototoxicity are limited. The

hypothesis of this study was that sodium 2-mercaptoethanesulfonate (MESNA) and methylprednisolone would exert protective effects against RT-induced ototoxicity, with MESNA providing superior histopathological preservation at the tissue level.

MATERIAL & METHODS

This randomized controlled experimental study included 24 adult male albino guinea pigs allocated into four groups (n = 6 per group): untreated control, RT-only, RT + MESNA, and RT + methylprednisolone. A unilateral RT dose of 7 Gy was delivered to the right ear in two fractions. MESNA and methylprednisolone were administered topically to the external auditory canal and intratympanically prior to RT. Audiological assessments, including distortion product otoacoustic emissions (DPOAE) and auditory brainstem response (ABR) testing, were performed before RT and four weeks after treatment. At the end of the fourth week, the animals were sacrificed, and tissues from the external, middle, and inner ear were harvested for histopathological examination using hematoxylin–eosin staining. Degenerative changes were evaluated using a semi-quantitative scoring system, and intergroup comparisons were conducted.

RESULTS

The RT-only group demonstrated marked degenerative changes throughout the auditory system. In the external ear, epidermal disruption, sebaceous gland degeneration, and elastic cartilage damage were observed. The middle ear exhibited mucoperiosteal disorganization, inflammatory infiltration, and vascular congestion. Inner ear findings included separation of the vestibular membrane, degeneration of the basilar membrane, deformation of the tectorial membrane, reduced vascularity of the stria vascularis, and collagen loss in the spiral ligament.

Both treatment groups showed attenuation of radiation-induced damage. MESNA provided more pronounced histological preservation, particularly in the middle and inner ear, with improved mucosal organization, better vascular preservation, and near-normal integrity of the tectorial membrane and spiral ligament. Audiologically, both treatment groups demonstrated trends toward better DPOAE preservation and lower ABR thresholds compared with the RT-only group; however, these differences were not statistically significant ($p > 0.05$).

CONCLUSIONS

RT induces significant degenerative alterations across the auditory system. Both MESNA and methylprednisolone exhibited protective effects; however, MESNA demonstrated superior tissue-level preservation. These findings suggest that MESNA may represent a promising otoprotective agent against RT-induced ototoxicity and warrants further translational and clinical investigation.

MESNA, methylprednisolone, radiotherapy, ototoxicity, guinea pig, histopathology

OP-703

Posterior Canal Wall Reconstruction- Our Experience

Dr. Hitendra Prakash Singh[1]

[1]*King George's Medical University, Lucknow, UP, India*

BACKGROUND & AIM

Canal wall down mastoidectomy has evolved significantly throughout its history; still as otologists, we are yet to find the perfect solution for the cavity problems, which occur quite commonly post CWD mastoidectomy. Authors investigated the application and effectiveness of posterior canal wall reconstruction using CMOF (Composite multifractured osteo-periosteal flap); also known as soft canal wall reconstruction for prevention of these problems.

MATERIAL & METHODS

A single center case-control interventional study was done in 320 patients during a period of seven years. Patients were equally distributed into two groups. Group 'A' comprised of patients, who underwent CWD mastoidectomy with reconstruction of posterior canal wall with CMOF and group 'B' was represented by conventional CWD mastoidectomy patients. All the patients were thoroughly examined preoperatively. All the patients were assessed clinically and radiologically for cavity problems, hearing improvement postoperatively.

RESULTS

It was seen that patients of group A (CMOF) fared well than group B (Open cavity) in terms of healing, hearing improvement and cosmesis; improvements being statistically significant.

CONCLUSIONS

Posterior canal wall reconstruction using CMOF (Composite multifractured osteo-periosteal flap) or soft canal wall reconstruction is an effective and easy method of avoiding post-operative cavity problems in Canal wall down mastoidectomy.

Spatial Relationship Between The External Auditory Canal And The Parotid Gland

Krittayot Patchanee[1,2], **In Seok Moon**[1]

[1]*Department of Otorhinolaryngology, Yonsei University College of Medicine, Seoul, Korea;* [2]*Department of Otolaryngology, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand*

BACKGROUND & AIM

The necessity of routine parotidectomy in early-stage (T1/T2) external auditory canal (EAC) carcinoma remains debated. This study utilizes the Magnetic Resonance Imaging (MRI) to define the precise spatial relationships between the EAC and the parotid gland, providing anatomical basis to reconsider both the necessity and extension of parotidectomy in these cases.

MATERIAL & METHODS

We conducted a retrospective MRI-base anatomical study of 39 patients treated for early-stage (T1/T2) EAC carcinoma. In coronal plane, the relative positions on the EAC corresponding to the superficial and deep parotid lobes along with the vertical distances between the EAC and the parotid gland were measured. The pathological results of those who underwent parotidectomy were assesed for the rate of occult metastasis.

RESULTS

The cartilaginous EAC corresponds exclusively to the superficial lobe of parotid gland while the bony EAC primarily corresponds to the deep lobe with a mean 3.2 ± 3.0 mm overlapping portion with superficial lobe. The mean vertical distances from the EAC to parotid gland was 7.9 ± 1.8 mm at the cartilaginous EAC and 12.1 ± 2.6 mm at the bony EAC. There is no direct parotid gland invasion in all patients. In the pathological study, none of parotidectomy specimen showed positive for malignancy.

CONCLUSIONS

This MRI-based anatomical study suggests that parotidectomy may not be necessary when the carcinoma is strictly confined in the EAC, given that there is no occult metastasis in this sample despite the close proximity of the EAC and parotid glands. However, when the carcinoma extends beyond the EAC, superficial parotidectomy alone may not achieve an oncologic safety due to a close proximity of the EAC and deep parotid lobe.

Analysis Of Trio-Based Whole Exome Sequencing In South Chinese Families With Hereditary Hearing Impairment

Ying Lin[1,2], **Yuanhui Zhang**[1,2], **Xiaoping Liu**[2], **Zeyang Liu**[1,2], **Bixiao Xu**[1,2], **Feng Yu**[1,2], **Yiwen Chen**[1,2]

[1]*Guangzhou Red Cross Hospital, Jinan University;* [2]*Institution of Otorhinolaryngology Head and Neck, Jinan University*

BACKGROUND & AIM

Hereditary hearing impairment is a prevalent sensory disorder affecting millions worldwide, with significant genetic heterogeneity. Whole Exome Sequencing (WES) has emerged as a pivotal tool in uncovering the genetic basis of hearing impairment, enabling the identification of both known and novel genetic mutations. Our study aimed to explore the genetic variations of WES in Trio family （mother, father and child）, proband and their parents, in a special school of hearing impairment in Guangzhou and its application value as the first choice for screening.

MATERIAL & METHODS

A total of 67 participants from 23 families were enrolled in this study. Among these families, there were 2 probands without parents' samples. All the 23 probands who had not undergone any hearing related genetic test before and who voluntarily participated in this study were selected for audiology test and Trio-based WES. The medical history registration form of the proband and his/her parents with normal hearing phenotype was filled in detail, and a pedigree charts were drawn.

RESULTS

Copy number variations (CNVs) of the STRC gene were identified in one proband without parents, and this presence was confirmed using multiplex ligation-dependent probe amplification (MLPA). Another proband carried heterozygous pathogenic MPZL2 and a Variant of Uncertain Significance (VUS) MYH14/SLC44A4. Among the 21 trio-families, only single gene or locus mutations were detected in 4 families (GJB2 109G>A homozygous, GJB2 109G>A heterozygous, MYO15A 964+3G>A homozygous, WFS1740_741delTT heterozygous, respectively), and 17 families were compound. Heterozygous variants. The common primary pathogenic gene GJB2 was detected in 8 families, mainly at the 109G>A locus. The remaining genes defined as pathogenic or suspected to be pathogenic according to the American College of Medical Genetics and Genomics(ACMG) guidelines include USH2A, POU3F4, TNFRSF11A, CPLANE1, CDH23, OTOF, KCNQ4, TMC1 … At the same time, patients with G6PD, Adams-Oliver syndrome type 2, congenital glycosylation disorder Icc type, neurodevelopmental disorders and other diseases were detected.

CONCLUSIONS

The Trio-based WES can identify pathogenic genetic variants of hereditary hearing impairment and detect potential disease-causing mutations. In regions with advanced healthcare infrastructure, WES may be considered as a first-line diagnostic approach and guidance to assist in evaluating patients before considering auditory interventions.

Beyond Hearing Recovery: Long-Term Quality Of Life After Idiopathic Sudden Sensorineural Hearing Loss

Mireya Bonet Loscertales[1], **Guillermo Velasco García**[1], **Ignacio Alcalá Rueda**[1], **Francisco Javier Guerra Blanco**[1], **David Pérez Pérez**[1], **Francisco Javier Cogolludo Pérez**[1], **José Miguel Villacampa Aubá**[1]

[1]*Hospital Fundación Jiménez Díaz, Madrid (Spain)*

BACKGROUND & AIM

Idiopathic sudden sensorineural hearing loss (ISSNHL) is an otological emergency with potential long-term consequences that extend beyond pure auditory recovery. The aim of this study was to assess long-term quality of life in patients with ISSNHL and to analyse the impact of residual hearing loss, vestibular symptoms and tinnitus.

MATERIAL & METHODS

A descriptive and analytical observational study was performed including 56 patients diagnosed with ISSNHL at a tertiary referral centre. Quality of life was evaluated at least six months after onset using the Hearing Handicap Inventory for Adults (HHIA). The influence of hearing loss severity, vestibular symptoms, tinnitus and age on HHIA scores was analysed.

RESULTS

ISSNHL was associated with a significant impairment in quality of life, with higher HHIA scores observed in patients with greater residual hearing loss. The presence of vestibular symptoms was significantly associated with worse HHIA outcomes. Although tinnitus did not show statistical significance, patients with tinnitus tended to report higher HHIA scores. Younger patients demonstrated greater perceived handicap. Compared with other non-sudden asymmetric hearing losses described in the literature, ISSNHL showed a greater impact on quality of life.

CONCLUSIONS

ISSNHL results in a persistent deterioration in quality of life, particularly in patients with severe hearing loss and vestibular involvement. These findings highlight the importance of incorporating validated quality-of-life measures into routine clinical practice and support a multidisciplinary approach including auditory rehabilitation and psychological support.

Prognostic Value Of Host İndex In Patients With Malignant Otitis Externa

Meltem Işıklı[1], **Sanem Okşan Erkan**[1], **İlhami Yıldırım**[1]

[1]*Health Sciences University Adana City Training and Research Hospital*

BACKGROUND & AIM

The Host Index (H-index) is a value obtained using laboratory parameters (hemoglobin, neutrophils, lymphocytes, monocytes, and albumin). In the literature, an elevated H-index has been correlated with a reduction in disease-free survival and overall survival in patients with squamous cell carcinoma of the head and neck. Malignant otitis externa is a rare, potentially life-threatening disease that involves inflammation of the external auditory canal with osteomyelitis of the temporal bone. The purpose of our study was to assess the prognostic impact of the H-index in patients with malignant otitis externa.

MATERIAL & METHODS

We performed a retrospective study on a cohort of patients with malignant otitis externa referred to our center between 2016 and 2025. H-index calculations were performed for all patients. We evaluated the association between progression-free survival (PFS) and overall survival (OS) with H-index values.

RESULTS

A total of 44 patients were studied, with a median age of 65 years. The preliminary analysis showed a 3-year OS of 96.8% and a PFS of 53.1% for patients with H-index < 3.6, and an OS of 66.7% and PFS of 0% for patients with H-index > 3.6 ($p < 0.001$). All patients with advanced-stage disease (stage 3–4) were classified in the high H-index group (100%), whereas 93.7% in the low H-index group had early-stage disease (stage 1–2) ($p < 0.001$). Facial paralysis was present in 100% of the high H-index group, compared with 6.3% in the low H-index group ($p < 0.001$).

CONCLUSIONS

The H-index might be used to better stratify the risk of facial paralysis, recurrence, and mortality in malignant otitis externa.

Effects Of Septoplasty And Inferior Turbinate Surgery On Eustachian Tube Function And Middle Ear Ventilation

Mursel Delil[1], **Onur Celik**[1], **Burak Ulkumen**[1]

[1]*Manisa Celal Bayar University, Faculty of Medicine, Department of Otorhinolaryngology*

BACKGROUND & AIM

Eustachian tube dysfunction may contribute to middle-ear ventilation problems, and nasal obstruction may influence tubal function through altered nasopharyngeal airflow and mucosal inflammation. Evidence on the effect of septoplasty with inferior turbinate surgery remains limited. This prospective study aimed to evaluate subjective Eustachian tube symptoms and objective middle-ear ventilation parameters before and after surgery in adults with septal deviation and inferior turbinate hypertrophy.

MATERIAL & METHODS

This prospective cohort study included 38 adult patients with nasal obstruction due to septal deviation and bilateral inferior turbinate hypertrophy who underwent septoplasty and bilateral inferior turbinate surgery. Patients were evaluated preoperatively, at postoperative month 1, and at postoperative month 3. Outcomes included the Nasal Obstruction Symptom Evaluation (NOSE) scale, visual analog scale (VAS), Eustachian Tube Dysfunction Questionnaire-7 (ETDQ-7), tympanometry, tympanometric peak pressure (TPP), tympanogram type, and the automatic Williams test (ETF-1).

RESULTS

NOSE and VAS scores decreased significantly after surgery compared with baseline (NOSE: 67.25±25.85 to 21.80±18.55; VAS: 6.68±2.39 to 2.42±2.38 at month 3; both $p<0.001$) (Figure 2). ETDQ-7 total scores also decreased significantly, mainly between baseline and postoperative month 3 ($p=0.021$) (Figure 3). TPP values, tympanogram types, and TPP categories did not show significant postoperative change (Figure 1). The proportion of patients classified as having dysfunction decreased for both ETDQ-7 and ETF-1, although these categorical changes were not statistically significant (Figure 4).

CONCLUSIONS

Septoplasty combined with inferior turbinate surgery improved nasal obstruction and patient-reported Eustachian tube symptoms, but did not produce significant objective changes in middle-ear ventilation tests. Nasal cavity pathology should be considered in patients with suspected Eustachian tube dysfunction, although larger controlled studies with longer follow-up and additional objective measures are needed.

OP-709

On Reliability Of Cervical Vestibular Evoked Myogenic Potentials In Cochlear Implant Candidates

Jonas Bruun Kjærsgaard[1,2], **Rodrigo Ordonez**[3], **Anne Vingaard Olesen**[4], **Herman Kingma**[1,2], **Dan Dupont Hougaard**[1,2]

[1]*Department of Otorhinolaryngology, Head & Neck Surgery and Audiology, Aalborg University Hospital, Aalborg, Denmark;* [2]*Department of Clinical Medicine, Aalborg University, Aalborg, Denmark;* [3]*Department of Electronic Systems, Aalborg University, Aalborg, Denmark;* [4]*Department of Research Data and Statistics, Aalborg University Hospital, Aalborg, Denmark*

BACKGROUND & AIM

Cervical vestibular evoked myogenic potentials (cVEMP), assessing the vestibulo-collic reflex, are used in specialized centres around the globe as part of a vestibular assessment before cochlear implantation that may inform side selection. Newer studies suggest that an absent response, which is normally regarded a strong indicator of vestibulopathy, is not necessarily a reliable outcome. We therefore examined the reliability of cVEMP elicitability and thresholds in a cohort of cochlear implant candidates. This reliability study of cVEMP assessment in patients is, to our knowledge, world-first at large.

MATERIAL & METHODS

Thirty-four adult cochlear implant candidates underwent two air-conducted sound cVEMP examinations (test–retest design). We quantified agreement for response status and estimated the reliability of the threshold, latency and corrected amplitude outcomes using intraclass correlation (ICC). The 95% bounds of measurement uncertainty for a single threshold score were calculated.

RESULTS

Elicitability: Responses were present at both visits in 22/34 right and 22/33 left ears; status changed between visits in 4/34 and 5/33 (disagreement 12–15%).

Threshold: ICC 0.73 (95% CI 0.60–0.87); single-session score uncertainty ±7.86 dB.

p13 latency: ICC 0.56 (95% CI 0.36–0.76); single-session score uncertainty ±2.65 miliseconds.

n23 latency: ICC 0.32 (95% CI 0.10–0.54); single-session score uncertainty ±3.68 miliseconds.

Corrected amplitude at threshold: ICC 0.16 (95% CI 0.00-0.36); single-session score uncertainty ±0.32.

Corrected amplitude at 128 pSPL, fixed intensity: ICC 0.50 (95% CI 0.24-0.76); single-session score uncertainty ±0.53.

CONCLUSIONS

The instability of cVEMP response status (present vs absent) is clinically important and challenges the utility of cVEMP testing to support side selection in unilateral cochlear implantation. Threshold, latency and amplitude outcomes also showed suboptimal reliability, limiting confidence in individual-level interpretation.

If cVEMP is used in preoperative cochlear implant evaluation to inform side selection, absent responses, unilaterally or bilaterally, should be treated as inconclusive unless confirmed by repeat testing.

Chronic Suppurative Otitis Media Leading To Otogenic Meningitis: Diagnostic And Therapeutic Insights

Rusescu Andreea[1,2], **Serban Simona**[1,2], **Tonu Angela**[2], **Voiosu Catalina**[1,2], **Ionita Irina Gabriela**[1,2], **Alius Oana Ruxandra**[1,2], **Hainarosie Razvan**[1,2], **Vasile Marian Tiberiu**[1,2], **Chirila Alexandra Diana**[1,2], **Sandu Alexandra Irina**[1,2]

[1]*"Carol Davila"University of Medicine and Pharmacy;* [2]*"Prof. Dr. D. Hociota"Institute of Phonoaudiology and Functional ENT Surgery*

BACKGROUND & AIM

Chronic suppurative otitis media (CSOM) is a long-standing inflammatory condition of the middle ear and mastoid that can occasionally lead to severe intracranial complications such as meningitis. Although the incidence has decreased in the antibiotic era, otogenic meningitis remains a potentially fatal condition when diagnosis and source control are delayed. This report presents the clinical evolution and management of a case of meningitis secondary to CSOM, highlighting diagnostic challenges and surgical strategy.

MATERIAL & METHODS

A 42-year-old patient with metabolic comorbidities, including type II diabetes and dyslipidemia, presented with subtle and nonspecific symptoms: persistent headache, mild somnolence, and minimal otorrhea. Imaging demonstrated chronic inflammatory middle ear changes without evidence of abscess formation. Lumbar puncture confirmed acute bacterial meningitis caused by Haemophilus influenzae, consistent with an otogenic source. Intravenous antibiotics and corticosteroids led to only partial clinical improvement. Ongoing symptoms prompted surgical intervention, which revealed extensive granulation tissue, dehiscence of the tegmen mastoideum, and exposure of the facial nerve. A canal wall-up mastoidectomy was initially performed, followed by conversion to canal wall-down revision surgery and adjunctive nasal procedures to optimize middle ear ventilation.

RESULTS

The patient experienced progressive neurological and otologic recovery postoperatively, with resolution of infection and improved audiometric outcomes. No recurrence of intracranial or local infection was observed during follow-up.

CONCLUSIONS

CSOM may harbor active infection even in the presence of minimal otologic symptoms and can lead to intracranial spread. Early multidisciplinary assessment, prompt imaging, and definitive surgical eradication of the infectious focus are critical to preventing neurological complications. This case highlights the importance of maintaining a high index of suspicion for indolent otogenic infections, particularly in adults with systemic comorbidities.

Comparison Of Partial Vs. Total Ossicular Chain Reconstruction Using Titanium Prosthesis

Ali Faramarzi[1]

[1]*Shiraz University of Medical Sciences*

BACKGROUND & AIM

Comparison of the hearing outcomes of titanium partial ossicular replacement prosthesis (PORP) vs. titanium total ossicular replacement prosthesis (TORP) with footplate shoe (Omega Connector) in second stage ossicular chain reconstruction surgeries.

MATERIAL & METHODS

In this retrospective cohort study in a tertiary hospital, we compared the hearing outcomes in 248 patients who had undergone ossicular chain reconstruction with titanium prostheses PORP (n = 115) vs. TORP (n = 133) from August 2017 to June 2021. Pre- and postoperative audiometric data were assessed.

RESULTS

In general, we found that there were no significant differences between PORP and TORP groups in gains of BC (P = 0.080), AC (P= 0.454), ABG (P= 0.928), SRT (P= 0.065), and SDS (P= 0.363). There were no significant differences in terms of ABG gain between the two groups. Regarding ABG gains frequency-specific analysis in the ears with pre-operative conductive hearing loss, there were no significant differences between low-frequencies (P =0.260) and high-frequencies (P= 0.973) between the two groups.

CONCLUSIONS

To sum up, this research provided additional evidence with respect to hearing outcomes after staged ossicular chain reconstruction with PORP and TORP. The practical application of our study is that TORP with footplate shoe (Omega Connector) is comparable with PORP in staged ossiculoplasty.

OP-712

IMPEDANCE AND FUNCTIONAL OUTCOMES IN ROBOTIC-ASSISTED OR MANUAL COCHLEAR IMPLANTATION: A COMPARATIVE STUDY

Guillaume Gersdorff, **Nicolas Peigneux**, **Unal Duran**, **Severine Camby**, **Philippe P. Lefebvre**

BACKGROUND & AIM

Preservation of residual hearing, particularly in the low-frequency range, is the primary objective of modern cochlear implantation. Recent years have seen the advent of robotic-assisted cochlear implant surgery, which aims to enhance the insertion process while safeguarding the delicate structures of the inner ear. Despite these advancements, the introduction of an electrode array can still result in fibrous tissue formation or osteogenesis within the cochlea. These changes can elevate impedance levels and adversely affect the long-term auditory performance. This study evaluated the impact of the RobOtol® robotic system on impedance changes over time and its potential to improve functional outcomes.

MATERIAL & METHODS

Cochlear implant surgeries were performed using a round window approach. Fifteen Med-El Flex24 electrode arrays were inserted manually, while 24 were inserted using RobOtol® . All subjects underwent pure-tone audiometry before surgery and at regular intervals for up to one year post-surgery. Patients were categorized based on their pure-tone averages at low frequencies (250-1,000 Hz) into groups with no significant loss (≤ 15 dB), partial loss (15-30 dB), and significant loss (> 30 dB). These groups were compared for impedance changes and auditory performance, particularly word recognition scores.

RESULTS

There were fewer instances of significant low-frequency hearing loss in the robot-assisted insertion group (41.67%) compared to the manual group (53.33%). Impedance changes at the apex of the electrode array, particularly at the first electrode, were more stable after robotic surgery, showing a continuous decreasing trend without secondary elevation and lower values in cases of complete residual hearing preservation. Speech intelligibility improved over time in patients with complete residual hearing preservation, regardless of the insertion method. However, in the absence of auditory preservation, speech intelligibility continued to improve for over six months after robotic surgery but stagnated after manual insertion (difference at 1 year, p = 0.038; median auditory capacity index 83% vs. 57%).

CONCLUSIONS

Robotic-assisted cochlear implant insertion with the RobOtol® system, characterized by a consistent and slow insertion speed, minimizes disturbances to the inner ear's neurosensory structures. This method leads to improved auditory performance and better preservation of residual hearing.

Acoustic Comparison Between The Zoellner Sucker And The Novel Zephyr Variable Sucker

Neil Donnelly[1], **Claire Lomax**[2], **Patrick Axon**[1], **Alex Spencer**[2], **Rory Waterhouse Stocks**[2]

[1]*Cambridge University Hospitals;* [2]*Salford University Acoustics Research Centre*

BACKGROUND & AIM

Microsuction is the gold standard for cerumen removal; however, noise generated during the procedure contributes to patient discomfort and has been associated with adverse outcomes including hearing loss, tinnitus, and vertigo. Conventional suction devices operate without airflow modulation, offering no control over associated acoustic output. A novel device, the Zephyr, incorporates variable airflow control, allowing continuous adjustment of suction and sound exposure. This study compares the A-weighted equivalent continuous sound pressure levels (LAeq) and maximum sound pressure levels (LAmax) generated by the Zephyr and a standard Zoellner sucker under controlled, clinically representative conditions.

MATERIAL & METHODS

Measurements were conducted in a hemi-anechoic chamber using an anatomically accurate 3D-printed adult temporal bone. A Brüel & Kjær Type 4182 probe microphone was positioned 0.5 mm through an aperture in the eardrum replica to capture near-field sound pressure levels representative of patient exposure. A standardised 3D-printed soft-wax simulant was positioned 5 mm from the eardrum to ensure consistent test conditions.

A medical suction unit was located outside the chamber and operated at a constant vacuum setting of 500 mmHg. Procedures were performed by a qualified medical practitioner, while suction activation and acoustic data acquisition were controlled remotely by an acoustic technician. Thirty Zephyr and thirty Zoellner devices were tested, each undergoing a complete measurement cycle. Acoustic data were recorded as 1/32 ms time-averaged A-weighted sound pressure levels and 1/12-octave band spectra. LAeq values were analysed across defined procedural phases and LAmax values over the full duration of the procedure.

RESULTS

LAeq levels were consistently higher for the Zoellner sucker across all phases and overall. Mean differences were 43.5 dBA in Phase 1 (108.5 vs 65 dBA), 10.3 dBA in Phase 2 (57.2 vs 46.9 dBA), 23.8 dBA in Phase 3 (119 vs 95.2 dBA), and 24.9 dBA overall (118.3 vs 93.4 dBA). The mean LAmax difference was 22.8 dBA (136.9 vs 114.1 dBA). All differences were statistically significant (Welch t-tests, $p < 0.001$).

CONCLUSIONS

The largest divergence occurred during sucker insertion into the ear canal (Phase 1), where the Zoellner generated LAeq levels over 40 dB higher than the Zephyr, corresponding to approximately 10,000-fold greater acoustic energy. Phase 2, during wax occlusion of the sucker, showed smaller differences. Large differences re-emerged in Phase 3, suggesting that interactions between the sucker and wax material contribute disproportionately to overall noise exposure. Perceptually, the Zephyr would be experienced as substantially quieter across all phases, up to 16-fold quieter, indicating benefits for patient comfort and auditory risk reduction.

BACKGROUND & AIM

Post-traumatic facial nerve paralysis remains a challenging condition, with persistent controversy regarding the indications, timing, and optimal surgical approach for facial nerve decompression. The optimal timing and surgical approach for decompression remain debated.The transmastoid approach represents a relevant and reliable surgical option, allowing exposure of the mastoid and tympanic segments of the facial nerve, with possible extension to the geniculate ganglion.

The aim of this study was to report our experience with transmastoid facial nerve decompression including the geniculate ganglion in post-traumatic facial paralysis and to review the relevant literature regarding surgical indications and outcomes

MATERIAL & METHODS

We retrospectively analyzed six patients treated in our department for severe post-traumatic facial nerve paralysis (House–Brackmann grades V–VI) following temporal bone trauma. All patients failed to demonstrate satisfactory recovery after initial conservative management.

Preoperative evaluation included high-resolution temporal bone CT and audiological assessment. Electrophysiological studies were performed when available.

All patients underwent facial nerve decompression via a transmastoid approach, targeting the mastoid and tympanic segments, with systematic extension toward the geniculate ganglion when radiological or intraoperative findings suggested proximal involvement.

Postoperative facial nerve function was assessed using the House–Brackmann grading system during follow-up.

RESULTS

Postoperative improvement of facial nerve function was observed in most patients. The majority achieved a final House–Brackmann grade III or better at last follow-up. No major intraoperative or postoperative complications were recorded. Hearing preservation was achieved in all cases.

The transmastoid approach allowed adequate exposure and effective decompression of the geniculate ganglion.

CONCLUSIONS

Transmastoid facial nerve decompression, including the geniculate ganglion, is a safe and effective option in selected cases of post-traumatic facial paralysis. Careful radiological assessment and appropriate patient selection are crucial to determine the feasibility of this approach.

Our experience supports the transmastoid route as a safe and effective surgical option for improving facial nerve function in post-traumatic paralysis.

OP-715

Bone Anchored Implantation BEFORE Microtia Reconstruction: Where Should The Implant Be Placed?

Kay W. Chang[1], **Lacey Nelson**[1], **Losorreli, Steven**[1], **Mai Thy Truong**[1]

[1]*Stanford University Hospital*

BACKGROUND & AIM

Active bone anchored implants (BAI)(Sentio, OSIA, Bonebridge) offer patients with microtia and aural atresia (MAA) excellent implantable options to treat their conductive hearing loss. Children with MAA with learning and speech delays are a particular vulnerable group who can benefit. However, early implantation can have an impact on future ear reconstruction. The aim of this review is to discuss the surgical considerations for early BAI and the impacts on future ear reconstruction.

MATERIAL & METHODS

Surgical techniques to place the Sentio, OSIA and Bonebridge very. Incision placement, and whether or not the cranial cortex or mastoid is drilled may impact soft tissue, fascial and skin flaps integral in future microtia repair. Whether future microtia reconstruction is undecided, or if the patient plans to have reconstruction with costal cartilage or porous polyethylene implants, surgical placement of bone anchored implants before reconstruction can have deliterious effects on outcomes. We provide an overview of the ideal incisions for each type of implant whether costal cartilage or porous polyethylene is planned for reconstruction. Ideal incisions are reviewed, incisions which are more posterior, not in the field of where the new ear will be placed, and not endangering the temporal parietal fascia. We also review our experience of placement of BAI done concurrently with microtia reconstruction with costal cartilage utilizing the Firmin technique.

RESULTS

Early implantation of Bone anchored implants in patients with Microtia and atresia can greatly improve a patients hearing status. However, implanation before microtia reconstruction can effect soft tissue, fascia and skin flaps integral for future surgery. In our retrospective review, we identified N=42 patients who underwent BAI concurrent with microtia reconstruction and N=3 had BAI before ear reconstruction. There were no complications of the reconstructed ear in those placed concurrently with microtia repair. Two of the 3 patients with early implantation had a negative implact on the microtia repair.

CONCLUSIONS

Bone anchored device implantation done before ear reconstruction can have serious effects on future ear reconstruction, and may be safest if done concurrently with microtia reconstruction. If needed early, incisions should be posterior, away from where the ear would be placed, and without violating the temporal parietal fascial for possible future reconstruction with cartilage or porous polyethylene.

OP-716

Surgical Approaches And Complications In OSIA: A Systematic Review

Abdulrahman Hagr[1], **Fida Almuhawas**[1], **Moayyad Malas**[1]

[1]*King abdullah ear specialist center, king saud medical city, riyadh, saudi arabia*

BACKGROUND & AIM

Background: The Osseointegrated Steady-State Implant (OSIA) is an active transcutaneous bone conduction system offering effective hearing rehabilitation via a piezoelectric actuator and osseointegrated anchor, while preserving skin integrity. espite the growing adoption of OSIA, the literature regarding optimal surgical approaches and complication patterns remains fragmented

Objective: To systematically evaluate intraoperative and postoperative complications associated with OSIA implantation, with specific focus on incision orientation, patient age, and prior surgical history.

MATERIAL & METHODS

Methods: A systematic review was registered with PROSPERO and conducted per PRISMA guidelines. PubMed, Embase, and CENTRAL were searched for studies published from January 2016 to April 2025. Fifteen eligible studies were included, encompassing 784 OSIA implants across prospective and retrospective cohorts.

RESULTS

Results: OSIA implantation was associated with a low pooled intraoperative complication rate of 0.77% and a postoperative complication rate of 5.25%. Most complications were mild and manageable, with no cases requiring permanent device removal. Incisions placed across the device had a significantly higher complication rate (14.4%) compared to incisions placed around the device (4.6%). Pediatric-predominant cohorts experienced more complications (10.2%) than adult-predominant cohorts (4.3%). Patients with prior mastoidectomy had a complication rate of 12.0%.

CONCLUSIONS

Conclusion: OSIA is a generally safe hearing solution, but surgical planning should consider patient-specific factors and incision orientation. Incisions placed across the device are linked to higher complication rates. These findings support evidence-based risk stratification and preoperative counseling.

BACKGROUND & AIM

Somatosensory tinnitus (SST) is associated with proprioceptive or mechanoreceptive alterations resulting from cervical or temporomandibular dysfunctions. However, studies relating pain patterns and impact on quality of life according to the region of strongest somatosensory influence are scarce. This study aimed to compare the number of tender points, trigger points, and the impact on quality of life in individuals with somatosensory tinnitus (SST), according to the region of strongest somatosensory influence.

MATERIAL & METHODS

Cross-sectional study approved by the Research Ethics Committee (No. 4,471,809), including individuals aged ≥18 years with complaints of tinnitus. The assessment was conducted by an interdisciplinary team (otolaryngologist, audiologists, and physical therapist) to determine the origin of tinnitus. Somatosensory influence was identified using a checklist adapted from the diagnostic criteria for somatosensory tinnitus (SST). Participants with SST were classified into three groups according to the region of strongest somatosensory influence: cervical, temporomandibular, or mixed. The assessment of tender points and trigger points was performed by bilateral palpation of the following muscles: temporalis (anterior, middle, and posterior), masseter (origin and insertion), digastric (anterior and posterior), suboccipitals, scalenes, sternocleidomastoid, upper trapezius, levator scapulae, and rhomboid. The impact of tinnitus on quality of life was measured using the Brazilian version of the Tinnitus Handicap Inventory (THI). Between-group comparisons were performed using the Kruskal-Wallis test, followed by Dunn's post hoc test.

RESULTS

Out of the 67 individuals evaluated, 34 presented somatosensory influence, with 9 in the cervical group, 9 in the temporomandibular group, and 16 in the mixed group. There were no significant differences among the groups regarding the number of tender points (p=0.079) or trigger points (p=0.398). The total THI score (p=0.083) and the emotional (p=0.258) and catastrophic (p=0.268) domains also showed no differences. However, a significant difference was observed in the functional domain, with greater impact in the temporomandibular group compared to the mixed group (p=0.028).

CONCLUSIONS

In this ongoing study, the number of tender and trigger points did not differ among the groups. However, individuals with somatosensory tinnitus (SST) of temporomandibular origin showed greater functional impact of tinnitus on quality of life compared to the mixed group.

Tinnitus Annoyance And Extended High-Frequency Audiometry In Patients With Normal Audiograms: An Interim Analysis

Ömer Faruk Zengin[1], **Mine Şahin**[2]

[1]Ordu University Training and Research Hospital, Otorhinolaryngology Dept.; [2]Ordu University Training and Research Hospital, Audiology Dept.

BACKGROUND & AIM

This study aims to investigate the clinical factors and extended high-frequency audiometry (EHFA) findings that may influence the level of annoyance in adult tinnitus patients with clinically normal hearing thresholds (≤25 dB HL between 0.25–8 kHz).

MATERIAL & METHODS

This prospective study includes patients aged 18–65 years presenting with tinnitus and bilateral normal hearing on standard audiometry. All participants undergo EHFA (10–16 kHz) and Visual Analogue Scale (VAS-A) assessment. For this interim analysis, data from the first 35 subjects who met the inclusion criteria were evaluated.

RESULTS

The interim study group (n=35) has a mean age of 39.1 ± 11.4 years. Female participants constitute 77.1% of the group. Tinnitus was localised to the left ear in 54.3%, the right ear in 17.1%, and was bilateral in 28.6% of the patients. Data collection regarding psychoacoustic parameters and detailed statistical comparisons of EHFA thresholds and annoyance levels are currently in progress.

CONCLUSIONS

The comprehensive analysis of extended high-frequency thresholds and other parameters with subjective annoyance levels will be presented.

OP-719

Neurophysiological Mechanisms Of 1Hz Rtms Targeting Left Temporoparietal Junction For Tinnitus Treatment: A TMS-EEG Study

Hongfu Zhang[1]

[1]*Department of Otolaryngology-Head and Neck Surgery, Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China*

BACKGROUND & AIM

Repetitive transcranial magnetic stimulation (rTMS) has shown promise in treating tinnitus, but its underlying neurophysiological mechanisms remain incompletely understood. This study aimed to investigate the dynamic neural changes induced by 1Hz rTMS targeting the left temporoparietal junction (TPJ) in tinnitus patients using combined TMS-EEG.

MATERIAL & METHODS

We recruited 45 patients with chronic tinnitus who underwent 5 sessions of 1Hz rTMS over left TPJ. TMS-EEG recordings were obtained before and after treatment. We analyzed TMS-evoked potentials (TEPs), Significant current density (SCD), Significant current scattering (SCS), and time-frequency oscillations.

RESULTS

Our findings revealed a multi-stage neurophysiological cascade: (1) At 37-47ms post-stimulus, local activity in a left-lateralized network involving auditory, emotional, and thalamic regions was significantly reduced (SCD, $p<0.05$). (2) At 123-135ms, functional connectivity between left TPJ and a right-lateralized cognitive control network (including right inferior frontal gyrus and posterior cingulate) was significantly enhanced (SCS, $p<0.05$). (3) At 160-200ms, the N180 component of TEPs showed significantly reduced amplitude ($p=0.0468$), indicating altered cortical inhibitory tone. (4) Time-frequency analysis revealed: reduced gamma oscillations (30-100Hz) in right prefrontal and posterior cingulate regions at 40-120ms; enhanced beta oscillations (12-30Hz) in the same regions at 150-250ms; and enhanced gamma oscillations at 170-180ms.

CONCLUSIONS

1Hz rTMS over left TPJ induces a dynamic neuroplastic cascade involving early local inhibition, followed by enhanced cross-hemispheric cognitive control connectivity, and reorganization of cortical inhibitory circuits. These findings provide a comprehensive neurophysiological framework for understanding rTMS efficacy in tinnitus treatment and identify potential biomarkers for treatment response.

OP-720

Recurrence Factors Of Benign Paroxysmal Positional Vertigo After Diagnosis And Treatment In The Otolaryngology Emergency Department

Joana Ida Dias[1], **Sofia Carvalho**[1], **João Carvalho Almeida**[1], **João Lino**[1]

[1]*Unidade Local de Saúde de Santo António*

BACKGROUND & AIM

Vestibular disorders are a frequent reason for evaluation in the emergency department (ED). Although benign, benign paroxysmal positional vertigo has a significant impact on quality of life, increasing the risk of falls and fractures, healthcare resource utilization, and absenteeism. The identification of factors associated with recurrence may support risk stratification and discharge planning. Our aim was to characterize patients with BPPV diagnosed and treated by Otolaryngology in the ED and to estimate recurrence rates and associated factors.

MATERIAL & METHODS

A retrospective study of adult patients evaluated in the Otolaryngology ED of a tertiary hospital with a diagnosis of BPPV in 2023 was conducted. Demographic and clinical data were collected, including the affected canal and ear, the repositioning maneuver performed, and the number of maneuvers. Recurrence was defined as a new ED visit for BPPV recorded up to December 31, 2025.

RESULTS

A total of 241 patients were included among 8,309 evaluated in the Otolaryngology ED during 2023; 71% were female, with a median age of 64 years. The posterior canal was most frequently affected (82.6%), followed by the lateral canal (17.4%). The Epley maneuver was most commonly performed (58.5% overall; 84.3% in posterior canal cases), whereas the modified Gufoni maneuver predominated in lateral canal BPPV (85.7%). Nearly 70% of patients required a single maneuver, and 9.1% underwent two maneuvers, with no significant differences in recurrence rates. During follow-up, 69 patients (28.6%; 95% CI 23.3–34.6) revisited the ED, with cumulative incidences of 9.1% at 30 days, 13.3% at 90 days, and 25.7% at one year. Recurrence cases had a median of two episodes and were associated with previous BPPV history (OR 4.62; 95% CI 2.35–9.07) and lateral canal involvement (OR 2.56; 95% CI 1.12–5.86).

CONCLUSIONS

Approximately one in three patients experienced recurrence requiring reassessment in the emergency department, including clinically relevant early recurrences (9.1% at 30 days, 13.3% at 90 days, and 25.7% at one year). These results are broadly consistent with the literature, which reports recurrence rates following repositioning maneuvers generally ranging from 15% to 37% within the first year.

A previous history of BPPV and lateral canal involvement identify higher-risk subgroups following ED treatment.

Risk stratification at diagnosis may help guide patient education, home-care recommendations, and structured follow-up, potentially reducing ED revisits and optimizing healthcare resource utilization.

Recurrent And Residual Cholesteatoma After Mastoid And Epitympanic Obliteration: A Descriptive CT And Clinical Study Of 23 Patients

Daniele Bernardeschi[1], **Matteo Di Bari**[1], **Margaux Campion**[1], **Hugo Delille**[1]

[1]*Hôpital Pitié Salpétrière, Paris, France*

BACKGROUND & AIM

Use of both scanographic and intraoperative data to investigate the location of cholesteatoma recidivism (both recurrent and residual) and its association with the quality of the mastoid and epitympanic obliteration performed during the previous surgery.

MATERIAL & METHODS

A retrospective monocentric study including 23 ears from 22 patients who underwent surgery for recurrent or residual cholesteatoma from January 2016 to January 2025. All patients had obliteration performed during the initial surgery (canal wall up or down technique) using various materials, mainly S53P4 bioactive glass. Analysis was based on clinical records, high-resolution CT scans, non–echo-planar diffusion-weighted MRI, and surgical findings.

RESULTS

Fourteen (61%) patients experienced recurrence and 9 (39%) had residual disease. In recurrent cases, all preoperative CT scans showed incomplete obliteration of the epitympanum. Recurrent disease mostly involved the epitympanum (86%), often extending to the mesotympanum or mastoid. Residual lesions were mainly located in the mesotympanum (55%) and were not affected by the obliteration.

CONCLUSIONS

Cholesteatoma recurrence after obliteration seems to be linked to insufficient obliteration, particularly of the epitympanum. Thorough obliteration, especially in complex areas such as the supratubal recess, is crucial to prevent recurrence.

OP-722

Outcomes Of Cochlear Implantation In Patients With Inner Ear Anomalies

Ahmet Boyar[1], **İsmail Aytaç**[2], **Elif Baysal**[3]

[1]*Karadeniz Ereğli State Hospital Otolaryngology Department;* [2]*Medical Point Gaziantep Hospital Otolaryngology Department;* [3]*Gaziantep University Medical Faculty Otolaryngology Department*

BACKGROUND & AIM

The aim of this study was to investigate the operative findings, postoperative follow-up, intraoperative and postoperative complications, the incidence of revision surgery, and the underlying causes in patients with inner ear anomalies who underwent cochlear implantation for bilateral total hearing loss.

MATERIAL & METHODS

Seventy-five patients with inner ear anomalies who underwent cochlear implantation at the Department of Ear, Nose, and Throat, Faculty of Medicine, Gaziantep University, were included. The malformations observed were: three cases of common cavity, seven vestibular dilatations, one internal acoustic canal hypoplasia, eight incomplete partition type I, one incomplete partition type III, one vestibular hypoplasia, two cochlear hypoplasia, 25 incomplete partition type II, 26 large vestibular aqueducts, and one case of semispherical canal aplasia. Intraoperative and postoperative complications, as well as postoperative follow-up, were assessed for each patient.

RESULTS

Among the patients, 22 (28.2%) experienced gusher, 3 (3.8%) developed rhinorrhea, 2 (2.6%) had swelling, seroma, or infection, 2 (2.6%) experienced facial paralysis, and 1 (1.3%) developed meningitis. No complications were observed in 48 patients (61.5%). Two patients experienced both gusher and rhinorrhea, and one patient had both gusher and facial paralysis. Revision surgery was required in 12 of the 75 patients. The indications for revision surgery included facial stimulation (one patient, 8.3%), flap infection (one patient, 8.3%), incorrect placement (one patient, 8.3%), BOS rhinorrhea (two patients, 16.7%), trauma (three patients, 25.0%), and device failure (four patients, 33.3%).

CONCLUSIONS

Today, with advanced imaging methods, patients with inner ear anomalies can be easily detected, and cochlear implantation surgery can be performed safely. As seen in our study, it should be kept in mind that there is a high probability of intraoperative gusher, and the facial nerve course may be abnormal; different surgical techniques should be used if necessary. In the postoperative period, more care should be taken regarding BOS rhinorrhea and meningitis than in normal patients. In patients requiring a second operation, the reasons for revision surgery should be clarified, and patients should be closely monitored to avoid repeat surgeries.

OP-723

Vestibular Dysfunction After Cochlear And Auditory Brainstem Implantation: A Decade-Long Clinical Experience

Rajika Ramakrishnan[1], **Kiran Natrajan**[1], **Prof Mohan Kameswaran**[1]

[1]*Madras ENT Research Foundation,.Chennai, Tamil Nadu, India*

BACKGROUND & AIM

Cochlear implantation (CI) and auditory brainstem implantation (ABI) are proven interventions for severe-to-profound sensorineural hearing loss. Although safe, these procedures may influence vestibular pathways due to the anatomical proximity of the cochlea and vestibular organs. This study evaluates the characteristics, mechanisms, and outcomes of vestibular disturbances following CI and ABI.

MATERIAL & METHODS

A retrospective analysis was performed on a large cohort of CI and pediatric ABI recipients over a ten-year period. Patients presenting with postoperative vertigo or imbalance underwent comprehensive vestibular testing, including videooculography (VOG), caloric testing, and cervical vestibular-evoked myogenic potentials (cVEMP). In ABI surgeries, the cerebellar flocculus was graded intra-operatively (Grades 1–4) to assess its association with postoperative vertigo.

RESULTS

Among CI recipients, 7.2% developed postoperative vestibular symptoms, most commonly otolithic dysfunction, reflected as absent or abnormal VEMP responses. Symptoms were mild, transient, and resolved within 2–10 days with conservative management.

In ABI recipients, 16.7% experienced early postoperative vertigo. A strong correlation was found between vestibular symptoms and larger flocculus grades (3 and 4), where increased cerebellar retraction was required for implant placement. All affected patients recovered within 2–5 days, with no long-term sequelae.

CONCLUSIONS

Vestibular dysfunction following CI and ABI is uncommon, short-lived, and generally non-disabling. CI most frequently affects saccular function, while ABI-related vertigo is associated with anatomical variations of the cerebellar flocculus. Emphasis on atraumatic surgical techniques, careful anatomical assessment, and postoperative vestibular rehabilitation can minimise morbidity and optimise outcomes in auditory implant recipients.

OP-724

The Star Flap Technique: Our Tympanomeatal Flap Approach In Endoscopic Tympanoplasty

Bülent Ulusoy[1], **Hürü Beyza Cerit**[1]

[1]*Department of Otorhinolaryngology, Faculty of Medicine, Selçuk University*

BACKGROUND & AIM

Tympanic membrane perforation is a common condition caused by trauma or recurrent middle ear infections. Perforations persisting longer than 3 months are considered chronic otitis media and often require surgical repair. The aim of tympanoplasty is to restore membrane integrity and improve hearing. Various tympanomeatal flap techniques have been described, depending on surgeon preference and patient factors. In this study, we retrospectively evaluated the outcomes of the our star-flap technique in endoscopic tympanoplasty.

MATERIAL & METHODS

This study included 9 patients who underwent endoscopic type 1 tympanoplasty for tympanic membrane perforation at our clinic. For middle ear access, the star flap technique was employed in place of the conventional posterior tympanomeatal flap technique. Following freshening of the perforation edges, a paralel incision was made to the manubrium of the malleus and elevated, thereby reflecting the anterior and posterior tympanic membrane remnants laterally. When required, a second incision perpendicular to the initial tympanic membrane incision may be performed, enabling separate lateral elevation of all four tympanic membrane quadrants and providing an expanded operative field. Following accomplishment of the middle ear procedures, graft placement was performed. The prepared flaps was then repositioned to cover the graft material. Perforation closure rates and postoperative audiometric outcomes were evaluated retrospectively.Due to the presence of a cochlear implant, one patient was not included in the postoperative audiological outcome analysis.

RESULTS

Of the participants included in the study, 3 were male and 6 were female, with a mean age of 26 years (range: 10 – 53). The mean preoperative air conduction hearing threshold (ACT) was 35 dB, whereas the mean bone conduction threshold (BCT) was 14 dB. At the 1-year postoperative follow-up, no residual or recurrent perforation was observed. At the 1-year postoperative follow-up, the mean ACT was 23 dB, whereas the mean BTC was 15 dB. The mean air–bone gap improved from 21 dB preoperatively to 8 dB postoperatively.

CONCLUSIONS

The star-flap technique may offer substantial advantages by providing a wide endoscopic surgical view without causing the risk of additional complications, facilitating routine middle ear procedures, and potentially reducing operative time owing to less intraoperative bleeding.

Comparative Audiological Outcomes Of Type III Tympanoplasty And Partial Ossicular Replacement Prosthesis

Fatih Mutlu[1], **Ali Aktürk**[1], **Murat Öztürk**[1], **Hasan Mervan Değer**[1]

[1]*Department of Otolaryngology – Head and Neck Surgery, Faculty of Medicine, Kocaeli University*

BACKGROUND & AIM

Restoring the ossicular chain is a central goal in the surgical management of chronic otitis media, especially in patients with a preserved stapes superstructure. Type III tympanoplasty and partial ossicular replacement prosthesis (PORP) reconstruction are both commonly used techniques in this setting, yet their relative hearing outcomes are still not clearly established. This study aimed to compare postoperative hearing results, including pure-tone averages, air–bone gap, and functional success rates, between patients undergoing PORP reconstruction and those treated with Type III tympanoplasty.

MATERIAL & METHODS

This retrospective comparative study included 71 patients who underwent ossicular chain reconstruction with either partial ossicular replacement prosthesis (PORP) or Type III tympanoplasty at a tertiary referral center. Patients with available preoperative and postoperative audiometric data were included. Demographic and clinical data were collected from medical records. Audiological outcomes were evaluated using pure-tone averages (PTA) and air–bone gap (ABG) values measured

preoperatively and postoperatively. Primary outcome measures included postoperative PTA, postoperative ABG, AC PTA gain, and ABG closure. Functional success was defined as achieving a postoperative ABG of ≤20 dB and ≤30 dB. Follow-up duration was calculated based on the interval between surgery and postoperative audiometric evaluation. Comparative analyses between groups were performed using appropriate statistical methods, with significance set at $p<0.05$.

RESULTS

The study included 37 patients in the PORP group and 34 patients in the Type III tympanoplasty group. The median follow-up duration was 210 days (IQR: 91–570) and did not differ significantly between groups. Postoperative AC PTA was significantly lower in the PORP group compared to the Type III tympanoplasty group [40.0 dB HL (26.2–56.2) vs. 45.0 dB HL (35.4–69.4), p=0.030]. Similarly, postoperative ABG was lower in the PORP group [21.2 dB (13.8–27.5) vs. 25.0 dB (20.4–36.0), p=0.022]. AC PTA gain was greater after PORP reconstruction [10.0 dB (3.8–17.5) vs. −0.4 dB (−11.4 to 9.0), p=0.005]. Although ABG closure was higher in the PORP group, the difference was not statistically significant (p=0.083). The rate of postoperative ABG ≤30 dB was significantly higher in the PORP group (91.9% vs. 67.6%, p=0.016), while ABG ≤20 dB showed a non-significant trend in favor of PORP (p=0.086).

CONCLUSIONS

PORP reconstruction was associated with lower postoperative ABG, greater AC PTA gain, and a higher rate of postoperative ABG ≤30 dB compared with Type III tympanoplasty. These findings suggest that PORP may offer an audiological advantage in selected patients with a mobile stapes superstructure, although retrospective design and potential selection bias should be considered.

Intratympanic Administration Of Human Umbilical Cord Mesenchymal Stem Cell-Derived Exosomes After Acoustic Trauma: An Experimental Rat Model

Emre Yakut[1], **Mahmut Tayyar Kalcıoğlu**[1], **Serdal Çelik**[1], **Erdoğan Bulut**[2], **Onur Ersoy**[3], **Emel Aslantaş**[4], **Ali Murati**[5]

[1]Department of Otorhinolaryngology - Head and Neck Surgery, Istanbul Medeniyet University, Faculty of Medicine,Goztepe Prof Dr Suleyman Yalcin City Hospital Istanbul, Türkiye; [2]Department of Audiology, Faculty of Health Sciences, Mirko TOS Ear and Hearing Research Center, Trakya University, Edirne, Türkiye; [3]Department of Pathology Laboratory Techniques, Vocational School of Health Services, Trakya University, Edirne, Türkiye; [4]ENT Clinic, Department of Audiology, Goztepe Prof Dr Suleyman Yalcin City Hospital, Istanbul, Türkiye; [5]Department of Otorhinolaryngology - Head and Neck Surgery, Medicana Atasehir Hospital, Istanbul, Türkiye

BACKGROUND & AIM

Acoustic trauma can cause permanent noise-induced hearing loss, yet no regenerative therapy is licensed. Mesenchymal stem cell (MSC)-derived exosomes have anti-apoptotic, anti-inflammatory, and pro-angiogenic properties, but intratympanic human umbilical cord (UC)-MSC exosomes have not been evaluated in acoustic trauma. We hypothesized that a single intratympanic dose of UC-MSC exosomes, delivered on the first day after acoustic trauma, would improve auditory outcomes and attenuate cochlear injury. We tested this hypothesis using ABR thresholds, hematoxylin-eosin (H&E) histopathology, and VEGF immunohistochemistry, and separately assessed whether exosome administration alone produced detectable short-term threshold changes.

MATERIAL & METHODS

We randomized 32 male Sprague-Dawley rats to positive control (acoustic trauma, untreated), study (trauma + exosome), negative control (intratympanic saline), and exosome-toxicity groups (n = 7 analyzed per group). Acoustic trauma was induced with 6-10 kHz noise at 120 dB SPL for 4 h; on post-trauma day 1, 30 µL of UC-MSC exosomes (5×10^9 particles/mL) was injected into the right middle ear. ABR thresholds at 8-32 kHz were measured at baseline and on days 3, 7, and 21, followed by histopathology and vascular endothelial growth factor (VEGF) immunohistochemistry.

RESULTS

Trauma increased thresholds by 23.6-27.1 dB. At day 7, 32 kHz favored the study group by 17.9 dB (false discovery rate-corrected p [pFDR] = 0.048; r = 0.70). At day 21, thresholds were lower at 8 kHz (12.1 dB; pFDR = 0.015) and 16 kHz (14.3 dB; pFDR = 0.030). Untreated controls showed no statistically detectable recovery; at 8 kHz, the day 3-21 change score favored treatment by 17.1 dB (pFDR = 0.025). No detectable threshold elevation occurred in exosome-only animals. Histology showed less hair-cell and stria vascularis injury and VEGF immunoreactivity closer to control levels after treatment.

CONCLUSIONS

Intratympanic UC-MSC exosomes were associated with frequency-specific functional improvement and attenuated cochlear injury, supporting further evaluation as a cell-free treatment.

WOUND HEALING OUTCOMES AT THE TRAGAL DONOR SITE FOLLOWING ENDOSCOPIC CARTILAGE TYMPANOPLASTY

Ayşe Çeçen[1], **Seda Nur Cihan**[1], **Gökhan Akgül**[2], **Esra Yılmaz**[1], **Asude Ünal**[1], **Doğukan Özdemir**[1]

[1]*Department of Otorhinolaryngology, Samsun University School of Medicine, Samsun, Turkey.;* [2]*Department of Otorhinolaryngology, Samsun Training and Research Hospital Otorhinolaryngology Department, Samsun, Turkey*

BACKGROUND & AIM

This study aimed to compare the effects of different incision closure techniques on postoperative wound healing at the tragal donor site in patients undergoing endoscopic cartilage tympanoplasty.

MATERIAL & METHODS

A total of 57 patients who underwent endoscopic tympanoplasty with tragal cartilage graft for chronic otitis media between January 2023 and January 2025 were included in the study. Patients were divided into three groups according to the incision closure technique: Group 1 – hemitransfixion suture, Group 2 – transfixion suture, and Group 3 – closure with pomade-impregnated packing without suturing. Ecchymosis, hyperpigmentation, hematoma, infection, wound dehiscence, scar formation, hypoesthesia, hyperesthesia, and pain were evaluated on postoperative day 1 and at week 1.

RESULTS

Fifty-seven patients were included in the study. A statistically significant difference was observed between the groups in terms of operative time ($p = 0.0035$). Wound dehiscence was significantly more frequent in Group 3 (no-suture group) ($p < 0.001$). No significant differences were found among the groups regarding ecchymosis, hyperpigmentation, hematoma, infection, hypoesthesia, hyperesthesia, or pressure-related pain. Additionally, there was no statistically significant difference in Visual Analog Scale (VAS) scores between postoperative day 1 and week 1 ($p = 0.93$).

CONCLUSIONS

Although different incision closure techniques may affect wound healing at the tragal donor site to varying degrees, wound dehiscence was more common in the non-sutured method. Selecting an appropriate closure technique may contribute to improved cosmetic and functional surgical outcomes.

Could Bee Venom Be A Novel Adjunctive Therapy For Cholesteatoma? Evidence From A Rat Model

Serdal Celik[1], **Ayse Yasemin Gunduz**[2], **Mustafa Alp Candemir**[1], **Tugay Mert**[3], **Elif Gelenli Dolanbay**[3], **Unal Uslu**[3], **Fahrin Zara Muhammad Nasseri**[4], **Mahmut Tayyar Kalcioglu**[1]

[1]*Istanbul Medeniyet University, Faculty of Medicine, Göztepe Prof. Dr. Süleyman Yalçın City Hospital, Department of Otorhinolaryngology, Istanbul, Türkiye;* [2]*Mardin Training and Research Hospital, Department of Otorhinolaryngology, Mardin, Türkiye;* [3]*Istanbul Medeniyet University, Faculty of Medicine, Department of Histology and Embryology, Istanbul, Türkiye;* [4]*National University of Malaysia (UKM), Faculty of Medicine, UKM Medical Centre, Department of Otorhinolaryngology–Head & Neck Surgery, Kuala Lumpur, Malaysia*

BACKGROUND & AIM

Cholesteatoma is a chronic ear disease associated with severe comorbidities due to its destructive progression. Currently, surgery remains the only accepted curative treatment for cholesteatoma; however, its high costs and complications make research on medical treatment alternatives highly significant. This study investigates the potential inhibitory effect of bee venom on a propylene glycol-induced cholesteatoma model in rats.

MATERIAL & METHODS

A total of 32 rats were included and randomly divided into 4 groups. The designated substances were administered bilaterally and intratympanically on days 1, 8, and 15. Group 1: control, in which no active substance was administered (only saline injections on the specified days), Group 2: cholesteatoma induced by propylene glycol administration (propylene glycol injections on the specified days), Group 3: only bee venom administration as the active substance (saline injections on the specified days, followed by single-dose bee venom injection on day 22), and Group 4: rats in which cholesteatoma induced by propylene glycol administration were subsequently administered bee venom (propylene glycol injections on the specified days, followed by single-dose bee venom injection on day 22). Twelve weeks after the last intratympanic injection, the rats were euthanized and their temporal bones were dissected, after which histopathological examinations were performed. Data were analyzed using SPSS.

RESULTS

Although histopathological improvement was observed in the bee venom-treated cholesteatoma group compared with the disease model, the overall change was not significant. Tympanic membrane thickening and fibrosis were significantly reduced. Apoptotic processes were observed to increase significantly. The Mitotic Index/Apoptotic Index ratio was found to be significantly suppressed.

CONCLUSIONS

Bee venom was shown to suppress fibrosis and proliferation and increase apoptotic processes in the rat middle ear. These results suggest that bee venom has an inhibitory effect on cholesteatoma and may guide further research into its treatment.

OP-729

Development And External Validation Of A Multicenter Machine Learning Model For Prognosis Prediction In Sudden Sensorineural Hearing Loss

DongYeon Lee[1], **Jeongwoo Lee**[1], **Mingyeong Kim**[2], **Tae Hoon Kong**[3]

[1]Department of Medical Informatics and Biostatistics, Yonsei University Wonju College of Medicine, Wonju, South Korea; [2]Department of AI-Bio Convergence, Yonsei University Wonju College of Medicine, Wonju, South Korea; [3]Department of Otorhinolaryngology – Head and Neck Surgery, Yonsei University Wonju College of Medicine, Wonju, South Korea

BACKGROUND & AIM

Sudden sensorineural hearing loss (SSNHL) is an acute otological emergency characterized by unexplained hearing loss of ≥30 dB within 72 hours. Although standardized treatment protocols exist, predicting hearing recovery remains challenging, making individualized treatment planning and patient counseling difficult. Most existing models rely on single-hospital datasets, limiting generalizability across diverse clinical environments. This study aimed to develop a multicenter AI model for SSNHL prognosis prediction using data from five university hospitals worldwide and evaluate its generalizability through external validation.

MATERIAL & METHODS

Retrospective data from 2,024 SSNHL patients across five hospitals were analyzed. Fifty-one clinical variables—including demographics, pure-tone audiometry (250–8000 Hz), laboratory findings, and treatment history—were used as inputs. Prognosis was defined as binary recovery per Siegel's criteria. Missing data were handled using MICE, and seven AI algorithms were applied with Optuna-based hyperparameter optimization. Internal validation used stratified 10-fold cross-validation. Two external validation strategies were employed: (1) each hospital's data was split 80:20, with the combined 80% for training and each hospital's 20% hold-out set for validation, and (2) single-hospital models were validated against all remaining hospitals. Model interpretability was assessed using SHAP (TreeExplainer).

RESULTS

The combined multicenter LightGBM model achieved an AUROC of 0.849 (95% CI: 0.810–0.883) on stratified 10-fold cross-validation. External validation across five hospitals yielded AUROCs of 0.84, 0.82, 0.83, 0.86, and 0.73, demonstrating consistent performance across domestic hospitals. Lower performance at the international hospital is attributable to differences in data volume, treatment protocols, follow-up duration, and patient characteristics. Single-hospital models also maintained AUROCs above 0.8 across most external hospitals, confirming generalizability across both strategies. While key predictors varied across single-hospital models, high-frequency hearing thresholds were consistently identified as important. In the combined model, SHAP analysis additionally identified hearing loss duration and contralateral ear thresholds as significant contributors.

CONCLUSIONS

This study demonstrates that a multicenter AI model can overcome the limitations of single-center research and enable reliable SSNHL prognosis prediction across heterogeneous clinical settings. Both combined and single-hospital models showed consistent predictive performance across external hospitals, supporting their potential clinical utility. Given the retrospective study design, further validation through prospective multicenter cohort studies is warranted.

OP-730

Predicting Hearing Outcome After Tympanoplasty: A Multifactorial Approach

Bakhtier Tadzhibaev[1]

[1]Avangard

BACKGROUND & AIM

To identify preoperative and intraoperative factors associated with postoperative hearing improvement after tympanoplasty in patients with chronic suppurative otitis media (CSOM), using a multifactorial approach, with particular emphasis on disease chronicity and prior exposure to ethanol-containing ear drops.

MATERIAL & METHODS

A retrospective observational study was conducted at a tertiary otorhinolaryngology center between January 2024 and January 2026. Patients aged 10–65 years with inactive mucosal CSOM who underwent type I–III tympanoplasty were included. Preoperative and 3-month postoperative pure-tone audiometry was analyzed, and hearing gain was defined as the change in air–bone gap (ABG). Clinically significant hearing improvement was defined as an ABG reduction ≥15 dB. Univariable and multivariable linear and logistic regression analyses were performed to identify predictors of postoperative hearing outcomes, including age, disease duration, frequency of otorrhea, perforation characteristics, CT findings, ossicular chain status, and prior use of ethanol-containing ear drops.

RESULTS

Twenty-nine patients with complete audiological data were included. The mean age was 31.8 ± 9.6 years. The median preoperative ABG was 39 dB (IQR 28–52), with a median postoperative improvement of 14 dB (IQR 0–20) at 3 months. Clinically significant hearing improvement was achieved in 41.3% of ears. Longer duration and higher frequency of otorrhea, as well as increasing age, were independently associated with reduced postoperative hearing gain. Prior exposure to ethanol-containing ear drops showed a consistent negative association with hearing improvement but did not retain independent statistical significance after adjustment. Perforation size, CT evidence of mastoid sclerosis or aditus opacification, and ossicular mobility were not independent predictors of short-term hearing outcome.

CONCLUSIONS

Hearing outcomes after tympanoplasty are primarily influenced by disease chronicity and patient age rather than isolated anatomical factors. Long-standing and frequently recurring otorrhea represents the strongest negative predictor of postoperative hearing improvement. Prior use of ethanol-containing ear drops may constitute a potentially modifiable regional risk factor. A multifactorial assessment approach can improve outcome prediction and patient counseling in CSOM surgery.

Auditory And Visual 3D Virtual Reality Therapy For Chronic Subjective Tinnitus

Beyazıt Bugra AKBAY[1], **Enis Alpin Güneri**[1]

[1]*Department of Otorhinolaryngology, Dokuz Eylul University School of Medicine, Izmir, Turkey*

BACKGROUND & AIM

Chronic subjective tinnitus is the perception of sound without an external source and is often associated with psychological distress and reduced quality of life. This study aims to evaluate the effectiveness of 3D auditory and visual virtual reality (VR) therapy as a novel and patient-centered approach to reduce tinnitus severity and emotional burden, potentially serving as an alternative to conventional treatments such as cognitive behavioral therapy.

MATERIAL & METHODS

This prospective, single-center study included patients aged 18 to 49 with unilateral or dominantly unilateral subjective tinnitus. VR therapy was delivered in immersive environments where patients interacted with auditory and visual avatars symbolizing their tinnitus perception. Pre-treatment evaluations included otoscopic examination, pure tone audiometry, and tinnitus matching to determine frequency and dB SL level. Therapy sessions were held three times per week over six weeks. Personalized auditory stimuli were embedded into VR scenes, including bedrooms, tropical islands, outer space, snowy islands, ancient Egypt, deserts, boxing gyms, and nature. Pre- and post-treatment outcomes were assessed using the Tinnitus Handicap Inventory (THI), Visual Analog Scale (VAS), and Simulation Sickness Questionnaire (SSQ).

RESULTS

Tinnitus-related audiological parameters such as frequency, intensity, and lateralization were recorded in a sound-treated booth. Tinnitus matching and auditory profiling were conducted for all patients. A statistical comparison of pre- and post-treatment scores is ongoing. The final analysis will evaluate whether virtual reality therapy reduces tinnitus severity and related functional impairment significantly. Comparison of pre- and post-treatment scores is ongoing. The final analysis will determine whether virtual reality therapy significantly reduces tinnitus severity and associated functional impairment. Results will be shared in detail at the congress presentation.

CONCLUSIONS

Virtual reality therapy is a promising, non-invasive, and immersive alternative for managing chronic subjective tinnitus. By combining personalized auditory stimulation with visual environments, VR may help improve emotional regulation and perceived control over tinnitus. Further research is needed to validate its efficacy and define its role alongside or in place of behavioral therapies.

Cochlear Implantation: Predicting The Scala Tympani Volume Of The Pediatric Recipients

Abdulrahman Alsanosi[2]

[1]*Otology, neurotology, and cochlear implantation consultant at a King Abdulaziz Medical City, Riyadh, Saudi Arabia.*; [2]*King Abdullah Ear Specialist Center (KAESC), King Saud University Medical City, King Saud University, Riyadh, Saudi Arabia*

BACKGROUND & AIM

The main aim of this study was to estimate the volume of the Scala Tympani (ST) of our pediatric cochlear implant (CI) recipients from the computed tomography (CT) images. Then, to study the association between ST volume and both demographic characteristics and cochlear parameters.

MATERIAL & METHODS

Methods: A retrospective study on the CT scans of pediatric CI patients at a tertiary referral CI center. Congenital or acquired cochlear defects were excluded. Two reviewers, with the same level of experience, blindly measured the main cochlear parameters and studied its anatomy. Then, the interrater reliability was tested to measure any differences between the two readings. After that, the ST volume of the included patients was calculated and analyzed. Furthermore, the correlations between the main cochlear parameters and ST volume were studied to propose a formula for estimating the ST volume from the cochlear duct length (CDL).

RESULTS

Results: The mean predicted ST volume among our pediatric CI recipients was 38.51 ± 5.54 µl (range;24.47–52.57 µl). The statistical analysis revealed that all cochlear parameters (A, B, H, and CDL values) could besignificant predictors of the ST volume (p=<0.0001).

CONCLUSIONS

Conclusion: The main cochlear parameters along with the CDL are positively linked to the ST volume. There are considerable differences in cochlear size and scala tympani volume among our pediatric population. These findings confirm the importance of pre-operative planning for proper electrode array selection.

IS SUDDEN HEARING LOSS UNDERRECOGNIZED? A MULTINATIONAL GOOGLE TRENDS COMPARISON WITH BELL'S PALSY

Beatriz de Sá Nicolau[1], **Cláudia Geraldes**[1], **André Alves Pereira**[2], **Jorge Mexia**[1], **Herédio de Sousa**[1]

[1]*Unidade Local de Saúde de São José;* [2]*Instituto Superior Técnico*

BACKGROUND & AIM

Sudden sensorineural hearing loss (SSNHL) is an otologic emergency with an estimated annual incidence of 5–27 cases per 100,000 individuals, comparable to Bell's palsy (15–30 per 100,000). Despite similar incidence, public awareness of these conditions may differ substantially. Early recognition of SSNHL is critical, as corticosteroid treatment initiated within the first 72 hours significantly improves hearing recovery, while treatment delays are associated with poorer outcomes. This study aimed to compare public interest in SSNHL and Bell's palsy using online search behavior as a proxy for public awareness.

MATERIAL & METHODS

Google Trends was queried using the "Topic" function within the Health category to extract weekly relative search volume (RSV; scale 0–100) for "Sudden hearing loss" and "Bell's palsy" over the past five years. Data were obtained for Portugal, Spain, Türkiye, and the United Kingdom. Approximately 265 paired weekly observations per country were analyzed. Mean weekly RSV values were calculated for each condition. Paired two-tailed t-tests were used to compare weekly RSV values between conditions within each country. Statistical significance was defined as $P < 0.05$.

RESULTS

Across all four countries, mean weekly RSV for SSNHL was substantially lower than for Bell's palsy. Mean RSV for SSNHL ranged from 0.04 to 0.73, compared with 1.6 to 19.7 for Bell's palsy across countries. The mean RSV ratio (SSNHL/Bell's palsy) ranged from 0.002 in Spain to 0.042 in the United Kingdom, indicating that SSNHL generated between 0.2% and 4.2% of the search interest observed for Bell's palsy. Absolute mean differences were consistent across countries and persisted throughout the 5-year study period. Paired analyses confirmed significantly lower weekly RSV for SSNHL in Portugal, Spain, Türkiye, and the United Kingdom (paired t-test, $P < 0.001$ for all comparisons).

CONCLUSIONS

Despite comparable incidence and acute presentation, SSNHL generates markedly lower public search interest than Bell's palsy across diverse countries. This consistent multinational disparity suggests comparatively lower public visibility of SSNHL and may contribute to delayed presentation, underscoring the potential value of targeted awareness initiatives to promote earlier recognition and timely treatment.

OP-734

Efficacy Of Artificial Intelligence For Diagnosing Ear Diseases From Otoscopic Images: A Systematic Review And Meta-Analysis

Thallys Yohanis Benício Fernandes[1], **Rayane Bezerra Freitas**[2], **Ana Cristina Mesquita de Campos**[1], **Priscila Farias de Oliveira**[3], **Daniel Elias Morais do Nascimento**[1], **Diana Andrade Safieh**[1], **Vinicius Tavares de Oliveira**[1], **Cibelle de Araújo Medeiros**[1], **Sara Dantas Nascimento Duarte**[1], **Louise Maria Dias Cortez Braga**[1]

[1]Department of Surgery, Universidade Federal do Rio Grande do Norte, Hospital Universitário Onofre Lopes, Natal, RN, Brazil; [2]Professional Master's Program in Health Education, Universidade Federal do Rio Grande do Norte, Natal, RN, Brazil; [3]Clínica Otossinus, Natal, RN, Brazil

BACKGROUND & AIM

Artificial intelligence (AI) has shown increasing potential in the analysis of medical images, particularly in otolaryngology, where the diagnostic accuracy of otoscopy is strongly dependent on clinician expertise and access to specialist evaluation. This study aimed to conduct a systematic review and meta-analysis of the diagnostic accuracy of AI-based systems for detecting ear diseases from otoscopic images, compared against a defined reference standard.

MATERIAL & METHODS

The study was conducted following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. A systematic search of PubMed, Embase, and IEEE Xplore was performed to identify diagnostic accuracy studies evaluating AI-based systems, including deep learning, machine learning, and convolutional neural networks, applied to otoscopic images for ear disease detection. Statistical analysis was performed using RStudio 2026.01.2. Pooled sensitivity and specificity were estimated using the bivariate random-effects model. Pooled accuracy was calculated using the DerSimonian-Laird model. A summary receiver operating characteristic (SROC) curve was constructed. Heterogeneity was assessed using Cochran's Q statistic and the I^2 statistic.

RESULTS

Fifty-two studies comprising 51,607 otoscopic images were included, with 48,117 correct diagnoses recorded. Pooled sensitivity was 94.6% (95% CI: 92.9%–96.0%) and pooled specificity was 94.8% (false-positive rate: 5.2%; 95% CI: 3.9%–6.9%). The area under the curve (AUC) was 0.98, with a partial normalized AUC of 0.965. The diagnostic odds ratio (DOR) was 350.2 (95% CI: 211.7–579.1). Pooled accuracy was 95% (95% CI: 94%–96%). Heterogeneity was low (I^2=16.1%; Q=60.8, p=0.165; Zhou-Dendukuri: 5.3%). All coefficients were statistically significant (p<0.001).

CONCLUSIONS

AI-based systems demonstrated excellent diagnostic performance for ear disease detection from otoscopic images, with high sensitivity, specificity, and discriminatory ability. These findings support the potential of AI as a supplementary tool for otoscopic diagnosis. Despite low statistical heterogeneity, relevant methodological variability was observed across studies. Continued investment in AI research applied to otoscopy is crucial to establish this technology in clinical practice.

OP-735

Association Between CBC-Derived Inflammatory Markers, Tinnitus Severity, And Audiometric Findings In Subjective Tinnitus

Efe Can[1], **Erkan Tezcan**[1], **Deniz Karaoğlu**[1], **Uluç Salihoğlu**[1], **Cemil Balaman**[1], **Halil İbrahim Naçar**[1]

[1]Antalya City Hospital

BACKGROUND & AIM

Subjective non-pulsatile tinnitus is a multifactorial condition with incompletely understood pathophysiology. Although neuroinflammatory mechanisms have been proposed, evidence regarding the role of systemic inflammation remains inconsistent. This study aimed to investigate the relationship between complete blood count (CBC) derived markers, including neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), systemic immune-inflammation index (SII), systemic inflammation marker (SIM), NPLHb (neutrophil × platelet / hemoglobin), and WMR (white blood cell / mean platelet volume), with tinnitus severity and hearing thresholds.

MATERIAL & METHODS

This retrospective observational study was conducted at Antalya City Hospital ENT clinic between September 2024 and November 2025. A total of 200 patient records were retrospectively reviewed, and 92 participants who met the inclusion criteria, comprising 46 patients with subjective non-pulsatile tinnitus and 46 age- and sex-matched healthy controls, were included in the final analysis. Severity was assessed using a Visual Analog Scale (VAS) and the Tinnitus Handicap Inventory (THI). Compound indices were calculated from CBC data. Statistical comparisons were performed using the Independent Samples T-Test, Pearson Chi-Square, and Mann-Whitney U tests.

RESULTS

Contrary to the initial hypothesis, median SII (447.52 vs. 627.93; p=0.007), PLR (112.30 vs. 129.58; p=0.037), and NPLHb (32.02 vs. 43.11; p=0.015) values were significantly lower in the tinnitus group compared to controls. No significant differences were found regarding age (36.54±9.13 vs. 35.85±8.66 years; p=0.709) or gender (p=0.400) between groups. No significant differences were found for NLR, SIM, or WMR levels (p>0.05). Mean VAS and THI scores were 4.49 and 28.44, respectively. No significant correlations were observed between inflammatory markers and THI scores, nor between THI and audiometric thresholds (p>0.05).

CONCLUSIONS

Unexpectedly, selected CBC-derived inflammatory markers were lower in tinnitus patients and showed no correlation with clinical severity. Consistent with recent longitudinal evidence, these findings suggest that systemic inflammatory alterations may not play a dominant role in subjective tinnitus and support further investigation into localized or neurobiological mechanisms.

Deep Learning Assisted Diagnosis Of Ear Diseases Using Tympanic Membrane Images

Mustafa Utku Akbaş[1], **Hasan Çanakçı**[1], **Erhan Arslan**[2], **Haşmet Yazıcı**[3]

[1]*Department of Otorhinolaryngology, Balıkesir University Faculty of Medicine, Balıkesir, Turkey;* [2]*Department of Otolaryngology, Etlik City Hospital, Ankara, Turkey;* [3]*Private Clinic, Balikesir, Turkey*

BACKGROUND & AIM

Accurate diagnosis of ear diseases using otoscopy remains challenging, particularly for non-otolaryngology physicians, with reported diagnostic accuracy ranging between 30% and 67.5% in primary care settings. Misdiagnosis may lead to delayed treatment and serious complications. Recent advances in deep learning have enabled automated analysis of medical images with high accuracy. However, the application of deep learning in tympanic membrane evaluation remains limited. This study aimed to evaluate the performance of a deep learning–based model for the detection and classification of ear diseases using tympanic membrane images.

MATERIAL & METHODS

This prospective study included tympanic membrane images obtained from patients examined at the Department of Otorhinolaryngology, Balıkesir University Medicine Faculty. A total of 5564 images were collected using routine otoendoscopic examinations and labeled by experienced otolaryngologists (Figure 1). The dataset was divided into training (80%), validation/test (20%) sets. A two-stage classification approach was applied. In the first stage, images were classified as normal or pathological. In the second stage, pathological images were further categorized into eight disease classes, including cerumen impaction, serous otitis media, chronic otitis media with perforation, acute otitis media, adhesive tympanic membrane, and external auditory canal pathologies. A transfer learning approach using pretrained convolutional neural network architectures, including ResNet50, EfficientNetB1, and DenseNet121, was employed for image classification, and their performances were comparatively evaluated. Model performance was evaluated using accuracy, sensitivity, specificity, F1-score, and ROC analysis.

RESULTS

In binary classification, the ResNet50 model achieved an accuracy of 92.75%, sensitivity of 90.65%, specificity of 94.67%, and an AUC of 0.973 (Figure 2), indicating excellent diagnostic performance.For multi-class classification of pathological tympanic membrane images, the model achieved an overall accuracy of 86.17% and a macro F1-score of 77.60%. The highest performance was observed in cerumen impaction (96%), serous otitis media (92%), and chronic otitis media with perforation (84%) (Figure 3). Comparative analysis demonstrated that ResNet50 outperformed EfficientNetB1 and DenseNet121 in both binary and multi-class classification tasks. Lower performance was observed in categories with relatively fewer samples (Figure 4).

CONCLUSIONS

Deep learning models demonstrate high accuracy in detecting and classifying ear diseases using tympanic membrane images. These findings suggest that deep learning–assisted systems may serve as reliable supportive tools in otoscopic diagnosis. Such

systems may be particularly beneficial in primary care and telemedicine settings where access to otolaryngology specialists is limited. Further studies with larger multi-center datasets are needed to validate these findings.

OP-737

Clinical And Radiological Discordances Between Ménière's Disease With And Without Concomitant Migraine

Kuei-You Lin[1,2], **Yu-Hsuan Kuo**[1]

[1]*Department of Otolaryngology, Head and Neck Surgery, Shin Kong Wu Ho-Su Memorial Hospital;* [2]*College of Medicine, Fu Jen Catholic University*

BACKGROUND & AIM

Migraine has long been noticed to associate with Ménière's disease, an inner-ear homeostatic failure characterized by endolymphatic hydrops (EH). Recent advances in hydrops magnetic resonance imaging (MRI) have enabled the visualization of EH, providing valuable insights into EH-related otological disorders. This study aims to investigate the attack durations, saccular functions, and EH grading trends in Ménière's disease patients with and without concomitant migraine, to explore the influence of migraines on Ménière's disease.

MATERIAL & METHODS

This prospective study was conducted at a tertiary hospital from August 2023 to January 2025. Subjects with unilateral definite Ménière's disease, as per the 2015 criteria, were enrolled. All enrolled 57 subjects were newly diagnosed and stratified by the presence of migraine into migrainous MD (MMD) and MD groups. Each subject underwent pure-tone audiometry, cervical vestibular-evoked myogenic potentials tests using air-conducted stimulation, and hydrops MRI. Vertigo severity was documented based on the duration of attacks. Another 25 age-matched healthy subjects were enrolled to establish cVEMP normal data for further comparisons. Statistical analyses included non-paired t-tests, Chi-square tests (Fisher's exact test), and Cochran-Armitage tests for trend.

RESULTS

Of the patients enrolled, the MMD group accounted for 35%. Among them, the ratios of women to men in the MMD and MD groups were respectively 4 and 1.5, showing a different trend. The average age of onset of the disease in the MMD group was 49 years, slightly lower than the 55 years in the MD group. In terms of attack severity, the MMD group showed significantly higher clinical vertigo severity than the MD group ($p<.05$, Chi-square test). In terms of balloon electrophysiological function, the cVEMP response in the MD group was significantly lower than that in the control group ($p<.05$, unpaired t test), while there was no difference in the MMD group. Finally, endolymphedema grading analysis showed a significantly lighter trend in cochlear and vestibular edema grading in the MMD group than in the MD group ($p< .05$, 2x3 and 2x4 Chi-square test)

CONCLUSIONS

The observed discordance between objective measures of inner ear damages and subjective reports of disease symptoms aligns well with current understanding of migraine as a CNS disorder causing global intensification and/or distortion of sensory signal processing, while "simple" MD is purely an inner ear disorder. Hence, controlling or mitigating potential migraine contributions to Ménière symptoms should be considered an essential early step in MMD treatment

OP-738

Gene Therapy For Deafness: From Basics To Clinical Practice

Renjie Chai[1]

[1]*Southeast University*

BACKGROUND & AIM

Hearing loss affects over 1.5 billion people globally, with hereditary factors accounting for more than 50% of cases. Current interventions such as hearing aids and cochlear implants only provide auditory compensation, while gene therapy offers a potential radical cure. However, challenges including cochlear cell type diversity, efficient delivery routes, and clinical applicability need to be addressed.

MATERIAL & METHODS

We established a precision gene therapy platform integrating four core strategies: (1) Vector evolution: Developed novel AAV vectors (e.g., coAAV-1, coAAV-2) via peptide insertion and ancestral sequence reconstruction, and identified cell-specific promoters (HCs, SCs, SGNs) for targeted transgene expression; AIassisted screening accelerated capsid and promoter optimization with high prediction accuracy. (2) Inner ear delivery: Optimized microneedle dimensions and validated the round window membrane (RWM) route across species (mouse, Bama pig, cynomolgus monkey, human) with trans-mastoid facial

recess surgery ensuring safe and efficient transduction. (3) Precise drug design: Applied gene replacement (OTOF, GJB2), gene editing (Cas9 variants, RNA editors) for diverse deafness-related genes; constructed dual AAV systems for large genes like OTOF. (4) Preclinical and clinical validation: Conducted cross-species efficacy and safety assessments, and launched a multicenter clinical trial (NCT05901480) for AAV-OTOF therapy.

RESULTS

Preclinical studies demonstrated that our AAV vectors achieved high transduction efficiency in cochlear hair cells and supporting cells. Gene therapy restored hearing in multiple animal models, including \(Tprn ^{-1}\) , Serpinb6a-/-, DFNA15, and DFNB9 mutant mice, with long-term efficacy and minimal off-target effects. The multicenter clinical trial enrolled 11 DFNB9 patients with OTOF mutations; AAVOTOF injection was well-tolerated (no serious adverse events) and effectively improved auditory function in toddlers, children, and adults, as evidenced by enhanced ABR and pure tone audiometry thresholds. Additionally, we formulated the first international clinical guideline for deafness gene therapy, and AAV-OTOF received FDA orphan-drug designation.

CONCLUSIONS

Our precision gene therapy platform bridges the gap between basic research and clinical practice, providing a scalable solution for both rare and common hereditary deafness. Further optimization of delivery systems and expansion to more deafness genes will facilitate broader clinical translation.

OP-739

Evaluation Of The Relationship Between Childhood Trauma And Attachment Styles In Patients With Peripheral Vertigo

AHMET AKSOY[1], **YAVUZ SARI**[2], **HAVVAGÜL TOPAL**[1], **SERHAT DEMİR**[1], **ENGİN KARAKIŞ**[3]

[1]*Department of Otorhinolaryngology, Sivas Cumhuriyet University Hospital, Sivas, Türkiye;* [2]*Department of Psychology, Sivas Cumhuriyet University;* [3]*Department of Econometrics, Faculty of Economics and Administrative Sciences, Sivas Cumhuriyet University, Sivas, Türkiye*

BACKGROUND & AIM

Peripheral vertigo is a vestibular symptom associated not only with physical manifestations but also with psychological factors. Recent studies have demonstrated that vertigo may be related to psychosocial factors. In particular, childhood trauma and attachment styles are thought to influence stress response, psychological resilience, and the development of psychosomatic symptoms. However, these variables have not been sufficiently investigated in patients with peripheral vertigo. The aim of this study was to evaluate the relationship between childhood trauma and attachment styles in individuals diagnosed with peripheral vertigo and to compare their psychological characteristics with those of healthy individuals.

MATERIAL & METHODS

A total of 64 individuals over the age of 18 were included in this cross-sectional and comparative study. The study group consisted of patients diagnosed with peripheral vertigo, while the control group consisted of healthy individuals without any neurological or systemic disease. Participants completed the Childhood Trauma Questionnaire and the Three-Dimensional Attachment Styles Scale. The normality of data distribution was assessed. Independent samples t-test was used for normally distributed variables, whereas the Mann–Whitney U test was used for non-normally distributed variables. A p value of <0.05 was considered statistically significant.

RESULTS

Emotional neglect and physical neglect scores were significantly higher in the vertigo group compared to the control group ($p<0.001$). Secure attachment scores were significantly lower, whereas avoidant and anxious attachment scores were significantly higher in the vertigo group ($p<0.001$). Significant differences were also found between the groups regarding emotional abuse and total childhood trauma questionnaire scores ($p<0.05$). No significant differences were observed in the physical abuse and sexual abuse subscales.

CONCLUSIONS

Childhood trauma and insecure attachment styles were found to be more common in individuals diagnosed with peripheral vertigo. In particular, emotional neglect, anxious attachment, and avoidant attachment styles may be associated with vertigo. These findings suggest that peripheral vertigo should be considered not only as a vestibular disorder but also as a multidimensional condition requiring a biopsychosocial approach.

OP-740

The Origin Of Cervical Vestibular Evoked Myogenic Potentials - An Ongoing Debate

Jonas Bruun Kjærsgaard[1,2], **Dan Dupont Hougaard**[1,2], **Professor Herman Kingma**[1,2]

[1]Department of Otorhinolaryngology, Head & Neck Surgery and Audiology, Aalborg University Hospital; [2]Department of Clinical Medicine, Aalborg University, Aalborg, Denmark

BACKGROUND & AIM

Cervical vestibular evoked myogenic potentials (cVEMPs) are routinely interpreted as a marker of saccular and inferior vestibular nerve function — an assumption that has shaped clinical localisation for two decades.

But how well do this interpretation align with the contemporary basic, translational and clinical evidence?

The foundational evidence is less definitive than commonly presented, and accumulating experimental work suggests that non-saccular afferents do respond at clinical stimulus levels. We aimed to re-examine what the basic and translational literature actually supports.

MATERIAL & METHODS

We performed a critical literature synthesis across: (i) animal single-unit and nerve-recording studies quantifying acoustic sensitivity of saccular, utricular, and semicircular canal afferents; (ii) data on vestibulo-collic pathways and convergence onto cervical motoneurons; and (iii) human "lesion" studies, with explicit appraisal of verification of lesion site and risk of circular inference (e.g., defining inferior nerve dysfunction partly by the cVEMP outcome). Evidence was mapped to answer: "Is saccular activation necessary for a cVEMP response?" and "Can other end-organs be excluded under routine testing?"

RESULTS

i) Across animal studies, exclusive saccular activation by air-conducted sound (ACS) is not consistently demonstrated. Multiple studies, across different animal species, document considerable utricular co-activation, and more novel studies furthermore indicate co-activation of afferents from the semicircular canals.

ii) Afferent pathway studies indicate that fibres from different end-organs converge and terminate at the same central vestibular neurons, possibly forming a common reflex pathway. This challenges the simple input-output model, that seems to guide cVEMP interpretation.

iii) Clinically, cVEMP abnormalities occur across heterogeneous vestibular disorders; however, specificity for saccular/inferior-nerve lesions is limited by incomplete independent verification and frequent circular case definitions. Some studies suggest that cVEMP responses may persist after sectioning the inferior vestibular nerve.

CONCLUSIONS

We conclude that interpreting the cVEMP as a measure of saccular function stands without strong evidential support. The saccular predominance theory on which this clinical interpretation is based is increasingly misaligned with empirical evidence, and its limited capacity to reconcile these observations weakens its explanatory validity.

We suggest that, until the origin of the cVEMP is more clearly understood, scholars and clinicians consider it a non-specific vestibulo-collic test and refrain from end-organ–specific interpretations in isolation.

We will also highlight the key points of the post-publication debate.

Association Between Preoperative Inflammatory Markers And Graft Success In Endoscopic Type 1 Tympanoplasty

Gözde Günay[1], **Melike Başak**[1], **Ertan Şenköken**[1], **Suat Turgut**[1]

[1]University of Health Sciences, Şişli Hamidiye Etfal Training and Research Hospital, Department of Otorhinolaryngology–Head and Neck Surgery, Istanbul, Türkiye

BACKGROUND & AIM

Graft success after tympanoplasty is influenced by multiple patient- and perforation-related factors. Recently, hemogram-derived inflammatory markers have gained attention as potential predictors of surgical outcomes. However, their clinical utility in endoscopic tympanoplasty remains unclear. This study aimed to evaluate the association between preoperative systemic inflammatory markers, particularly the systemic immune-inflammation index (SII), and graft success following endoscopic type 1 tympanoplasty.

MATERIAL & METHODS

In this retrospective, single-center study, 49 adult patients who underwent primary endoscopic type 1 tympanoplasty were included. Preoperative complete blood count parameters were used to calculate neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), monocyte-to-lymphocyte ratio (MLR), and the systemic immune-inflammation index (SII). Patients were divided into two groups based on postoperative graft status (intact vs. reperforation). Intergroup comparisons were performed, and multivariate logistic regression analysis was used to identify independent predictors of graft success, adjusting for perforation size, malleus involvement, and surgical technique. Receiver operating characteristic (ROC) analysis was performed to assess the predictive performance of the inflammatory markers.

RESULTS

Graft integrity was achieved in 39 patients (79.6%), while 10 patients (20.4%) developed reperforation. There were no statistically significant differences between groups in terms of NLR, SII, or MLR (p>0.05), whereas PLR showed a trend toward higher values in the failure group (p=0.055). In multivariate analysis, SII was independently associated with graft success after adjustment for perforation size, surgical technique, and malleus involvement (OR=0.81, p=0.031), suggesting a possible association between systemic inflammatory burden and impaired graft healing. Patients with higher SII levels demonstrated an increased risk of graft failure, supporting its potential role as a clinically relevant marker. ROC analysis demonstrated moderate discriminative ability of PLR for predicting graft failure (AUC=0.70).

CONCLUSIONS

Preoperative systemic immune-inflammation index may be associated with graft success in endoscopic type 1 tympanoplasty. Higher SII levels may negatively affect graft healing, independent of other clinical factors. These findings suggest that systemic inflammatory status may be associated with graft healing outcomes and could contribute to preoperative risk assessment. Further prospective studies with larger cohorts are needed to validate these findings.

OP-742

Title: First Clinical Experience With An Automated Insertion Tool For Cochlear Implantation

Astrid Magele[1], **Philipp Glocknitzer1**[1], **Philipp Schoerg1**[1], **Georg Mathias Sprinzl1,2**[1,2]

[1]1 University Clinic St. Poelten, Department of Otorhinolaryngology, Head & Neck Surgery, Dunant-Platz 1, 3100 St. Poelten, Austria; [2]2 Karl Landsteiner Institute of Implantable Hearing Devices, 3100 St. Poelten, Austria

BACKGROUND & AIM

To preserve residual hearing during cochlear implantation, it is necessary, among other things, to insert the electrode gently and slowly. The automated insertion tool OTODRIVE (MED-EL GmbH, Austria) enables a slow, even movement of the forceps at a predetermined speed and should thus facilitate gentle electrode insertion.

The aim of the present study is to gain initial experience with the automated insertion tool regarding surgical handling and to investigate any influence on residual hearing retention.

MATERIAL & METHODS

Patients who were routinely fitted with a cochlear implant between September 2024 and December 2025 and inserted with the automated insertion tool will be included in the evaluation. In the case of existing pre-operative residual hearing, the extent to which this can be preserved during the operation will be investigated. In addition, parameters such as complication rate, duration of insertion and final insertion depth are documented.

RESULTS

The initial results show a complication-free electrode insertion and a mean postoperative bone conduction hearing loss of approx. under 10 dB HL. The average time for electrode insertion is about 4 minutes, whereby a minimum insertion speed of 0.1 mm/s can be achieved.

CONCLUSIONS

Initial clinical experience with the OTODRIVE automated insertion tool shows that it is easy to use during surgery, although there is a certain learning curve to overcome. Automated insertion has the potential to enable good residual hearing retention.

OP-743

Cervicogenic Dizziness In Otolaryngology Practice: Do Cervical MRI Findings Correlate With Clinical Characteristics?

Fuat Bulut[1], **Melih Alpay**[1]

[1]Department of Otorhinolaryngology, University of Health Sciences, Bursa Training and Research Hospital, Bursa, Türkiye

BACKGROUND & AIM

Cervicogenic dizziness is a diagnosis of exclusion frequently encountered in otolaryngology practice. This study aimed to evaluate the relationship between cervical MRI findings and clinical characteristics in patients with suspected cervicogenic dizziness. Specifically, it investigated the correlation between radiological findings—such as degenerative disc changes, disc protrusion, osteophyte formation, neural foraminal narrowing, and spinal canal stenosis—and the presence, duration, and severity of dizziness, as well as their association with vestibular test results. The relationship between age and cervical degenerative changes was also assessed.

MATERIAL & METHODS

This retrospective cross-sectional study included 45 adult patients presenting with dizziness between January 2023 and April 2026. Patients with alternative vestibular, neurological, or central causes were excluded. Demographic data, clinical characteristics, symptom duration, VAS scores, and vHIT/VNG results were obtained from medical records. Cervical MRI findings—including disc degeneration, annular bulging, disc protrusion, osteophytes, foraminal narrowing, spinal canal stenosis, and cord compression—were evaluated across levels C2–3 to C6–7. Statistical analyses were performed to assess associations between clinical and radiological variables.

RESULTS

Age was significantly associated with osteophyte formation ($p = 0.004$), and logistic regression confirmed age as an independent predictor ($p = 0.002$; OR = 1.18). No association was found between age and other MRI findings ($p > 0.05$). C3–C4 disc pathology showed a positive correlation with VAS scores ($r = 0.433$, $p = 0.003$), and multilevel degeneration was associated with higher symptom severity ($p = 0.014$). No significant relationships were found between other MRI findings and VAS or nausea ($p > 0.05$). All patients had normal vHIT and VNG results. Age correlated with symptom duration ($r = 0.30$, $p = 0.043$).

CONCLUSIONS

Cervical MRI findings show limited correlation with clinical symptoms. While age predicts osteophyte formation, only specific pathologies such as C3–C4 involvement and multilevel degeneration are associated with symptom severity. Normal vestibular test results support a non-vestibular origin. These findings emphasize the importance of comprehensive clinical evaluation beyond imaging.

Exclusive Endoscopic Surgery For Attical Cholesteatoma: A Prospective PROM-Based Outcome Study

Luana-Maria Gherasie[1,2], **Andreea Rusescu**[1,2], **Irina Gabriela Ionita**[1,2], **Razvan Hainarosie**[1,2], **Corina Negrila**[2], **Catalina Voiosu**[1,2], **Tamer Ebaied**[3], **Viorel Zainea**[1,2]

[1]Carol Davila University of Medicine and Pharmacy; [2]Prof. Dr. Hociota Institute of Phonoaudiology and Functional ENT Surgery; [3]Sheikh Shakhbout Medical City (SSMC), Abu Dhabi 11001, United Arab Emirates

BACKGROUND & AIM

Attical (epitympanic) cholesteatoma represents a frequent and potentially aggressive form of middle ear disease, often involving hidden recesses such as the anterior epitympanum and sinus tympani. Endoscopic ear surgery (EES) offers enhanced visualization of these difficult areas; however, prospective data focusing on patient-reported quality of life (QoL) outcomes remain limited.

To prospectively evaluate quality of life, audiological outcomes, and short-term disease control following exclusive transcanal endoscopic surgery for attical cholesteatoma.

MATERIAL & METHODS

A prospective cohort study was conducted including 41 consecutive patients with attical cholesteatoma (ChOLE Stage I–II) managed exclusively by transcanal endoscopic surgery in a tertiary referral center. Quality of life was assessed preoperatively and postoperatively using validated patient-reported outcome measures (COMQ-12 and Glasgow Benefit Inventory). Audiological outcomes were measured using four-frequency pure-tone average (PTA). Residual or recurrent disease was evaluated at 12 months with non-echo-planar diffusion-weighted MRI.

RESULTS

Preoperative COMQ-12 scores indicated severe disease burden (54.0 ± 4.2). At 12 months, scores improved significantly to 10.2 ± 3.3 (mean reduction −43.8; 95% CI −46.1 to −41.5; $p < 0.001$), representing an 81% improvement. GBI scores demonstrated high and sustained patient-perceived benefit (82.6 ± 4.8 at 6 months; 84.1 ± 4.9 at 12 months; $p < 0.001$). Mean PTA improved from 52.1 ± 5.3 dB HL preoperatively to 26.4 ± 4.7 dB HL at 12 months (mean gain 25.7 dB; $p < 0.001$). No major complications occurred, and no residual or recurrent cholesteatoma was detected at 12 months. No significant correlation was observed between hearing gain and QoL improvement.

CONCLUSIONS

Exclusive endoscopic management of attical cholesteatoma provides substantial and sustained improvement in patient-reported quality of life, significant hearing restoration, and excellent short-term disease control. These findings support the endoscopic transcanal approach as a safe, minimally invasive, and patient-centered strategy for selected epitympanic cholesteatomas.

Concurrent Inner And Outer Ear Anomaly: Case Report And Literature Review

Dr.Khaled Alhussinan[1], **Dr.Abdullah Alshathry**[1], **Dr.Nawwaf Alsubaie**[1], **Dr. Raghad Alkhaldi**[2], **Dr. Mohammed Alyousef**[1], **Dr. Fida Almuhawas**[1]

[1]*King Saud University Medical City, Department of Otolaryngology, Head and Neck Surgery, King Saud University College of Medicine, Riyadh, Kingdom of Saudi Arabia.*; [2]*Imam Mohammed Ibn Saud Islamic University, College of Medicine, Riyadh, Saudi Arabia.*

BACKGROUND & AIM

Microtia is a congenital condition characterized by an irregular formation of the outer ear. Microtia has been related to anomalies or identifiable syndrome. In the literature, inner ear anomalies in microtia patients are not extensively studied, given the rare association between both conditions, as they have different embryological origins. This case illustrates the importance of choosing the right cochlear implantation location, the type of electrode that is proper for this condition, and the difficulty in diagnosing the patient.

MATERIAL & METHODS

A 1-day-old baby girl, examination reveals the patient had a right-sided microtia ear, consistent with microtia grade 3, with the left ear consistent with microtia grade 1.

At 4 months, the patient underwent her first audiological assessment, which revealed a conductive hearing loss pattern. At the age of 6 months, findings from the brain MRI showed that the right-sided microtia, along with a small internal auditory canal on the left side, had evidence of cochlear hypoplasia. Also, neither vestibulocochlear nerve is visualized.

RESULTS

At the age of 15 months old, she underwent left-sided cochlear implantation with a small 19 form of Medel electrode with intra-operative ABR. Electrical ABR confirmed the procedure with favorable results.

At 16 months, her first speech-language pathology session was promising; the family reported a response to loud voices and her sibling's names.

CONCLUSIONS

In conclusion, this case aims to emphasize the barriers to managing congenital microtia in association with inner ear malformation regarding diagnosis and management. A re-establishment of hearing function following cochlear implantation demonstrated that cochlear implants can function adequately even in complicated inner ear malformations. Thus, this case highlights the significance of thorough imaging and a customized approach to management.

Translation, Cross-Cultural Adaptation, And Validation Of The Arabic Version Of The Youth Quality Of Life Instrument–Deaf And Hard Of Hearing Module (YQOL-DHH)

yazeed alshawi[1]

[1]*Department of Otolaryngology—Head & Neck Surgery (ORL—H&N), Prince Sultan Military Medical City (PSMMC), Riyadh, Saudi Arabia*

BACKGROUND & AIM

Hearing loss is the one of the leading causes of disability among children and adolescents globally, with Saudi Arabia having a higher incidence of neonatal hearing loss. Deaf or hard of hearing adolescents experience diminished life satisfaction in self-perception, family relationships, social connections, and living environment. Social self-esteem is typically diminished in children with hearing loss due to language and communication difficulties.

Objectives: The purpose of this study is to translate and validate the YQOL-DHH into the Arabic language to develop the ArabicQOL instrument for deaf adolescents.

MATERIAL & METHODS

The study aims to translate and adapt an Arabic YQOL-DHH instrument for DHH patients aged 11-18 in the ENT department of Prince Sultan military city. The process involves two comparisons of DHH patients' responses and thoseof their parents. Participants are recruited from clinic visitors and fill out the questionnaire using the Arabic YQOL-DHH for inter-rater reliability. Data is analyzed using SPSS version 23.0, with a p-value of <0.05 considered statistically significan

RESULTS

The assessment of the adolescent DHH children andYQOL-DHH parents' assessments showed a high degree of agreement 66 (69.5%). However, there was a statistically significant difference between the study subjects' mean Arabic YQOL-DHH scores among the DHH children and their parents($p<0.001$). The results revealed a notable gender difference in perceived stigma out of the three areas evaluated. The mean perceived stigma score for male participants was significantly higher (45.73 ± 16.23) than for female participants (32.38 ± 3.57, $p = 0.009$).

CONCLUSIONS

According to the study, the Arabic YQOL-DHH is a valid and reliable instrument for assessing the quality of life of children with hearing loss. It demonstrated a moderately goodinternal consistency and reliability. In order to demonstrate the Arabic YQOL-DHH's generalizability and sensitivity across clinical situations, future research should concentrate on assessing it over a broader and more diversified sample of children, including different and wide age groups, hearing loss levels, and intervention modalities.

Histopathologic Patterns Of Cochlear Endosteal And Round Window Involvement In Otosclerosis: Implications For Cochlear Implantation

Rafael Monsanto[1], **Robert Briggs**[3], **Tomotaka Shimura**[1], **Nevra Keslin Yilmaz**[1], **Maurício Noschang**[2], **Maura Eggink**[3], **JM Gerard**[3], **Sady Selaimen da Costa**[2]

[1]*Paparella Otopathology & Pathogenesis Laboratory ; University of Minnesota;* [2]*Department of Otolaryngology - University of Rio Grande do Sul, Brazil;* [3]*1 Department of Otolaryngology, Cochlear Implant Clinic, The Royal Victorian Eye and Ear Hospital, Melbourne, Australia*

BACKGROUND & AIM

To determine the prevalence and severity of cochlear endosteal involvement in otosclerosis, propose a histopathological grading system to standardize its evaluation, and explore its clinical implications for cochlear implantation

MATERIAL & METHODS

Human temporal bone specimens with otosclerosis were analyzed histopathologically. A three-tier grading system (Grades I–III) was applied to midmodiolar sections to assess the extent and distribution of endosteal involvement in each cochlear turn. Lesion involvement grade, site distribution, multiplicity, and round window (RW) involvement were examined to assess their interrelationships.

RESULTS

Cochlear endosteal involvement was observed in 17.9% of evaluable ears. A distinct site-specific heterogeneity was identified: all lesions with cochlear involvement observed in the lower basal turn were Grade III, whereas Grade I lesions predominated in the upper basal turn. Multifocal cochlear endosteal involvement correlated with higher involvement grades. In the subgroup analysis, greater RW involvement was generally accompanied by higher grades of cochlear involvement, suggesting that advanced RW pathology may reflect more extensive endosteal changes, predominantly within the basal turn.

CONCLUSIONS

The proposed grading system provides a reproducible framework for assessing cochlear endosteal involvement and reveals intrinsic site-dependent variability within the otic capsule. The observed distribution patterns, including the association with RW involvement, may contribute to improved clinicopathologic correlation, enhanced radiologic interpretation, and more informed surgical planning for cochlear implantation in advanced otosclerosis.

OP-748

FROM AN ISOLATED OTOLOGIC SYMPTOM TO PULMONARY-RENAL SYNDROME: A CASE OF GRANULOMATOSIS WITH POLYANGIITIS (WEGENER'S) PRESENTING WITH ATYPICAL MIDDLE EAR INVOLVEMENT

Orkun Celil Sel[1], **Recep Yağız**[1]

[1]*Department of Otolaryngology, Trakya University Faculty of Medicine, Edirne Türkiye*

BACKGROUND & AIM

Granulomatosis with polyangiitis (GPA), formerly known as Wegener's granulomatosis, is a rare, ANCA-associated systemic necrotizing vasculitis that predominantly targets small-to-medium-sized blood vessels, typically manifesting in the upper and lower respiratory tracts along with the kidneys. Although head and neck manifestations are frequently encountered during the disease course, GPA initiating solely with isolated otologic symptoms and radiologically mimicking vascular masses leads to significant diagnostic challenges and delays.

MATERIAL & METHODS

In this case report, we present a 63-year-old male patient who initially presented with hearing loss and severe otalgia in the left ear.

RESULTS

Due to mass-like imaging findings, the patient was radiologically pre-diagnosed with a glomus tumor. Despite undergoing multiple superficial biopsies and an explorative tympanotomy, the histopathological evaluation of the isolated ear

involvement remained inconclusive and non-diagnostic for systemic vasculitis. Within a few months, the clinical course progressed aggressively into a life-threatening pulmonary-renal syndrome before a definitive diagnosis could be established. Repeated superficial biopsies performed on the middle ear lesions revealed only non-specific necrotizing inflammation rather than diagnostic granulomas. Ultimately, through a multidisciplinary approach following systemic involvement, the definitive diagnosis of GPA was established via a renal biopsy demonstrating crescentic glomerulonephritis, accompanied by c-ANCA positivity. Following the prompt initiation of aggressive immunosuppressive therapy combined with plasmapheresis sessions, the patient's severe clinical condition successfully regressed, and the requirement for hemodialysis was completely eliminated.

CONCLUSIONS

This case underscores that in patients presenting with refractory, destructive, or atypical otologic findings, it is of vital importance for otolaryngologists to maintain a high index of suspicion for systemic vasculitis, even when initial histopathological and exploratory surgical evidence remains insufficient.

Granulomatosis with polyangiitis, Wegener's granulomatosis, hearing loss, glomus tumor, explorative tympanotomy, pulmonary-renal syndrome, otology

OP-749

Comparison Of Commercial Artificial Intelligence Applications For Predicting Siegel Outcomes In Idiopathic Sudden Sensorineural Hearing Loss

TUBA DOĞAN KARATAŞ[1], **HAVVAGÜL TOPAL**[1], **YAVUZ TAÇYILDIZ**[1], **AHMET AKSOY**[1], **DENİZ ÖNCÜL**[1]

[1]*Department of Otorhinolaryngology, Sivas Cumhuriyet University, Sivas, Türkiye*

BACKGROUND & AIM

Idiopathic sudden sensorineural hearing loss is an otologic emergency characterized by rapid-onset sensorineural hearing impairment and variable clinical outcomes. Although systemic corticosteroid therapy is commonly used, treatment response may differ considerably among patients. Early prediction of hearing recovery may contribute to patient counseling, treatment planning, and clinical decision support.

This study aimed to evaluate the ability of commercial artificial intelligence applications to predict post-treatment hearing recovery according to Siegel criteria using only pre-treatment clinical, audiological, and laboratory data in patients with idiopathic sudden sensorineural hearing loss.

MATERIAL & METHODS

This retrospective single-center methodological study included patients diagnosed with idiopathic sudden sensorineural hearing loss at Sivas Cumhuriyet University Department of Otorhinolaryngology between January 1, 2016, and the date of data extraction. Patients treated with systemic prednisolone therapy and having both pre- and post-treatment audiometric records were included. Demographic characteristics, pretreatment pure-tone audiometry thresholds, and routine laboratory parameters were analyzed. Pure tone average (PTA) was calculated using air-conduction thresholds at 500, 1000, 2000, and 4000 Hz, and PTA gain was defined as the difference between pre- and post-treatment PTA values. Real Siegel classifications were determined according to standardized PTA-based criteria. For artificial intelligence prediction, only pretreatment anonymized clinical, audiological, and laboratory data were provided to ChatGPT Plus, Claude, and Manus using a standardized prompt. Post-treatment audiometric findings and actual Siegel classes were withheld during prediction. AI-generated predictions were compared with actual clinical outcomes using four-class Siegel classification accuracy.

RESULTS

A total of 117 patients were included in the analysis. The mean pre-treatment pure-tone average (PTA) was 49.5 dB, and the mean post-treatment PTA was 38.5 dB, with a mean PTA gain of 11.0 dB. According to real post-treatment audiometric outcomes, 54 patients were classified as Siegel I, 8 as Siegel II, 7 as Siegel III, and 48 as Siegel IV. Overall recovery (Siegel I–III) was observed in 59.0% of patients.

For four-class Siegel prediction, artificial intelligence applications demonstrated limited accuracy. ChatGPT Plus achieved 54.7% accuracy, Manus 49.6%, and Claude 45.3%. In the broader binary clinical classification of good response (Siegel I–II) versus poor/insufficient response (Siegel III–IV), ChatGPT Plus achieved 71.8% accuracy with 79.0% sensitivity and 63.6% specificity, while Manus achieved 65.8% accuracy with 82.0% sensitivity and 48.2% specificity. Overall, artificial intelligence applications showed limited performance in detailed Siegel prediction but demonstrated more clinically useful results in broader binary response classification.

CONCLUSIONS

Commercial artificial intelligence applications showed limited accuracy in four-class Siegel prediction for idiopathic sudden sensorineural hearing loss, with accuracies ranging from 45.3% to 54.7%. However, binary response classification produced more promising results, particularly for ChatGPT Plus and Manus. These findings suggest that AI tools may be more useful for broad prognostic assessment than precise Siegel class prediction. Missing prognostic variables, including treatment delay, vertigo, tinnitus, and salvage therapy status, may have reduced predictive performance. Although these systems cannot

replace physician judgment, they may support clinical decision-making. Larger prospective multicenter studies are needed to validate AI-assisted prediction models.

OP-750

A Novel Technique Utilizing Polymethylmethacrylate Cement For The Treatment Of Pulsatile Tinnitus Across Multiple Vascular Pathologies

Dr saleh alamry[1], **Dr homood almutairi**[1]

[1]*Prince sultan military medical city*

BACKGROUND & AIM

Pulsatile tinnitus is a distressing condition commonly associated with vascular structural abnormalities such as sigmoid sinus dehiscence, sigmoid sinus diverticulum, jugular bulb anomalies, and emissary vein defects. Surgical resurfacing has emerged as an effective treatment; however, technical challenges and optimal materials remain under evaluation. We present a novel approach utilizing polymethylmethacrylate (PMMA) bone cement across different vascular etiologies.

MATERIAL & METHODS

Four representative cases from a larger series of approximately 30 patients will be presented to demonstrate the versatility of this technique and highlight key intraoperative challenges.

- Case 1: Challenging jugular bulb dehiscence managed with PMMA resurfacing, with significant improvement in Tinnitus Handicap Inventory (THI).
- Case 2: Sigmoid sinus dehiscence in a patient with profound sensorineural hearing loss, successfully treated with symptomatic improvement.
- Case 3: A complex case with combined Superior Semicircular Canal Dehiscence, sigmoid sinus dehiscence, and sigmoid sinus diverticulum. The patient underwent tailored PMMA resurfacing with adjustment of cement viscosity to address both dehiscence and diverticular components, resulting in complete resolution of pulsatile tinnitus and vestibular symptoms.
- Case 4: Emissary vein dehiscence treated with PMMA cement, with immediate postoperative improvement.

RESULTS

All cases demonstrated immediate and significant reduction in pulsatile tinnitus following surgery. No intraoperative or postoperative complications were observed. Outcomes from the broader cohort (n≈30) support the safety and reproducibility of this approach.

CONCLUSIONS

This presentation highlights the effectiveness of PMMA bone cement resurfacing across a spectrum of vascular causes of pulsatile tinnitus. Case 3 illustrates the technical challenge of dual pathology management and the importance of tailoring cement properties, including viscosity, to achieve optimal reconstruction and symptom resolution.

OP-751

Efficacy Of Nigella Sativa Oil In Eczematous Otitis Externa: A Randomized Controlled Study

Nazan Değirmenci[1], **Nurtaç Dağistanlı**[2], **Muhammed Said Ekinci**[1], **Remzi Doğan**[1], **Orhan Özturan**[1]

[1]*Bezmailem Vakıf Üniversity;* [2]*Kırklareli Training and Research Hospital*

BACKGROUND & AIM

Eczematous otitis externa is a common inflammatory condition of the external auditory canal, often associated with itching, scaling, and recurrent symptoms. Topical corticosteroids are widely used but may have limitations due to potential adverse effects with prolonged use. Nigella sativa has known anti-inflammatory, antimicrobial, and antioxidant properties and has shown benefits in dermatologic conditions. This study aimed to compare the clinical efficacy of Nigella sativa oil with topical mometasone furoate in the treatment of eczematous otitis externa.

MATERIAL & METHODS

This prospective, randomized, single-blinded controlled study included adult patients diagnosed with eczematous otitis externa. Participants were randomized into two groups: Nigella sativa (NS) oil (2 drops twice daily) or topical mometasone furoate (MF) 0.1% solution for 10 days. Clinical symptoms (itching, discomfort, otorrhea, pain) were assessed using a Numeric Rating Scale, and inflammatory findings (hyperemia, squamation) were evaluated via standardized otoscopic imaging by a

blinded otolaryngologist at baseline and day 10. Statistical analyses were performed using nonparametric tests, with significance set at $p < 0.05$.

RESULTS

Both groups showed significant improvement in all clinical symptoms and inflammatory findings after treatment ($p < 0.001$). Between-group comparisons revealed that the mometasone furoate group demonstrated significantly greater improvement in pain, discomfort, and hyperemia. In contrast, the Nigella sativa group showed significantly greater reduction in squamation both within the external auditory canal and on the external ear. No significant differences were observed between groups in terms of itching and otorrhea. Baseline characteristics and pre-treatment scores were comparable between the groups.

CONCLUSIONS

Both Nigella sativa oil and mometasone furoate were effective in the short-term treatment of eczematous otitis externa. While mometasone provided greater improvement in acute inflammatory symptoms such as pain, discomfort, and hyperemia, Nigella sativa demonstrated superior efficacy in reducing squamation. These findings suggest that Nigella sativa may serve as a potential steroid-sparing alternative in selected patients, particularly in cases with predominant scaling and dryness. Further large-scale and long-term studies are needed to confirm these results.

OP-752

Association Between Preoperative Neutrophil/Lymphocyte Ratio And Graft Success Following Type 1 Tympanoplasty

Sümeyye Atahan[1], **Orhan Kemal Kahveci**[1], **Abdulkadir Burak**[1], **Fatih Çelenk**[1], **Selçuk Kuzu**[1], **Erkan Yıldız**[1], **Çağlar Günebakan**[1]

[1]*Afyonkarahisar University Faculty of Health Science, Department of Otorhinolaryngology*

BACKGROUND & AIM

Chronic inflammation may impair tissue healing and graft integration by affecting microvascular circulation and epithelial regeneration following type 1 tympanoplasty. The neutrophil/lymphocyte ratio (NLR) is a simple and accessible marker of systemic inflammation that has been associated with postoperative outcomes in various surgical fields. This study aimed to investigate the relationship between preoperative NLR levels and surgical outcomes following type 1 tympanoplasty.

MATERIAL & METHODS

This retrospective study included 372 patients who underwent type 1 tympanoplasty for chronic tympanic membrane perforation between January 2023 and June 2025. Patients with at least 6 months of postoperative follow-up were included, while those with active infection, systemic inflammatory disease, hematological disorder, or immunosuppressive treatment were excluded. Preoperative NLR values were calculated from routine complete blood count parameters. Demographic characteristics, smoking status, perforation size, graft material, and preoperative audiological findings were recorded. Anatomical success was defined as an intact tympanic membrane at the final follow-up visit, while functional outcome was assessed using postoperative air-bone gap values. Comparative and multivariable logistic regression analyses were performed to identify predictors of graft failure.

RESULTS

Anatomical success was achieved in 306 patients (82.3%). Patients with graft failure had significantly higher preoperative NLR values compared with those with anatomical success (2.64 ± 0.91 vs. 2.21 ± 0.78, $p=0.018$). Preoperative NLR values showed a significant positive correlation with postoperative air-bone gap values ($r=0.24$, $p=0.031$). ROC analysis demonstrated that preoperative NLR predicted graft failure with an AUC of 0.66, and an optimal cut-off value of 2.45 provided 63.0% sensitivity and 61.5% specificity. Elevated preoperative NLR was identified as an independent predictor of graft failure (OR: 1.42, 95% CI: 1.08–1.89, $p=0.014$).

CONCLUSIONS

Elevated preoperative NLR was associated with graft failure and higher postoperative air-bone gap values following type 1 tympanoplasty. Preoperative NLR may serve as a simple adjunctive marker for predicting surgical outcomes in clinical practice; however, its modest predictive performance suggests that it should be interpreted cautiously and potentially combined with other clinical parameters.

OP-753

Modulating ATOH1 And POU4F3 Pathways To Enhance Hair Cell Regeneration And Inhibit Ferroptosis In Cochlear Support Cells

Yu Rong[2], **Yang Hua**[1]

[1]*Department of Otorhinolaryngology, Peking Union Medical College Hospital, Beijing, China.*; [2]*Department of Otorhinolaryngology, First Affiliated Hospital of Nanchang University, Nanchang, China*

BACKGROUND & AIM

Hearing loss affects millions worldwide, yet effective regenerative treatments remain limited.This study systematically investigated how the ATOH1/POU4F3 axis drives supporting cell reprogramming and hair cell regeneration while suppressing autophagy-dependent ferroptosis in cochlear hair cells.

MATERIAL & METHODS

We combined single-cell RNA sequencing of mouse cochlear tissue across developmental stages with bulk transcriptomics, protein–protein interaction analysis, and pathway enrichment to identify key regulators. Using lentiviral overexpression and silencing, ChIP-qPCR, dual-luciferase reporter assays, Western blotting, immunofluorescence, and EdU labeling.And also make an oxidative stress model.

RESULTS

we demonstrated that ATOH1 directly activates POU4F3, upregulates MYO7A expression, enhances supporting cell proliferation, and promotes mitotic entry. In an oxidative stress model, activation of this pathway reduced autophagy flux, lipid peroxidation, and Fe2+ levels, improving cell survival. In a cisplatin-induced hearing loss mouse model, modulating the ATOH1/POU4F3 axis significantly improved ABR and DPOAE thresholds and restored hair cell structure and arrangement, confirmed by SEM and immuno staining.

CONCLUSIONS

Together, these findings provide new mechanistic insights into how transcriptional regulation links regeneration and cell death resistance, highlighting a promising therapeutic target for hearing restoration.

OP-754

Complete Hearing Recovery After Intratympanic Steroid Therapy In A Patient With MRI-Confirmed Intracanalicular Vestibular Schwannoma Subsequently Treated With Gamma Knife

merve akyol çetinkaya[1]

[1]*Department of Otorhinolaryngology, Karabük Training and Research Hospital, Karabük, Turkey*

BACKGROUND & AIM

Sudden sensorineural hearing loss (SSNHL) can be the first clinical sign of vestibular schwannoma, posing a therapeutic dilemma between urgent hearing treatment and oncologic evaluation. Delaying therapy may compromise auditory recovery. The primary aim of this study is to emphasize that intratympanic steroid therapy should be initiated promptly, even in patients with MRI-confirmed intracanalicular vestibular schwannoma. We present a 40-year-old woman who developed acute unilateral hearing loss and achieved complete recovery after early intratympanic steroid injections, followed by Gamma Knife radiosurgery. This case underscores the critical importance of immediate hearing-directed management to preserve auditory function while planning definitive tumor treatment.

MATERIAL & METHODS

This study presents a single-patient case report of a 40-year-old female admitted with sudden right-sided sensorineural hearing loss. Clinical evaluation included otoscopic examination, pure-tone audiometry, and contrast-enhanced magnetic resonance imaging (MRI). Audiometric thresholds were recorded at presentation and during follow-up visits. MRI revealed a 9.7 × 5.9 mm enhancing lesion within the right internal auditory canal, consistent with an intracanalicular vestibular schwannoma. Intratympanic dexamethasone (8 mg) was administered under microscopic guidance on five occasions (March 19, 21, 24, 26, and 28, 2025). Hearing levels were reassessed after each injection and during long-term follow-up. Serial MRI examinations were performed to evaluate tumor size progression. After radiological confirmation and interval growth, the patient was referred for Gamma Knife radiosurgery. Clinical, audiological, and radiological findings were analyzed descriptively.

RESULTS

An initial audiogram performed at an external center on March 18, 2025 demonstrated right ear thresholds of 50/45 dB, with normal hearing in the left ear (10/10 dB). The patient presented to our clinic on March 19, and repeat pure-tone audiometry performed the same day confirmed worsening right-sided hearing loss at 68/53 dB.

Following five intratympanic dexamethasone injections, progressive audiological improvement was observed. On March 24, thresholds improved to 32/8 dB, and by March 28, hearing levels reached 18/10 dB. Long-term follow-up audiometry demonstrated stable and near-normal thresholds: 15/13 dB on June 30 and 18/15 dB on October 2, consistent with complete functional recovery.

Serial MRI measurements showed tumor dimensions of 13 × 7 mm on July 4 and 11 × 7 mm on October 8. Despite radiological persistence, hearing remained stable after Gamma Knife referral.

CONCLUSIONS

Sudden sensorineural hearing loss may represent the first clinical manifestation of intracanalicular vestibular schwannoma. This case demonstrates that intratympanic steroid therapy can achieve complete hearing recovery even in the presence of a radiologically confirmed tumor. Treatment for SSNHL should not be postponed while evaluating retrocochlear pathology. Early hearing-directed intervention may preserve auditory function and provide a valuable therapeutic window for definitive tumor management, such as radiosurgery. Prompt multidisciplinary coordination enables both oncologic control and hearing preservation. Intratympanic steroid therapy appears to be a safe and effective strategy in carefully selected patients with tumor-associated sudden hearing loss.

The 'Utrecht Experience' In The Management Of The Fisch Type A And B Paragangliomas. A Cohort Study

Christos Tsilivigkos[1,2], **Robert J. Stokroos**[1,3], **Eduard H. Voormolen**[3,4], **Rachel S. Van Leeuwaarde**[6], **Ernst Smid**[5], **Johannes A. Rijken**[1,3], **Hans G. X. M. Thomeer**[1,3]

[1]Department of Otorhinolaryngology and Head & Neck Surgery, University Medical Center Utrecht, Utrecht University, The Netherlands; [2]First Department of Otolaryngology, Hippokration General Hospital, National and Kapodistrian University of Athens, Athens, Greece; [3]UMC Utrecht Brain Center; [4]Department of Neurosurgery Skull Base Surgery; [5]Department of Radiotherapy; [6]Department of Endocrine Oncology, University Medical Center Utrecht, Utrecht University, The Netherlands

BACKGROUND & AIM

Paragangliomas of the middle ear and jugular foramen are highly vascularized neoplasms that are predominantly benign. They typically present with unilateral pulsatile tinnitus and a reddish-blue middle ear mass on otoscopy. This study aimed to describe the diagnostic work-up and treatment outcomes of Fisch type A and B paragangliomas at a tertiary referral center in the Netherlands.

MATERIAL & METHODS

A retrospective cohort study was conducted including adults diagnosed with Fisch type A or B paragangliomas who presented to our tertiary referral center between 2015 and 2026. Patients were managed with either a watch-and-scan strategy, surgery, or stereotactic radiosurgery. Evaluated outcomes included demographics, clinical presentation, genetic testing results, hormonal activity, audiometric outcomes (pure-tone average [PTA] and speech audiometry in quiet), imaging characteristics (tumor size on MRI, presence of synchronous glomus tumors, and tumor classification) at presentation and at the last follow-up. Data were analyzed descriptively and continuous variables are presented as mean ± standard deviation.

RESULTS

Fifteen patients were included (14 females, 1 male; mean age 59.3±11.4 years). A positive family history was reported in 1/15(6.7%) patients , hormone secretion was detected in 1/15(6.7%), and pathogenic genetic variants were identified in 4/15(26.7%). Additional head and neck paragangliomas were found in 2/15(13.3%) patients . At presentation, hearing loss was reported by 13/15 patients (86.7%), pulsatile tinnitus by 12/15(80.0%), vestibular symptoms by 4/15 (26.7%), and aural fullness or otalgia by 6/15(40.0%). Ten tumors (66.7%) were classified as Fisch type A and five (33.3%) as type B. Mean tumor diameter at diagnosis was 12.2±7.1 mm. Management consisted of surgery in 10/15(66.7%) patients , stereotactic radiosurgery in 2/15(13.3%), and watch-and-scan in 3/15(20.0%). In the surgical group, pulsatile tinnitus persisted in one patient (10%), recurred after two years in one patient (10%), and one patient (10%) required staged ossiculoplasty. No tumor recurrences were observed during follow-up. Audiometric outcomes remained stable overall.

CONCLUSIONS

Fisch type A and B paragangliomas exhibit variable clinical and anatomical characteristics. Management should be individualized; however, surgery appears to be a safe and effective treatment option with excellent local tumor control.

OP-756

A NOVEL RADIOLOGICAL SOFTWARE PROTOTYPE FOR AUTOMATICALLY DETECTING THE INNER EAR AND CLASSIFYING NORMAL FROM MALFORMED ANATOMY

Fida almuhawas[1]

[1]KSUMC

BACKGROUND & AIM

To develop an effective radiological software prototype that could read Digital Imaging and Communications in Medicine (DICOM) files, crop the inner ear automatically based on head computed tomography (CT), and classify normal and inner ear malformation (IEM).

MATERIAL & METHODS

A retrospective analysis was conducted on 2053 patients from 3 hospitals. We extracted 1200 inner ear CTs for importing, cropping, and training, testing, and validating an artificial intelligence (AI) model. Automated cropping algorithms based on CTs were developed to precisely isolate the inner ear volume. Additionally, a simple graphical user interface (GUI) was implemented for user interaction. Using cropped CTs as input, a deep learning convolutional neural network (DL CNN) with 5-fold cross-validation was used to classify inner ear anatomy as normal or abnormal. Five specific IEM types (cochlear hypoplasia, ossification, incomplete partition types I and III, and common cavity) were included, with data equally distributed between classes. Both the cropping tool and the AI model were extensively validated.

RESULTS

The newly developed DICOM viewer/software successfully achieved its objectives: reading CT files, automatically cropping inner ear volumes, and classifying them as normal or malformed. The cropping tool demonstrated an average accuracy of 92.25%. The DL CNN model achieved an area under the curve (AUC) of 0.86 (95% confidence interval: 0.81-0.91). Performance metrics for the AI model were: accuracy (0.812), precision (0.791), recall (0.8), and F1-score (0.766).

CONCLUSIONS

This study successfully developed and validated a fully automated workflow for classifying normal versus abnormal inner ear anatomy using a combination of advanced image processing and deep learning techniques. The tool exhibited good diagnostic accuracy, suggesting its potential application in risk stratification. However, it is crucial to emphasize the need for supervision by qualified medical professionals when utilizing this tool for clinical decision-making.

Evaluation Of The Ototoxicity Of Calendula Officinalis Extract

Yavuz Beşli[1], **Züheyla Dilek Gülmez**[2], **Gülnur Ekşi Bona**[3], **Doğan Çakan**[1]

[1]Department of Otorhinolaryngology, Cerrahpaşa Faculty of Medicine, Istanbul University-Cerrahpaşa, Istanbul, Türkiye; [2]Department of Audiology, Division of Audiology, Faculty of Health Sciences, Istanbul University-Cerrahpaşa, Istanbul, Türkiye; [3]Department of Pharmaceutical Botany, Division of Pharmaceutical Sciences, Faculty of Pharmacy, Istanbul University-Cerrahpaşa, Istanbul, Türkiye

BACKGROUND & AIM

Calendula officinalis has demonstrated significant wound-healing effects in numerous ethnobotanical and medical studies, with recognized anti-inflammatory, antimicrobial, and tissue-reparative properties. However, despite its broad therapeutic use, no study has investigated its otologic application, including possible ototoxic, otoprotective, or otologic wound-healing effects. The absence of evidence regarding its safety in the auditory system represents a critical knowledge gap. Before investigating whether the well-documented regenerative effects of Calendula officinalis on various tissue injuries can be translated to otologic wounds, it is essential to first establish its safety profile within the auditory system.

MATERIAL & METHODS

Following approval from the Istanbul University-Cerrahpaşa Animal Experiments Local Ethics Committee, the study was initiated. A total of 21 rats (42 ears), with 7 rats in each group, were included. Distilled water was administered intratympanically to the negative control group, gentamicin to the positive control group, and a prepared solution of C. officinalis extract to the study group. MTT assay testing was performed on extracts obtained from the relevant plant material, and the non-cytotoxic dose was determined. Hearing thresholds at 8, 16, 24, and 32 kHz were evaluated using auditory brainstem response (ABR) testing. The obtained data were analyzed statistically.

RESULTS

At baseline, ABR testing demonstrated no statistically significant differences among the groups at any frequency ($p > 0.05$).On day 3, significant differences were detected among the groups across all evaluated frequencies ($p< 0.001$, $p< 0.05$). In pairwise comparisons, ABR thresholds of the study group at all frequencies were significantly lower than those of both the negative and positive control groups ($p< 0.05$). Additionally, ABR thresholds in the negative control group were significantly lower than those in the positive control group ($p < 0.05$).On day21, significant intergroup differences persisted across all frequencies ($p < 0.001$, $p < 0.05$). Pairwise analyses revealed that ABR thresholds of the study group remained significantly lower than those of the positive control group at all frequencies ($p = 0.001$, $p < 0.05$). Similarly, ABR thresholds in the negative control group were also significantly lower than those in the positive control group ($p=0.001$, $p < 0.05$).

CONCLUSIONS

The aqueous extract of Calendula officinalis does not exhibit ototoxic properties and may demonstrate an otoprotective effect. In light of these findings, the demonstrated otoprotective potential of this plant-derived aqueous extract in animal models may pave the way for future clinical studies investigating its applicability in external auditory canal and tympanic membrane wound healing.

OP-758

Effect Of Automated Chair Maneuver On Benign Paroxysmal Positional Vertigo: A Randomized Clinical Trial

Shankai Yin[1]

[1]*Department of Otolaryngology-Head and Neck Surgery, Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China*

BACKGROUND & AIM

Manual canalith repositioning manoeuvre (manual-CRM) and software-controlled benign paroxysmal positional vertigo (BPPV) repositioning chair (automated-CRM) are used to treat BPPV, but their comparative efficacy remains unclear due to the lack of randomized controlled clinical trials.

MATERIAL & METHODS

In this prospective, multicentre, open-label, stratified blocked randomized, parallel group clinical trial, patients with unilateral BPPV were randomly assigned to automated-CRM or Manual-CRM in 1:1 ratio. Efficacy was evaluated immediately after the first treatment and then weekly for 4 weeks. The primary outcome was the response (cured and improved) rate at week 1 post-treatment. The secondary outcomes were response rates immediately post-treatment upon enrollment; at the weeks 2, 3, and 4 follow-up assessments; and curative rates at all follow-up assessments. Analysis was applied in full analysis set (FAS) and per-protocol set (PPS). The outcome assessors and statisticians were blinded to the treatment allocations. Missing efficacy data were imputed using the last observation carried forward method.

RESULTS

A total of 406 patients were randomly assigned to treatment groups, and 404 (mean age, 47 y; 65.3% female) were ultimately included in the analysis. The response rate was significantly higher in the automated-CRM group than in the manual-CRM group (97.51 vs. 86.70%, respectively, P<0.001) at week 1 post-treatment. The response rates immediately after treatment and at the week 2 follow-up assessment were higher in the automated-CRM group than in the manual-CRM group (97.01 vs. 91.62% and 98.51 vs. 93.60%, respectively). A generalized estimation equation revealed that the response and curative rates were significantly higher in the automated-CRM group than in the manual-CRM group (response rate, OR=6.13, 95% CI=3.16–11.82; curative rate, OR=1.44, 95% CI=1.06–1.95). The adverse event rate was similar between the two groups (automated-CRM group: 39 events among 31 participants; manual-CRM group: 32 events among 28 participants).

CONCLUSIONS

Compared with the manual-CRM, the automated-CRM resulted in superior therapeutic outcomes by accelerating symptom relief and early resolution in BPPV patients.

OP-759

Facial Canal Dehiscence: Systematic Review And Meta-Analysis Of Prevalence In Healthy Subjects

Preena Patel[1], **Riccardo Ansbro**[1], **John C Hardman**[1]

[1]*Imperial College NHS Trust*

BACKGROUND & AIM

Purpose: A thorough understanding of facial canal dehiscence (FCD) is imperative for informed consent prior to otological surgery. A broad range of published rates for FCD exists, varying by method of assessment, location along the canal and year of investigation. This study aims to determine a clinically relevant prevalence of FCD in healthy populations.

MATERIAL & METHODS

Methods: A systematic review of Embase, Medline, Cochrane Library, Google Scholar, Science Direct, and Scopus identified eligible studies reporting prevalence of FCD in subjects aged ≥10 without erosive bone disease. Prevalence, location of dehiscence and method of assessment was extracted. Pooled prevalence was calculated using a random-effects model with the generic inverse variance method.

RESULTS

Results: A total of 2,186 unique studies provided 52 eligible cohorts for analysis (15,090 facial canals). The overall pooled prevalence of FCD was 22% (95% CI: 17–28%). Pooled prevalence of dehiscence in the tympanic segment varied significantly by

method of assessment (p=0.0494): radiological imaging 32% (95% CI: 15-55%), cadaveric dissection 23% (95% CI: 14-35%), and intraoperative finding 7% (95% CI: 1-29%).

CONCLUSIONS

Conclusion: This is the first clinically focused and comprehensive estimate of FCD in non-erosive ears of healthy subjects. The rate from cadaveric studies showed dehiscence in ~2 in 10 ears, whereas CT was higher at ~3 in 10, and intraoperative findings were lowest at ~1 in 10. Understanding these variations in reported rates of FCD has direct implications for preoperative risk assessment, patient counselling, and surgical planning in otological practice.

OP-760

Long-Term Ventilation Tubes: A Retrospective Comparison Between Subannular And Transtympanic Techniques

Pedro Barros[1,2], **Sofia Moutinho**[1,2], **Ricardo Vaz**[1], **Carla Pinto Moura**[1]

[1]*Department of Otorhinolaryngology, Unidade Local Saúde de São João, Porto, Portugal;* [2]*Department of Surgery and Physiology, Faculty of Medicine of University of Porto, Porto, Portugal*

BACKGROUND & AIM

Long-term middle ear ventilation is required in patients with chronic Eustachian tube dysfunction and refractory middle ear disease. Long-term transtympanic tubes are associated with significant complication rates and limited durability. Subannular tube (SAT) placement has been proposed as an alternative technique that preserves the tympanic membrane (TM) and provides prolonged ventilation.

The aim of the work was to evaluate the outcomes of subannular ventilation tubes over a 10-year period and compare their complication profile with long-term transtympanic tubes.

MATERIAL & METHODS

A retrospective cohort study was conducted including patients who underwent long-term ventilation tube placement between 2015 and 2025 at a tertiary center. Patients receiving SAT were analyzed as the primary cohort and compared with those receiving long-term transtympanic tubes. Data collected included demographics, indications, tube duration, audiological outcomes, average duration of tubes, and postoperative complications.

RESULTS

A total of 131 patients were included, 98 underwent SAT placement (150 tubes) and 33 received long-term transtympanic tubes (40 tubes). Among the subannular group, 42.9% had history of cleft palate. The mean lifespan of SAT was 36.4 months, with 8 tubes extruding within the first 6 months. This was markedly longer than the mean duration of prior transtympanic tubes in these patients (8.2 months). Mean pure-tone average improved from 37.2 dB to 17.3 dB ($p < 0.01$), while air–bone gap decreased from 28.7 dB to 10.3 dB ($p < 0.01$) following SAT insertion. During follow-up, 52.1% of patients experienced no complications. The most common complications was otorrhea (26.4%). By the end of the study, 64.6% of SAT had extruded. TM perforation occurred in 8 patients (5.3%), resolving spontaneously in 5. In contrast, persistent TM perforation following long-term transtympanic tubes was observed in 35% of cases, all requiring tympanoplasty.

CONCLUSIONS

Subannular tube placement demonstrated a favorable safety profile, with low complication rates and effective long-term middle ear ventilation. This approach appears particularly advantageous in patients with atrophic or previously operated tympanic membranes. Notably, the incidence of persistent tympanic membrane perforation was substantially lower in the subannular group compared with the transtympanic group, which exhibited higher rates of persistent perforation, frequently necessitating subsequent tympanoplasty.

OP-761

Coupled Ultra-Safe Radio Electrical Stimulation Corrects Acx-IL Transmission To Alleviate Noise-Induced Anxiety

Wenxin Shen[1], **Yueyi Shang**[1]

[1]*Department of Otolaryngology-Head and Neck Surgery, Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine*

BACKGROUND & AIM

Brain electrical stimulation holds significant promise for treating neurological and psychiatric disorders. However, current wireless and chipless electrical stimulation systems face challenges in digital logic due to the lack of dynamic energy-switching carriers. This study aims to investigate the neural circuit mechanism by which chronic exposure to moderate-intensity noise

induces anxiety-like behaviors, and to evaluate the therapeutic efficacy and mechanism of Coupled ultra-safe radio electrical stimulation (CURES) in treating noise-induced anxiety.

MATERIAL & METHODS

We developed a CURES system capable of harvesting ambient electromagnetic energy and enabling wireless electrical stimulation via a single electrode. An anxiety-like behavior model was established in mice through chronic exposure to moderate-intensity white noise [80 dB sound pressure level (SPL), 2 h/d] for 4 weeks, with CURES intervention initiated at the beginning of the third week. Viral tracing, immunofluorescence confocal imaging, and fiber photometry were employed to characterize the projection from the auditory cortex (ACx) to the infralimbic cortex (IL). Optogenetics and chemogenetics were utilized to manipulate specific neural circuits. Changes in neuronal activity following CURES intervention in awake mice were assessed using in vivo multi-electrode recordings and brain slice patch-clamp techniques.

RESULTS

Viral tracing revealed that the infralimbic cortex (IL) receives monosynaptic projections from the auditory cortex (ACx). Mice chronically exposed to moderate-intensity noise exhibited increased neuronal activity in the IL. Acute optogenetic activation of the ACx-IL pathway induced anxiety-like behaviors, while chemogenetic inactivation of this circuit abolished noise-induced anxiety-like behaviors. In vivo electrophysiological recordings and fiber photometry showed that CURES reversed this pathological activation of the IL, which play a critical role in noise-induced anxiety-like behaviors in these model mice.

CONCLUSIONS

This findings provide a further explanation of the mechanism underlying noise-induced anxiety and propose a novel wireless therapeutic strategy.

OP-762

Prognostic Value Of Volumetric 18F-FDG PET/CT Parameters (MTV And TLG) In Skull Base Osteomyelitis

Melis Senem Bal[1], **Mehmet Murat Günay**[1], **Muharrem Dağlı**[1], **Ilker Akyıldız**[1], **Samet Özlügedik**[1]

[1]*Etlik City Hospital, ENT & Head and Neck Surgery Department, Ankara, Turkey*

BACKGROUND & AIM

Skull base osteomyelitis (SBO) is a rare, life-threatening infection associated with high mortality. Due to the insidious nature of the disease, conventional radiological methods can lead to false-negative diagnoses. PET/CT is gaining prominence as it offers earlier disease assessment. However, current practice relies predominantly on SUVmax, a single-voxel metric that may inadequately reflect the true inflammatory burden of this heterogeneously spreading infection. Metabolic Tumor Volume (MTV) and Total Lesion Glycolysis (TLG) capture the volumetric metabolic burden of the lesion. This study aimed to evaluate whether baseline volumetric PET parameters predict clinical remission in SBO patients.

MATERIAL & METHODS

We retrospectively evaluated an analytical cohort of 29 patients diagnosed with SBO. For this specific prognostic analysis, a subgroup of 12 patients who underwent baseline 18F-FDG PET/CT prior to treatment were included. Clinical findings, systemic inflammatory markers (CRP, ESR, WBC), and PET metrics (SUVmax, MTV, TLG) were recorded. Outcomes were categorized as clinical remission or mortality. Predictive performance was evaluated using ROC curve analysis, and independent predictors of remission were identified using Firth penalized logistic regression.

RESULTS

All patients had diabetes mellitus and 66.7% presented with cranial nerve palsies. Remission was achieved in 41.7% of patients. All three PET parameters were significantly lower in patients achieving remission (SUVmax p=0.030, MTV p=0.017, TLG p=0.009). MTV and TLG demonstrated strong correlations with systemic inflammatory markers (MTV–CRP: r=0.764, p=0.006; TLG–CRP: r=0.764, p=0.006), while SUVmax showed no significant correlation with CRP or ESR. ROC analysis yielded AUC values of 0.967 for TLG, 0.933 for MTV, and 0.900 for SUVmax. MTV ≥11.57 cm^3 and TLG ≥37.20 provided 100% sensitivity with 83.3% specificity; a TLG cut-off of 18.20 achieved 100% specificity for predicting clinical remission. In Firth logistic regression, TLG was the only statistically significant independent predictor of non-remission (OR=0.95, 95% CI: 0.84–0.99, p=0.008). Overall mortality was 41.7%. Notably, chronic kidney disease was associated with failure to achieve remission in all affected patients (p=0.038).

CONCLUSIONS

Volumetric PET/CT parameters (MTV and TLG) provide superior prognostic information compared to SUVmax in SBO and have higher correlation with systemic inflammatory burden. Integrating MTV and TLG into the SBO risk classification, rather than simply using SUVmax, can strongly guide clinicians in determining the treatment protocol and duration of targeted antimicrobial therapy.

Histologic Correlates Of European Academy Of Otology-Neurotology/Japan Otologic Society (EAONO/JOS) Cholesteatoma Classification

Nadir Yıldırım[1], **Sercan Şimşek**[2], **Fikret Zeybek**[1], **Mehmet Varol**[3]

[1]*Department of Otorhinolaryngology, Kütahya Health Sciences University, Kütahya, Türkiye;* [2]*Department of Pathology, Evliya Çelebi Training and Research Hospital, Kütahya, Türkiye;* [3]*Department of Otorhinolaryngology, Kütahya City Hospital, Kütahya, Türkiye*

BACKGROUND & AIM

Current classification of acquired middle ear cholesteatoma (MEC), devised by EAONO/JOS (2017) divides it into 7 groups: the ones originated from retraction pockets in pars tensa (PTRP), in pars flaccida (PFRP), involving both pars tensa and flaccida (PTPFRP); tympanic membrane (TM) perforation originated (TMP); traumatic/iatrogenic (TI); residual (Res) and recurring (Rec) MECs. Cholesteatoma is a clinical diagnosis; therefore, histopathologic confirmation is rarely indicated. We, however, routinely examine surgical samples to rule out pathologies that superposed or mixed with MEC. The aim of this study is to test the histologic relevance of the clinical MEC classification of EAONO/JOS.

MATERIAL & METHODS

The study was conducted on the pathologic archive specimens from consecutive patients allocated to the above groups (excluding TI) retrospectively. Additionally, PTRP cholesteatomas were split into two groups: sinus tympani (ST) and adhesion-originated (Adh) ones. Following parameters were looked for in the Hematoxylene&Eosine stained slides in both matrix and perimatrix and graded 0-3 according to the number or size: neutrophil, plasma cell, lymphocyte, fibroblast, keratinocyte counts; neovascularization and epithelium thickness. Presence of Langhans giant cells, tympanosclerotic plaques, cholesterin clefts, basal membrane defects were taken as binary variables.

RESULTS

Inflammatory cells were most numerous in PFRP matrix and perimatrix, least numerous in ST matrix. In perimatrix no significant difference was found in any parameter between the groups except residues, Acanthosis and keratinocyte hyperplasia was present in all, yet, more intensely in pars flaccida involving groups. Basal membrane gaps appeared only in two of the specimens.

CONCLUSIONS

These findings indicated predominance of inflammatory cells and metaplastic changes across the groups. Basal membrane defects do not seem to play a major role in MEC pathogenesis. Histologic differences among the groups correspond with clinical categories. However, pars tensa retraction origin ST and Adh groups somewhat differ histologically.

OP-764

Complications, Endoscopic Versus Microscopic Ear Surgery, Is There Any Difference? A 19-Year Institutional Experience (2007-2026)

Dr Hammaad Khan[1], **Professor Arunachalam Iyer**[1], **Dr Ahmed Elnour**[2]

[1]*University Hospital Monklands;* [2]*Queen Elizabeth University Hospital*

BACKGROUND & AIM

Endoscopic ear surgery (EES) has emerged as an alternative or adjunct to conventional microscopic ear surgery (MES), offering improved visualisation of middle ear recesses and potentially reducing the need for more invasive approaches. Despite increasing adoption, concerns remain regarding complication rates and the technical demands of single-handed surgery. This study evaluates the safety profile of endoscopic and microscopic ear surgery.

MATERIAL & METHODS

A retrospective review of ear surgeries performed between 2007 and 2026 at our otology centre was undertaken using a prospective audit database. Procedures were categorised as purely endoscopic, endoscopic with microscopic assistance, or purely microscopic. Procedures included myringoplasty, ossiculoplasty, stapedectomy, and cholesteatoma surgery, including atticoantrostomy. Post-operative complications were identified from clinical records.

RESULTS

A total of 1,030 procedures were analysed. Of these, 510(49.5%) were performed solely endoscopically, 139 (13.5%) used an endoscopic approach with microscopic assistance, and 381 (37.0%) were performed solely using the operating microscope.

Overall, 141 complications were recorded (13.7%). Majority being minor postoperative complaints, most commonly otalgia followed by infection. Less frequent complications included numbness, dizziness, and tinnitus. Intraoperative division of the chorda tympani occurred in 279 cases, 167 in microscopic cases and 112 in endoscopic or combined techniques. No major complications, such as dead ear or permanent facial palsy, were observed.

CONCLUSIONS

Both endoscopic and microscopic ear surgery demonstrate acceptable safety profiles across a range of otological procedures. Most complications were minor and self-limiting. Endoscopic techniques represent a safe and effective alternative to conventional microscopic surgery in this large institutional series.

OP-765

Correlation Of Radiologic And Audiometric Findings In Patients With Otosclerosis

Carolina da Fonseca Mussel Jones[1], **Mauricio Noschang Lopes da Silva**[1], **Leticia Rossetto Daudt**[1], **Fabio Andre Selaimen**[1], **Sady Selaimen da Costa**[1]

[1]*Hospital de Clínicas de Porto Alegre, Porto Alegre, Rio Grande do Sul, Brasil*

BACKGROUND & AIM

The study objective was to compare computed tomography (CT) findings with audiometric thresholds in patients with otosclerosis.

MATERIAL & METHODS

The Study type was a cross-sectional observational study. Diagnosis was based on history, audiometry, and temporal bone CT, with all patients evaluated before treatment. Audiometry used four-frequency pure-tone averages for air conduction, bone conduction, and the air–bone gap (ABG). Patients were grouped as follows: A) otosclerotic foci at the fissula ante fenestram (FAF); B) foci at the FAF and retrofenestral regions; C) foci at the FAF and retrofenestral regions with cochlear endosteum involvement.

RESULTS

We evaluated 196 ears: 133 with lesions limited to the FAF (Group A), 26 with retrofenestral foci (Group B), and 37 with cochlear endosteal involvement (Group C). Mean four-frequency averages were: Group A—bone 30.61 dB, air 60.96 dB, ABG 30.59 dB; Group B—bone 46.06 dB, air 78.38 dB, ABG 32.5 dB; Group C—bone 61.92 dB, air 97.58 dB, ABG 33.98 dB. Bone and air conduction thresholds differed significantly across groups, worsening with increasing pericochlear and intracochlear involvement. The ABG remained similar among groups, likely reflecting audiometric limitations in isolating the conductive component as sensorineural loss progresses. Notably, Group A showed bone thresholds >30 dB, diverging from reports describing purely conductive loss in fenestral disease. We also introduce a category for lesions involving the cochlear endosteum, supporting the hypothesis that pericochlear and intracochlear foci are associated with more pronounced sensorineural impairment.

CONCLUSIONS

Progression of otosclerotic foci to pericochlear and intracochlear regions is associated with worse hearing thresholds. Even lesions confined to the FAF may present as mixed hearing loss.

OP-766

Management Of Patulous Eustachian Tube: Experience From A Tertiary Referral Center With More Than 100 Cases

Saleh Alamry[1]

[1]*Prince Sultan Military Medical City (PSMMC)*

BACKGROUND & AIM

Patulous Eustachian tube (PET) is an uncommon but troublesome condition that can cause ear fullness, autophony, pulsatile tinnitus, and even clicking sounds. It may arise without a clear cause or develop after weight loss from diet, exercise, medication, or bariatric surgery. In this study, we share our experience treating over 100 patients and highlight a practical, stepwise strategy for management.

MATERIAL & METHODS

Patients with PET symptoms were carefully evaluated for possible causes and contributing factors. Treatment began with conservative measures, such as encouraging weight gain in underweight patients. If symptoms persisted, medical therapies were introduced. For those who did not respond, surgical options were considered. Each treatment plan was tailored to the patient's individual condition and severity of symptoms.

RESULTS

More than 100 patients were treated using this structured approach. Many with low body weight improved after regaining weight. Others experienced relief with medical therapy, while a smaller number required surgery. Across all groups, most

patients reported noticeable improvement in their symptoms—particularly in ear fullness, autophony, and tinnitus. Outcomes varied depending on the underlying cause, but the stepwise approach consistently provided benefit.

CONCLUSIONS

PET remains a challenging condition because of its diverse presentations and causes. Our experience shows that beginning with simple, conservative options, moving to medical therapy when needed, and reserving surgery for resistant cases is both effective and patient-centered. When treatment is individualized, most patients achieve meaningful relief and improved quality of life.

OP-767

A NEW TYMPANOPLASTY TECHNIQUE WITH THE COMBINED USE OF BILATERALLY STRIPPED CARTILAGE AND PERICHONDRIAL GRAFTS

Ramazan bahadır küçük[1], **Sabri Baki Eren**[1], **Fadlullah Aksoy**[1], **Erol Senturk**[1], **Remzi Dogan**[1], **Alper Yenigun**[1], **Çagrı Yildiz**[1], **Orhan Ozturan**[1]

[1]*Bezmialem Vakif University, Faculty of Medicine, Department of Otorhinolaryngology*

BACKGROUND & AIM

Tympanoplasty aims not only to close tympanic membrane perforations but also to restore long-term anatomical stability and hearing function. Since cartilage grafts may bend, curl, or displace despite their durability, this study hypothesized that bilaterally perichondrium-stripped cartilage combined with a separate perichondrial graft may provide superior anatomical stability compared with conventional cartilage techniques.

MATERIAL & METHODS

This ethics-approved retrospective comparative clinical study reviewed 391 patients operated on for chronic otitis media, tympanic membrane perforation, and/or cholesteatoma between February 2019 and February 2025. After eligibility assessment, 281 patients were included. The main analysis included 228 cholesteatoma-free tympanoplasty patients divided into three graft groups: bilaterally stripped cartilage with a separate perichondrial layer, cartilage island graft, and accordion cartilage graft. Cholesteatoma cases requiring mastoidectomy were analyzed separately. Demographic, clinical, surgical, audiological, MERI, and CES data were recorded. Anatomical success was defined as intact graft without perforation, significant retraction, lateralization, or persistent otorrhea. Functional success was defined as postoperative ABG ≤20 dB. Parametric/non-parametric tests and logistic regression were used.

RESULTS

Anatomical success was highest in the bilaterally stripped cartilage with separate perichondrial layer group (98.4%), compared with the cartilage island graft (87.0%) and accordion cartilage graft groups (86.3%). Functional success and postoperative audiological outcomes were better particularly in the accordion cartilage group. However, all three groups showed significant postoperative improvement in audiological parameters and patient-reported CES outcomes. Anatomical failure was associated with previous surgery, postoperative infection, higher MERI score, and ossicular chain repair. Functional failure was associated with poorer audiological values, higher MERI score, and ossicular reconstruction. Additional analyses suggested stronger anatomical stability with bilaterally stripped cartilage, whereas techniques preserving unilateral perichondrium may provide functional advantages.

CONCLUSIONS

The bilaterally stripped cartilage and perichondrial graft technique appears reliable for achieving anatomical stability, especially in high-risk ears. However, anatomical superiority did not fully translate into functional superiority, indicating that hearing outcomes also depend on middle ear pathology and ossicular chain status.

OP-768

Anatomical Bony Defects In Revision Mastoidectomy: A 16-Year Single-Center Retrospective Study Of Tegmen, Facial Canal And Lateral Semicircular Canal Involvement

İbrahim Ömer Gürlek[1], **Tuğba Küpeli Sarı**[1], **Burak Kaan İnan**[1], **Bahar Atasoy Badur**[2], **Zahide Mine Yazıcı**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, University of Health Sciences, Bakırköy Dr. Sadi Konuk Training and Research Hospital, Istanbul, Türkiye;* [2]*Department of Radiology, University of Health Sciences, Bakırköy Dr. Sadi Konuk Training and Research Hospital, Istanbul, Türkiye*

BACKGROUND & AIM

Revision mastoidectomy is frequently required in patients with residual or recurrent cholesteatoma and is often associated with bony defects of the tegmen, facial canal, and lateral semicircular canal, which may complicate surgical management. Recognizing the distribution of these defects and the factors predisposing to revision surgery is important for surgical planning and postoperative follow-up. This study aims to evaluate the demographic characteristics, intraoperatively identified anatomical defect patterns, and predisposing factors for revision surgery in patients undergoing revision mastoidectomy for residual or recurrent disease.

MATERIAL & METHODS

A total of 617 mastoidectomy operations performed at our clinic between 2010 and 2026 were retrospectively reviewed. Patients without MRI follow-up, those with inaccessible or off-site MRI scans, cases whose primary surgery had been performed at an outside institution, patients with malignancy, pediatric patients operated for acute mastoiditis, mastoid abscess cases, and patients with incomplete pathology data were excluded. After applying these criteria, 313 mastoidectomy operations performed in 270 patients aged 2 to 75 years, all of whom had undergone primary surgery at our clinic, were included and retrospectively evaluated. All patients underwent a minimum of three non-EPI diffusion-weighted MRI examinations over a follow-up period of at least one year. The associations of tegmen, facial canal, and lateral semicircular canal defects, as well as pediatric age, with the need for revision surgery were evaluated using descriptive statistics.

RESULTS

During the study period, 270 patients (52 pediatric, 218 adult) were included; 230 underwent a single operation, while 40 (14.8%) required revision surgery for residual or recurrent disease. Of the 52 pediatric patients, 19 (36.5%) underwent revision, compared to 21 (9.6%) of the 218 adults (12 males, 9 females). Intraoperative evaluation revealed no bony defect in 23 revision patients (57.5%), while isolated or combined defects were identified in 17 (42.5%). Isolated defects involved the tegmen in 2 (5%), facial canal in 4 (10%), and lateral semicircular canal in 4 (10%). Multi-site involvement was observed in 7 patients: combined facial canal and lateral semicircular canal defects in 4, tegmen and facial canal in 1, tegmen and lateral semicircular canal in 1, and all three sites in 1. Overall, tegmen, facial canal, and lateral semicircular canal defects were present in 5 (12.5%), 10 (25%), and 10 (25%) revision patients, respectively.

CONCLUSIONS

The high proportion of pediatric cases among revisions is consistent with the literature describing the more aggressive course of childhood cholesteatoma. Bony defects detected in nearly half of the revision cases represent a notable finding regarding disease extension and surgical planning, with the coexistence of lateral semicircular canal and facial canal defects being particularly prominent. Adequate disease eradication and complete clearance of the aeration system at the primary surgery remain critical to reducing revision rates. Non-EPI diffusion-weighted MRI stands out as a reliable tool for the early detection of residual or recurrent disease, potentially decreasing the need for second-look surgery.

OP-769

Reducing Cholesteatoma Recidivism: Evidence From A 5-Year Follow-Up Case-Control Study Of Canal-Wall-Up Surgery With Or Without Bioactive Glass Obliteration

Daniele Bernardeschi[1], **Matteo Di Bari**[1], **Hugo Delille**[1,2]

[1]*Hôpital Pitié Salpétrière, Paris, France;* [2]*Sorbonne Université*

BACKGROUND & AIM

The aim of this study was to compare canal-wall-up tympano- mastoidectomy with or without mastoid and epitympanic obliteration, and to estimate the 5-year recidivism rate using Kaplan–Meier survival analysis.

MATERIAL & METHODS

This retrospective cohort study included 172 consecutive ears diagnosed with cholesteatoma that underwent canal wall–up tympanomastoidectomy between January 2008 and December 2019. Patients were divided into two groups according to whether mastoid obliteration was performed using S53P4 bioactive glass granules (BAG group) or not (NO group). The intervention of interest was mastoid obliteration with S53P4 bioactive glass.

RESULTS

In our population cholesteatoma recidivism rate was 18% in the NO group and 5% in the S53P4 group ($p<0.01$). The overall cholesteatoma-free survival rate at 5- year, calculated with the log-rank test for survival analysis, was 87.8% (95% CI, 77.4- 99) in the S53P4 group and 58.2% (95% CI, 42.6-79.5) in the NO group ($p<0.01$). The recurrent cholesteatoma-free survival rate at 5-year was 89% (95% CI, 79.1-100) in the S53P4 group and 65.8% (95% CI, 49.4-87.6) in the NO group. Recurrent disease significantly differed between the 2 groups ($p = 0.018$).

CONCLUSIONS

Mastoid and epitympanic obliteration using S53P4 bioactive glass significantly reduced the recurrence of cholesteatoma in patients undergoing canal- wall-up tympano-mastoidectomy. These findings suggest a potential benefit of obliteration when mastoidectomy is required.

VROOM – Virtual Reality Intervention For Outcomes In Ongoing Motion Sickness: A Pilot Study

Louise Devantier[1]

[1]*Department of Otorhinolaryngology – Head and Neck Surgery, Aarhus University Hospital, Denmark*

BACKGROUND & AIM

Motion sickness (MS) affects roughly one-third of adults in provocative environments and substantially impairs daily functioning. Pharmacological options are limited by side effects, and no standardized non-pharmacological treatment exists. Virtual reality (VR) enables controlled, graded visuo-vestibular exposure and may promote sensory adaptation, but its role in everyday MS is poorly investigated. This pilot evaluates the feasibility, tolerability and preliminary efficacy of a 4-week VR program using the Virtualis platform in adults with moderate to severe MS. We hypothesize the intervention is feasible, well tolerated, and reduces symptom severity from baseline.

MATERIAL & METHODS

Prospective single-arm study at Aarhus University Hospital. Up to 40 adults (≥18 years) with moderate to severe MS, confirmed by the Motion Sickness Susceptibility Questionnaire–short (MSSQ-short), are recruited via social media. Participants attend 2–3 supervised sessions/week for 4 weeks (8–12 sessions, 20–30 min) of graded optokinetic stimulation, optical flow, sea simulation and visuo-vestibular conflict tasks following habituation principles. Pre/post assessment includes Sensory Organization Test, Visual Motion Sensitivity and Rod and Frame Test. Primary outcome: change in Motion Sickness Assessment Questionnaire (MSAQ) from baseline (T0) to post-intervention (T1). Secondary outcomes: adherence, drop-out, per-session nausea/dizziness ratings (0–10), and persistence at 3-month follow-up (T2). Paired analyses with 95% confidence intervals will be performed.

RESULTS

Recruitment is ongoing; baseline characteristics, feasibility metrics and within-subject MSAQ changes will be presented at the congress.

CONCLUSIONS

This pilot will establish whether VR-based visuo-vestibular training is feasible and tolerable in adults with MS, and provide effect estimates to inform a future randomized controlled trial.

OP-771

Turkish Adaptation And Preliminary Validation Of The Otology Questionnaire Amsterdam

Kadir Emre KILIÇ[1], **Emel TAHİR**[1]

[1]*Department of Otorhinolaryngology , Faculty of Medicine, Ondokuz Mayıs University , Samsun, TURKEY*

BACKGROUND & AIM

Patient-reported outcome measures (PROMs) are essential for evaluating symptom severity and quality of life in otology. The Otology Questionnaire Amsterdam (OQUA) is a validated generic PROM assessing multiple ear complaints and their impact. This study aims to perform cross-cultural adaptation of the OQUA into Turkish and to evaluate its reliability, validity, and responsiveness

MATERIAL & METHODS

This is a single-center, prospective methodological study conducted in a tertiary otolaryngology clinic. Adult patients presenting with ear complaints were included. The Turkish version of OQUA (OQUA-TR) was administered at baseline. Test–retest reliability was assessed in clinically stable non-surgical patients with repeated administration after 7–14 days. In surgical patients, the questionnaire was applied preoperatively and at 3-month follow-up to assess responsiveness. Internal consistency was evaluated using Cronbach's alpha, and test–retest reliability was analyzed using intraclass correlation coefficient (ICC). Construct validity was planned using confirmatory factor analysis. Descriptive statistics were used for demographic and clinical characteristics.

RESULTS

A total of 110 patients have been included to date. Of these, 38 were surgical patients who completed preoperative assessment, and 20 completed postoperative 3-month follow-up. Test–retest analysis was performed in 40 non-surgical

patients. Data collection is ongoing, with a target sample size of approximately 200 participants. Preliminary data indicate good feasibility and patient compliance with the questionnaire. Final statistical analyses, including reliability and validity assessments, are currently in progress.

CONCLUSIONS

The Turkish adaptation of the OQUA appears feasible in clinical practice. Upon completion, this study is expected to provide a valid and reliable PROM for assessing ear-related symptoms and treatment outcomes in Turkish-speaking populations.

otology, questionnaire validation, reliability analysis, quality of life

OP-772

Evaluation Of The Impact Of Magnetic Resonance Imaging Device Noise On Hearing In Radiology Technicians

Cevahir Bulut Turay[1], **Rashad Gadirli**[1], **Berkay Arslan**[2], **Isilay Öz**[1], **Levent Naci Ozluoglu**[1]

[1]*Department of Otorhinolaryngology, Başkent University Faculty of Medicine, Ankara, Turkey;* [2]*Health Sciences Faculty, Department of Audiology, Atılım University, Ankara, Turkey*

BACKGROUND & AIM

This study was designed to evaluate the effects of exposure to high levels of acoustic noise generated by MRI devices on the auditory system of radiology technicians working with such equipment.The sounds produced during the operation of MRI devices can exceed 100 dB and with prolonged exposure,may lead to irreversible cochlear damage. In this context, the aim of the study was to assess the cochlear functions of radiology technicians working with MRI devices by comparing them with a healthy control group of similar age and professional background who do not work with MRI

MATERIAL & METHODS

The study included 34 radiology technicians aged between 21 and 48 years, and 32 control group participants aged between 21 and 45 years. All participants underwent comprehensive audiological evaluations. These evaluations included Pure-Tone Audiometry, High-Frequency Audiometry, Transient Evoked Otoacoustic Emissions , Distortion Product Otoacoustic Emissions , and the Tinnitus Handicap Inventory . Additionally, 15-minute noise measurements were conducted in the MRI rooms where the technicians worked, and the peak instantaneous sound level was found to reach up to 105.1 dB

RESULTS

When comparing the MRI technicians to the control group, no statistically significant differences were found in the TEOAE and DPOAE results. However significant differences were observed in the results of Pure-Tone Audiometry and High-Frequency Audiometry. In PTA, threshold shifts were observed at 500 Hz and at 1000 Hz ($p< 0.05$) in both ears. Within the study group, when comparing the ear closer to the MRI room door with the opposite ear, asymmetric threshold shifts were observed at 4000 Hz, 6000 Hz and 8000 Hz ($p < 0.05$). In the High-Frequency Audiometry results, significant differences were observed between the study and control groups in the ear closer to the door at 10,000 , 12,500 , 14,000 , 16,000 and 18,000 Hz and in the ear farther from the door at 16,000 Hz ($p<0.05$).Furthermore within the study group, an asymmetric threshold shift was detected at 16,000 Hz when comparing the two ears

CONCLUSIONS

In conclusion, long-term exposure to MRI device noise in radiology technicians may result in hearing loss, particularly at high frequencies. These findings highlight the necessity of implementing noise control measures and promoting the use of hearing protection equipment to preserve the auditory health of personnel working in clinical environments

OP-773

Focused Ultrasound-Mediated Drug Delivery Of Bevacizumab In Treating NF2-Related Schwannomatosis In An Animal Model.

Jennifer L. Spiegel[1], **Joseph Chen**[1], **Vincent Lin**[1], **Trung Le**[1]

[1]*Sunnybrook Research Institute, University of Toronto, Canada*

BACKGROUND & AIM

Neurofibromatosis type 2 (NF2)-related schwannomatosis is an autosomal dominant genetic disorder characterized by the development of cranial and peripheral nerve schwannomas, including bilateral vestibular schwannomas which are associated with substantial morbidity. Current therapeutic strategies comprise surgical resection, radiotherapy, and systemic administration of bevacizumab; however, these approaches are frequently limited by high recurrence rates and morbidity.

MATERIAL & METHODS

In this study, a transgenic murine model (Postn-Cre;Nf2flox/flox) was employed to investigate the combined effect of intraperitoneally administered human bevacizumab (5 mg/kg b. w.) and focused ultrasound (FUS) on drug delivery and tumor growth in DRG schwannomas.

RESULTS

ELISA-based analysis demonstrated a 3.8-fold increase in intratumoral bevacizumab concentration following the combined application of human bevacizumab and FUS, compared to bevacizumab alone. Tumor growth was assessed using 7-tesla MRI of the spine with intravenous gadolinium contrast, and outcomes were compared across five experimental groups: 1) human bevacizumab alone, 2) murine bevacizumab alone, 3) human bevacizumab combined with FUS, 4) FUS alone, and 5) untreated controls. Treatments, including drug administration and FUS exposure, were performed three times at two-week intervals.

CONCLUSIONS

The combined treatment group (human bevacizumab + FUS) exhibited a trend toward tumor size reduction.

OP-774

Clinical Outcomes Of Revision Cochlear Implantation

Osman Turgut SAHAN[1], **Elif BAYSAL**[2]

[1]*Kahramanmaras Necip Fazıl City Hospital;* [2]*Gaziantep University Medicine Faculty, Department of Otolaryngology*

BACKGROUND & AIM

This study aims to identify the reasons for revision of cochlear implant surgeries.

MATERIAL & METHODS

This study was conducted retrospectively between January 2010 and January 2024. A total of 1,348 cochlear implants were applied to 1,267 patients. The reasons for revision were classified into two main groups: device-related failures and medical causes. Revision surgery included both revision and reimplantation procedures.

RESULTS

Out of the 1,348 cochlear implantation surgeries, 69 underwent revision surgery (5.1%). Among these patients, 66 were children (95.6%) and 3 were adults (4.4%)Surgical intervention was performed in 68 patients due to hard failure (%98,5), whereas one patient underwent surgery for a soft failure.Reimplantation was performed in 59 patients (85.5%), while revision surgery without reimplantation was performed in 10 patients (14.5%). The most common cause of reimplantation was external trauma, observed in 54 patients (91.5%). The mean interval between the initial cochlear implantation and subsequent revision surgery was approximately 45 months in the pediatric group and 77 months in the adult group. Four patients underwent revision surgery twice due to recurrent head trauma, while one patient required two revision procedures due to medical complications.

CONCLUSIONS

Recently cochlear implantation is the most effective treatment option for profound sensorineural hearing loss. As the number of cochlear implant surgeries increases, the number of revision surgeries is rising as well. In the pediatric population, the high incidence of external trauma may be attributed to early implantation combined with vestibular issues and frequent falls during the learning-to-walk phase.

OP-775

Clinical Value Of Systemic Inflammatory Indexes In Pediatric Acute Complicated Mastoiditis: A Retrospective Study

Selin Üstün Bezgin[1], **Begüm Bahar Yılmaz**[1], **Safiye Giran Örtekin**[1], **Nursena Nair Polat**[1], **Berra Şerefoğlu**[1], **Kaan Uncu**[1], **Özgür Yiğit**[1]

[1]*Basaksehir Cam and Sakura City Hospital, Otorhinolaryngology Department*

BACKGROUND & AIM

Acute mastoiditis is the most common intratemporal complication of acute otitis media. Most cases follow a benign course, however some cases of acute mastoiditis can progress to life-threatening serious complications, and currently there are no reliable predictors of such complications. The aim of this study is to evaluate the diagnostic and prognostic value of inflammatory indexes in pediatric patients with acute mastoiditis and its advanced complications such as subperiostal abscess, sigmoid sinus trombus, meningitis.

MATERIAL & METHODS

This single-center retrospective study included 43 patients under 18 years of age who were hospitalized and operated for acute mastoiditis and its related complications. Patients were divided into two groups: Group 1 (n=16) with isolated acute mastoiditis and Group 2 (n=27) with acute mastoiditis and its advanced complications. Demographic, clinical, and laboratory data of the patients were analyzed. Inflammatory indexes, including neutrophil-to-lymphocyte ratio, platelet-to-lymphocyte ratio, systemic immune-inflammation index (SII), systemic inflammatory response index (SIRI), and multiple inflammatory indices (MII 1-3), were calculated.

RESULTS

No significant differences were observed between Group 1 and Group 2 in terms of demographic characteristics, laboratory parameters, or inflammatory indexes ($p>0.05$). However, length of hospital stay showed a moderately positive correlation with SIRI ($r=0.419$, $p=0.005$) and a weak positive correlation with SII ($r=0.341$, $p=0.025$). In patients with advanced complications (Group 2), both SII ($r=0.529$, $p=0.005$) and SIRI ($r=0.492$, $p=0.009$) showed stronger correlations with length of hospital stay. No significant association was observed between C-reactive protein values.

CONCLUSIONS

Inflammatory indexes did not differentiate between isolated mastoiditis and advanced complications. SII and SIRI correlated with length of hospital stay, an important indicator of disease severity, suggesting their potential usefulness as prognostic markers. This suggests that cellular immune response-based indices may provide greater clinical benefit in predicting disease course than traditional inflammatory markers.

OP-776

BEYOND THE AURICLE: CRANIAL NERVE POLYNEURITIS AS A RARE COMPLICATION OF RAMSAY HUNT SYNDROME

Marta Santiago Horcajada[1], **Asier Blanco Goñi**[1], **Araly Hivama Chacón Uribe**[1], **Fernando González Galán**[1], **Luz López Flórez**[1], **José Miguel Villacampa Aubá**[1]

[1]*Fundación Jiménez Díaz University Hospital*

BACKGROUND & AIM

Ramsay Hunt syndrome (RHS) is an uncommon condition caused by varicella-zoster virus (VZV) reactivation in the geniculate ganglion, presenting typically with facial paralysis, otalgia, and auricular vesicles. While involvement of cranial nerves VII and VIII is typical, multiple cranial neuropathies are rare complications associated with poorer prognosis and significant morbidity. The pathogenesis involves direct perineural spread of viral inflammation between contiguous cranial nerves and vasculopathy of arteries supplying multiple cranial nerves. This case aims to describe the clinical progression and outcomes of a patient with RHS who developed cranial multineuritis.

MATERIAL & METHODS

A 28-year-old male with no medical history presented to our emergency department with one-week history of fever, severe right otalgia, ipsilateral hearing loss, dizziness, and right facial paralysis (House-Brackmann III). Diagnostic workup included otoscopy, audiometry, neurological examination, brain MRI, and cerebrospinal fluid (CSF) analysis. With a suspected diagnosis of RHS treatment consisted of intravenous corticosteroids, vestibular suppressants and acyclovir.

RESULTS

Initial examination revealed right sensorineural hearing loss, vestibular dysfunction with right lateralization and right peripheral facial paralysis. Within 24 hours, vesicular lesions appeared on the right auricle, confirming RHS. Despite treatment, the patient developed left facial paralysis (House-Brackmann III) and bilateral trigeminal hypoesthesia. MRI showed right facial neuritis. CSF revealed lymphocytic pleocytosis and hyperproteinorraquia with negative PCR (under acyclovir), consistent with lymphocytic meningitis. Final diagnosis was VZV cranial multineuritis affecting nerves V, VII (bilateral), and VIII (right). After 14 days of intravenous acyclovir, progressive pain improvement and partial facial function recovery were achieved, though residual right hearing loss persisted.

CONCLUSIONS

This case demonstrates that RHS can progress to multineuritic forms despite early antiviral therapy. Positive outcomes included recovery of facial motor and sensory function and pain resolution with prolonged antiviral treatment. However, persistent sensorineural hearing loss indicates that auditory sequelae may be irreversible. A multidisciplinary assesment, exahustive initial neurological examination and close monitoring in RHS patients is essential for early recognition of progressive symptoms and prompt treatment escalation to optimize outcomes in these rare complications

OP-777

Regenerative Medicine In Otology: Clinical Outcomes Of Mesenchymal Stem Cell Therapy For Tympanic Membrane Perforations

Svistushkin Mikhail[1], **Nikiforova Galina**[1], **Zinchenko Igor**[1], **Timashev Petr**[1]

[1]*Sechenov First Moscow State Medical University (Sechenov University) Moscow, Russia*

BACKGROUND & AIM

Repair of persistent tympanic membrane perforations remains a relevant problem in otorhinolaryngology. Despite the undeniable gold standard of tympanoplasty and myringoplasty, there is a need for the development of minimally invasive occlusion methods. This is due to the large number of patients with central perforations not requiring revision of the tympanic cavity, the native membrane's potentially better sound conduction, and the desire to reduce overall surgical trauma. This study aimed to evaluate the efficacy and safety of topical administration of a cell product—human autologous adipose-derived mesenchymal stromal cell spheroids—for repairing persistent central perforations.

MATERIAL & METHODS

The study included 8 patients with central tympanic membrane perforations (mean duration 3.7 years, diameter 6.7 mm ± 1.8 mm, air-bone gap 27 dB). Inclusion criteria: positive ETF test, no CT changes of the temporal bones, and no otorrhea for ≥4 months. Ethical approval was obtained (Protocol No. 12-24). The two-stage treatment began with an abdominal wall biopsy (2 cm^3 adipose tissue). After 4–6 weeks, the cell product (2×10^6 MSCs as spheroids, $\geq1\times10^3$ cells/spheroid in 1 mL saline) was applied. In the second stage, perforation edges were de-epithelialized, and spheroids were injected into the edges and the area near the fibrous ring adjacent to the defect. A gelatin sponge was placed and secured with fibrin glue.

RESULTS

Tympanic membrane perforations closed in 7 out of 8 patients (87.5%). The mean healing time was 21 days [range 17–26 days]. One patient developed otorrhea on day 2, requiring topical antibacterial therapy, and perforation closure was not achieved. No other adverse reactions were observed. On otoscopy, the area of the closed perforation appeared as tissue nearly indistinguishable from the intact areas and did not prolapse during the Valsalva maneuver. The mean air-bone gap reduction was 22 ± 4 dB.

CONCLUSIONS

This pilot study demonstrates the efficacy and safety of adipose-derived MSC spheroids for persistent tympanic membrane perforations. The 87.5% closure rate with a mean healing time of 21 days and a 22 ± 4 dB air-bone gap reduction confirms functional restoration. Regenerated tissue closely resembled native membrane both otoscopically and functionally. One failure occurred due to postoperative infection; no adverse reactions were noted. Building on preclinical success in the regeneration of vibrating ENT tissues [1,2], this minimally invasive approach offers an alternative to traditional tympanoplasty for central perforations while preserving native properties. Further studies with larger cohorts are warranted.

OP-778

The Role Of The Trigeminovascular Unit Of The Inner Ear In Cochlear And Vestibular Disorders

Fady Bou Malhab[1], **Jad Hosri**[2], **Nadine El Hadi**[3], **Romain Kania**[4], **Usamah Hadi**[2]

[1]*Department of Otolaryngology-Head & Neck Surgery, Saint Joseph Hospital, Beirut, Lebanon;* [2]*Department of Otolaryngology-Head & Neck Surgery, American University of Beirut Medical Center, Beirut, Lebanon;* [3]*Department of Otolaryngology-Head & Neck Surgery, Lebanese American University Medical Center - Rizk Hospital, Beirut, Lebanon;* [4]*Department of Otolaryngology-Head & Neck Surgery, Lariboisiere University Hospital, Paris, France*

BACKGROUND & AIM

The inner ear relies on a specialized neurovascular network to preserve hearing and balance. Central to this system is the trigeminovascular unit (TVU), composed of trigeminal sensory fibers, endothelial cells, pericytes, and extracellular matrix elements that coordinate cochlear and vestibular blood flow, blood–labyrinth barrier integrity, ionic homeostasis, and neuronal support. This systematic review aimed to synthesize current evidence on the structural and functional organization of the TVU within the cochlea and vestibular labyrinth and to clarify how TVU dysfunction may contribute to common cochleovestibular disorders.

MATERIAL & METHODS

A systematic review of the literature was conducted to identify studies describing the distribution and roles of TVU components in key inner ear regions, including the stria vascularis, dark cell region, spiral ganglion, Scarpa's ganglion, and their associated microvasculature. Data were extracted on endothelial and pericyte functions in vascular tone, permeability, and ionic balance; neurotrophic and neuroimmune interactions supporting neuronal homeostasis; and the modulatory influence of trigeminal C-fiber–derived neuropeptides, particularly calcitonin gene-related peptide and substance P. Findings were

qualitatively synthesized to develop an integrated pathophysiological framework linking neurovascular signaling changes to clinical phenotypes.

RESULTS

Across included studies, the TVU consistently emerged as an integrated neurovascular interface that stabilizes microvascular function and supports sensory and ganglion cell viability in both cochlear and vestibular compartments. Endothelial cells and pericytes contributed to blood–labyrinth barrier maintenance, regulation of vascular permeability, and preservation of local ionic gradients crucial for transduction. Trigeminal sensory inputs, via neuropeptide signaling, appeared to modulate vasoreactivity and inflammatory pathways, suggesting a mechanism by which craniofacial nociceptive circuits influence inner ear physiology. Disruption of TVU signaling was associated with endothelial dysfunction, pericyte loss, impaired barrier function, and subsequent neuronal degeneration. These alterations provided a unifying mechanistic framework for several disorders, including Ménière's disease, vestibular migraine, benign paroxysmal positional vertigo, noise-induced hearing loss, and syndromes linked to head and neck myofascial pain.

CONCLUSIONS

Reframing inner ear disease through trigeminovascular and broader neurovascular dysfunction offers a cohesive explanation that bridges vascular, inflammatory, and sensory mechanisms. The TVU represents a compelling therapeutic and research target for future mechanistic studies and interventions.

OP-779

Peripheral Blood-Based Inflammatory And Hematological Biomarkers In Subjective Tinnitus: A Systematic Review

Serkan ŞERİFLER[1], **Fatih Recai KABLAN**[2], **Fatih GÜL**[2]

[1]*Department of Otorhinolaryngology, Ankara Yıldırım Beyazıt University, Ankara, Türkiye;* [2]*Department of Otorhinolaryngology, Lokman Hekim University, Ankara, Türkiye*

BACKGROUND & AIM

Subjective tinnitus is a multifactorial condition with an incompletely understood pathophysiology. In recent years, systemic inflammation, platelet activation, and microvascular dysfunction have been proposed as potential contributors. This systematic review aimed to synthesize the available clinical evidence on peripheral blood-based inflammatory and hematological biomarkers in patients with subjective tinnitus.

MATERIAL & METHODS

A systematic literature search was performed in PubMed/MEDLINE and Scopus using terms related to tinnitus and peripheral blood-based biomarkers, including neutrophil-to-lymphocyte ratio, platelet-to-lymphocyte ratio, mean platelet volume, platelet distribution width, complete blood count-derived indices, and cytokines. Original human studies evaluating the association between these biomarkers and subjective tinnitus presence, severity, duration, or audiological findings were included. Data were extracted on study design, sample size, biomarker type, tinnitus assessment, and main findings. Given the heterogeneity of study designs and outcomes, a narrative synthesis was performed.

RESULTS

Seventeen studies met the inclusion criteria. The included studies evaluated inflammatory indices, platelet-related markers, cytokines, and broader hematological or hemorheological parameters. Findings regarding classical inflammatory markers such as neutrophil-to-lymphocyte ratio and platelet-to-lymphocyte ratio were inconsistent, with some studies reporting higher values in tinnitus patients and others showing no association or opposite trends. Platelet-related markers, particularly mean platelet volume and platelet distribution width, were more frequently associated with tinnitus than classical inflammatory ratios, although the direction of these associations was not uniform across studies. Cytokine-based studies suggested possible relationships between inflammatory mediators and tinnitus severity, although evidence remained limited. A small number of studies also reported associations between biomarkers and audiological parameters such as high-frequency audiometry and distortion product otoacoustic emissions.

CONCLUSIONS

Peripheral blood-based biomarkers may provide insight into inflammatory and microvascular mechanisms in subjective tinnitus; however, current evidence remains heterogeneous and largely observational. Platelet-related markers appear more frequently altered than classical inflammatory indices, but their direction of change is not uniform across studies. Further prospective studies with standardized tinnitus phenotyping and careful control of confounding factors are needed.

Effect Of Deviated Nasal Septum On Eustachian Tube Dysfunction: A Systematic Review & Meta-Analysis

Dimitrios Spinos[2], **Muzamil Hamid Hussain**[1], **Jameel Muzaffar**[2], **Aman Khanna**[2], **Asad Qayyum**[3], **Remo Accorona**[4], **Haissan Iftikhar**[2], **Muhammad Ozair Awan**[1]

[1]Aga Khan University, Karachi, Pakistan; [2]University Hospital Birmingham; [3]Northwest Anglia NHS Trust; [4]ASST Grande Ospedale Metropolitano Niguarda

BACKGROUND & AIM

A range of chronic ear complaints may be attributed to eustachian tube dysfunction. Many different etiologies have been postulated in previous literature to help understand ETD better. ETD secondary to DNS has been described in a number of clinical studies, with symptomatic improvement demonstrated following septoplasty. However, uncertainty exists as to the size of effect and consistency between studies.

MATERIAL & METHODS

Systematic review and meta-analysis according to the PRISMA guidelines. Electronic searches of PubMed, EMBASE and the Cochrane Library of adult patients with complaints of nasal obstruction/impairment and/or complaints of ear fullness undergoing nasal surgery including septoplasty, FESS, submucosal diathermy and/or inferior turbinectomy.

RESULTS

7 studies met the inclusion criteria. Studies evaluated the effect of nasal surgery on ETD using a variety of outcomes, including as ETF Tests, ETDQ-7, Tympanometry, and NOSE Scores. Results demonstrate the positive impact of nasal surgery on various outcomes related to ETD, including improvements in ETDQ-7 scores, tympanometry findings, NOSE Scores, and ETF tests.

CONCLUSIONS

Evaluation of nasal symptoms and anatomy and discussion of operative intervention should be considered in any patient presenting with ETD. Future research should focus on elucidating the mechanisms underlying these improvements and refining treatment algorithms for ETD management.

Deviated Nasal Septum; Eustachian Tube Dysfunction; Nasal Surgery; Septoplasty

OP-781

Immediate Symptom Relief After Endoscopic Assisted SPG Block In ETD With Normal Tympanometry

Martin Nue Møller[1], **Karen Hoffmann**[2], **Marc R Dean**[3,4]

[1]Soernes Privathospital, ENT, Copenhagen, Denmark; [2]Piedmont ENT & Related Allergy, Atlanta, Giorgia, United States; [3]VIMA (Vitruvious Institute for Medical Advancement), Dallas, Texas, United States; [4]Ear and Sinus Institute, Fort Worth, Dallas, United States

BACKGROUND & AIM

Eustachian tube dysfunction (ETD) is typically classified as obstructive or patulous. However, some patients present with chronic dynamic aural symptoms despite normal tympanometry and without characteristic features of patulous ETD. We evaluated symptom response after unilateral transnasal sphenopalatine ganglion (SPG) block in a consecutive series of such patients.

MATERIAL & METHODS

One hundred consecutive adult patients with chronic aural fullness, clicking, and pressure instability were included. All demonstrated type A tympanograms, preserved ability to perform Valsalva maneuvers, no history of barotrauma, no improvement after needle paracentesis, and no autophony or respiratory tympanic membrane movement. A unilateral transnasal SPG block was performed using 2 mL of 0.5% bupivacaine. Immediate response and 4-week symptom status were recorded. Available paranasal sinus computed tomography (CT) scans were reviewed descriptively for sinus opacification and sphenoid sinus anatomy and compared to CT scans of classical obstructive ETD

RESULTS

Immediate symptom improvement was reported by 87 of 100 patients (87%). Relief was typically transient and described as lasting several hours, broadly corresponding to the expected pharmacologic duration of bupivacaine. Sustained improvement at 4 weeks was reported by 11 of 100 patients (11%). No major adverse events were observed. Among patients with available CT imaging (n = 77), 19% demonstrated significant mucosal thickening (Lund-McKay score >6), whereas 82% demonstrated a recurring sphenoid configuration characterized by extensive pneumatization, partial bony dehiscence of the vidian canal, and narrowing of the natural sphenoid ostium <2mm. Compared with CT scans of classic ETD, which only showed 6% of the same findings ($p<0.01$).

CONCLUSIONS

In this consecutive case series, unilateral transnasal SPG block was associated with frequent but transient symptom relief in patients with dynamic aural symptoms, normal tympanometry, and no classic features of patulous ETD. These findings suggest that some patients with non-obstructive, non-patulous aural symptoms may reflect a symptom pattern consistent with a

functional or neuromodulatory mechanism not fully captured by the current binary classification of ETD. Further studies are needed to better define this subgroup, clarify mechanisms, and determine the diagnostic or therapeutic role of SPG blockade

Matrix Metalloproteinases And Stromal Cells In Vestibular Schwannoma

Abigail Hodgson[2], **Christopher Mahony**[2], **Holly Adams**[2], **Elizabeth Clay**[2], **Peter Monksfield**[3], **Richard Irving**[3], **Christopher D. Buckley**[2], **Ingrid. E. Dumitriu**[2], **Adam Croft**[2], **Paramita Baruah**[1,2,3]

[1]*University Hospitals of Leicester NHS Trust;* [2]*University of Birmingham;* [3]*University Hospitals of Birmingham NHS Trust*

BACKGROUND & AIM

Vestibular schwannomas (VS) remain a challenge due to their anatomical location and propensity to growth. Matrix metalloproteinases are expressed in VS but their precise roles are not well understood.

MATERIAL & METHODS

Data was mined from scRNAseq experiments on three VS samples to analyse the MMP family. Immunohistochemistry and immunofluorescence was carried out on twenty VS samples for expression of MMP14 and MMP2 and their cellular sources. Fibroblasts isolated from VS were analysed for expression of MMP2 and MMP14 with confocal microscopy.

RESULTS

Several matrix metalloproteinases expressed in VS were identified on scRNA sequencing. It revealed expression of MMP14 and MMP2 predominantly in macrophage and fibroblast subsets within VS. MMP2 and MMP14 staining was confirmed in VS samples on immunohistochemistry and confocal microscopy and semiquantitative assessment performed to correlate with tumour size and cystic nature of disease. Fibroblasts from VS express higher levels of MMP2 and MMP14 than control tissue fibroblasts on RTPCR and validation of this at the protein level with confocal microscopy and flowcytometry is ongoing.

CONCLUSIONS

Stromal cells appear to be the main source of MMP2 and MMP14 in VS both on the scRNAseq and immunohistochemistry analysis. Expression of these two proteins in VS is heterogenous. Further analysis of the MMP pathways will further our knowledge about their roles in the pathogenesis of VS and their potential as therapeutic targets.

AUDİOLOGİCAL EVALUATİON İN PEDİATRİC GROUPS WİTH BİOTİNİDASE DEFİCİENCY

İsmail İynen[1], **Büşra Nur Bicek**[1], **İbrahim Ünal**[1]

[1]*Department of Otorhinolaryngology at Harran University*

BACKGROUND & AIM

Biotinidase is a vital enzyme responsible for the reutilization of biotin (vitamin B7) in the body. A deficiency in this enzyme can cause serious neurological and physical disorders, particularly during infancy and childhood. One of the symptoms associated with biotinidase deficiency is hearing loss. This study aims to analyze the prevalence of hearing loss in individuals with biotinidase deficiency and to determine whether there is a statistically significant relationship between the two conditions.

MATERIAL & METHODS

In our hospital, individuals with a biotinidase activity level of “10% or below” are diagnosed with “profound deficiency,” while those with activity “up to 45%” are considered to have “partial biotinidase deficiency.” A total of 90 participants were included in this study, consisting of 50 individuals diagnosed with biotinidase deficiency and 40 individuals without any risk factors or disabilities. This prospective clinical study was designed not only to explore the broader effects of biotinidase deficiency on children, but also to determine whether it constitutes a specific risk factor for hearing loss.

RESULTS

All participants underwent auditory brainstem response (ABR) testing. Findings consistent with hearing loss were identified in 5 individuals (10%) within the biotinidase-deficient group, whereas all individuals in the control group exhibited normal ABR results. The difference between the groups was analyzed using Fisher’s Exact Test, with a resulting p-value of approximately 0.06—close to the threshold of statistical significance. This finding suggests that individuals with biotinidase deficiency may experience subclinical or mild auditory transmission issues.The detection of hearing loss indicators in 10% of biotinidase-deficient individuals implies that neural transmission pathways or post-cochlear structures might be affected. The absence of similar findings in the control group indicates this difference may have clinical relevance. The results reveal a higher rate of hearing loss among individuals with biotinidase deficiency (10% vs. 0%). The near-significant p-value suggests that studies with larger sample sizes may reveal stronger statistical significance

CONCLUSIONS

Previous literature has documented associations between biotinidase deficiency and sensorineural hearing loss. At the cellular level, biotinidase deficiency may disrupt myelin synthesis and energy metabolism, potentially leading to permanent cochlear damage and resulting in hearing impairment.

OP-784

Combined Transcutaneous Vagus Nerve And Sound Stimulation (Soricle) For Subjective Tinnitus: A Randomized Sham-Controlled Trial

Jae Jun Song[1], **Jae-Gu Cho**[1], **Jae-Man Park**[1], **Hyuck Choi**[1]

[1]*Korea University Guro Hospital*

BACKGROUND & AIM

Subjective tinnitus is a prevalent and debilitating auditory condition lacking universally effective treatments. Emerging evidence suggests that transcutaneous auricular vagus nerve stimulation (tVNS) may modulate maladaptive cortical reorganization implicated in chronic tinnitus pathophysiology through GABAergic inhibitory circuit activation. Sound stimulation has similarly demonstrated capacity to reverse aberrant auditory cortical hyperexcitability. Preclinical and early clinical studies have proposed that pairing tVNS with acoustic stimulation may yield synergistic neuroplastic effects superior to either modality alone.

MATERIAL & METHODS

This prospective, single-center, randomized, double-blind, sham-controlled exploratory trial enrolled 36 adults with chronic subjective tinnitus (duration ≥3 months; Tinnitus Handicap Inventory [THI] score 18–76; pure-tone average ≤50 dB). Participants were allocated 1:1:1 to three arms: sham device (n=12), electrical stimulation only (tVNS; n=12), and combined electrical plus sound stimulation (tVNS+Sound; n=12). All participants used the investigational device "Soricle," which delivers transcutaneous electrical stimulation (1–14 mA) to the auricular branch of the vagus nerve with or without white noise, for 8 weeks. Assessments were conducted at baseline and at weeks 2, 4, 5, 6, 7, and 8. The primary efficacy endpoint was the change in THI total score from baseline to week 8. Secondary endpoints included the Tinnitus Functional Index (TFI), Visual Analogue Scale (VAS) for tinnitus loudness and discomfort. Efficacy analyses were performed on the full analysis set (FAS; n=36) and per-protocol set (PPS; n=25) using ANCOVA with baseline values.

RESULTS

In the FAS analysis, mean THI change from baseline to week 8 was −14.83 (±22.46) points in the tVNS group, −10.83 (±15.00) points in the tVNS+Sound group, and +2.00 (±6.55) points in the sham group. ANCOVA revealed a statistically significant difference between the sham and tVNS+Sound groups (p=0.0109), and a significant within-group reduction was observed in the tVNS group (p=0.0429). These findings were reproduced in the PPS, wherein THI reductions were −16.60 (±24.24) and −17.67 (±7.09) points for the tVNS and tVNS+Sound groups, respectively, versus +0.44 (±6.23) points in sham, with a highly significant between-group difference for sham vs. tVNS+Sound (p=0.0003). Secondary endpoints, including VAS and TFI, demonstrated improvement trends across active groups, with statistically significant reductions observed at select time points. No serious adverse events or device-related safety signals were identified across all groups.

CONCLUSIONS

This exploratory trial demonstrates that transcutaneous vagus nerve stimulation, particularly when combined with sound stimulation, produces clinically meaningful and statistically significant reductions in THI scores in patients with chronic subjective tinnitus compared to sham treatment. The favorable safety profile and consistent directionality across both FAS and PPS analyses support the potential clinical utility of tVNS-based combination neuromodulation for tinnitus management. Given the exploratory nature and limited sample size of this study, adequately powered, multicenter confirmatory trials are warranted to establish definitive clinical evidence and inform future regulatory approval pathways.

Bezold Abscess Without Cervical Swelling: Early CT Findings And Pain-Only Presentation

Kiyonobu Taiki[1], **Kanazawa Yuji**[1], **Kitani Yoshiharu**[1], **Torii Hiroko**[1], **Matsubara Aya**[1], **Hattori Norishige**[1], **Goda Riki**[1]

[1]*Department of Otolaryngology-Head and Neck Surgery, Shizuoka General Hospital, Shizuoka, Japan*

BACKGROUND & AIM

Bezold abscess typically presents with cervical swelling due to extension of mastoid infection into deep neck spaces. However, atypical presentations lacking external signs may delay diagnosis and allow extensive progression. We hypothesized that

Bezold abscess can develop with minimal clinical findings but may exhibit subtle early radiologic changes preceding overt abscess formation.

MATERIAL & METHODS

A 70-year-old male presented with a long history of recurrent otitis externa with habitual ear manipulation and progressive untreated hearing loss. Initial computed tomography (CT) showed soft tissue density in the tympanomastoid cavity without obvious extracranial abscess, raising suspicion of middle ear cholesteatoma. However, retrospective review identified a low-density area suggesting underlying bone erosion at the site of later extracranial perforation. Although elective surgery was planned, the patient presented one month later with isolated retroauricular pain without cervical swelling. Repeat CT and magnetic resonance imaging demonstrated new bone erosion and a deep abscess extending to the jugular foramen, accessory nerve region, vertebral artery, and C1 transverse process.

RESULTS

Bezold abscess secondary to middle ear cholesteatoma was diagnosed. Canal-up mastoidectomy with drainage was performed. Intraoperatively, purulent discharge was identified through a deep bone defect medial to the facial nerve and anterior to the sigmoid sinus, corresponding to the previously noted low-attenuation area. No superficial cervical abscess was observed. Postoperatively, pain resolved promptly, and the patient remained symptom-free at 10 months.

CONCLUSIONS

Bezold abscess may present without cervical swelling, with pain as the sole initial symptom, while spreading extensively along skull base pathways. Subtle early CT attenuation changes at the site of eventual extracranial perforation may precede overt abscess formation. Careful evaluation of such findings, particularly when EAC stenosis limits otoscopic assessment, may facilitate earlier diagnosis and prevent disease progression.

OP-786

An Innovative Approach In Revision Cartilage Tympanoplasty: A Prospective Study With Platelet-Rich Fibrin (PRF) Support

İbrahim Ömer Gürlek[1], **Ece Şevval Eğe**[1], **Burak Kaan İnan**[1], **Zahide Mine Yazıcı**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, University of Health Sciences, Bakırköy Dr. Sadi Konuk Training and Research Hospital, Istanbul, Türkiye*

BACKGROUND & AIM

Revision tympanoplasty remains surgically challenging due to scar tissue formation, compromised vascularity, and higher rates of recurrent perforation compared to primary procedures. Platelet-rich fibrin (PRF), an autologous biomaterial enriched with growth factors, has been shown to promote angiogenesis and tissue regeneration. However, evidence regarding its role in revision cartilage tympanoplasty is limited. This study aimed to evaluate the short-term anatomical and functional outcomes of PRF-supported conchal cartilage grafting in revision cases.

MATERIAL & METHODS

In this ongoing prospective cohort study, consecutive eligible patients with persistent tympanic membrane perforation ≥3 months after prior cartilage tympanoplasty were enrolled between 2020 and 2025. Exclusion criteria included active infection, cholesteatoma, systemic inflammatory or hematologic disease, and age <16 or >65 years. At the time of interim analysis, 20 patients had completed 3-month follow-up and were included in the analysis. Autologous PRF was prepared from 9 mL of venous blood via centrifugation. Under local anesthesia, perforation edges were refreshed and a conchal cartilage graft was prepared. The graft was supported with PRF on both medial and lateral surfaces prior to placement and stabilized with absorbable gelatin sponge. Anatomical closure was assessed endoscopically at 1 and 3 months. Audiometric thresholds, air–bone gap (ABG), Visual Analog Scale (VAS), and Chronic Otitis Media Questionnaire – 12 (COMQ-12) scores were analyzed.

RESULTS

Twenty patients (mean age 36.2 years; 70% female) were analyzed. Mean perforation size was 7.13 mm^2. At 3 months, complete graft uptake was achieved in 19 patients (95%). Mean air conduction thresholds improved significantly from 28.8 ± 8.9 dB preoperatively to 23.4 ± 9.7 dB postoperatively ($p<0.001$). ABG decreased from 17.3 ± 5.3 dB to 13.6 ± 4.7 dB ($p=0.001$), while bone conduction thresholds remained stable ($p=0.246$). COMQ-12 scores improved significantly from 19.6 to 10.5 ($p=0.017$). No major complications or graft-related adverse events were observed. All procedures were completed under local anesthesia with a mean operative time of 42 minutes.

CONCLUSIONS

PRF-supported cartilage grafting in revision tympanoplasty appears safe and associated with high short-term graft success and significant functional improvement. Ongoing enrollment and longer follow-up will further clarify its potential additive benefit in revision middle ear surgery.

OP-787

Labyrinthitis Ossificans Diagnosis And Management: A Narrative Review

João Guilherme Rapacci Tedrus[1], **Giovanna Rasmussen**[1], **Paola Ferrari Schwarz**[1], **Isabela Marchand Rocha Guimarães**[1], **Henrique Furlan Pauna**[1]

[1]*School of Medicine and Life Sciences, Pontifical Catholic University of Paraná, Curitiba, PR, Brazil*

BACKGROUND & AIM

Labyrinthitis ossificans (LO) is a pathological condition characterized by ossification of the membranous labyrinth, leading to progressive sensorineural hearing loss. It is often associated with chronic inflammatory processes, trauma, autoimmune disease and neoplastic processes affecting the inner ear. The early diagnosis is essential to prevent the progression of hearing loss and treatment.

MATERIAL & METHODS

This narrative review synthesizes findings from a comprehensive literature search in databases such as PubMed, Scielo, Google Scholar, and Web of Science. Studies focusing on the epidemiology, etiology, pathophysiology, diagnostic, cochlear implantation (CI), clinical treatment and prevention of LO were analyzed. Priority was given to the most recently published articles and new approaches to CI and auditory rehabilitation.

RESULTS

LO commonly is the result of bacterial labyrinthitis, otitis media, meningitidis infection, often caused by Streptococcus pneumoniae, or trauma. High-resolution computed tomography (CT) and magnetic resonance imaging (MRI) are essential for surgical planning and detecting early ossification, respectively. CI remains the main surgical treatment for profound hearing loss, however in advanced cases of cochlear ossification CROS (Contralateral Routing of Signal) and BAHA (Bone-Anchored Hearing Aid) may be considered as options for auditory rehabilitation.

CONCLUSIONS

Early diagnosis and treatment are important to prevent auditory damage in patients with LO. Although CI is the best treatment available, in advanced stages of cochlear ossification there are limitations to their use. Further research is needed to develop surgical strategies for CI in patients with advanced ossification, to improve auditory rehabilitation with CROS, BAHA and ultimately improving patient prognosis.

OP-788

THE 12-ITEM TINNITUS PRIMARY FUNCTION QUESTIONNAIRE WITH HIGH FREQUENCY HEARING THRESH VALUE IN TINITUS PATIENTS

Nyilo Purnami[1]

[1]*Universitas Airlangga*

BACKGROUND & AIM

Background: Tinnitus is the sensation of hearing sound without any external or internal stimulus or acoustic source. Tinnitus patient complaints are generally subjective, whereas there is no objective examination in making a tinnitus diagnosis until now, so a questionnaire is needed to help enforce it. Conventional pure tone audiometry (PTA) (125 Hz – 8.000 Hz) is not reliable for detecting cochlear damage. Tinnitus patients with normal audiograms are more likely to have cochlear damage, outer hair cell damage and hearing threshold disturbances in the high frequency region (10.000 Hz – 16.000 Hz).

MATERIAL & METHODS

Analytical observational with cross sectional design. Sampling with consecutive sampling technique. Basic data such as age, sex, type of tinnitus, duration of tinnitus, hearing loss and comorbidities were taken from medical records. High-frequency pure tone audiometry examination by a nurse under the supervision of a Neurotology consultant ENT-HNS Specialist doctor. Assessment of the impact on the patient's quality of life by filling out the Indonesian version of the 12-item TPFQ questionnaire

RESULTS

The total sample obtained was 55 patients. The results of statistical calculations using the Spearman correlation test between high frequency hearing threshold values and the Indonesian version of the TPFQ 12-item total ($p = 0.98$).

CONCLUSIONS

there is no relationship between the score of the 12-item TPFQ questionnaire and the threshold value of high-frequency hearing. Tinnitus is a clinically confusing condition due to the lack of effective treatment to stop its perception, so the assessment of tinnitus relies on questionnaires.

OP-789

Two Decades Of Neurotology Research From Otorhinolaryngology Clinics In Türkiye: A Bibliometric Analysis Of Output, Institutional Concentration And Research Hotspots

Gökçe Aydemir[2], **Fazıl Necdet Ardıç**[1]

[1]*Department of Otolaryngology, Pamukkale University;* [2]*Bitlis State Hospital*

BACKGROUND & AIM

Neurotology is a resource-intensive subspecialty whose national research profile has never been described for Türkiye. We quantified the volume, institutional distribution, citation impact and thematic structure of neurotology research produced by Turkish otorhinolaryngology and audiology clinics, and asked how that output is distributed across the country's clinics.

MATERIAL & METHODS

PubMed/MEDLINE was searched for records combining the neurotology field terms tinnitus, vertigo, dizziness, sensorineural hearing loss, facial paralysis, hearing implant, cochlear implant, inner ear, cochlear and vestibular with an otology, otolaryngology, otorhinolaryngology or audiology affiliation and a Türkiye address. 2,241 records were retrieved and the 1,866 published between 2005 and 2025 were analysed. Affiliation strings were transliterated and mapped to a curated dictionary of Turkish universities, training-and-research hospitals and city hospitals; renamed and merged institutions were consolidated, and author names were canonicalised across Turkish-diacritic spelling variants. Citation counts came from linking records to Web of Science by PubMed ID (1862/1866, 99.8%). Co-authorship and MeSH co-occurrence networks were clustered by modularity optimisation. Because MEDLINE indexed only the first author's affiliation before 2014, collaboration analyses were restricted to 2016–2025.

RESULTS

Annual output rose from 27 papers in 2005 to 205 in 2025 (compound annual growth 10.7%; with 1,385 of the 1,866 papers (74%) appearing in the last decade. The corpus attracted 18,864 citations (mean 10.13, median 5, h-index 49). Output came from 253 named institutions in 77 cities but was highly concentrated: the ten most productive clinics accounted for 28.7% of all institution–paper links, Ankara, İstanbul and İzmir for 56.4% of city attributions, and 72.7% of contributing authors published only once in the field. Hacettepe University led on volume (248 papers, 13.3% of the corpus), citations (3,112) and h-index (25). IThematically, sensorineural hearing loss fell from 44% to 27% of output while cochlear implantation and auditory rehabilitation rose from 9% to 22%; facial nerve and lateral skull base work contracted. Neurotology accounted for 18.1% of all Turkish otorhinolaryngology output indexed in Web of Science, rising from 13.5% to 22.3%.

CONCLUSIONS

Turkish neurotology research has grown faster than its parent specialty for two decades and is now dominated by cochlear implantation and vestibular work. Its productivity nevertheless remains concentrated in a small number of clinics in three cities, and nearly three quarters of contributing authors publish in the field only once. International collaboration, though still a minority of output, is both rising and associated with measurably higher citation rates, making it the most tractable lever for raising national impact.

OP-790

Evaluation Of S-Value In Relation To Cochlear Anatomy In Pediatric Cochlear Implant Users

Abdulrahman Alsanosi[2]

[1]*Otology, neurotology, and cochlear implantation consultant at a King Abdulaziz Medical City, Riyadh, Saudi Arabia.;* [2]*King Abdullah Ear Specialist Center (KAESC), King Saud University Medical City, King Saud University, Riyadh, Saudi Arabia*

BACKGROUND & AIM

To assess the S-value in pediatric cochlear implant (CI) patients using high-resolution CT images and examine its correlation with main cochlear parameters and angular insertion depth (AID).

MATERIAL & METHODS

A retrospective review of preoperative CT images from pediatric CI recipients with normal cochlear anatomy was conducted at a referral hearing implant center. Cases involving congenital or acquired inner-ear abnormalities were excluded. Two independent reviewers with equivalent expertise used OTOPLAN to measure the main cochlear parameters, and the interrater reliability study revealed good agreement. S-values (the straight section of the cochlear basal turn) were measured and examined, and their correlation to electrode insertion angles and cochlear parameters (A- and B-values) was evaluated.

RESULTS

The average cochlear duct length (CDL) of the included patients was 36.14 ± 0.26 mm, with an average S-value of 7.06 ± 0.40 mm, insertion angle of 598.20° ± 48.72°, and cochlear coverage of 77.49% ± 0.57. A statistically significant relationship was found between A- and the S-values (r = 0.65, p = 0.004). However, the B-value showed a moderate, non-significant correlation with the S-value (r = 0.43). Furthermore, a consistent negative, but not statistically significant, association was found between the S-value and the angular insertion depths of all electrode contacts (r = − 0.28 to − 0.30).

CONCLUSIONS

The S-value is a dependable anatomical parameter that correlates positively with the A-value. The evaluated lateral-wall array showed consistent insertion depths among patients with similar CDL, even when S-values differed. Further studies are needed to investigate the impact of greater variability in S-values on clinical outcomes and electrode-array position among CI users.

OP-791

Audiological Outcomes After Attic Cholesteatoma Surgery

Fatih Mutlu[1], **Doğukaan Ruhi Aktürk**[1], **Muzaffer Doğukan Üsgüdar**[1], **Akhat Zhumagulov**[1], **Murat Öztürk**[1]

[1]*Department of Otorhinolaryngology – Head and Neck Surgery, Kocaeli University Faculty of Medicine, Kocaeli, Türkiye*

BACKGROUND & AIM

Attic cholesteatoma is a destructive middle ear disease that may result in ossicular chain erosion and hearing loss. Surgical treatment aims not only to eradicate the disease but also to preserve or improve hearing outcomes. This study aimed to evaluate postoperative audiological and surgical outcomes in patients undergoing surgery for attic cholesteatoma

MATERIAL & METHODS

A retrospective single-center study was conducted including 75 patients who underwent surgery for attic cholesteatoma between 2017 and 2025. Demographic characteristics, surgical approaches, ossicular chain status, hearing reconstruction techniques, graft outcomes, recurrence rates, revision surgeries, and audiological outcomes were analyzed. Microscopic and endoscopic approaches, as well as canal wall up (CWU), canal wall down (CWD), and tympanoplasty procedures were included. Preoperative and postoperative air conduction (AC) and bone conduction (BC) thresholds were compared during early (2 months) and long-term follow-up (6-91; median 21 months) periods. Statistical analyses were performed using non-parametric tests, including the Wilcoxon signed-rank test.

RESULTS

The median age was 32 years (interquartile range [IQR]: 23–46 years), and 61.3% of the patients were female. Microscopic surgery was performed in 93.3% of cases, while 6.7% underwent endoscopic surgery. Incus erosion was the most common ossicular abnormality (74.7%), followed by stapes (26.7%) and malleus erosion (24%). Intact postoperative graft status was observed in 73.3% of patients, while recurrent cholesteatoma occurred in 16%. Revision surgery was required in 10.7% of cases. Comparison of preoperative and postoperative AC and BC thresholds demonstrated stable hearing outcomes without statistically significant deterioration during early and long-term follow-up ($p>0.05$). Subgroup analysis demonstrated significant early postoperative AC improvement in patients undergoing total ossicular replacement prosthesis (TORP) reconstruction ($p=0.042$) (median 58 dB vs 46 dB).

CONCLUSIONS

Attic cholesteatoma surgery effectively eradicates disease with acceptable recurrence rates. Crucially, despite extensive ossicular destruction requiring complex reconstruction, baseline hearing can be successfully preserved, and significant auditory improvement is achievable, particularly in patients undergoing TORP reconstruction.

OP-792

Explainable Multimodal Visualization Of Vestibulo-Auditory Function: Clinical Validation Of Polar Plot-Based Representation And 3D Anatomical Mapping

Mingyeong Kim[1], **Dongyeon Lee**[2], **Jeongwoo Lee**[2], **Taehoon Kong**[3]

[1]*Department of Bio-AI Convergence, Yonsei University Wonju College of Medicine, Wonju, Republic of Korea;* [2]*Department of Medical Informatics and Biostatistics, Yonsei University Wonju College of Medicine, Wonju, Republic of Korea;* [3]*Department of Otorhinolaryngology, Yonsei University Wonju College of Medicine, Wonju, Republic of Korea*

BACKGROUND & AIM

Conventional vestibular assessments rely on rule-based criteria such as canal paresis (CP%) and video head impluse test (vHIT) gain thresholds, which reduce complex responses to binary judgments and fail to capture directional and intensity patterns. Explainable tools that integrate vestibular and auditory function within an anatomical context remain lacking. This study

develops and validates a framework combining Polar plot-based multimodal representation with 3D anatomical mapping to enable interpretable visualization of vestibulo-auditory function.

MATERIAL & METHODS

Vestibular function tests including caloric test, vHIT, posturography, and subjective visual vertical and horizontal (SVV/SVH) tests of 6,137 patients from a tertiary university hospital were analyzed. Frequency-specific hearing thresholds (dB HL) from pure-tone audiometry (PTA) were additionally included for 2,039 patients. Each test result was converted into a Polar plot, and the circular space was divided into 25 wedge segments to extract pixel area ratios and angular features, yielding a 50-dimensional feature vector. To assess clinical validity, a multi-input neural network (CNN backbone + MLP branch) was trained using Dense–Sparse–Dense (DSD) learning for vestibular dysfunction classification and subtype differentiation. Post-pruning residual features were analyzed to evaluate directional explainability. A 3D anatomical model of semicircular canals and cochlear structures was built from a standard anatomical reference. vHIT gain values and PTA thresholds were mapped onto canal surfaces and cochlear positions using the Greenwood function as an interactive visualization.

RESULTS

Features retained after DSD pruning were significantly concentrated in specific directional regions rather than a random distribution ($p < 0.05$), supporting the clinical validity of the Polar plot-based representation. The proposed model outperformed conventional threshold-based methods in vestibular dysfunction classification, with improved differentiation of unilateral and bilateral patterns. In the 3D mapping, concurrent vHIT gain reduction and high-frequency hearing loss were observed in anatomically adjacent structures, enabling clear spatial visualization of lesion differences across diagnostic groups.

CONCLUSIONS

Polar plot-based multimodal representation captures directional vestibular patterns beyond conventional rule-based criteria, with validity verified through explainable data-driven feature selection. Combined with 3D vestibulo-auditory mapping, this framework offers an explainable AI-based diagnostic support tool for lesion localization and subtype classification, with potential extension to personalized treatment and rehabilitation monitoring.

Vestibular Safety Of 980-Nm Diode Laser-Assisted Stapedotomy: A Prospective Vhit-Based Evaluation

Fatih Mutlu[1], **Merve Durgut**[1], **Sümeyye Bozkuş**[1], **Murat Öztürk**[1]

[1]*Department of Otorhinolaryngology and Audiology, Kocaeli University Faculty of Medicine*

BACKGROUND & AIM

Although diode laser-assisted stapedotomy is widely used in the surgical management of otosclerosis, its vestibular effects have not been fully clarified. Several mechanisms, including mechanical footplate manipulation, pressure transmission, and potential thermal effects, have been proposed to explain postoperative vestibular symptoms. This prospective study aimed to evaluate vestibular function after 980-nm diode laser-assisted stapedotomy using the video head impulse test (vHIT).

MATERIAL & METHODS

Seventeen patients with otosclerosis who underwent primary diode laser-assisted stapedotomy were prospectively included. All procedures were performed by a single surgeon using a standardized transcanal microscopic technique. Laser applications were performed with a 980-nm diode laser in pulse mode using power settings of 6-8 W and pulse durations of 150-200 ms. vHIT was performed one day before surgery and at two months postoperatively to assess vestibulo-ocular reflex (VOR) gain in the lateral, anterior, and posterior semicircular canals. Audiological outcomes and postoperative vestibular symptoms were also recorded.

RESULTS

Seventeen patients were included in the analysis. No significant differences were observed in vHIT VOR gains between preoperative and postoperative measurements in the lateral, anterior, or posterior semicircular canals. Transient postoperative dizziness occurred in six patients and resolved within 24 hours in all cases. Audiological outcomes improved significantly, with a postoperative median air-conduction pure-tone average of 30 dB HL (IQR, 24-55) and a median air-bone gap of 13 dB (IQR, 10-20; p=0.004). An air-bone gap <=20 dB was achieved in 76.5% of patients, and no postoperative sensorineural hearing loss was observed.

CONCLUSIONS

Diode laser-assisted stapedotomy performed with standardized parameters did not result in clinically evident semicircular canal dysfunction as assessed by vHIT at two months postoperatively. These findings support the vestibular safety of 980-nm diode laser-assisted stapedotomy while confirming effective audiological improvement.

Correlation Between Endolymphatic Hydrops MRI Findings And Clinical Ménière's Disease Categories:

William Aragonés Sanzen-Baker[1,2,3], **Virginia Ruiz San-José**[1,2], **Álvaro Sánchez Barrueco**[1,2,3], **Ignacio Asensi Marcuello**[3], **Jose Miguel Villacampa Aubá**[2,3], **Gonzalo Díaz Tapia**[1,2,3]

[1]*Hospital General Universitario Villalba;* [2]*Hospital Universitario Fundación Jimenez Díaz;* [3]*Universidad Alfonso X el sabio*

BACKGROUND & AIM

Delayed gadolinium-enhanced MRI has emerged as a useful tool for visualizing endolymphatic hydrops (EH), but its relationship with clinical Ménière's disease (MD) classifications remains incompletely defined. This study aimed to assess the correlation between MRI-detected EH and clinical MD categories, comparing the diagnostic agreement of the Bárány Society criteria with the Japanese criteria.

MATERIAL & METHODS

We conducted a retrospective observational study of patients who underwent MRI for suspected endolymphatic hydrops. Clinical, audiological, and radiological data were collected from a structured database. MRI variables included cochlear and vestibular hydrops grades for each ear, as well as ipsilateral and contralateral involvement. Clinical categorization was established according to both Bárány Society and Japanese criteria. Audiometric features, including hearing fluctuation and audiogram pattern, were also recorded. The main objectives were: (1) to compare the association between positive MRI hydrops and clinical classification systems, and (2) to determine whether higher MRI hydrops grades were associated with greater clinical correlation.

RESULTS

MRI-positive endolymphatic hydrops showed a clearer association with the Japanese clinical classification than with the Bárány criteria. Overall, patients with radiological hydrops were more likely to fit Japanese diagnostic categories, whereas discordant cases were more frequent when Bárány criteria were applied. In addition, increasing MRI hydrops grade was associated with stronger clinical-radiological concordance. This relationship was particularly evident in the symptomatic ear, although contralateral hydrops and clinically discordant cases were also observed. These findings support the concept that MRI may detect structural inner ear changes even in patients with incomplete or atypical clinical phenotypes

CONCLUSIONS

MRI-detected endolymphatic hydrops correlates with clinical Ménière's disease classification, with better agreement for Japanese criteria than for Bárány criteria. Higher hydrops grades are associated with greater clinical concordance. Inner ear MRI may therefore provide useful adjunctive information for phenotyping, stratification, and diagnostic refinement in patients with suspected Ménière's disease

Evaluating The Safety Of Topical Mesna In Middle Ear Surgery Using An Animal Model

Ostap Orishchak[1,2], **Inabat Yermesheva**[1], **Hady Tall**[1], **Danah Quttaineh**[1,5], **Karina Theoret**[1,6], **Don Nguyen**[1], **Marie-France Lusignan**[4], **Kevork H. Atamian**[1,3], **Emily Kay-Rivest**[1,5], **Sam J. Daniel**[1,2,4,5]

[1]*McGill Otolaryngology Sciences Laboratory, Department of Pediatric Surgery, McGill University, McGill University Health Centre, Montreal, Canada;* [2]*Division of Pediatric Otolaryngology, Montreal Children's Hospital, McGill University Health Centre, Montreal, Canada;* [3]*Faculty of Medicine and Health Sciences, McGill University, Montreal, Canada;* [4]*The Research Institute of the McGill University Health Centre, Montreal, Canada;* [5]*Department of Otolaryngology-Head and Neck Surgery, McGill University Health Centre, Montreal, Canada;* [6]*School of Communication Sciences and Disorders, Dalhousie University, Halifax, Canada*

BACKGROUND & AIM

Mesna is a thiol-containing compound used in otologic surgery for conditions such as cholesteatoma, tympanosclerosis, adhesive otitis media, and atelectatic ears. Through its mucolytic properties, Mesna helps break down pathological tissues and may act as a chemical dissector. The objective of this study was to evaluate the ototoxic potential of 100% topical Mesna applied to the middle ear in an animal model.

MATERIAL & METHODS

Sixteen female albino guinea pigs were enrolled, and twelve animals were included in the final analysis. The guinea pigs were randomly divided into two groups. In Group 1, six guinea pigs received 100% Mesna powder in one ear, while the contralateral ear received powdered boric acid as a non-ototoxic control. In Group 2, six guinea pigs received 100% Mesna solution in one ear, while the contralateral ear received saline solution as a non-ototoxic control. Ototoxicity was assessed using auditory brainstem response testing at baseline after myringotomy and four weeks after application. Scanning electron microscopy of cochlear hair cells was performed approximately two months after application.

RESULTS

No inflammation was observed in any ear canal. Auditory brainstem response thresholds remained stable between baseline and four weeks after application. Scanning electron microscopy showed no evidence of damage to inner or outer hair cells in any group.

CONCLUSIONS

Topical application of 100% Mesna, in both powder and solution forms, did not demonstrate ototoxic effects in this guinea pig model. These findings support the potential safety of Mesna for middle ear use and may encourage its broader adoption in otologic surgical practice.

OP-796

Relationship Between Mastoid Pneumatization And Incus-Stapes Distance In Otosclerosis: A High-Resolution Computed Tomography Evaluation

Hüseyin IŞIK[1], **Şahin YENER**[1]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, Faculty of Medicine, Zonguldak Bülent Ecevit University, Türkiye*

BACKGROUND & AIM

Stapes surgery is the gold standard treatment for conductive hearing loss in otosclerosis, where precise prosthesis sizing is critical for optimal post-operative functional outcomes. Preoperative planning via high-resolution computed tomography (HRCT) provides detailed anatomical data. This study aimed to investigate the potential relationship between the degree of mastoid pneumatization and the distance from the long process of the incus to the stapes footplate using temporal HRCT, thereby evaluating its predictive value for surgical technique and prosthesis selection.

MATERIAL & METHODS

This retrospective study evaluated temporal bone HRCT scans of 58 patients diagnosed with otosclerosis. Detailed morphometric measurements of the distance between the long process of the incus and the stapes footplate were performed. Mastoid pneumatization was classified into four distinct groups (Group 1 to Group 4) based on regional aeration boundaries. Statistical analyses were performed using non-parametric methods, specifically Spearman's correlation coefficient to assess the relationship between ordinal pneumatization groups and the continuous distance parameter, and the Kruskal-Wallis test to compare distances across different pneumatization cohorts.

RESULTS

The study population consisted of 58 patients with a mean age of 45.48±10.50 years, comprising 55.2% females and 44.8% males. Right ear involvement was present in 48.3% and left ear involvement in 51.7% of cases. The overall mean distance between the long process of the incus and the stapes footplate was 4.62±0.35 mm (minimum: 3.92 mm, maximum: 5.58 mm). Regarding mastoid pneumatization, Group 3 was the most frequent (32.8%), followed by Group 4 (25.9%). Spearman correlation analysis revealed no statistically significant relationship between the mastoid pneumatization group and the incus-stapes distance ($r=-0.069$, $p=0.605$). Furthermore, the Kruskal-Wallis test demonstrated no significant difference in incus-stapes distances among the four pneumatization groups ($\chi^2=1.448$, $df=3$, $p=0.694$), indicating a homogeneous distribution of measurements across categories.

CONCLUSIONS

Our findings demonstrate that mastoid pneumatization does not significantly influence or correlate with the distance between the long process of the incus and the stapes footplate in otosclerosis patients. Consequently, variations in mastoid aeration should not be considered a predictive anatomical landmark for anticipating stapes prosthesis length during preoperative surgical planning.

OP-797

Comparison Of Spontaneous Healing Of The Tympanic Membrane After Pars Tensa Retraction Excision With Or Without Grommet Insertion

Syed Zohaib Maroof Hussain[1], **Maryam Nowghani**[1], **Mr John Hamilton**[1]

[1]*Gloucestershire Royal Hospital*

BACKGROUND & AIM

Pars tensa retraction (PTR) involves loss of the fibrous layer and medial displacement of the pars tensa, often resulting from COM.

This study investigates healing following retraction excision.

History of excision of retraction with spontaneous healing:

Stewart (1985) - simple excision & Wayloff (1985) - simple excision

Marquet (1989)- excision with grommet insertion

No comparison of the two treatments.

No quantification of time course of healing

Aim: •Compare tympanic membrane healing in two groups: with and without grommet insertion

•Record time course of healing

MATERIAL & METHODS

A retrospective analysis of patients with pars tensa retraction who underwent surgical excision of the retracted part of their tympanic membrane without surgical repair of the defect. Time to event analysis was used to compare perforation closure of the group who underwent ancillary ventilation tube insertion to that of the group with retraction excision alone.

RESULTS

Eligible were 149 ears from 149 patients with a median age of 11 years (IQR: 8 to 21 years), where 47 underwent excision only and 102 underwent excision plus tube insertion. At six months after surgery, a higher percentage of patients who underwent excision alone healed (89%) compared to those who had excision with tube insertion (75%). Depth of retraction pocket and integrity of the ossicular chain were also independently associated with the tympanic membrane closure. Age, sex, side of ear surgery, and location of retraction were not associated with this outcome. At six months, the probability that the difference between the two surgical groups is due to chance is 0.004.

CONCLUSIONS

In our series, ancillary ventilation tube insertion had a detrimental effect on the complete spontaneously healing of the tympanic membrane after retraction pocket excision without surgical repair of the defect

Prognostic Value Of The Pan-Immune-Inflammation Value In Sudden Sensorineural Hearing Loss

Çağrı Becerik[1], **Baturalp Çetin**[1], **Emre Çelik**[1], **Artun Kırmızıtaş**[1], **Muhammed Mirza Doğan**[1], **Ejder Ciğer**[1], **Abdülkadir İmre**[1]

[1]*İzmir Katip Çelebi University, Faculty of Medicine, Department of Otorhinolaryngology*

BACKGROUND & AIM

Sudden sensorineural hearing loss (SSHL) is considered an otologic emergency characterized by a predominantly idiopathic and multifactorial etiology, in which inflammation and immune system dysregulation are thought to be fundamental mechanisms. Although various clinical prognostic factors have been identified, there remains a lack of reliable, easily accessible biomarkers to predict auditory recovery. Hematological inflammatory indices have demonstrated potential in this regard; however, the role of the Pan-Immune-Inflammation Value (PIV) remains unclear. Therefore, this study aimed to assess the prognostic value of PIV in patients with SSHL.

MATERIAL & METHODS

This retrospective study included 148 patients diagnosed with SSHL and 151 healthy control subjects. All patients received standardized treatment in accordance with established clinical guidelines. Pure-tone audiometry (PTA) was performed at baseline and at two months post-treatment. Patients were initially categorized as having complete or incomplete recovery; the incomplete recovery group was then subdivided into three categories: non-recovery (PTA improvement <10 dB), slight improvement (10–30 dB), and marked improvement (>30 dB). Complete recovery was defined as post-treatment PTA ≤20 dB. PIV was calculated using routine hematological parameters. Statistical analyses included group comparisons and Receiver Operating Characteristic (ROC) analysis.

RESULTS

PIV values were significantly higher in the SSHL group in comparison to the control group ($p<0.001$). PIV values decreased progressively as recovery levels increased, although the difference did not reach statistical significance ($p=0.059$). Nevertheless, incomplete recovery patients demonstrated significantly higher PIV values than those with complete recovery ($p=0.011$). ROC analysis showed that PIV had a statistically significant but moderate ability to predict complete recovery (AUC=0.645, 95% CI: 0.537–0.744, $p=0.011$). The optimal cut-off value was ≤338.31, yielding a sensitivity of 67.6% and a specificity of 60.5%. The negative predictive value was notably high (86.2%).

CONCLUSIONS

PIV is elevated in patients with SSHL and is associated with hearing recovery. Although its predictive performance is moderate, it may serve as a simple, cost-effective, and accessible adjunctive biomarker for prognostic evaluation. Incorporating PIV into routine clinical assessment may help identify patients at higher risk of poor recovery and support more individualized management strategies.

OP-799

Clinical Outcomes Of Cochlear Implantation And Patient Satisfaction In Patients Treated With Subtotal Petrosectomy

Abdullah Dalğıç[1], **Canberk Kertmen**[1], **Kaan Işıklar**[1]

[1]*İzmir City Hospital, University of Health Sciences, Türkiye*

BACKGROUND & AIM

Subtotal petrosectomy combined with cochlear implantation (CI) is a well-established surgical approach in patients with chronic otitis media, cholesteatoma, and complex middle ear pathology. However, data regarding postoperative patient satisfaction following this combined procedure are limited. This study aimed to evaluate subjective hearing satisfaction using the Abbreviated Profile of Hearing Aid Benefit (APHAB) questionnaire in patients who underwent subtotal petrosectomy and cochlear implantation, and to investigate the effects of demographic and clinical variables on satisfaction outcomes.

MATERIAL & METHODS

This retrospective study included 18 patients who underwent subtotal petrosectomy with cochlear implantation at a tertiary referral center. Patient satisfaction was assessed using the APHAB questionnaire, including its subscales: Ease of Communication (EC), Background Noise (BN), Reverberation (RV), and Aversiveness (AV), as well as the overall satisfaction score. Statistical analyses were performed using SPSS version 22. Normality was assessed with the Shapiro–Wilk test. Group comparisons were conducted using the Mann–Whitney U test, and correlations between APHAB scores and aided audiometric thresholds (512, 1024, 2048, and 4096 Hz) were evaluated using Pearson correlation analysis. Statistical significance was set at $p < 0.05$.

RESULTS

The mean overall APHAB satisfaction score was 3.86 ± 0.41, indicating moderate-to-high patient satisfaction. No statistically significant differences were observed in APHAB subscale or total scores based on gender, timing between surgeries, postoperative complications, or presence of comorbidities ($p > 0.05$ for all). Additionally, no significant correlations were found between APHAB scores and aided audiometric thresholds across all tested frequencies ($p > 0.05$).

CONCLUSIONS

Patients undergoing subtotal petrosectomy with cochlear implantation report favorable subjective hearing satisfaction as measured by the APHAB questionnaire. Satisfaction outcomes appear to be independent of demographic factors, surgical timing, postoperative complications, and objective audiometric thresholds. These findings highlight the importance of subjective outcome measures in the comprehensive evaluation of cochlear implant success

Can Exclusive Endoscopic Tympanoplasty Replace Microscopic Techniques In Advanced Ossiculoplasty? A Consecutive Cohort Study

Andreea Rusescu[1,2], **Irina Ionita**[1,2], **Daiana Gligor**[2], **Razvan Hainarosie**[1,2], **Viorel Zainea**[1,2], **Luana-Maria Gherasie**[1,2], **Andrei Ghenciulescu**[1,2]

[1]*Carol Davila University of Medicine and Pharmacy;* [2]*Professor Dr. Hociota Institute of Phonoaudiology and Functional ENT Surgery*

BACKGROUND & AIM

Exclusive transcanal endoscopic tympanoplasty (EET) has emerged as a minimally invasive alternative to conventional microscopic surgery for tympanic membrane repair and ossicular chain reconstruction. However, evidence regarding its effectiveness in advanced ossicular pathology remains limited. This study evaluated anatomical and functional outcomes of EET across the full spectrum of Wullstein tympanoplasty types (I–V).

MATERIAL & METHODS

A retrospective, single-centre cohort study was conducted over 20 months (October 2023–May 2025) in a tertiary referral centre. Ninety consecutive patients (aged 16–68 years) undergoing exclusive endoscopic tympanoplasty were included. Procedures were classified according to Wullstein types I–V. Ossiculoplasty techniques included incus transposition, titanium partial ossicular replacement prosthesis (PORP), titanium total ossicular replacement prosthesis (TORP), and Teflon PORP.

Primary outcome was graft integration rate. Secondary outcomes included postoperative air–bone gap (ABG) improvement, complication rates (Clavien–Dindo classification), operative time, and hospitalization. Statistical analysis used paired t-tests and chi-squared tests with significance set at $p < 0.05$.

RESULTS

Type III tympanoplasty was most frequent (34.4%), followed by Type II (26.7%), Type I (22.2%), Type IV (13.3%), and Type V (3.3%).

Overall graft integration rate was 98.9%. Mean postoperative ABG improvement was:

- 12.5 dB in Types I–II ($p = 0.004$),
- 16.8 dB in Type III ($p = 0.03$ vs Type I),
- 16.4–18.3 dB in Types IV–V.

Functional success (postoperative ABG ≤ 30 dB) was significantly associated with a mobile stapes footplate ($p = 0.031$) and adequate middle ear ventilation ($p = 0.048$).

Incus transposition achieved the best audiological outcomes, followed by titanium PORP; TORP reconstruction showed comparatively higher residual ABG values.

No major complications (Clavien–Dindo ≥ II) occurred. Transient vertigo was observed in 7.8% of patients. Prosthesis extrusion occurred in 4.4% of cases and was significantly associated with advanced ossicular destruction ($\chi^2 = 4.86$, $p = 0.027$).

Operative time and hospital stay increased proportionally with tympanoplasty complexity.

CONCLUSIONS

Exclusive transcanal endoscopic tympanoplasty provides high anatomical success and significant functional hearing improvement, including in advanced ossicular reconstruction. Outcomes are strongly influenced by ossicular integrity and middle ear ventilation status.

These findings support EET as a reliable minimally invasive alternative to conventional microscopic techniques, particularly when autologous reconstruction or titanium PORP can be applied.

OP-801

Evaluation Of A Planned Staged Surgery Strategy For Congenital Cholesteatoma

Shintaroh Amano[1], **Takanari Goto**[1], **Chikako Shinkawa**[1], **Shino Godo**[1], **Toshinori Kubota**[1], **Tsukasa Ito**[1]

[1]*Department of Otolaryngology, Head and Neck Surgery, Yamagata University Faculty of Medicine, Yamagata, Japan*

BACKGROUND & AIM

Open-type congenital cholesteatoma has been reported to be associated with a higher risk of residual disease after surgery. In our previous institutional report of congenital cholesteatoma treated between 2011 and 2017, residual disease was frequently observed in open-type cases, particularly when one-stage surgery with simultaneous ossicular reconstruction was performed. Based on these findings, our department has preferentially adopted a planned staged surgery strategy since 2018 for open-type congenital cholesteatoma to control residual disease strictly. The aim of this study was to evaluate the appropriateness of this post-2018 treatment strategy.

MATERIAL & METHODS

This retrospective single-center study included patients who underwent primary surgery for congenital cholesteatoma at our department between January 2018 and December 2025 and had at least 1 year of postoperative follow-up. Medical records and operative reports were reviewed. Patient characteristics, cholesteatoma type and stage, surgical approach, selection of one-stage or staged surgery, and postoperative recidivism after completion of ossicular reconstruction, categorized as residual or recurrent disease, were analyzed. In patients who underwent staged surgery, the presence and location of residual disease at the time of planned staged surgery were also evaluated.

RESULTS

Twenty-four patients (16 males and 8 females) were evaluated. Mean age was 8.5 years (range, 1–65 years; median, 5.5 years). Mean follow-up period was 50.1 months (range, 20.0–96.3 months). Seventeen cases were open-type and seven were closed-type. According to Potsic staging, there were 5 patients with stage I disease, 3 with stage II, 12 with stage III, and 4 with stage IV. Staged surgery was performed in 18 patients, including 15 of 17 open-type cases. Residual disease was identified in 7 patients at second-stage surgery and in 1 additional patient at third-stage surgery. The most common residual sites were the tensor tympani tendon (4 cases) and stapes region (3 cases).

Importantly, no patient was found to have residual cholesteatoma after completion of ossicular reconstruction. However, recurrent cholesteatoma developed in 2 patients, both of whom had open-type disease managed with staged surgery.

CONCLUSIONS

These findings support our post-2018 strategy of preferentially selecting staged surgery for open-type congenital cholesteatoma. Planned staged surgery enabled identification and removal of residual disease before ossicular reconstruction.

OP-802

Is The History Of Classical Migraine Essential For The Diagnosis Of Vestibular Migraine?

Dr. Mahmoud Mahrous[1]

[1]*aAudio-Vestibular Medicine Unit, Otorhinolaryngology Department, King Fahad Hospital of University, Imam Abdulrahman Bin Faisal University, Dammam, Saudi Arabia;* [2]*Audio-Vestibular Medicine Unit, Otorhinolaryngology Department, Faculty of Medicine, Ain Shams University, Cairo, Egypt*

BACKGROUND & AIM

In patients with vestibular migraine (VM), from a clinical standpoint, it is not uncommon for patients to lack the complete criteria of vestibular migraine. The study aimed to identify possible signs of vestibular migraine (VM) and suggest a protocol for diagnosing patients who may not meet all the usual criteria.

MATERIAL & METHODS

During the period from March 2019 to February 2024, 57 patients with VM out of 265 dizzy patients (21.5%) were retrospectively selected and reviewed. All patients underwent full history taking, basic audiologic evaluation, office vestibular examination, videonystagmography (VNG) and brain magnetic resonance imaging (MRI) with contrast. Migraine prophylactic drugs (topiramate or amitriptyline) were prescribed, and the dosages were modified based on the patient's therapeutic response.

RESULTS

Three categories of patients were identified: definite migraine (25 patients, 44%), probable migraine (10 patients, 19%) and investigational non-migraine recurrent headache (22 patients, 39%). The VNG test outcomes of all 57 patients showed positioning and/or positional nystagmus with mixed peripheral and central characteristics. Other VNG test results for all patients were normal (spontaneous nystagmus, oculomotor tests, and caloric test). Migraine preventive medicines significantly reduced headache and dizziness episodes in the three studied groups.

CONCLUSIONS

Vestibular migraine is not merely a disease but a spectrum of wide clinical presentations. A history of classical migraine supported but was not mandatory for diagnosis. Vestibular migraine patients presented with positional nystagmus exhibiting mixed peripheral and central characters.

OP-803

The Association Between Shape Of Cochlea And Electrode-To-Modiolus Distance

Moayyad Malas[1], **Mariam Aljehani**[1], **Abdulrahman Alsanosi**[1]

[1]*Department of Otolaryngology-Head and Neck Surgery, College of Medicine, King Saud University, Riyadh, Saudi Arabia.;* [2]*King Abdullah Ear Specialist Center (KAESC), King Saud University Medical City, Riyadh, Saudi Arabia*

BACKGROUND & AIM

Introduction: As the number of cochlear implant (CI) surgeries increases, greater emphasis should be placed on incremental improvements and on planning for a patient-centered approach. The shape of the basal turn (BT) of the cochlea has recently been evaluated and classified as either elliptical or round. However, the electrode position inside different shapes was not investigated.

Objective: This study aims to evaluate the impact of different cochlear shapes on the electrode-to-modiolus distance (EMD) among the CI patients.

MATERIAL & METHODS

Methods: A retrospective study was conducted on patients with normal cochleae who underwent cochlear implantation. Postoperative imaging was reconstructed using dedicated Otological planning software to assess cochlear morphology and electrode positioning. The cochlear shape was quantified using the basal turn width-to-height ratio (B/A ratio), and the EMD distance was measured.

RESULTS

Results: The final analysis included 41 ears. The mean EMD was 3.3 mm in the basal electrodes, decreasing to 2.8 mm in the middle region and reaching 1.9 mm at the apical electrodes. The mean basal turn width-to-height ratio (B/A) was 0.8 (range: 0.7–0.9). Simple linear regression revealed that cochleae with a round-shaped basal turn (B/A > 0.75) had a slightly shorter, but comparable, EMD in the basal region compared to those with an elliptical shape (3.3 mm vs. 3.5 mm). The apical region showed a bigger but non-significant distance in round-shaped cochleae (2.0 mm vs. 1.8 mm). Additionally, impedance measurements at the 12-month interval showed a significant difference in basal electrode impedance between round and elliptical cochleae.

CONCLUSIONS

Conclusion: This study reported no statistically significant association between cochlear anatomical parameters and electrode-to-modiolus distance. Lateral wall electrodes demonstrated comparable distances to the modiolus in both elliptical- and

round-shaped basal turn cochleae, suggesting stable positioning across anatomical variations. Although descriptive trends were observed, these findings should be interpreted as exploratory. Larger prospective studies are needed to further evaluate the influence of cochlear morphology on electrode positioning across different electrode designs.

OP-804

Fascia Or Cartilage? Tympanoplasty Outcomes In A Teaching Hospital Setting

Fabio Andre Selaimen[2], **Flávia Rauber Felkl**[2], **Maurício Noschang Lopes da Silva**[1], **Julia Werlang**[2], **Wiquinylson França de Oliveira**[2], **Sady Selaimen da Costa**[2]

[1]*Hospital de Clínicas de Porto Alegre;* [2]*Universidade Federal do Rio Grande do Sul*

BACKGROUND & AIM

Although numerous studies have evaluated tympanoplasty outcomes, most include heterogeneous perforation types. A recently proposed classification distinguishes inside-out perforations (without signs of prior retraction) from outside-in perforations (associated with retraction). Limiting analysis to inside-out perforations reduces heterogeneity related to middle ear dysfunction and allows a more precise comparison of graft materials. This study aims to compare anatomical and functional outcomes of temporalis fascia versus cartilage grafts in primary tympanoplasty for inside-out (without retraction) perforations.

MATERIAL & METHODS

This retrospective cohort study included ears with inside-out perforations undergoing primary underlay tympanoplasty at a tertiary teaching hospital in southern Brazil. Exclusion criteria were intraoperative ossicular chain abnormalities, incomplete data, or refusal to participate. Ears were divided into two groups according to graft material: temporalis fascia or cartilage. The primary outcome was graft integrity at a mean follow-up of 41.6 weeks. Secondary outcomes included perforation size stratification (<25% and ≥25% of the tympanic membrane) and postoperative air-bone gap variation.

RESULTS

A total of 287 ears from 257 patients were analyzed, including 230 fascia and 57 cartilage grafts. At 41.6 weeks, graft integrity was significantly higher in the cartilage group (84.2%) compared to the fascia group (60.9%) ($p = 0.0009$). For perforations <25%, cartilage achieved superior closure rates (82.9% vs 60.3%, $p = 0.006$). In larger perforations (≥25%), success rates were 86.7% for cartilage and 62.7% for fascia ($p = 0.08$). Both groups demonstrated comparable postoperative air-bone gap improvement.

CONCLUSIONS

Cartilage grafting in primary tympanoplasty demonstrated greater long-term anatomical stability than temporalis fascia, even in small inside-out perforations without prior tympanic retraction. Audiological outcomes were similar between groups. These findings suggest that cartilage may provide superior graft reliability without compromising hearing results in favorable perforation types.

OP-805

Clinical Course Of Otitis Media With ANCA-Associated Vasculitis: A Case Series Of Six Patients

Misaki Takaoka[1], **Hiroko Monobe**[1]

[1]*Japanese Red Cross Medical Center*

BACKGROUND & AIM

Otitis media with ANCA-associated vasculitis (OMAAV) is a disorder characterized by refractory otitis media and hearing loss caused by ANCA-associated vasculitis. Although the diagnostic criteria established in 2015 have enabled earlier diagnosis in some patients, a considerable number of cases remain diagnostically challenging, especially those with MPO-or PR3-ANCA-negative or without typical histopathological findings. In this study, we examined the clinical features of six patients with OMAAV.

MATERIAL & METHODS

We retrospectively reviewed six patients diagnosed with OMAAV between January 2018 and August 2025. The variables analyzed included sex, age, otologic symptoms, tympanic membrane findings, audiometric thresholds, MPO-ANCA and PR3-ANCA status, histopathological diagnosis, systemic manifestations, and treatment regimens.

RESULTS

Of the six patients (3 male, 3 female), aged 59-82 (median 72.5) years. Presenting symptoms included hearing loss, aural fullness, and otorrhea. In four patients, the otologic symptoms were the initial manifestation, whereas in two patients, otologic symptoms developed during follow-up by other specialties. Five patients presented with otitis media with effusion, and one patient exhibited otorrhea. Audiometric testing revealed hearing thresholds ≥25 dB in five patients; all affected ears

demonstrated mixed hearing loss. Four patients were positive for MPO-ANCA only, while two patients were negative for both MPO-ANCA and PR3-ANCA. Histopathological evidence of vasculitis on biopsy was observed in one patient, who was MPO-ANCA positive. Imaging studies identified hypertrophic pachymeningitis in two patients, and five patients had pulmonary involvement, such as interstitial pneumonia. Systemic corticosteroid therapy was administered to all patients, and immunosuppressive agents were added as indicated; however, marked hearing recovery was not achieved in every case.

CONCLUSIONS

Early diagnosis and prompt treatment can lead to a favorable prognosis.

otitis media, ANCA-associated vasculitis

OP-806

Comparison Of Vestibular Aqueduct Width In Children With And Without Sensorineural Hearing Loss: A Regional Analysis From Eastern Anatolia, Turkey

Ozan Kuduban[1]

[1]*Atatürk University Department of Otolaryngology Head and Neck Surgery*

BACKGROUND & AIM

The vestibular aqueduct (VA) is a narrow osseous channel located in the temporal bone that houses the endolymphatic duct and sac. Enlargement of this structure (EVA) represents one of the most frequently identified radiologic findings in children with sensorineural hearing loss (SNHL) (1). Contemporary diagnostic standards increasingly rely on more sensitive definitions, such as the Cincinnati criteria, which consider an opercular diameter of ≥2.0 mm as indicative of EVA (2). This study aims to systematically assess VA dimensions and to elucidate their clinical relevance in a pediatric population from Eastern Anatolia of Turkey.

MATERIAL & METHODS

This retrospective study included 25 children diagnosed with SNHL and 25 age-matched controls with normal hearing. All subjects underwent high-resolution computed tomography (HRCT) of the temporal bone. VA diameters were measured on axial images at the operculum according to standardized radiological protocols. EVA was defined based on the Cincinnati criteria (operculum>2.0 mm). Statistical analyses were performed to compare VA measurements between groups and to assess correlations with hearing loss severity.

RESULTS

Statistical analysis demonstrated a significant difference between groups ($p < 0.05$). Correlation analysis revealed a significant relationship between VA diameter and the degree of hearing loss.

CONCLUSIONS

Our findings demonstrate an association between increased VA diameter and SNHL in the pediatric population. An improved understanding of the association between an enlarged vestibular aqueduct and sensorineural hearing loss may help inform early diagnosis and guide clinical management strategies. Regional data from Eastern Anatolia underscore the need for careful assessment and follow-up of VA measurements in children with hearing loss.

OP-807

Postnatally Detected And Progressive Hearing Loss In Children With Biotinidase Deficiency: Clinical, Biochemical, And Genetic Correlates

Servet Erdemes[1], **Mahmut Ağırtmış**[1]

[1]*Harran University Faculty of Medicine, Şanlıurfa, Turkey*

BACKGROUND & AIM

Biotinidase deficiency (BTD) is a rare autosomal recessive metabolic disorder that can lead to multisystemic manifestations, including sensorineural hearing loss. This study aimed to investigate the relationship between hearing loss and biochemical, genetic, and electrophysiological parameters in patients diagnosed with BTD.

MATERIAL & METHODS

This retrospective study included 63 pediatric patients diagnosed with BTD through newborn screening between 2017 and 2024. All patients had passed the initial ABR screening during the neonatal period. Clinical auditory assessments were performed using otoacoustic emission (OAE) and detailed auditory brainstem response (ABR) testing. Patients were grouped according to the presence of hearing loss and compared in terms of biotinidase activity, genetic mutations, and ABR findings.

RESULTS

Hearing loss was identified in 9 patients (14.3%). All of these patients had bilateral OAE failure and showed significant prolongation in ABR wave latencies, especially in wave V (mean 5.63 ms vs. 5.32 ms, p = 0.00008). All individuals with hearing loss had biotinidase activity below 10 U/L and were classified as having severe BTD. The most frequently observed genetic variants were c.1270G>C and c.410G>A, both of which were associated with hearing loss in homozygous and heterozygous forms. ABR and OAE findings suggest that BTD can affect both peripheral and central auditory pathways.

CONCLUSIONS

This study suggests that hearing loss associated with BTD may follow a postnatally detected and progressive course based on serial clinical ABR findings, particularly in individuals with markedly reduced enzyme activity. The combined use of ABR and OAE testing provided valuable insight for comprehensive auditory evaluation. These findings emphasize the need for long-term auditory monitoring as part of routine follow-up in BTD patients, even in those who initially pass newborn hearing screening.

External Ear Anthropometry In Children With Autism Spectrum Disorder : A Case-Control Study

SİNEM ÖZCAN[1], **GİZEM ÖZCAN**[1], **PINAR ALGEDİK**[3], **BURAK ERKMEN**[2], **ŞAMİL ŞAHİN**[2], **ASLI BEGÜM CAN AYDIN**[3], **YAŞAR KEMAL DUYMAZ**[1]

[1]*Department of Otorhinolaryngology and Head & Neck Surgery, Sultan 2. Abdulhamid Han Training and Research Hospital, Istanbul, Turkey;* [2]*Department of Otorhinolaryngology and Head & Neck Surgery, Private Clinic, Istanbul, Turkey;* [3]*Department of Child and Adolescent Psychiatry, Private Clinic, Istanbul, Turkey*

BACKGROUND & AIM

Craniofacial anthropometric measurements vary according to age, sex, ethnicity, and disease status, and are useful for identifying morphological differences between patient groups. The external ear is a clinically important structure with applications in genetics, reconstructive surgery, and forensic medicine. Autism spectrum disorder (ASD) is a common neurodevelopmental disorder lacking objective biomarkers. Studies on craniofacial features in ASD are limited, and data on external ear anthropometry are scarce. This study aimed to compare external ear anthropometric measurements between children with ASD and healthy controls.

MATERIAL & METHODS

This study included 140 children with ASD aged 7–13 years and 140 healthy controls aged 8–13 years. Ethical approval was obtained from the Clinical Research Ethics Committee. Standardized bilateral ear photographs were obtained under identical conditions. Four previously defined anatomical landmarks were used: superaurel (spa), subaurel (sba), preaurel (pra), and postaurel (pa). Based on these points, ear length (spa–sba), ear width (pra–pa), and ear inclination angle were measured using ImageJ software. Statistical analyses were performed using SPSS.

RESULTS

The measurements of spa–sba, pra–pa, and ear inclination angle showed no statistically significant differences between the ASD and control groups (p=0.86, p=0.136, and p=0.341, respectively). No significant side-to-side differences were observed for any parameter.

CONCLUSIONS

No statistically significant differences in external ear anthropometric measurements were found between children with ASD and controls. These findings suggest that external ear morphology may not be a reliable distinguishing biomarker for ASD. Further multicenter studies with larger samples are needed.

Beyond The Tradition: A Retrospective Cohort Study On The New Modified Palisade Tympanoplasty Technique

Rula Jamal Naqi[1], **Isra Sinan**[2], **Noora Althawadi**[3], **Hesham Alrayyes**[1]

[1]*Royal Medical services;* [2]*Faculty of Genomics and Biotechonology, Canadore College;* [3]*London North West University Healthcare Trust*

BACKGROUND & AIM

Tympanic membrane perforation is a common cause of conductive hearing loss and otology morbidities. The most common cause is trauma, which tends to heal spontaneously. Conversely, perforations caused by infections or middle ear pathology, needs surgical intervention, which is tympanoplasty. While cartilage tympanoplasty provides benefits of durability and resistance to retraction, concerns persist regarding graft rigidity and its adverse effects on hearing outcomes. This study was implemented to assess anatomical and functional successes of an innovative and novel form of modified palisade cartilage tympanoplasty, which is designed to improve graft flexibility, stability, and audiological results.

MATERIAL & METHODS

A retrospective cohort study was conducted at a tertiary referral center between 2019 and 2023. Nineteen patients (age range 9-64 years) who underwent the modified palisade tympanoplasty using a tragal composite cartilage-perichondrium graft were included and alternative grafting techniques were excluded. Variables including demographic data, clinical history, surgical information, and post-operative follow-up regarding graft uptake and both functional and anatomical success were assessed for each patient. Functional success was defined as a postoperative air-bone gap (ABG) ≤ 20 dB, while anatomical success as an intact, dry tympanic membrane. Pre- and post-operative audiometric outcomes were compared using paired statistical analysis.

RESULTS

Complete graft uptake was accomplished in 89.5% of cases. Anatomical success was achieved in 78.9% of patients, and functional success in 84.2%. Audiometric evaluation showed a statistically significant improvement in postoperative ABG compared to preoperative values ($p = 0.004$). Disrupted ossicular chain and the presence of cholesteatoma or tympanosclerosis were significantly associated with poorer outcomes ($p < 0.001$). No significant associations were found between outcomes and patient demographics, perforation characteristics, smoking status, or surgical approach. Favorable results were achieved across surgeons with varying levels of experience.

CONCLUSIONS

The Modified Palisade Tympanoplasty technique is shown to have effective graft uptake and considerable improvement in hearing by overcoming the stiffness of cartilage graft. The effectiveness of this technique has been exhibited across wide ages range, co-existing health conditions and across different surgeons level, proving that all patients can be subjected to the procedure.Further studies need to be conducted to validate our findings.

OP-810

Presenting Complaint And Diagnostic Yield Of Mris For Vestibular Schwannomas

Dr Sebastian Powell[1], **Mr Wei Jia**[1], **Mr Chang Woo Lee**[1], **Professor Emma King**[1]

[1]*Department of Otolaryngology- Head and Neck surgery, University Hospital Dorset, Poole, United Kingdom*

BACKGROUND & AIM

Vestibular schwannomas are benign tumours of the vestibulocochlear nerve. The diagnostic yield of MRIs for vestibular schwannoma is low and its value in some patients remains uncertain. We aimed to determine the diagnostic yield of MRIs for vestibular schwannomas and to identify clinical predictors such as age and presenting symptoms that may refine patient selection for imaging.

MATERIAL & METHODS

A retrospective cohort study at a single centre. All MRI internal acoustic meatus ordered by otolaryngologists from 01/01/2022 to 31/12/2023 for a suspected vestibular schwannoma were included. Presenting symptoms, audiogram results, demographics and management outcomes were extracted from clinical records.

RESULTS

A total of 1,814 MRIs met inclusion criteria. The overall diagnostic yield was 1.65% with 30 diagnoses of vestibular schwannomas. Mild asymmetrical hearing loss alone (defined as <15 dB difference between ears at two consecutive frequencies) was not associated with vestibular schwannoma, no patients with this finding were diagnosed (p=0.025). On multivariate analysis, presenting with vertigo (odds ratio [OR] 4.03, p<0.001) or severe unilateral hearing loss (OR 5.26, p=0.002) were independently associated with a diagnosis of vestibular schwannoma. Unilateral tinnitus (OR 2.10, p=0.062), sudden onset asymmetrical hearing loss (OR 0.57, p=0.46), mild hearing loss (OR=1.03, p=0.98) or age (OR 0.74, p=0.48) were not associated with a vestibular schwannoma. Greater severity of unilateral hearing loss correlated with a larger tumour size at diagnosis (p=0.011). Incidental findings were very common (23%) and most patients (80%) were manged conservatively with serial MRIs.

CONCLUSIONS

To our knowledge this study is the largest cohort study evaluating the relationship between presenting symptoms and MRI yield for vestibular schwannomas. The diagnostic yield is low as in previous studies. Isolated mild asymmetrical hearing loss may not warrant further investigation and are unlikely to benefit from a MRI. Presenting with unilateral tinnitus was a poor discriminator for a diagnosis of vestibular schwannoma. However, patients with unexplained vertigo should be considered for an MRI. These results have important implications for resource utilisation and guideline development. Further research is needed to consider whether age related thresholds are appropriate.

OP-811

Big Cut Or Small Hole? Influence Of Stapes Surgery Technique On Complications And Audiological Outcomes

Mariana Borges dos Santos[1], **Catarina Martins Pinto**[1], **Duarte Morgado**[1], **Ines Veloso**[1], **João Rodrigues**[1], **Sérgio Caselhos**[1]

[1]*ULS Alto Ave*

BACKGROUND & AIM

Stapes surgery is an established treatment for otosclerosis, with stapedotomy and stapedectomy being the two most performed techniques. Although both techniques provide effective hearing improvement, differences in complication rates and their impact on audiological outcomes remain a significant subject for further investigation. The aim is compare the incidence and type of adverse events associated with stapedotomy and stapedectomy, and to evaluate whether surgical technique influences postoperative audiological outcomes.

MATERIAL & METHODS

This retrospective study reviewed cases of primary otosclerosis treated with stapes surgery from January 2015 to June 2025. Patients were grouped by technique: stapedotomy or stapedectomy. Both intraoperative and postoperative complications were documented and categorized as early or late. Hearing results were measured by pure-tone audiometry, focusing on air–bone gap closure and bone conduction thresholds before surgery and at 6 months post-op. Statistical comparisons of complications and hearing outcomes were performed between groups.

RESULTS

A total of 128 ears from 112 patients were included, with 107 undergoing stapedotomy and 21 stapedectomy. Mean age was 45.2 years, mostly female. Complications occurred in 14% of stapedotomy and 23.8% of stapedectomy cases, most frequently vertigo or revision surgery for lack of hearing improvement. Complications were more frequent in the stapedectomy group, without statistical significance. The SRT before (64.57 ± 12.56) and after (39.77 ± 15.49) stapedotomy showed statistical significance ($p < 0.001$). For stapedectomy, the SRT before (65.32 ± 14.18) and after (40.51 ± 10.37) surgery was statistically significant ($p < 0.001$). There was no statistically significant difference in SRT between the two groups.

CONCLUSIONS

Although stapedotomy is the preferred technique for most surgeons, both stapedotomy and stapedectomy are effective for the surgical management of otosclerosis, yielding satisfactory audiological outcomes and a low rate of complications.

OP-812

Long-Term Outcomes Of Ossiculoplasty After Tympanomastoidectomy: The Impact Of Surgical And Reconstruction Techniques

Müslüm AYRAL[1]

[1]*Gazi Yaşargil Training and Research Hospital, Department of Otorhinolaryngology, Head and Neck Surgery*

BACKGROUND & AIM

Chronic otitis media (COM) frequently results in ossicular chain damage and conductive hearing loss. Ossiculoplasty aims to restore sound transmission; however, postoperative outcomes may vary depending on the reconstruction material and surgical technique. Long-term stability of hearing outcomes remains a key concern. In this study, we aimed to compare the short- and long-term audiological and anatomical outcomes of different ossiculoplasty materials and to evaluate the effect of surgical technique on hearing outcomes.

MATERIAL & METHODS

This retrospective study included 74 patients who underwent tympanomastoidectomy with ossiculoplasty between 2019 and 2023. Patients were categorized according to reconstruction material (autograft, bone cement, partial ossicular replacement prosthesis [PORP], and total ossicular replacement prosthesis [TORP]) and surgical technique (canal wall up [CWU] vs canal wall down [CWD]). Audiological outcomes were assessed using pure-tone audiometry. Air–bone gap (ABG) ≤20 dB was defined as functional success. Short-term outcomes were evaluated at 6 months, and long-term outcomes at final follow-up. Multivariable linear and logistic regression analyses were performed to identify factors associated with ABG changes and clinically significant deterioration.

RESULTS

The mean age was 34.7 ± 13.5 years with a mean follow-up of 31.4 ± 4.1 months. Air conduction and ABG improved significantly at 6 months ($p < 0.001$), while bone conduction remained unchanged ($p = 0.55$). Mean ABG decreased from 31.5 ± 12.1 dB preoperatively to 15.5 ± 8.5 dB at 6 months and slightly increased to 17.2 ± 7.6 dB at long-term follow-up ($p < 0.001$). Success rates (ABG ≤20 dB) were 68.9% at 6 months and 63.5% at long-term. Bone cement showed the highest stability (73.7%). PORP and TORP had similar short-term success, while PORP showed slightly better long-term outcomes. CWU achieved higher success than CWD. Bone cement was associated with less ABG deterioration, whereas PORP was associated with increased risk of ABG worsening.

CONCLUSIONS

Ossiculoplasty outcomes in COM are influenced by both reconstruction material and surgical technique. Bone cement provides the most stable long-term hearing results, while autografts offer reliable outcomes. Although PORP and TORP yield comparable short-term results, PORP may offer better long-term stability. The CWU technique is associated with superior hearing outcomes compared to CWD. Careful selection of reconstruction method and preservation of middle ear anatomy are critical for optimizing long-term functional success.

Trans-Impedance Matrix Heatmap Patterns In Cochlear Implant Patients With Different Cochlear Pathologies: Meningitis, Otosclerosis, And Temporal Bone Fractures

Dalal Alrushaydan[2], Atheer A. Alsufyani[1], Khaled Alhussinan[1], Fida Almuhawas[1,3], Mada Aljabr[2], Hassan Yalcouy[2], Abdulrahman Alsanosi[1,3]

[1]Department of Otolaryngology, Head and Neck Surgery, King Saud University Medical City, Riyadh - Saudi Arabia; [2]Cochlear Arabia Regional Headquarters, Riyadh - Saudi Arabia; [3]King Abdullah Ear Specialist Center (KAESC), King Saud University Medical City, Riyadh - Saudi Arabia

BACKGROUND & AIM

Transimpedance matrix (TIM) imaging is an electrical field–based modality that visualizes intracochlear current spread and may detect electrode malposition and subtle cochlear pathology beyond radiological resolution. This study aimed to evaluate etiology-specific TIM heatmap patterns in adult cochlear implant recipients and to assess the utility of TIM as an adjunct to conventional imaging.

MATERIAL & METHODS

This observational retrospective case series included 11 adult cochlear implant recipients (15 implanted ears) with defined etiologies: head trauma/temporal bone fracture (5 ears), post-meningitis deafness (5 ears), and cochlear ossification or otosclerosis (5 ears). Preoperative CT and/or MRI confirmed pathology, and postoperative X-ray verified electrode position. TIM measurements were obtained using Cochlear® CustomSound EP software. A normal TIM pattern was defined as a continuous diagonal gradient from bottom-left to top-right. Deviations from this pattern were analyzed and correlated with etiology and radiological findings.

RESULTS

Distinct etiology-related TIM deviations were identified. Trauma cases showed off-diagonal irregularities and signal dissociation suggestive of fractures or over-insertion, including one abnormal TIM with normal imaging. Post-meningitis ears commonly demonstrated off-diagonal signal loss or apical attenuation without radiological correlations. Severe ossification with under-insertion produced an Ocean Pattern of low potentials, whereas one otosclerosis case preserved a normal diagonal pattern configuration.

CONCLUSIONS

TIM imaging is highly sensitive to changes in tissue conductivity and electrode–tissue interface integrity, enabling detection of early fibrosis or ossification not visible on standard imaging. TIM may serve as a useful adjunct in postoperative cochlear implant evaluation. Further prospective validation is required.

OP-814

Traveling Wave Delay (Velocity) In Cochlear Implantees

Mehmet Emin KELEŞ[1], Bülent SATAR[2], Hatice Kübra BOZKURT[3], Fatma Ceyda AKIN ÖÇAL[1], Ceren KARAÇAYLI[1], Emine AYDIN[1]

[1]University of Health Sciences, Gulhane Training and Research Hospital, Department of Otorhinolaryngology, Ankara, Türkiye; [2]University of Health Sciences, Gulhane Medical School, Department of Otorhinolaryngology, Ankara, Türkiye; [3]University of Health Sciences, Faculty of Health Sciences, Department of Audiology, Ankara, Türkiye

BACKGROUND & AIM

Background: Auditory performance in cochlear implant (CI) users varies significantly. Unlike normal hearing's "travelling wave" mechanism, CIs stimulate the auditory nerve via discrete electrodes. It remains unclear if natural tonotopic temporal dynamics are preserved during electrical stimulation.

Aim: This study investigates N1 latency differences between basal and apical electrodes using Neural Response Telemetry (NRT) in 25 CI users. We aim to determine if these variations reflect natural travelling wave delay and whether they correlate with clinical outcomes, specifically SRT, SD, and CAP-2 scores.

MATERIAL & METHODS

Neural Response Telemetry (NRT) was evaluated in 25 cochlear implant users (8 prelingual, 17 postlingual) with a mean age of 38.3 years. Prior to testing, electrode integrity and functionality were verified using Impedance Telemetry (IT); only electrodes within the normal impedance range were included in the study. NRT measurements were then performed on eligible subjects, and N1 latency values were recorded to conduct a comparative analysis between Electrode 1 (basal) and Electrode 22 (apical). Ethical approval was granted by the Non-Interventional Scientific Research Ethics Committee of the University of Health Sciences, Gulhane Training and Research Hospital (Approval No: 2025/250, 04.12.2025).

RESULTS

Analyses included 25 patients (mean age: 38.3±19.7 years). Overall mean Speech Reception Threshold (SRT) was 34.2±12.0 dB, and Speech Discrimination (SD) was 49.2±27.6%. Electrode 22 (apical) showed a significantly longer mean N1 latency than Electrode 1 (basal) (333.5±62.4 µs vs. 313.9±49.2 µs; p=0.047). Subgroup analysis between prelingual and postlingual patients revealed no significant differences in N1 latencies for E22 (p=0.500) or E1 (p=0.786), nor in ΔNRT values (p=0.280). However, clinical outcomes differed significantly: postlingual patients demonstrated higher CAP-II scores (7.35±1.46 vs. 5.75±1.91; p=0.045) and lower, better SRT values (30.88±11.35 dB vs. 41.25±10.61 dB; p=0.036) compared to prelinguals. SD scores did not differ significantly between groups (p=0.202).

CONCLUSIONS

Longer apical N1 latencies align with the cochlea's tonotopic organization and travelling wave delay. Comparable latencies between prelingual and postlingual groups suggest peripheral cochlear nerve capacity is preserved regardless of deafness duration. However, superior clinical outcomes (CAP-II, SRT) in postlingual patients indicate distinct advantages in central auditory processing. Thus, while NRT provides objective tonotopic data, peripheral responses alone do not dictate functional success. These findings highlight the critical role of central neural integration and the need to combine objective telemetry with tailored rehabilitation.

Knockdown And Mutation Of Pou4F3 Gene Mutation Promotes Pyroptosis Of Cochleae In Cisplatin-Induced Deafness Mice By NLRP3/Caspase-3/ GSDME Pathway

Yu Rong[2], **Yang Hua**[1]

[1]*Department of Otorhinolaryngology, Peking Union Medical College Hospital, Beijing, China;* [2]*Department of ENT, First Affiliated Hospital of Nanchang University, Nanchang, China*

BACKGROUND & AIM

To investigate the effect and mechanism of Pou4f3 gene mutation on pyroptosis in cochleae of cisplatin-induced deafness mice.

MATERIAL & METHODS

Mice were intraperitoneally injected with cisplatin to construct an animal model of deafness, and sh-Pou4f3 and mutant vector were injected to alter gene expression. TUNEL staining was used to assess the apoptosis level of cochlear hair cells, ELISA was used to detect the secretion of inflammatory factors, and immunofluorescence and Western Blot were used to detect the expression of pyroptosis related factors.

RESULTS

Cisplatin induced pyroptosis through NLRP3/Caspase-3/GSDME pathway and significantly down-regulated Pou4f3 level. Pou4f3 mutations promote cochlear hair cell pyroptosis by activating the NLRP3/Caspase-3/GSDME pathway. Knockdown of Pou4f3 can superimpose cisplatin treatment to induce pyroptosis of cochlear hair cells through NLRP3/Caspase-3/GSDME pathway.

CONCLUSIONS

Pou4f3 gene mutation promotes pyroptosis of cochleae in cisplatin-induced deafness mice through NLRP3/Caspase-3/GSDME pathway.

Assessment Of Vestibular Functions Before And After Cochlear Implantation In Pediatric Patients

H.F Elgarem[1], **A.M. Mehanna**[1], **M.M. El Ghazaly**[1], **Ismail Nouh**[1]

[1]*Alexandria University, Egypt*

BACKGROUND & AIM

Cochlear implantation (CI) carries a potential risk of iatrogenic injury to the vestibular system. This study aimed to evaluate early postoperative changes in otolithic and semicircular canal functions among pediatric CI recipients.

MATERIAL & METHODS

A prospective study was conducted on ten children (aged 10–18 years) undergoing unilateral CI. A comprehensive vestibular assessment, including cervical and ocular Vestibular Evoked Myogenic Potentials (cVEMP, oVEMP) and the Video Head Impulse Test (vHIT), was performed one week preoperatively and one month postoperatively. Statistical analysis was performed using Wilcoxon signed-rank and exact McNemar tests.

RESULTS

cVEMP responses decreased from 100% to 30% with amplitude dropping from 74.54 ± 27.14 µV to 16.63 ± 26.00 µV ($p = 0.0039$). oVEMP responses declined from 90% to 20% with amplitude decreasing from 4.18 ± 3.15 µV to 1.25 ± 2.79 µV ($p = 0.0117$). Implanted-side horizontal vHIT gain decreased slightly (1.00 ± 0.09 to 0.92 ± 0.10, $p = 0.0391$) but remained normal. Vertical canal and contralateral horizontal canal gains showed no significant change.

CONCLUSIONS

Pediatric CI appears to preserve semicircular canal function while frequently impairing the otolithic pathways (saccule and utricle). Routine pre- and postoperative vestibular assessment is recommended to facilitate early detection and timely vestibular rehabilitation.

High-Resolution Computed Tomography After Stapedotomy: Understanding Prosthesis-Related Artifacts And Apparent Vestibular Penetration

Andrea Di Laora[1,5], **Matteo Di Bari**[1,2], **Erica Spina**[3], **Bruno Law-Ye**[4], **Gaetano Davide Drago**[1], **Hugo Delille**[1], **Daniele Bernardeschi**[1]

[1]*Department of Otology, Auditory implants, and Skull Base Surgery, Hospital Pitié-Salpêtrière, Sorbonne University, Paris, France;* [2]*Otorhinolaryngology, Head and Neck Department, Ospedale Nuovo di Legnano, ASST Ovest Milanese, Legnano, Milan, Italy;* [3]*Department of Radiology, Ospedale Nuovo di Legnano, ASST Ovest Milanese, Legnano, Milan, Italy;* [4]*Department of Radiology, Hospital Pitié-Salpêtrière, Sorbonne University, Paris, France;* [5]*Otorhinolaryngology, Head and Neck Department, Hospital Saint Louis, La Rochelle, France*

BACKGROUND & AIM

High-resolution computed tomography (HRCT) plays a key role in the pre-revision assessment of patients with persistent vertigo or absence of audiological benefit after stapedotomy. Accurate evaluation of prosthesis position and vestibular penetration is essential for clinical decision-making; however, HRCT measurements may be affected by prosthesis-related imaging artifacts, potentially leading to misinterpretation. The aim of this study was to quantify HRCT measurement artifacts of stapes prostheses according to prosthesis material and diameter, with particular emphasis on their impact on apparent vestibular penetration.

MATERIAL & METHODS

A retrospective analysis of HRCT was conducted in patients who underwent revision stapedotomy at a tertiary referral center between 2016 to 2022. HRCT was performed following primary stapedotomy in cases of post-operative complications, such as vertigo or worsening of hearing loss, or at a later stage in patients with unsatisfactory hearing outcomes. Prosthesis length and vestibular penetration were measured on reconstructed HRCT images. Measurement artifact was defined as the difference between radiologically measured and actual prosthesis length. Data collected included prosthesis type, actual length, diameter, radiological artifact and degree of vestibular penetration.

RESULTS

Fifty-seven ears from forty-nine patients were included. Titanium/Nitinol and Titanium/Platinum pistons were analyzed. Titanium/Nitinol prostheses with a diameter of 0.4 mm showed the smallest HRCT measurement artifact (mean error 0.28 mm), while Titanium/Platinum prostheses tended to be overestimated in length (mean error 0.54 mm). Artifact and apparent vestibular penetration on HRCT varied according to prosthesis diameter and material.

CONCLUSIONS

Titanium prosthesis demonstrated variable degrees of artifact on HRCT-scan. Therefore, HRCT findings prior to revision stapes surgery should be interpreted with consideration of prosthesis-specific imaging artifacts. Assessment of vestibular penetration on HRCT does not necessarily reflect true extent of prothesis intrusion and may be either overestimated or underestimated depending on the prosthesis material and diameter. Awareness of these imaging limitations is essential to prevent misinterpretation and to avoid potentially unnecessary revision surgery.

Analysis Of Audiovisual Synesthetes' Regions Of Interest

Shujian Huang[1], **Yiming Ma**[1], **Hui Wang**[1], **Shankai Yin**[1]

[1]*Shanghai Sixth People's Hospital and Shanghai Jiao Tong University School of Medicine*

BACKGROUND & AIM

This study employed a high-density electroencephalography (EEG) system to comparatively analyze the changes and differences in the regions of interest (ROIs) between individuals with and without audiovisual synesthesia, aiming to explore the underlying mechanisms of audiovisual synesthetic perception.

MATERIAL & METHODS

The study included 14 young adults with normal hearing. Based on whether audiovisual synesthesia could be induced, participants were divided into a synesthesia group (n=4) and a control group (n=10). All participants underwent pure-tone audiometry, Montreal Cognitive Assessment (MoCA), and Trail Making Test (Parts A and B). Brain electrical activity was recorded using a 256-channel high-density EEG system during both an eyes-open resting state and an eyes-open task state involving viewing animations designed to induce audiovisual synesthesia. Scalp-level power spectral changes were analyzed and compared between the two groups. Source localization was performed using standardized low-resolution brain electromagnetic tomography (sLORETA), followed by functional connectivity analysis involving auditory and visual cortices.

RESULTS

The synesthesia group showed significantly better performance on TMT-B ($p<0.05$). EEG revealed significantly higher delta/theta power and lower alpha1/alpha2/beta3/gamma power in synesthetes ($p<0.05$). sLORETA indicated reduced activity in left superior posterior cingulate (BA31, alpha2) and insula (BA13, beta2) in synesthetes ($p<0.05$). Enhanced beta3 connectivity was found between right posterior cingulate (BA31) and right primary auditory cortex (BA41) in synesthetes.

CONCLUSIONS

Audiovisual synesthetes demonstrate significant advantages over controls in cognitive comprehension and tests involving visual processing. They exhibit stronger regional connectivity characteristics within specific ROIs compared to non-synesthetes. High-density EEG technology shows significant advantages in detecting functional brain changes associated with synesthesia.

OP-819

ASSOCIATION BETWEEN WIDEBAND TYMPANOMETRY FINDINGS AND ETDQ-7 SCORES IN EUSTACHIAN TUBE DYSFUNCTION

Fuat Bulut[1], **Melih Alpay**[1]

[1]*Department of Otorhinolaryngology, University of Health Sciences, Bursa Training and Research Hospital, Bursa, Türkiye*

BACKGROUND & AIM

This study aimed to evaluate the correlation between the Eustachian Tube Dysfunction Questionnaire-7 (ETDQ-7) scores and wideband tympanometry (WBT) findings in patients with Eustachian tube dysfunction (ETD), and to determine their value in clinical diagnosis.

MATERIAL & METHODS

A prospective observational cross-sectional study was conducted including 50 adults aged 18–64 years diagnosed with ETD (20 males and 30 females). Participants in the ETD group repeated the 7-item Eustachian Tube Dysfunction Questionnaire (ETDQ-7) within a two-week interval. WBT was performed in all participants, and resonance frequency (Hz), peak pressure (daPa), and pressure point values were analyzed according to age groups and sex. The study data were assessed for normality assumptions. Comparisons of continuous variables across age groups and between sexes were performed using the independent samples t-test, and associations between continuous variables were evaluated using Pearson’s correlation analysis. A p-value of <0.05 was considered statistically significant.

RESULTS

A statistically significant negative correlation was identified between resonance frequency values obtained by WBT and ETDQ-7 scores ($r = -0.336$, $p = 0.017$). ETDQ-7 scores increased with age, and a stronger negative correlation between WBT findings and ETDQ-7 scores was observed in older age groups ($r = -0.643$, $p = 0.013$). Female participants demonstrated higher ETDQ-7 scores than male participants, and a significant positive correlation between WBT parameters and symptom severity was observed among women ($r = 0.372$, $p = 0.028$).

CONCLUSIONS

The combined use of ETDQ-7 and WBT may enhance the sensitivity of functional ET assessment and offers a complementary diagnostic approach for functional ETD. Reduced low-frequency acoustic absorbance measured by WBT may serve as a valuable marker for early diagnosis and treatment monitoring. Accurate diagnosis should rely on the integrated interpretation of subjective and objective findings alongside clinical history and physical examination. Further large-scale multicenter studies are warranted to establish a consensus on standardized diagnostic criteria and approaches.

Tubercular Mastoiditis With Unusual Clinical Presentations: A Case Series

Farhan Tarafder[1], **Dr.Kanu Lal Saha**[1]

[1]*Bangladesh Medical University*

BACKGROUND & AIM

Tubercular mastoiditis is a rare form of temporal bone tuberculosis with diverse and often misleading clinical manifestations. It may mimic chronic otitis media, cholesteatoma, granulomatous otitis media, osteomyelitis, or vascular lesions, making early diagnosis challenging. Delayed recognition may result in significant morbidity and serious complications. This case series aims to describe the unusual clinical presentations, diagnostic challenges, management, and outcomes of tubercular mastoiditis.

MATERIAL & METHODS

A case series of five patients with tubercular mastoiditis managed at Bangladesh Medical University was reviewed(from March 2020-April 2026). Clinical presentation, otoendoscopic findings, radiological features, operative findings, histopathological results, GeneXpert MTB/RIF analysis where available, treatment modality, and clinical outcomes were analyzed.

RESULTS

Five patients presented with atypical tubercular mastoiditis. Clinical features included persistent otorrhea, hearing impairment, otalgia, external auditory canal granulation tissue or polypoidal mass, postauricular abscess, recurrent symptoms after previous mastoid surgery, and complicated mastoiditis. Initial clinical and radiological findings were inconclusive in several cases, with differential diagnoses including cholesteatoma, paraganglioma, chronic granulation otitis media, and complicated mastoiditis. One patient developed lateral sinus thrombosis confirmed by CT and MRI, while another showed extensive middle ear and mastoid soft-tissue disease with cortical bone erosion, posterior fossa dural plate involvement, dural enhancement, and subperiosteal collection. Diagnosis was confirmed by histopathological evidence of granulomatous inflammation with caseous necrosis; GeneXpert MTB/RIF detected Mycobacterium tuberculosis in one case. All patients received standard four-drug antitubercular therapy. Surgery was performed when indicated. All patients showed clinical improvement, with resolution or gradual improvement of otorrhea and inflammatory symptoms, although hearing improvement was variable.

CONCLUSIONS

Tubercular mastoiditis should be considered in patients with persistent external auditory canal granulation tissue, atypical mastoid disease, recurrent symptoms after mastoid surgery, postauricular abscess, complicated mastoiditis, or poor response to conventional treatment. Early biopsy, histopathological confirmation, and prompt antitubercular therapy, with surgery when required, are essential to achieve recovery and prevent potentially serious or fatal complications.

BACKGROUND & AIM

Monopolar electrocautery is frequently used in middle ear surgery, yet its potential thermal or electrical effects on the inner ear structures remain a concern.To evaluate the audiological and histopathological effects of monopolar electrocautery applied to the promontory at different power settings.

MATERIAL & METHODS

Thirty-two healthy female Sprague Dawley rats (200–240 g) were divided into four groups (n = 8 each): monopolar electrocautery 5 W, 10 W, 20 W, and control. Baseline Distortion Product Otoacoustic Emission (DPOAE) and Auditory Brainstem Response (ABR) measurements were obtained. In Groups 1–3, transtympanic cauterization was performed on the promontory with a monopolar needle tip for 2 seconds. DPOAE and ABR were repeated on days 7 and 14. Cochleae were then excised for histopathological evaluation.

RESULTS

No significant differences were observed in DPOAE amplitudes or ABR thresholds between baseline and follow-up days within any group ($p > 0.05$). Histopathological evaluation showed normal cochlear structure in all groups; hydropic degeneration or nuclear loss was not observed in spiral ganglion cells or nerve fibers, with no significant differences between groups ($p > 0.05$).

CONCLUSIONS

Monopolar electrocautery applied to the promontory at 5 W, 10 W, or 20 W for 2 seconds did not demonstrate harmful effects on the inner ear in audiological or histopathological evaluations in this rat model.

PROTECTIVE EFFECTS OF ROYAL JELLY AGAINST CISPLATIN-INDUCED OTOTOXICITY: A COMBINED FUNCTIONAL AND HISTOPATHOLOGICAL ANALYSIS

Mehmet Korkmaz[1], **Yunus Emre Oruç**[1], **Fakih Cihat Eravcı**[1], **Fahriye Kılınç**[2], **Hasan Furkan Çaycı**[2], **Malik Afifoğlu**[3], **Mustafa Atay**[1], **Hamdi Arbağ**[1]

[1]*Necmettin Erbakan University, Department of Otorhinolaryngology, Konya, Turkey;* [2]*Necmettin Erbakan University, Department of Pathology, Konya, Turkey;* [3]*Bursa City Hospital, Department of Otorhinolaryngology, Bursa, Turkey*

BACKGROUND & AIM

Cisplatin-induced ototoxicity is a significant clinical problem characterized by irreversible sensorineural hearing loss, primarily mediated by oxidative stress. Although various antioxidant agents have been investigated, an effective and widely accepted protective strategy has not yet been established. Royal jelly, a natural product rich in bioactive components, has demonstrated antioxidant and cytoprotective effects in various organ systems. This study aimed to evaluate the potential protective effects of royal jelly against cisplatin-induced ototoxicity using functional and histopathological methods.

MATERIAL & METHODS

A total of 32 adult female Wistar albino rats were randomly assigned to four groups (n = 8): control, royal jelly, cisplatin, and cisplatin + royal jelly. Royal jelly was administered orally at a dose of 100 mg/kg/day for 14 days. Cisplatin was administered as a single intraperitoneal dose of 10 mg/kg on day 7. Auditory function was evaluated at baseline, day 7, and day 14 using distortion product otoacoustic emissions (DPOAE) and auditory brainstem responses (ABR). At the end of the study (day 14), cochlear tissues were harvested and histopathological analyses were performed using a semi-quantitative scoring system

RESULTS

At day 14, no significant differences were observed among groups in DPOAE signal-to-noise ratio values at 4, 6, and 8 kHz frequencies ($p > 0.05$). In contrast, ABR threshold values differed significantly among groups ($p < 0.001$). The cisplatin group demonstrated significantly elevated thresholds compared to the control and royal jelly groups, whereas significant improvement was observed in the cisplatin + royal jelly group ($p < 0.001$). Total histopathological scores also showed significant differences among groups ($p < 0.001$), with the highest damage observed in the cisplatin group. Total histopathological scores were significantly lower in the cisplatin + royal jelly group compared to the cisplatin group ($p < 0.001$). Subgroup analyses revealed significant protective effects in the stria vascularis and spiral ligament ($p < 0.001$), whereas no significant differences were observed in the spiral ganglion.

CONCLUSIONS

Royal jelly demonstrated a protective effect against cisplatin-induced ototoxicity, with more pronounced effects in metabolically active cochlear structures such as the stria vascularis and spiral ligament. These findings suggest that royal jelly has potential as an otoprotective agent against cisplatin-induced ototoxicity.

External Auditory Canal Cholesteatoma

S.Rouadi[1], **M. Mahtar**[1]

[1]*ENT Department - 20 August Hospital - IBN ROCHD University Hospital of Casablanca*

BACKGROUND & AIM

cholesteatoma of external auditory canal remains uncommon and not well known. we describe this entity through several case report, wich is still misdiagnosed,

MATERIAL & METHODS

we report five cases including two primary cholesteatoma, one secondary cholesteatoma and two keratosis obturans of the external auditory canal wich is a very close pathology with similar clinical signs.

RESULTS

we permormed CWD in three cases , and CWU in two remaining cases. evolution was good without any reccurence. we discuss the physiopathology and clinical aspect of this pathology and also the importance of differencial diagnosis wich can lead to long delay for diagnosis (malignant external otitis , epidermoid carcinoma of the middle ear, skin pathology of external auditory canal)

CONCLUSIONS

it's a rare and misdiagnosed entity ; it must be well known, as miltiples differential diagnosis, the traitment is surgery with good results desribed in the litterature.

KEYWORDS

external auditory canal, Cholesteatoma , keratosis obturans

OP-824

Diagnostic Performance Of DWI In Cholesteatoma: Comparison With Surgical Findings And Histopathology

Muhammed Enes Bakır[1], **Ayşe Enise Göker**[1]

[1]*Department of Otorhinolaryngology, Prof. Dr. Cemil Taşcıoğlu City Hospital, Istanbul, Turkey*

BACKGROUND & AIM

Cholesteatoma is a destructive middle ear disease requiring surgical treatment. Diffusion-weighted imaging (DWI) is widely used for its detection; however, granulation tissue and inflammatory changes may lead to false-positive results. This study aimed to evaluate the diagnostic accuracy of DWI in cholesteatoma and to compare its findings with intraoperative observations and histopathological results. Additionally, differences in diagnostic performance between primary and revision cases were investigated.

MATERIAL & METHODS

This retrospective observational study included 96 patients who underwent surgery for suspected cholesteatoma at the Otorhinolaryngology Department of Prof. Dr. Cemil Taşcıoğlu City Hospital between 2024 and 2026 and had preoperative DWI. Patients with incomplete data, without preoperative imaging, or lacking histopathological confirmation were excluded. Imaging findings were categorized as positive or negative for cholesteatoma, with suspicious findings considered positive. Surgical findings and histopathology were used as reference standards. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy were calculated. Subgroup analyses were performed for primary and revision cases.

RESULTS

The mean age of patients was 35.25 ± 15.9 years, with 52.1% females and 47.9% males. The sensitivity and specificity of DWI compared to histopathology were 78.7% and 54.3%, respectively ($p=0.001$). Compared to surgical findings, DWI demonstrated a sensitivity of 86.8% and specificity of 58.1%. Surgical findings showed a sensitivity of 77.0% and specificity of 82.9% compared to histopathology ($p<0.001$). In subgroup analysis, DWI sensitivity was markedly higher in revision cases (92.9%) compared to primary cases (74.5%). A statistically significant association was observed in primary cases ($p=0.006$), while no significance was found in revision cases ($p>0.05$).

CONCLUSIONS

DWI demonstrates high sensitivity but limited specificity in the diagnosis of cholesteatoma. Surgical findings provide higher specificity, whereas DWI offers greater sensitivity. Notably, the diagnostic performance of DWI is significantly improved in revision cases. These findings highlight that DWI plays a crucial role in clinical decision-making, particularly in revision cases, but should be interpreted in conjunction with surgical findings and histopathological results.

OP-825

Meningitis Post-Cochlear Implant And Role Of Vaccinations Systematic Review

Khalid AlQarni[1]

[1]*Prince Sultan Medical Military City*

BACKGROUND & AIM

To investigate the incidence, risk factors, and management of meningitis in cochlear implant (CI)users.

MATERIAL & METHODS

A systematic review was carried out using PubMed, Scopus, Web of Science, and Cochrane Central Register. Articles were considered relevant if reported any data on incidence, clinical presentations, the role of vaccination, management, and outcomes of meningitis after CI.

RESULTS

A total of 32 studies including 27358 patients were included, and meningitis was reported in only 202 cases. Meningitis occurred in the period ranging from 1 day to 72 months after CI. A total of 55 patients received the pneumococcal vaccine, while 20 patients received the Haemophilus influenzae type B vaccine. A large number of participants (n=47) had associated anatomical malformations, while 62 had otitis media before meningitis. A total of 24 cases required revision surgery along with medical treatment. Full recovery was the outcome reported by the included studies in 19 patients.

CONCLUSIONS

Cochlear implant users seem to be at possible risk of bacterial meningitis at any time after implantation, especially in the presence of risk factors, such as otitis media and anatomical malformations of the cochlea.

KEYWORDS

cochlear implant, bacterial meningitis, vaccine, otitis media

OP-826

Intratympanic Bevacizumab Reduces Histopathological Changes In Experimental Otitis Media With Effusion

Hüseyin Çubuk[1], **Ahmet Adnan Cırık**[1], **Ömer Faruk Çalış**[2]

[1]*Department of Otorhinolaryngology – Head and Neck Surgery, Ümraniye Training and Research Hospital, Istanbul, Türkiye;* [2]*Department of Pathology – Head and Neck Surgery, Ümraniye Training and Research Hospital, Istanbul, Türkiye*

BACKGROUND & AIM

Otitis media with effusion (OME) is a common pediatric disease that may lead to hearing loss. In recent years, vascular endothelial growth factor (VEGF) has been increasingly recognized as an important mediator in the pathogenesis of OME. The aim of this study was to investigate the effects of intratympanic administration of bevacizumab, a recombinant monoclonal antibody against VEGF, on histopathological changes in an endotoxin-induced OME rat model.

MATERIAL & METHODS

A total of 32 male Wistar Albino rats were included in the study. OME was induced by injection of Escherichia coli lipopolysaccharide (LPS) into the middle ear. Six hours after LPS administration, intratympanic bevacizumab was administered to the study group, while the control group received intratympanic saline solution. Rats were sacrificed at 12 hours, 24 hours, 72 hours, and 7 days. Temporal bone specimens were harvested and evaluated histopathologically. Submucosal thickness, capillary vessel density, vascular diameter and submucosal neutrophil count were analyzed.

RESULTS

At 12 hours, the bevacizumab group demonstrated significantly higher neutrophil counts and effusion levels compared with the saline group. At 24 hours, vascular diameter was significantly lower in the bevacizumab group. At 72 hours, submucosal thickness was significantly reduced in the bevacizumab group. On day 7, submucosal thickness, vascular diameter, and vessel density were all significantly lower in the bevacizumab group compared with the saline group.

CONCLUSIONS

This study demonstrated that intratympanic administration of bevacizumab significantly suppresses vascular and mucosal histopathological changes, particularly in the late phase, in an experimental OME model. These findings support the role of VEGF as an active and targetable mediator in the pathogenesis of OME and suggest that anti-VEGF therapies may represent a potential treatment option. However, further experimental and clinical studies are required before clinical application.

OP-827

SURGICAL TREATMENT OF MIDDLE EAR CHOLESTEATOMA IN CHILDREN

Aleh Khorau[1]

[1]*Grodno State Medical University*

BACKGROUND & AIM

To analyze the disease structure and results of surgical treatment in children with middle ear cholesteatoma.

MATERIAL & METHODS

Between 2019 and 2023, 56 children with chronic suppurative otitis media were operated on in the Otorhinolaryngology Department of the Grodno University Clinic. Chronic epitympano-antral suppurative otitis media was diagnosed in 36 patients (64%), with intraoperative confirmation of cholesteatoma in 19 of these children (53%). The average age of patients with cholesteatoma was 11.8 years. All children underwent CT scanning of the temporal bones; in complex diagnostic cases, MRI with non-echoplanar diffusion-weighted imaging (non-EPI DWI) was used, allowing visualization of residual cholesteatoma down to 3 mm.

RESULTS

Analysis of anamnestic data revealed that 25% of children with cholesteatoma had a history of tympanotomy for acute otitis media. This suggests a possible iatrogenic role of tympanotomy in the etiology of acquired cholesteatoma in children.The choice of surgical procedure was determined by the extent of the disease. Canal Wall Down procedures were performed in 9 patients with invasive growth where complete eradication could not be confidently ensured. A closed technique with reconstruction of the walls using auricular cartilage was applied in 10 children. Reconstruction of the ossicular chain was performed in 19 patients (titanium prostheses, autologous incus bone, ossiculoplasty). In the long-term postoperative period (6 months or more), significant hearing improvement was achieved: the mean air-bone gap decreased from 37.1 dB to 19.8 dB. The rate of recurrent and residual cholesteatoma was 15.8% (3 children), consistent with global data and confirming the need for dynamic follow-up, including MRI monitoring.

CONCLUSIONS

Surgical treatment of cholesteatoma in children requires a differentiated approach. Open techniques ensure radicality in extensive forms, while closed techniques with cartilage reconstruction can improve functional outcomes. The identified high frequency of tympanotomies in the medical history necessitates a balanced approach to this procedure. The use of modern imaging methods (non-EPI DWI) is key for the early detection of residual cholesteatoma and reducing the number of revision surgeries.

OP-828

Incus Long Columella Ossiculoplasty: A Retrospective Evaluation

Halit Altunkaynak[1], **İsmail Aytaç**[2], **Elif Baysal**[3]

[1]*Bursa Karacabey State Hospital Otolaryngology Department;* [2]*Medical Point Gaziantep Hospital Otolaryngology Department;* [3]*Gaziantep University Medical Faculty Otolaryngology Department*

BACKGROUND & AIM

This study evaluated the effectiveness of reshaping the incus into a long columella for ossicular chain reconstruction in patients with chronic otitis media undergoing tympanoplasty.

MATERIAL & METHODS

A retrospective analysis included 96 patients who underwent tympanoplasty between January 2014 and January 2024 at a tertiary referral center. Patients with chronic otorrhea and conductive hearing loss were included. Audiological outcomes, including air–bone gap (ABG) and hearing thresholds, were assessed before and after surgery. Intraoperative findings and follow-up data were collected from medical records. Statistical analyses compared preoperative and postoperative results.

RESULTS

Of the 96 patients, 62.5% were male and 37.5% were female. Surgery was performed on the right ear in 40.6% of cases and on the left in 59.4%. The mean age was 27.54±14.17 years for right-ear operations and 28.84±15.24 years for left-ear operations, with no significant age difference between groups. There was no significant difference between preoperative and postoperative hearing thresholds in either ear (right: $p=0.450$; left: $p=0.391$). Open cavity tympanoplasty was performed in 62.5% of cases, mastoidectomy tympanoplasty in 22.9%, and tympanoplasty alone in 14.6%. The procedure involved removing epithelial tissue and reshaping the incus into a long columella. Postoperative ABG values improved significantly compared to preoperative measurements ($p<0.001$), indicating better conductive hearing. No intraoperative or postoperative complications, including prosthesis extrusion, were observed. Nine patients required revision surgery for recurrent cholesteatoma.

CONCLUSIONS

This technique is reliable and provides both functional and surgical benefits in appropriately selected cases. While many options exist for ossiculoplasty, the reliability of this method depends largely on the surgeon's experience and the availability of clinical resources. Further validation through prospective studies with larger patient cohorts and longer follow-up is recommended.

OP-829

Investigation Of Outcomes Of Sliding Cartilage Tympanoplasty For Improving Tympanic Membrane Closure

reza jahangiri[1]

[1]*Shiraz Unoversity of mdical Sciences*

BACKGROUND & AIM

Recent studies indicate that in the Tympanoplasty procedure, the failure rate in anterior perforations is significantly higher compared to central or posterior perforations. To address these challenges, this study evaluates the efficacy of a novel technique called Sliding cartilage tympanoplasty. This method is designed to simplify the repair of anterior and marginal perforations and to improve graft success rates.

MATERIAL & METHODS

This study includes 10 patients aged 18 to 65 years with chronic otitis media or tympanic membrane perforation (specifically, anterior marginal perforation with a residual margin of less than 1 mm) and either conductive or sensorineural hearing loss. Exclusion criteria include active ear infection, cholesteatoma, previous tympanoplasty, and systemic diseases that affect healing. All patients undergo cartilage tympanoplasty, in which cartilage is harvested from the tragus or concha. The surgical procedure involves creating a groove in the anterior mesotympanum beneath the bony sulcus to secure the anterior edge of the cartilage graft. Graft success will be evaluated through microscopic examination by the surgeon three months postoperatively, and hearing thresholds will be measured using pure-tone audiometry (PTA) before and three months after the surgery.

RESULTS

All the cartilage grafts healed successfully after a 6-month follow-up. Hearing improvement and Air-Bone gap closure were acceptable.

CONCLUSIONS

Sliding cartilage tympanoplasty was simple, effective, and safe in the repair of marginal anterior tympanic membrane perforation.

OP-830

Assessing The Surgical And Audiological Outcomes Of Simultaneous Compared To Sequential Cochlear Implant In Pediatrics With Hearing Loss: A Systematic Review And Comprehensive Meta-Analysis.

hamdan alguydi[1]

[1]*national guard hospital jeddah*

BACKGROUND & AIM

Hearing loss profoundly affects daily life, with cochlear implants (CI) serving as a key remedy. While CIs offer benefits like enhanced sound localization, outcomes can vary based on implantation timing and age. In pediatrics, there's debate about the best implantation method. Early intervention, especially within the first year, is believed to harness neural plasticity, optimizing auditory rehabilitation. This study delves into the merits of simultaneous vs. sequential cochlear implantation in pediatric patients to guide clinical decisions.

MATERIAL & METHODS

Following the PRISMA-P 2020 guidelines, we searched MEDLINE, EMBASE, Google Scholar, and Web of Science on November 1, 2025, using pediatric cochlear implantation-related terms. Included studies were primary, peer-reviewed, and compared simultaneous vs. sequential implant outcomes in pediatrics ≤18 years. Data, encompassing surgical and audiological metrics, were extracted by two reviewers, with bias assessed using the MINORS tool. Due to study heterogeneity, we opted for a narrative synthesis over a meta-analysis.

RESULTS

We analyzed Eight observational studies on cochlear implants from four countries. Simultaneous implant surgeries often had shorter cumulative times but were longer than single implant surgeries. Surgical complications were minor, with occasional extended hospital stays. Simultaneous implant surgeries typically had shorter cumulative hospitalization times. The inter-implant delay showed varied impacts on auditory perception. Speech perception in the second implanted ear remained poorer than the first, but bilateral scores outperformed individual implants.

CONCLUSIONS

Our study provides evidence that simultaneous implantation offers superior surgical and audiological outcomes for pediatric patients due to simultaneous implantation having shorter surgical times and hospital stays.

OP-831

Evaluation Of The Long-Term Outcomes Of Surgical Treatment Methods For Typmanic Membrane Pars Tensa Retractions

Kağan Avcı[1], **Said Sönmez**[1], **Hakan Kara**[1], **Mehmet Çelik**[1], **Kadir Serkan Orhan**[1], **Beldan Polat**[1]

[1]*Istanbul University, Istanbul Faculty of Medicine Department of Otolaryngology-Head and Neck Surgery;* [2]*Diyarbakır Ergani State Hospital*

BACKGROUND & AIM

The primary objective of our study was to determine the long-term recurrence rate of pars tensa retraction pockets (PTRP) and to identify clinical and surgical factors associated with recurrence in three patient groups undergoing cartilage reinforcement tympanoplasty, ventilation tube insertion, or a combination of both surgical methods. The secondary objective was to evaluate preoperative and long-term postoperative hearing outcomes and to identify factors affecting hearing.

MATERIAL & METHODS

A total of 61 patients (61 ears) who underwent surgical treatment for PTRP between 2018 and 2023, with a minimum postoperative follow-up period of 18 months, were retrospectively analyzed. Patients were categorized into three groups based on surgical technique performed (cartilage reinforcement tympanoplasty, T-tube insertion, cartilage reinforcement tympanoplasty with T-tube insertion). Postoperative PTRP recurrence, factors potentially associated with recurrence and hearing outcomes were assessed. Statistical analysis was performed.

RESULTS

Of the 61 patients, 40 underwent cartilage reinforcement tympanoplasty, 11 underwent T-tube insertion, and 10 underwent cartilage reinforcement tympanoplasty with T-tube insertion. The T-tube insertion group demonstrated a statistically significantly higher recurrence rate compared to the cartilage reinforcement tympanoplasty group (p=0.01). Statistical analysis revealed no significant association between recurrence and preoperative PTRP location or stage, prior surgery history, adenoid hypertrophy grade, or history of allergy. Air-bone gap (ABG) improvement was statistically significant in both the reinforcement tympanoplasty group (p=0.003) and the T-tube group (p=0.035), but did not reach statistical significance in the combined group (p=0.102).

CONCLUSIONS

Cartilage reinforcement tympanoplasty apperars to be safe and effective technique for both early and advanced stage PTRP in terms of recurrence rates and functional outcomes. In patients with early stage PTRP, where eustachian tube function is expected to improve, ventilation tube insertion may be considered; however, due to the high recurrence rate, regular long-term follow-up is necessary. For early stage PTRP patients requiring surgical intervention who may not comply with regular follow-up, cartilage reinforcement tympanoplasty may be considered as first-line treatment.

OP-832

Stapedotomy Outcomes In Patients With “HRCT Negative Otosclerosis”

Daniele Bernardeschi[1], **Matteo Di Bari**[1], **Riham Altaisan**[1], **Hugo Delille**[1]

[1]*Hôpital Pitié Salpétrière, Paris, France*

BACKGROUND & AIM

Do patients with clinically suggestive otosclerosis and negative preoperative high-resolution computed tomography (HRCT) achieve hearing outcomes comparable to those with radiologically confirmed disease after primary stapedotomy?

MATERIAL & METHODS

This retrospective matched case–control study was conducted at a single tertiary referral center between January 2019 and December 2024. Ninety-two ears undergoing primary stapedotomy for intraoperatively confirmed stapes fixation were included. Thirty-nine ears with preoperative HRCT reported as negative for otosclerotic foci formed the CT-negative group, while 53 CT-positive cases were selected using nearest-neighbor matching. CT-negative scans were independently re-evaluated by two expert neuroradiologists and subclassified as CT–false-negative (n = 24) or CT–true-negative (n = 15). The exposure of interest was preoperative HRCT status (CT-positive, CT–false-negative, or CT–true-negative).

RESULTS

Baseline AC PTA (mean, 48.55 dB HL), BC PTA (mean, 27.01 dB HL), and ABG (mean, 21.54 dB HL) did not differ significantly between groups (P = 0.21, P = 0.42, and P = 0.09, respectively). Postoperatively, significant improvement in AC PTA was achieved across the groups (mean postoperative AC = 25.49 dB HL; $p < 0.001$), with no significant difference between groups ($p = 0.081$). A postoperative ABG ≤ 10 dB HL was achieved in 89.13% of cases. Complication rates were low and did not differ significantly between groups; one case (1.9%) of postoperative sensorineural hearing loss occurred in the CT-positive group, and no cases of anacusis were observed.

CONCLUSIONS

Stapedotomy is a safe and effective procedure for patients with CT-negative but clinically suggestive otosclerosis, with outcomes and complication rates comparable to CT-positive cases. In typical clinical presentations, negative HRCT findings alone should not preclude surgical exploration when clinical suspicion remains high.

OP-833

IS THE CONE OF LIGHT A RELIABLE INDICATOR OF TYMPANIC MEMBRANE NORMALITY? A LARGE-SCALE ENDOSCOPIC IMAGE ANALYSIS

Onur Yegin[1], **Mehmet Korkmaz**[1], **Fakih Cihat Eravcı**[1]

[1]*Konya Necmettin Erbakan University Faculty of Medicine*

BACKGROUND & AIM

The tympanic membrane light reflex, also known as the cone of light, is commonly regarded as an indicator of a normal tympanic membrane during clinical otoscopic examination. This study aimed to evaluate the diagnostic value of the light reflex in predicting tympanic membrane normality using a large series of endoscopic images.

MATERIAL & METHODS

In this retrospective, single-center observational study, 14,429 tympanic membrane images obtained between January 2020 and January 2026 were analyzed. All images were acquired using the same endoscopic system and were classified as normal or pathological by three experienced otorhinolaryngologists. The presence or absence of the light reflex was recorded for each image. Diagnostic performance was assessed by calculating sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and overall accuracy.

RESULTS

Of the 14,429 images, 10,893 (75.5%) were classified as normal and 3,536 (24.5%) as pathological. The light reflex was observed in 7,269 normal tympanic membranes (66.73%), whereas it was absent in 3,624 (33.27%). Among pathological tympanic membranes, the light reflex was present in 917 cases (25.93%). The sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of the light reflex in predicting tympanic membrane normality were 66.73%, 74.07%, 88.80%, and 41.95%, respectively. The overall accuracy was calculated as 68.53% ($p < 0.001$). Subgroup analyses showed that the light reflex could be preserved at relatively high rates in certain pathological conditions, such as serous otitis media (60.69%) and tympanic membrane retraction.

CONCLUSIONS

Although the light reflex is a commonly used finding in tympanic membrane assessment, the results of this study indicate that the light reflex alone is not sufficient to determine tympanic membrane normality. Therefore, in otoscopic evaluation, the light reflex should be interpreted as a supportive finding in conjunction with other clinical findings and audiological tests, rather than as an independent diagnostic criterion.

Is Mastoid Head Bandage Really Required In Patients Undergoing Middle Ear Surgery? A Randomized Control Trial

Muhammad Hammad Deewani[1], **Muhammad Wasif Siddiqui**[2], **Hassan Danish**[3], **Muhammad Ozair Awan**[1], **Muhammad Sohail Awan**[1], **Ainulakbar Mughal**[1], **Abdul Basit Vardag**[1], **Hamdan Pasha**[1], **Haissan Iftikhar**[4]

[1]*Aga Khan University, Karachi, Pakistan;* [2]*Dr. Ziauddin University and Hospital, Karachi, Pakistan;* [3]*Mukhtar A. Sheikh Hospital, Multan, Pakistan;* [4]*University Hospital Northampton*

BACKGROUND & AIM

Middle ear surgery is a common procedure addressing various pathologies. Postoperative head bandaging has traditionally been used to provide support and prevent complications. However, its necessity remains controversial, with limited empirical evidence supporting its routine use. This randomized controlled trial (RCT) evaluated the necessity of head bandaging in middle ear surgery by comparing postoperative complications between a mastoid head bandage and a simple gauze dressing.

MATERIAL & METHODS

Eighty patients scheduled for middle ear surgery were randomly assigned to two groups: the Pressure Bandage group, where a crepe bandage was wrapped around the head, and the No Pressure Bandage group, where a gauze dressing was secured with Mefix tape. All surgeries were performed by a single otolaryngologist using standardized techniques, with the surgeon blinded to the dressing type. Postoperative complications, including hematoma, erythema, skin abrasion, and wound infection, were recorded and compared.

RESULTS

The mastoid bandage group had a significantly higher incidence of forehead skin abrasions (6/40 vs. 0/40, P = 0.026). No significant differences were observed in hematoma or seroma formation, as neither group developed these complications.

CONCLUSIONS

Routine mastoid head bandaging does not appear necessary, as it does not reduce postoperative complications and may increase patient discomfort due to skin abrasions. Larger studies with longer follow-ups are recommended to strengthen these findings and guide clinical practice.

From Symptoms To Outcomes: Linking Patient-Reported Disease Burden To Outcomes In Ear Surgery

Catarina Pinto[1], **Duarte Morgado**[1], **Ines Veloso**[1], **João Rodrigues**[1], **Sergio Caselhos**[1], **Rui Fonseca**[1], **Mariana B Santos**[1]

[1]*Uls alto ave*

BACKGROUND & AIM

Revision tympanoplasty is often required in patients with persistent disease or failure of primary surgery, representing a greater surgical and clinical challenge. Beyond anatomical repair and hearing outcomes, these patients frequently experience a significant impact on quality of life due to symptoms. Therefore, evaluating the benefits of revision tympanoplasty should include patient-reported outcomes to better capture its real impact on daily functioning and well-being. Our goals are evaluate the impact on quality of life in adult patients undergoing revision tympanoplasty and to analyze its statistical relationship with graft type and surgical outcomes, namely hearing gain and tympanic membrane perforation closure.

MATERIAL & METHODS

Retrospective study of patients who underwent revision tympanoplasty between July 2023 and July 2025. The Portuguese version of the COMQ-12 was administered pre- and postoperatively to assess perceived benefit, and its relationship with clinical and audiological outcomes was analyzed using data extracted from electronic medical records.

RESULTS

Nineteen patients who underwent revision tympanoplasty were included, with a mean age of 47.8 years. A significant improvement in symptom severity, quality of life, and overall well-being was observed as assessed by the COMQ-12, with no statistical association with the type of graft used. The mean COMQ-12 score decreased from 24.65 ± 10.12 preoperatively to 8.52 ± 7.14 postoperatively ($p<0.001$). A statistically significant correlation was found between COMQ-12 scores and hearing outcomes across all subdimensions, while results were less favorable regarding its relationship with tympanic membrane closure.

CONCLUSIONS

The COMQ-12 proved to be a reliable and sensitive tool for assessing perceived benefit in patients after tympanoplasty, showing a significant correlation with clinical and audiological outcomes, which reinforces its usefulness as a complementary instrument in evaluating surgical results.

Clinical Characteristics, Radiological Findings And Outcomes Of Skull Base Osteomyelitis: A Retrospective Case Series

Dursun Mehmet MEHEL[1], **Asude ÜNAL**[2], **Seda Nur CİHAN**[2], **Levent AY**[2], **Hande ARSLAN**[1], **Esra YILMAZ**[2], **Doğukan ÖZDEMİR**[2]

[1]*Health Sciences University Samsun Training and Research Hospital, Department of Otorhinolaryngology;* [2]*Samsun University Samsun Training and Research Hospital, Department of Otorhinolaryngology*

BACKGROUND & AIM

Skull base osteomyelitis (SBO) is a severe and potentially life-threatening infection characterized by progressive destruction of the skull base, most commonly arising as a complication of malignant otitis externa (MOE). In addition to its classic presentation, SBO may also develop secondary to chronic otitis media or following head and neck radiotherapy. This study aimed to evaluate the clinical characteristics, radiological findings, and prognostic factors of SBO cases with different etiologies.

MATERIAL & METHODS

In this retrospective study, the medical records of 10 patients (age >18 years) diagnosed with SBO in our clinic between January 2021 and January 2026 were reviewed. Demographic data, presenting symptoms, laboratory parameters (WBC, CRP, ESR, HbA1c), microbiological culture results, radiological findings (CT, MRI, Tc-99m scintigraphy), cranial nerve involvement, treatment modalities, and mortality rates were analyzed.

RESULTS

The study cohort consisted of 10 patients (9 males, 1 female) with a mean age of 70.5 years. Uncontrolled type 2 diabetes mellitus was present in all patients. SBO developed as a complication of MOE in six patients, while one patient developed osteoradionecrosis following radiotherapy for nasopharyngeal carcinoma. All patients presented with severe unilateral otalgia refractory to non-steroidal anti-inflammatory drugs and requiring narcotic analgesics. Microbiological cultures identified Pseudomonas aeruginosa in three patients (30%), while no growth was detected in seven patients (70%). Cranial nerve palsy, most commonly involving the facial nerve (CN VII), developed in six patients (60%). Intracranial complications, including meningitis, venous thrombosis, and cerebrovascular events, occurred in six patients. Radiological evaluation revealed bilateral disease in four patients (40%). Despite prolonged intravenous antibiotic therapy, adjunctive hyperbaric oxygen therapy, and canal wall down mastoidectomy in selected cases, mortality occurred in four patients (40%) due to intracranial spread.

CONCLUSIONS

SBO is an aggressive infection associated with significant morbidity and mortality, particularly in elderly, diabetic, and immunocompromised patients. Lower cranial nerve involvement and intracranial complications are strongly associated with poor prognosis. Early recognition of atypical presentations, especially in patients with chronic otitis media or a history of head and neck radiotherapy, is essential to prevent diagnostic delays and improve outcomes through timely multidisciplinary management

Skull base osteomyelitis, Cranial nerve palsy, Intracranial complications, Diabetes mellitus

OP-837

Drying Of Ossicles In Glass Ionomer Cement Application With Air Drying Technique

Sabri Baki Eren[1], **Ramazan Bahadır Küçük**[1], **Alper Yenigün**[1], **Orhan Ozturan**[1]

[1]*Bezmialem Vakif University, Faculty of Medicine, Department of Otorhinolaryngology*

BACKGROUND & AIM

Bone cement application plays an important role in ossicular chain reconstruction due to its biocompatibility and ability to provide stable ossicular continuity. However, successful bonding of glass ionomer cement requires a completely dry ossicular surface. Conventional drying methods, including mechanical suction or electrocautery, may result in thermal injury or mechanical trauma to the ossicles.

MATERIAL & METHODS

The technique was applied during ossicular chain reconstruction, particularly in cases of long process incus defects. After microscopic exposure and removal of residual mucosal or pathological tissue, the ossicular surface was dried using a controlled dry oxygen flow delivered through a modified suction catheter system. Dry oxygen was applied for 30–60 seconds to achieve complete surface dehydration. Glass ionomer cement was then prepared to a viscous consistency and applied in a drop-wise fashion, shaped according to native ossicular anatomy. The air-drying method was also used during cement setting to maintain a blood-free and moisture-free field.

RESULTS

The Air Drying Technique allowed rapid and uniform drying of the ossicular surface without the use of thermal energy or direct mechanical manipulation. Adequate cement adhesion and stabilization were achieved in all cases. No intraoperative complications or adverse effects related to the drying method were observed.

CONCLUSIONS

Effective surface drying is a critical determinant of successful bone cement application in ossicular chain reconstruction. The Air Drying Technique provides a simple, atraumatic, and reproducible method for preparing the ossicular surface, potentially enhancing cement bonding and surgical efficiency. This technique represents a novel application in otologic surgery and may be safely adapted for use in other middle ear procedures. Further clinical studies are warranted to evaluate long-term outcomes.

XRCC1 Genetic Polymorphisms And The Risk Of Sudden Hearing Loss

CHEN-YU CHIEN[1,2], **SHU-YU TAI**[3,4]

[1]*Department of Otorhinolaryngology, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan;* [2]*Department of Otorhinolaryngology, School of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan;* [3]*Department of Family Medicine, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan;* [4]*Department of Family Medicine, School of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan*

BACKGROUND & AIM

Sudden sensorineural hearing loss (SSNHL) is a condition of unknown etiology, but vascular and genetic factors are implicated in its pathogenesis. The X-ray repair cross-complementing group 1 (XRCC1) gene has been associated with ischemic stroke and noise-induced hearing loss, potentially through its influence on reactive oxygen species (ROSs), which can cause oxidative damage to nucleic acids. DNA repair mechanisms mitigate such damage, but unbalanced ROS levels have been associated with SSNHL susceptibility. We hypothesized that XRCC1 genetic variants are associated with SSNHL risk. This study examined the association between XRCC1 single nucleotide polymorphisms (SNPs) and SSNHL in Taiwan.

MATERIAL & METHODS

A case–control study was conducted involving 276 patients with SSNHL and 293 healthy controls. Three XRCC1 SNPs (rs1799782, rs25489, and rs25487) were genotyped using TaqMan assays. Each SNP was tested for the Hardy–Weinberg equilibrium, and genetic associations were evaluated under dominant and recessive models.

RESULTS

The TT genotype of rs1799782 was significantly associated with higher SSNHL risk (adjusted odds ratio [aOR] = 2.005; 95% confidence interval [CI] = 1.13–3.62; P = 0.0164) compared with the CC genotype. Under the recessive model (TT vs. CC+CT), rs1799782 remained significantly associated with SSNHL (aOR = 1.983; 95% CI = 1.15–3.49; P = 0.0134). No significant associations were discovered for SNPs rs25489 and rs25487. A multivariate logistic regression analysis revealed that high-tone (aOR = 6.42; P = 0.0043) and flat-type (aOR = 4.12; P = 0.0071) hearing loss patterns, compared with low-tone loss, and longer delay from onset to treatment (each additional day increased the risk of unfavorable recovery by 8%; P = 0.0132) were associated with unfavorable clinical outcomes. XRCC1 genotypes were not significantly associated with treatment outcomes.

CONCLUSIONS

The TT genotype of XRCC1 rs1799782 is associated with an increased risk of SSNHL in the Taiwanese population.

Cholesteatoma Complications In The Era Of Modern Otology: A Persistent Challenge In A Moroccan Tertiary Care Center

Walid Bijou[1,2], **Meryem Azouani**[1], **Youssef Oukessou**[1,2], **Sami Roundi**[1,2], **Reda Allah Abada**[1,2], **Mohamed Roubal**[1,2], **Mohamed Mahtar**[1,2], **Sarah Hafidi**[1]

[1]Ibn Rochd Hospital university; [2]Hassan II university

BACKGROUND & AIM

Middle ear cholesteatoma is an expansive and destructive lesion whose intracranial and extracranial complications, while uncommon in contemporary Western series (1–3%), remain a significant burden in resource-limited settings due to diagnostic delays and restricted access to specialized care.

The aim is to determine the incidence and clinical spectrum of cholesteatoma complications, identify independent predictors of their occurrence, and evaluate functional and surgical outcomes in a high-volume Moroccan tertiary center.

MATERIAL & METHODS

Retrospective cohort study over 9 years (2015–2024) including 700 consecutive patients operated for acquired middle ear cholesteatoma. The 30 complicated cases (4.28%) were compared to 670 uncomplicated cases across the following variables: age, sex, symptom-to-surgery delay, affected side, preoperative audiometric profile and cholesteatoma extension. Bivariate analysis followed by multivariate logistic regression was performed to identify independent predictors of complication.

RESULTS

The complication rate was 4.28% (30/700). Mean age in the complicated group was 30.93 years, with a peak in the 21–30-year age group (30%), significantly younger than uncomplicated patients (41.2 years, p=0.003). The male-to-female ratio was 3:1. Median symptom-to-surgery delay was 48 months in the complicated group versus 18 months in uncomplicated patients (p<0.001). Mixed hearing loss predominated (53.33%), reflecting cochlear involvement. Extracranial complications accounted for 60% of cases: mastoiditis (54.55%), facial nerve palsy (18.18%), and labyrinthine fistula (13.64%). Intracranial complications (40%) included cerebral/cerebellar abscess (41.67%), cerebral empyema (33.33%), and lateral sinus thrombosis (25%). On multivariate analysis, two factors were independently associated with complication risk: diagnostic delay >36 months, advanced cholesteatoma extension. Canal wall-up mastoidectomy was the predominant surgical approach, performed in 72.7% of extracranial cases and 83.3% of intracranial cases; canal wall-down mastoidectomy was reserved for cases with extensive disease destruction. Overall outcome was favorable in 80% of patients.

CONCLUSIONS

In this largest North African cohort reported to date, diagnostic delay exceeding 36 months, advanced cholesteatoma extension, and lack of specialized ENT follow-up are the three independent determinants of life-threatening complications. Despite aggressive surgical management yielding favorable outcomes in 80% of cases, the 8.3% intracranial mortality

underscores the need for early detection programs, primary care physician education, and improved access to specialized otologic care in developing countries.

A Comparison Of Our VITOM 3D EXOSCOPE Tympanoplasty Results With Microscope- And Endoscope-Assisted Tympanoplasty

İsmail Aytaç[1], **Erhan Çiftel**[2], **Elif Baysal**[3], **Orhan Tunç**[3], **Behçet Günsoy**[3], **Koray Tümüklü**[4]

[1]*Gaziantep Medical Point Hospital;* [2]*Batman Training and Research Hospital;* [3]*Gaziantep University School of Medicine;* [4]*private practitioner*

BACKGROUND & AIM

Tympanoplasty surgeries are procedures aimed at surgically repairing perforations of the eardrum and restoring hearing. Various imaging systems are used in these surgeries to enhance the surgeon's field of view and control over the surgical site. The aim of this study was to compare tympanoplasty surgeries performed with the VITOM 3D exoscope, alongside a microscope and an endoscope, in terms of hearing gain, surgeon comfort, and contribution to surgical training.

MATERIAL & METHODS

A total of 60 patients were evaluated in the project conducted at the Department of Otolaryngology, Faculty of Medicine, Gaziantep University. Patients were randomly divided into 3 groups: the group undergoing tympanoplasty with the VITOM 3D exoscope (n=20), the group undergoing tympanoplasty with a microscope (n=20), and the group undergoing tympanoplasty with an endoscope (n=20). Preoperative pure-tone audiometry values (averages at 0.5, 1, 2, and 4 kHz) were recorded for all patients, and the same parameters were re-evaluated at the 3-month postoperative follow-up. The surgeon's comfort level during the procedure was assessed using the 'Difficulties and Comfort Questionnaire,' and the contribution to surgical training for each method was measured using the 'Contribution to Training Questionnaire.'

RESULTS

No significant difference was found between the groups in terms of audiometric improvement. Upon reviewing the survey results, it was observed that the VITOM 3D exoscope group demonstrated a significant advantage over other methods in terms of the surgeon's comfort level and contribution to training. The average scores in the Difficulty and Comfort Survey were determined as follows: VITOM 8.4, Microscope 6.9, Endoscope 5.7.

CONCLUSIONS

The VITOM 3D exoscope was found to be equivalent to the microscope and endoscope in terms of postoperative audiometric improvement. However, it demonstrated clear advantages in terms of ergonomics, surgeon comfort, and contributions to surgical training. Consequently, it was determined that the VITOM 3D exoscope offers a valuable alternative for clinical use, particularly due to its advantages in improving the surgeon's posture and providing educational benefits such as multi-view observation capabilities.

OP-841

Postoperative Follow-Up And Recurrence After Cholesteatoma Surgery: A Retrospective Study

Bülent Ulusoy[1], **Özgür Demir**[1], **Hürü Beyza Cerit**[1]

[1]*The Department of Otolaryngology and Head and Neck Surgery at Selçuk University Faculty of Medicine Hospital, Konya, Turkey*

BACKGROUND & AIM

The primary objective of this study was to retrospectively evaluate the data of patients who underwent surgery for cholesteatoma at a tertiary care center, with particular emphasis on the recurrence rate.

MATERIAL & METHODS

All individuals included in this study were patients managed according to the treatment and follow-up protocol of a single faculty member. The study included 144 patients who underwent surgery in our clinic with a preliminary diagnosis of cholesteatoma between May 2017 and June 2024 and were ultimately diagnosed with cholesteatoma. At our clinic, patients diagnosed with cholesteatoma are followed up in the otorhinolaryngology outpatient setting within 2 days at the latest if symptomatic, or at 3-month intervals if asymptomatic, and are assessed annually using diffusion-weighted magnetic resonance imaging (MRI).

RESULTS

Among the 144 patients included in the study, 74 were male and 70 were female. According to age distribution, 21 patients were aged 0–18 years, 112 were aged 18–64 years, and 11 were aged 65 years or older. Adherence to the routine follow-up protocol of our clinic was observed in 71 patients (49.30%), while 18 patients (12.50%) attended follow-up visits every 6 months. The remaining 55 patients (38.20%) presented for follow-up irregularly. Recurrent cholesteatoma was identified in 33

patients (22.9%). Recurrence was detected by diffusion-weighted MRI in 29 patients (20.13% of the overall patients and 87.88% of recurrent cases), whereas it was diagnosed on clinical examination in 4 patients (2.77% of the overall patients and 12.12% of recurrent cases). Age-group analysis showed recurrence in 8 patients (38.09%) aged 0–18 years, 22 patients (19.6%) aged 18–64 years, and 3 patients (27.2%) aged 65 years or older.

CONCLUSIONS

Cholesteatoma may result in complications that can be life-threatening. To minimize these complications, we believe that regular postoperative follow-up is of paramount importance. Even in the absence of symptoms, patients should undergo clinical follow-up every 3 months, and annual diffusion-weighted MRI should be performed even when no clinical signs are evident.

The Relationship Between Audiological And Body Fluid Volume Parameters In End-Stage Renal Disease Patients Undergoing Hemodialysis: Investigation Of Endolymphatic Fluid Dynamics

Yasin Çetinkaya[1], **Mehmet Çelik**[1], **Said Sönmez**[1], **Beldan Polat**[1], **Kadir Serkan Orhan**[1]

[1]*Istanbul University Istanbul Faculty of Medicine*

BACKGROUND & AIM

In dialysis patients, fluid variability may influence inner and middle ear pressure balance mechanisms. Ultrafiltration during hemodialysis leads to marked changes in extracellular and intracellular fluid distribution, potentially altering middle ear pressure regulation and Wide band tympanometry (WBT) parameters. This study aimed to evaluate pre- and post-dialysis differences in bioimpedance, wide-band tympanometry, and pure-tone audiometry in patients with Chronic Kidney Disease receiving hemodialysis. Additionally, it investigated the relationship between ultrafiltration volume and bioimpedance values, the correlation of bioimpedance with WBT and audiometric findings, and the implications of these interactions for endolymphatic fluid exchange dynamics.

MATERIAL & METHODS

In this study, 31 patients receiving treatment at the Hemodialysis Unit of the Department of Nephrology, Istanbul Faculty of Medicine, Istanbul University, were initially enrolled. The patients were evaluated at the bedside in the hemodialysis unit and underwent otoscopic examination prior to the procedure. Four patients with a history of ear surgery or with pathological findings such as perforation or retraction on examination were excluded. Additionally, one patient who developed complications during hemodialysis was excluded from the study. Consequently, a total of 26 patients were included in the final analysis. These patients underwent bioimpedance measurements, wideband tympanometry, and audiometry both before and after bedside hemodialysis. Routine pre-hemodialysis measurements of B-type natriuretic peptide (BNP) were also performed. The bioimpedance measurements, wideband tympanometry and audiometry results, along with the patients' clinical parameters, were analyzed using the SPSS statistical program.

RESULTS

The mean age of the study group was 55.3 ± 18.3 years, with 11 (42.3%) females and 15 (57.7%) males. All body fluid volume parameters, except diastolic blood pressure, changed significantly after hemodialysis. In pure-tone audiometry, a significant difference was found only in the right ear air conduction threshold at 250 Hz ($p < 0.001$). Wideband tympanometry showed significant pre- and post-dialysis differences in peak pressure and resonance frequency in both ears. Peak pressure absorbance differed at 500 Hz in the right ear and 4000 Hz in the left ear, while ambient pressure absorbance changed at 2000 Hz in the right ear and 4000 Hz in the left ear. Correlation analysis demonstrated weak-to-moderate positive relationships between body fluid volume changes and selected audiometric and WBT frequencies. Overall, post-hemodialysis peak pressure and resonance frequency values showed significant alterations, indicating measurable effects on middle ear mechanics and fluid dynamics.

CONCLUSIONS

Our study is the first to assess pre- and post-hemodialysis body fluid volume, pure-tone audiometry, and wideband tympanometry (WBT) in patients with end-stage renal disease. Dialysis-related fluid shifts appear to influence middle and inner ear impedance, suggesting changes in endolymphatic fluid dynamics. Post-dialysis WBT findings of less negative tympanometric pressure and higher resonance frequency indicate that WBT may be a potential tool for detecting endolymphatic hydrops. These results demonstrate the sensitivity of WBT to fluid-related auditory changes and support its possible clinical value. Nevertheless, further studies are needed to clarify its diagnostic accuracy and clinical role in evaluating endolymphatic hydrops.

OP-843

A Novel Marker For Graft Success In Tympanoplasty: Can The Triglyceride-Glucose Index Predict Graft Viability?

Batuhan Pişet[1], **Nurdan Köse Çelebi**[1], **Semra Külekçi Öztürk**[1], **Seyit Mehmet Ceylan**[2], **Umut Can Musaoğlu**[3]

[1]*University of Health Sciences Fatih Sultan Mehmet Training and Research Hospital ENT;* [2]*Memorial Sisli Hospital ENT;* [3]*Yuksekova State Hospital ENT*

BACKGROUND & AIM

Factors determining tympanoplasty success are mostly explained by local and surgical variables, while the role of systemic metabolic status is largely overlooked. This study aimed to investigate the effect of the preoperative triglyceride-glucose (TyG) index on graft viability.

MATERIAL & METHODS

This prospective observational study included 70 patients who underwent primary type 1 tympanoplasty due to central tympanic membrane perforation and had no additional systemic diseases. Preoperative fasting triglyceride and glucose levels were measured in all patients, and the TyG index was calculated. Demographic and clinical variables were recorded. Graft viability was evaluated at 3 months postoperatively. Non-parametric tests and multivariate logistic regression analysis were used for statistical analyses.

RESULTS

The overall graft success rate was found to be 82.9%. The TyG index was significantly higher in the failed group ($p<0.001$). It was particularly noteworthy that the TyG index in the failed group was above the threshold values associated with insulin resistance in the literature. Logistic regression analysis showed that the TyG index was an independent and strong predictor of graft failure; each unit increase in the TyG index was found to increase the risk of failure approximately 36.9 times ($p<0.001$).

CONCLUSIONS

This study reveals that tympanoplasty success may be closely related not only to local factors but also to the patient's metabolic status. The TyG index can be a powerful and clinically significant biomarker for predicting graft success, easily applicable in the pre-surgical period. This finding suggests that metabolic risk analysis should be integrated into pre-tympanoplasty evaluation algorithms.

Diagonal Earlobe Crease Is Associated With Reduced Coronary Flow Reserve And Peripheral Endothelial Dysfunction: A Cross Sectional Study

Yusuf Yilmaz[1], **Fatma Betul Celik**[1], **Batın Berkay Öznacar**[2], **Tolga Sinan Guvenc**[3], **Narmin Ismayilzada**[1], **Ahmet Eren Caliskan**[4], **Burak Ozun**[1], **Mahmut Tayyar Kalcioglu**[2], **Mustafa Caliskan**[1]

[1]*Istanbul Medeniyet University Faculty of Medicine, Department of Cardiology, Istanbul, Turkey;* [2]*Istanbul Medeniyet University Faculty of Medicine, Department of Otorhinolaryngology, Istanbul, Turkey;* [3]*Memorial Goztepe Hospital, Department of Cardiology, Istanbul, Turkey;* [4]*Bezmialem University Faculty of Medicine, Istanbul, Turkey*

BACKGROUND & AIM

Diagonal earlobe crease (DELC) is a physical examination sign of premature aging that is associated with atherosclerotic cardiovascular disease. Coronary microvascular dysfunction (CMD) is the initial manifestation of subclinical atherosclerosis in the heart and is associated with significant morbidity and mortality. This study aimed to understand whether DELC was associated with CMD and peripheral endothelial dysfunction (ED) and whether this association could be explained on the basis of accelerated vascular aging.

MATERIAL & METHODS

A total of 30 individuals with DELC and 35 controls were enrolled. Participants underwent assessment of CMD, ED and vascular age via sonographic measurement of coronary flow reserve (CFR), flow-mediated vasodilatation (FMD) and pulse-wave analysis (PWA).

RESULTS

Participants with DELC had significantly lower CFR (2.51 ± 0.45 vs. 3.14 ± 0.36, $p<0.001$) and FMD (10.4 [9.5 - 11.5] vs. 12.2 [9.6 - 13.8], $p=0.007$) compared to controls, and these findings remained robust following adjustment for covariates ($p<0.001$ for CFR and $p=0.005$ for FMD). Vascular age, as determined by PWA, was a significantly better indicator of DELC compared to chronological age (ΔAUC:0.14 (95%CI:0.08 - 0.27), $p<0.001$). When vascular age replaced chronological age in the adjustment models, DELC was no longer associated with FMD ($p=0.140$), however, the association between DELC and CFR remained significant but with a diminished effect size ($p<0.001$, partial η^2:0.216).

CONCLUSIONS

DELC is independently associated with CMD and peripheral ED. Advanced vascular aging in individuals with DELC partially explains these associations, particularly the link between DELC and peripheral ED.

Vestibular Evoked Myogenic Potentials In The Assessment Of Vestibular Functions In Children And Adolescents With Internal Auditory Canal Stenosis

Peng Han[1], **Qing Zhang**[2], **Pengyu Ren**[1]

[1]*The First Affiliated Hospital of Xi'an Jiaotong University;* [2]*Shanghai Jiaotong University*

BACKGROUND & AIM
To determine the vestibular involvement in children and adolescents with internal auditory canal (IAC) stenosis using cervical and ocular vestibular-evoked myogenic potentials (VEMP).

MATERIAL & METHODS
Ten patients with IAC stenosis (study group) and 12 age-and-gender-matched healthy subjects (control group) were enrolled. All patients underwent air-conducted sound cervical VEMP (cVEMP) and ocular VEMP (oVEMP) tests. The elicit rate , amplitudes, thresholds, and latencies of VEMPs were evaluated.

RESULTS
The abnormal rate of cVEMP was 40%, which probably indicates possible inferior vestibular nerve dysfunction or hypoplasia due to the IAC stenosis. The abnormal rate of oVEMP was 30%, which indicates superior vestibular nerve involvements. The 12 controls all showed normal VEMP response and normal parameters.

CONCLUSIONS
Children and adolescents with IAC stenosis may have vestibular dysfunction or hypoplasia, and VEMPs could reflect the degree of damages of the vestibular input pathways.

Long-Term Outcomes And Failure Patterns Of Malleostapedotomy In Complex Middle Ear Pathology

Süleyman Emre CILIZ[1], **İbrahim Emrehan DEREKÖY**[2], **İlker Burak ARSLAN**[1], **Doğukan DEMİR**[3], **İbrahim ÇUKUROVA**[2]

[1]*University of Health Sciences, Izmir City Hospital, Department of Otorhinolaryngology, Izmir, Türkiye;* [2]*University of Health Sciences, Tepecik Training and Research Hospital, Department of Otorhinolaryngology, Izmir, Türkiye;* [3]*Bandirma Onyedi Eylul University, School of Medicine, Department of Otorhinolaryngology, Balıkesir, Türkiye*

BACKGROUND & AIM
Malleostapedotomy is a technically demanding malleus-anchored stapes procedure performed when conventional incus-anchoring stapedoplasty is not feasible. Although favourable audiological outcomes have been reported mainly in otosclerosis and revision stapes surgery, results in ears with tympanosclerosis and other complex middle-ear pathologies remain less predictable. Long-term data regarding durability, complications and failure patterns in these challenging ears are limited. This study aimed to evaluate long-term audiological outcomes and failure patterns after malleostapedotomy in patients with complex middle-ear pathology.

MATERIAL & METHODS
Patients who underwent malleostapedotomy between 2009 and 2023 were retrospectively reviewed. Clinical and audiological follow-up data were collected through 2026. Demographic characteristics, underlying middle-ear pathology, prior surgical history, operative staging and tympanic membrane/graft status at the time of malleostapedotomy were recorded. Pure-tone audiometry was evaluated at 500, 1000, 2000 and 4000 Hz. Air-bone gap (ABG) closure and postoperative hearing status were assessed using the latest available audiogram after malleostapedotomy. Surgical success was defined as postoperative ABG ≤20 dB and clinically meaningful improvement as ≥10 dB ABG closure. Complications including profound sensorineural hearing loss/dead ear, vertigo, prosthesis displacement, tympanic membrane retraction and perforation were documented.

RESULTS
Eighteen patients (10 male, 8 female; mean age 28 years, range 11–49) were included with a mean follow-up of 12.1 years (range 3–17). Tympanosclerosis was present in 16 ears (89%), the remaining cases were revision otosclerosis and congenital ossicular anomaly. Preoperatively, 12 tympanic membranes/grafts were intact, 3 were perforated and 3 were retracted. Malleostapedotomy was performed as a second-stage procedure in 10 patients (56%). Among 13 audiologically evaluable ears, median ABG improved from 37 dB preoperatively to 20 dB postoperatively (p=0.011). Surgical success (ABG ≤20 dB) was achieved in 7 patients (39%) with ≥10 dB closure in 1 additional ear. Four ears showed no meaningful ABG improvement and 1 had ABG worsening with bone-conduction decline. Profound sensorineural hearing loss/dead ear developed in 5 patients

(28%). Prosthesis displacement occurred in 2 patients, including 1 with malleus erosion. Postoperative retraction accounted for 4 of the 5 profound hearing loss cases (p=0.022).

CONCLUSIONS

Malleostapedotomy may provide meaningful hearing improvement in selected patients with complex middle-ear pathology, including tympanosclerosis and chronic otitis media sequelae. However, in this long-term cohort, outcomes were heterogeneous with surgical success achieved in 39% and profound sensorineural hearing loss/dead ear occurring in 28%. Postoperative tympanic membrane retraction and prosthesis displacement emerged as the main failure patterns, emphasizing that durable reconstruction depends on a stable middle-ear environment. These findings suggest that careful patient selection and prolonged audiological and otoscopic follow-up are essential, particularly in ears prone to retraction.

OP-847

Role Of High Resolution Computed Tomography Scan In Otosclerosis.

Dr. Abirvab Naha[1], **Dr. Mohammad Habibur Rahman**[1], **Dr. Anindiat Datta**[1], **Dr. Joyosree Saha**[2]

[1]*Bangladesh Medical University;* [2]*Dhaka Medical College*

BACKGROUND & AIM

Otosclerosis, also known as otospongiosis, is an autosomal dominant disorder of the otic capsule characterized by abnormal bone remodeling, leading to progressive conductive, sensorineural, or mixed hearing loss, often with tinnitus or vestibular symptoms. Accurate preoperative assessment is crucial for surgical planning, and high-resolution computed tomography (HRCT) of the petromastoid region has emerged as the gold standard for detecting otosclerotic foci and anatomical variations.

To evaluate the role of HRCT in diagnosing otosclerosis, assessing disease extent, predicting surgical difficulty, and guiding prosthesis planning.

MATERIAL & METHODS

A prospective cross-sectional study was conducted at Bangladesh Medical University from October 2024 to December 2025. Fifty-two patients with clinically and audiologically confirmed otosclerosis were included. HRCT findings, including fenestral and cochlear involvement, stapedial footplate thickening, pericochlear radiolucency, and anatomical variations, were recorded and correlated with intraoperative findings. Diagnostic accuracy metrics and HRCT-based surgical predictions were analyzed.

RESULTS

Among 52 patients, the mean age was 39.1 ± 8.7 years, with female predominance (63.5%) and bilateral involvement in 69.2%. Conductive hearing loss was most common (76.9%), with Carhart's notch present in 80.8%. HRCT detected fenestral otosclerosis in 82.7% and retrofenestral involvement in 30.8%. HRCT grading (Marshall classification) identified 53.8% as Grade 1, and higher grades correlated with mixed hearing loss. HRCT showed strong agreement with intraoperative findings (87.2–100%), with a sensitivity 92.3%, a specificity 86.7%, and overall accuracy 90.4%. Thick footplates, narrow oval windows, facial nerve dehiscence, and higher HRCT grades were significant predictors of surgical difficulty. Predicted prosthesis length closely matched intraoperative measurements ($r = 0.86$, $p < 0.001$).

CONCLUSIONS

HRCT of the petromastoid region is a highly sensitive and accurate tool for diagnosing otosclerosis, assessing disease extent, identifying anatomical variations, predicting surgical challenges, and guiding prosthesis selection. Routine preoperative HRCT is recommended to optimize surgical planning and outcomes in otosclerosis patients.

Prognostic Factors And Clinical Outcomes In Malignant External Otitis And Skull Base Osteomyelitis: A Retrospective Analysis

Dilara Ülkü İlbaş Aydin[1], **Dilay Arslan Uzunçimen**[2], **Osman Cerlet**[1], **Mehmet Ali Çetin**[1]

[1]*Ankara Bilkent City Hospital;* [2]*Polatlı Duatepe Public Hospital*

BACKGROUND & AIM

Malignant External Otitis (MEO) is an aggressive, potentially fatal infection that can progress to Skull Base Osteomyelitis (SBO). We hypothesized that specific clinical, laboratory, and radiological markers serve as significant prognostic factors for disease severity and patient survival. This study aims to evaluate these markers and treatment outcomes in a tertiary referral center.

MATERIAL & METHODS

This retrospective clinical study was conducted at Ankara Bilkent City Hospital between 2024 and 2025. Subjects included 9 male patients diagnosed with MEO and SBO in a tertiary referral setting. Interventions comprised targeted systemic antimicrobial therapy, surgical debridement (mastoidectomy), and Hyperbaric Oxygen Therapy (HBOT). Outcome measurements included hospital stay duration, treatment response, and mortality. Independent variables analyzed were age, Hemoglobin A1c (HbA1c), C-reactive protein (CRP), and Neutrophil-to-Lymphocyte Ratio (NLR). Statistical analysis was performed using SPSS v27.0, utilizing descriptive statistics (mean ± standard deviation).

RESULTS

All patients (100%) had Diabetes Mellitus (DM), with a mean HbA1c of 7.46 ± 1.67%. Hypertension (HT) was present in 55.5% of cases. Laboratory analysis revealed an elevated mean CRP of 36.27 ± 30.79 mg/L and a mean NLR of 3.7 ± 1.41. Computed Tomography (CT) identified temporal bone erosion in 100% of subjects, while Magnetic Resonance Imaging (MRI) confirmed bone marrow involvement in 88.8%. Microbiology results notably isolated Candida parapsilosis in cultures. The mean duration of systemic antibiotic therapy was 7.22 ± 3.55 weeks. Surgical intervention was performed in 5 patients (55.5%), and 3 patients (33.3%) received HBOT. The mean hospital stay was 45.2 ± 22.65 days. The overall mortality rate was 22.2% .

CONCLUSIONS

MEO and SBO cause significant morbidity in elderly diabetic patients. High HbA1c, CRP, and NLR are key indicators of disease progression. While CT is essential for detecting bone erosion, MRI provides critical detail on skull base involvement. The emergence of fungal isolates like Candida necessitates individualized treatment strategies. Early diagnosis combined with aggressive medical and surgical management is vital for improving survival outcomes.

OP-849

The Protective Effect Of Citicoline Against Cisplatin-Induced Ototoxicity.

Ali TOPAL[1], **Tankut UZUN**[1]

[1]*Izmir Bakircay University Faculty of Medicine, Otorhinolaryngology, Head and Neck Surgery, Izmir, Turkey*

BACKGROUND & AIM

Cisplatin is a potent chemotherapeutic agent widely used in solid tumors; however, its clinical application is often limited by permanent, bilateral sensorineural hearing loss. This ototoxicity is primarily mediated by the accumulation of reactive oxygen species (ROS), the release of pro-inflammatory cytokines, and the activation of apoptotic pathways within the cochlea. Citicoline, a neuroprotective molecule, has demonstrated the potential to maintain cellular integrity and reduce oxidative stress. This study aimed to evaluate the otoprotective efficacy of systemic citicoline administration against cisplatin-induced damage in a rat model.

MATERIAL & METHODS

Twenty-eight adult rats were randomized into four groups (n=7/group): Control, Cisplatin (4.6 mg/kg/day i.p. for 3 days), Citicoline (250 mg/kg/day oral gavage for 27 days), and Cisplatin+Citicoline. Auditory Brainstem Response (ABR) and Distortion Product Otoacoustic Emissions (DPOAE) were recorded at baseline and on day 21. Following functional tests, cochleae were harvested for Myosin VIIa immunohistochemistry, TUNEL assay, and Scanning Electron Microscopy (SEM). Histopathological scoring was performed to evaluate hair cell loss, stria vascularis atrophy, and spiral ganglion degeneration. Statistical analyses were conducted using Kruskal-Wallis and Mann-Whitney U tests with SPSS v23.0 ($p<0.05$).

RESULTS

Cisplatin administration led to significant threshold shifts in ABR (mean: 65.4±4.2 dB SPL) and marked reductions in DPOAE amplitudes across all frequencies ($p<0.001$). In the Cisplatin+Citicoline group, these functional deficits were significantly attenuated, with ABR thresholds preserved at 38.6±3.8 dB SPL ($p<0.01$). Histopathologically, the cisplatin group exhibited extensive outer hair cell loss and high TUNEL-positive apoptotic activity. Conversely, citicoline treatment resulted in significantly higher Myosin VIIa-positive hair cell counts (88.4%±5.2%) and reduced apoptotic cells (12.4±2.1) compared to the cisplatin-only group ($p<0.001$). SEM observations confirmed that citicoline effectively protected stereocilia bundles and stria vascularis integrity from cisplatin-induced ultrastructural degradation. These results suggest that citicoline provides significant functional and structural protection against cisplatin-induced ototoxicity by inhibiting apoptosis and preserving cochlear integrity.

CONCLUSIONS

This study demonstrates that citicoline effectively reduces cisplatin-induced ototoxicity by preserving hearing thresholds and cochlear hair cell integrity. Our findings suggest that the neuroprotective effects of citicoline occur primarily through stabilization of cell membranes and inhibition of apoptotic pathways. The significant reduction in TUNEL-positive cells and preservation of Myosin VIIa expression in the citicoline-treated group highlight the potential of this molecule as a prophylactic agent. These results position citicoline as a promising therapeutic strategy to prevent permanent hearing loss in patients receiving cisplatin-based chemotherapy. Further clinical trials are needed to confirm these findings in human subjects.

Predicting Radiological Mastoid Parameters And Jugular Bulb Position Via Preoperative Wideband Tympanometry In Type 1 Tympanoplasty Patients

Hande Arslan[1], **Mehmet Maruf Aydın**[1], **Zeynep Özer**[1], **Onur Günaydın**[1,2], **Gökhan Akgül**[1], **Doğukan Özdemir**[1,2]

[1]*Samsun City Hospital;* [2]*Samsun University*

BACKGROUND & AIM

Mastoid pneumatization, mastoid volume, and anatomical variations such as jugular bulb height are recognized determinants of middle ear physiology. Wideband tympanometry (WBT) is an objective diagnostic modality that evaluates middle ear mechanics across a broad frequency spectrum between 226 and 8000 Hz. This study aimed to investigate whether preoperative WBT parameters can predict temporal bone computed tomography findings, including mastoid volume, mastoid surface area, and jugular bulb position in patients undergone type 1 tympanoplasty. We hypothesized that specific WBT absorbance patterns would demonstrate significant correlations with radiological mastoid dimensions and jugular bulb classification.

MATERIAL & METHODS

This prospective study initially enrolled 37 patients scheduled for Type 1 tympanoplasty. Four patients were excluded because of the absence of preoperative CT imaging (n: 4) and technical PACS-related issues (n: 1), resulting in a final cohort of 32 patients. The mean age of patients was 36.4 ± 12.3, and 18 (56.3%) of patients were women. Temporal bone CT images were analyzed by an experienced radiologist using Horos imaging software to calculate mastoid volume and surface area bilaterally. Jugular bulb height was categorized according to the Manjila classification system. 64 ears of 32 patients underwent standardized preoperative WBT and pure-tone audiometry. Absorbance values, resonance frequency, and air bone gap (ABG) were evaluated to determine their predictive value for radiological measurements. Perioperative findings were also noted. Tympanic membrane perforation was noted as the percentage of the perforated area.

RESULTS

14 (43.8%) patients had 50-75%, 13 (24.9%) patients had 25-50%, and 10 (31.3%) patients had subtotal perforation, and 13 (40.6%) patients had right-sided perforation. The mean of ABG in the perforated side was 22.1±7.2 and 4.6±1.8 in the healthy ear ($p<0.01$). Absorbance values of 250 Hz, 500 Hz, 1000 Hz, and 2000 Hz in the perforated ear were lower than those of the healthy ear ($p<0.01$ for four frequencies). The mean of mastoid volume in healthy ears was 4630.1±2494.2, and in the perforated side was 2774.1±1552.3 (p: 0.01). A significant positive correlations were observed between WBT absorbance in 250, 500, 1000, 2000, and 4000 Hz frequencies and radiological mastoid volume ($p<0.01$, p: 0.2; p: 0.01; p: 0.04; p: 0.03, respectively). WBT parameters didn't demonstrate concordance with jugular bulb position. There was also a significant positive correlation between resonance frequency and wide-band volume in healthy ears (ρ: 0.63; $p< 0.01$).

CONCLUSIONS

The results suggest that functional acoustic measurements may reflect the three-dimensional anatomical status of the temporal bone and enable identification of reduced mastoid capacity through non-invasive testing. The demonstrated relationship between WBT-derived functional metrics and CT-based anatomical parameters indicates that WBT may provide a reliable non-invasive approach for preoperative assessment. Integrating WBT with radiological classification systems could enhance surgical planning, facilitate risk stratification, and improve patient counseling in candidates undergoing tympanoplasty. Additional prospective studies with a larger sample size are warranted.

OP-851

Back In The Water In 2 Weeks: Keyhole Surgery For Surfer's Ear

Gary Kroukamp[1], **Sarena Maistry**[1]

[1]*Department of Otorhinolaryngology, Department of Stellenbosch*

BACKGROUND & AIM

Background: External auditory canal exostosis (EAE), commonly known as "surfer's ear," is a benign bony proliferation associated with repeated cold-water exposure. Surgical management is indicated in symptomatic cases with significant canal obstruction, recurrent infections, or hearing impairment. Traditional approaches have been associated with morbidity and prolonged recovery. Minimally invasive per meatal techniques have emerged as an alternative, aiming to reduce complications and recovery time.

Objective: To evaluate the outcomes of a minimally invasive transcanal (keyhole) surgical approach for the management of EAE in a high-volume, single-surgeon series.

MATERIAL & METHODS

Methods: A retrospective review was conducted of all patients undergoing surgical management of external auditory canal exostosis by a single surgeon from 2017 onwards. Data collected included patient demographics, indication for surgery, surgical technique, postoperative recovery, complications, and time to return to water exposure.

RESULTS

Results: A total of 600 cases were included. All patients underwent minimally invasive transcanal canalplasty using a keyhole approach. The technique allowed effective removal of exostoses with preservation of canal skin and minimal disruption to surrounding structures. Postoperative recovery was favorable, with minimal downtime reported across the cohort. The majority of patients resumed water exposure at approximately 2 weeks postoperatively. Complication rates were low, and outcomes demonstrated effective symptom resolution, including reduction in recurrent infections and improvement in canal patency.

CONCLUSIONS

Conclusion:Minimally invasive transcanal (keyhole) surgery is a safe and effective technique for the management of external auditory canal exostosis. In this large single-surgeon series, the approach was associated with low morbidity, rapid recovery, and early return to water activities. These findings support the use of transcanal techniques as a preferred surgical approach in appropriately selected patients.

Spontaneous Pneumocephalus Associated With Leptomeningeal Glioneuronal Tumor In An Adult; A Rare Case Report

Mohammad H. Shaheen[1], **Syed Raza**[2], **Bassam AlZuraiqi**[2], **Mohammad Ghazi Abdoh**[3], **Essam Saleh**[2]

[1]Otolaryngology Department, Hera General Hospital, Makkah, Saudi Arabia; [2]Otolaryngology-Head and Neck Surgery Department, King Abdullah Medical City, Makkah, Saudi Arabia; [3]Neurosurgery Department, King Abdullah Medical City, Makkah, Saudi Arabia

BACKGROUND & AIM

Objective: To report a rare case of otogenic tension pneumocephalus as a complication of a diffuse leptomeningeal glioneuronal tumor in a patient with a ventriculoperitoneal (V. P.) shunt.

MATERIAL & METHODS

Patients: Twenty-three- year-old man with a confirmed diffuse leptomeningeal glioneuronal tumor diagnosis was treated for temporal bone defect and considerable pneumocephalus one year after V. P. shunt.

Intervention(s): The patient underwent a Transmastoid, retrolabyrinthine approach. The defect was closed with temporalis facia graft and conchal cartilage as a double-layer closure, and then DuraSeal® was placed over the repaired area.

Main outcome measure(s): Resolution of the pneumocephalus.

RESULTS

Results: There was a significant reduction in the pneumocephalus on the first day post-operatively.

CONCLUSIONS

Conclusions: Spontaneous or secondary pneumocephalus development should be considered in patients with brain tumors, hydrocephalus, and patients who undergo V.P. shunt insertion.

Outcomes Of Stapedotomy Performed By Residents Under Direct Supervision Versus Experienced Otologists: A Single-Center Cohort Study

Caio Eddie de Melo Alves[1], **Maurício Noschang Lopes da Silva**[1], **Fábio Selaimen**[1], **Sady Selaimen da Costa**[1]

[1]Department of Otolaryngology, Head & Neck Surgery - Federal University of Rio Grande do Sul - Brazil

BACKGROUND & AIM

Background: Stapedotomy is the preferred surgical treatment for otosclerosis but demands high microsurgical precision and experience. Prior studies indicate that outcomes achieved by trainees are inferior to those of attending otologists, likely reflecting a short learning curve and limited case volume during residency

Objective: To compare hearing outcomes and complication rates between primary stapedotomies performed by third-year otolaryngology residents under direct faculty

supervision and those performed by attending otologists.

MATERIAL & METHODS

Methods: Retrospective cohort at a tertiary academic center including 83 patients (89 primary stapedotomies) from 2019–2023. Air–bone gap (ABG) closure was classified as successful (≤10 dB), partial (>10 to ≤20 dB), or unsuccessful (>20 dB). Bone-conduction thresholds and perioperative complications were assessed.

RESULTS

Results: Complete ABG closure (≤10 dB) occurred in 77.8% of resident-performed cases versus 95.5% by attendings (p = 0.026). Using the broader criterion of ABG ≤20 dB, results were comparable between groups (p = 0.67). Bone-conduction thresholds remained stable in both cohorts, and complications were more frequent in resident cases but without permanent sequelae.

CONCLUSIONS

Conclusion: Under direct faculty supervision, stapedotomy can be safely performed by residents, yielding favorable functional hearing outcomes and an acceptable complication profile.

OP-854

Mastoid Obliteration For Problematic Cavities- Technique Refinements And Lessons Learned From Revision

Codruta Neumann[1], **Shan Yuen**[1], **Sophie Bondje**[1], **Stephanie Germain**[1]

[1]East Kent Hospitals University Foundation Trust; [2]Kent and Medway Medical School

BACKGROUND & AIM

Problematic mastoid cavities following canal wall down mastoidectomy can cause chronic otorrhoea, recurrent infection, difficulty with water exposure, and a persistent need for outpatient cleaning. These cases are often complex and may have undergone multiple previous revisions. Secondary mastoid obliteration aims to create a dry, safe, low-maintenance and water-proof ear. This study evaluates the long-term effectiveness of secondary mastoid obliteration in managing difficult mastoid cavities.

MATERIAL & METHODS

A prospective study of secondary mastoid obliterations undertaken between July 2014 and June 2026 is presented. A total of 102 obliterations were performed in 102 ears of 100 patients, including two bilateral cases. Ninety-five cases completing at least one year of follow-up were included. Twelve patients were lost to follow-up, including one unrelated death. The obliteration technique used a combination of local vascularised flaps and graft material, including fascia-periosteal flap, mid-temporal flap, cartilage, bone pâté and Tisseel, with selective use of synthetic material. Patients were followed at 3 and 6 months postoperatively, then annually for a minimum of 5 years. MRI surveillance was performed at 1 and 3 years, with selected cases imaged at 5 years.

RESULTS

Secondary mastoid obliteration achieved long-term control of cavity-related symptoms in the majority of patients, converting difficult cavities into dry, safe and water-resistant ears. Nineteen patients required revision surgery, giving a revision rate of 18.6%. Four patients involving six ears underwent endoscopic revision, while eleven patients underwent open revision; all open revision cases were dry at follow-up. One false-positive MRI led to negative exploration, although subsequent second revision at 11 years demonstrated residual disease.

CONCLUSIONS

Secondary mastoid obliteration is an effective technique for controlling difficult, chronically discharging and multiply revised mastoid cavities. Long-term follow-up extending to 11 years demonstrated durable cavity stability in most patients. Careful analysis of revision patterns allowed refinement of the operative technique, informing practice and improving success rates over time.

OP-855

Optimal Head Position For Intratympanic Dexamethasone Injection Relative To The Round Window

Kihun Jo[1], **Michelle Kwon BS**[2], **Jeonggeum Lee**[1], **Jamol Ergashev**[1,3], **Udi Shapira**[1], **Inseok Moon**[1]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, Yonsei University College of Medicine;* [2]*City University of New York School of Medicine;* [3]*Tashkent Pediatric Medical Institute*

BACKGROUND & AIM

Intratympanic dexamethasone injection (ITDI) is widely used for inner ear disorders. However, optimal head positioning to maximize drug absorption through the round window membrane (RWM) while minimizing Eustachian tube (ET) washout remains undefined. This study aimed to determine the ideal head position for ITDI using a multimodal approach and to compare it with the traditional 45° head rotation.

MATERIAL & METHODS

A multimodal analysis incorporating cadaveric dissection, clinical patient perilymph sampling, and three-dimensional (3D) anatomical modeling was performed. Twelve sagittal-sectioned human temporal bone cadavers were dissected to identify the transcanal angle required for direct RWM contact, and corresponding yaw, roll, and pitch head position angles were measured. Additional cadavers were used to compare perilymph dexamethasone concentrations following ITDI administered in either the traditional or optimal head position. Clinically, five patients undergoing translabyrinthine vestibular schwannoma resection received ITDI before surgery, followed by perilymph sampling. A 3D printed anatomical model of the external auditory canal, RWM, and ET was constructed to confirm fluid flow to the RW.

RESULTS

The optimal head position relative to the RWM was identified as 58.9° yaw, 31.1° roll, and 22.5° pitch. Cadaveric and clinical patient perilymph sampling demonstrated a 2.94-fold increase in perilymph dexamethasone concentration in the optimal head position compared with the traditional 45° position (0.0447% vs 0.0152%). Three-dimensional modeling demonstrated increased drug flow toward the RWM and reduced ET washout when roll and pitch were optimized conjunctively, while yaw alone had minimal effect.

CONCLUSIONS

Ideal intratympanic dexamethasone delivery requires adjustment of roll and pitch in addition to yaw. implementing a three-axis ideal head position is a simple, cost-effective strategy to improve intratympanic steroid absorption and therapeutic efficacy.

OP-856

Intraoperative Ossicular Findings And Surgical Outcomes In Traumatic Conductive Hearing Loss: A Retrospective Analysis

İlker Akyıldız[1], **Habib Ali Suadiye**[1], **Sibel Alicura Tokgöz**[1], **Mehmet Murat Günay**[1], **Samet Özlügedik**[1]

[1]*Ankara Etlik City Hospital, Department of Otorhinolaryngology – Head and Neck Surgery, Ankara, Türkiye*

BACKGROUND & AIM

Conductive hearing loss following temporal bone trauma is an important consequence of ossicular chain disruption. Among the ossicular pathologies that cause conductive hearing loss, incudostapedial (IS) joint dislocation is the most frequently encountered finding; however, erosion of the long process of the incus, stapes discontinuity, and malleus fixation may also be observed. The aim of this study was to retrospectively evaluate the intraoperative ossicular findings, the surgical techniques performed, and the postoperative audiological outcomes in patients who underwent ossiculoplasty for traumatic conductive hearing loss.

MATERIAL & METHODS

In this retrospective study, a total of 10 patients who underwent ossiculoplasty for trauma-related conductive hearing loss at the Department of Otorhinolaryngology of Ankara Etlik City Hospital between January 2023 and February 2026 were analyzed. Patients with persistent post-traumatic conductive hearing loss, available preoperative pure-tone audiometry (PTA) and temporal bone computed tomography (CT), and a postoperative follow-up of at least 3 months were included. Patients with congenital ossicular anomalies, chronic otitis media, secondary ossicular damage due to cholesteatoma or tympanosclerosis, isolated sensorineural hearing loss, or otosclerosis were excluded. Age, sex, trauma etiology, temporal bone CT findings, status of the tympanic membrane, intraoperative ossicular pathology, surgical approach, and ossiculoplasty technique were recorded. Preoperative and postoperative pure-tone audiometric values (air conduction [AC], bone conduction [BC], and air–bone gap [ABG]) were compared using the paired-samples t-test. Surgical success was defined as a postoperative ABG ≤20 dB.

RESULTS

Of the 10 patients included, 5 (50%) were male and 5 (50%) were female. The mean age was 24.8 ± 11.5 years. Trauma etiologies comprised blunt head trauma (n=8) and motor vehicle accidents (n=2). The most frequent ossicular pathology was

incudostapedial joint dislocation (n=6, 60%), followed by erosion of the long process of the incus (n=2, 20%), malleus fixation (n = 1, 10%), and stapes discontinuity with separation of the crura from the footplate (n=1, 10%). Reconstruction was performed with bone cement (Ketacem) in 8 patients, TORP (plastipore) prosthesis in 1 patient. And 1 patient was managed with a Teflon (fluoroplastic) piston without stapedetomy. The mean preoperative air conduction (AC) threshold improved significantly from 53.1 ± 13.4 dB to 24.3 ± 8.3 dB postoperatively ($p < 0.001$), and the mean preoperative air–bone gap (ABG) decreased significantly from 35.9 ± 7.3 dB to 9.5 ± 5.7 dB ($p< 0.001$).

CONCLUSIONS

In traumatic ossicular chain disruption, ossiculoplasty provides statistically and clinically significant improvement in hearing outcomes. In our series, incudostapedial joint pathology was the most common intraoperative finding, and in cases in which the remaining components of the ossicular chain were intact, reconstruction with bone cement was performed with low morbidity and a high success rate (postoperative ABG ≤20 dB in 100% of cases).

OP-857

Dementia Screening In Routine ENT And Audiology Clinics: Barriers And Enablers

Meghna Ray[1], **Larissa Greenwood**[1], **Vicki Proctor**[1], **Jaydip Ray**[1]

[1]*Sheffield Teaching Hospitals*

BACKGROUND & AIM

Dementia is a global health challenge in the 21st century and Age-Related Hearing Impairment is the major modifiable risk factor. This study aimed to explore the feasibility of including a memory screen as part of a standard hearing assessment.

MATERIAL & METHODS

NIHR portfolio adoption and Ethics approval (ID: 257362).

Audiologists were trained to administer Mini Mental State Examination (MMSE). Potential patients referred for hearing assessment were sent Patient Information Sheet. Those over 40 years and average hearing thresholds worse than 35dB were included.

Full history, examination, pure tone audiometry were undertaken and patients were consented if meeting inclusion criteria. Participants completed MMSE with the audiologist. Results shared with them and their GP with advise for onward referral if results outside range.

Declining patients were requested to share their reasons which were recorded with consent.

RESULTS

Of 1145 patients considered 572 failed preliminary screening. 467 (80%) of those invited agreed to participate, 18% declined (42% of them declined to give a reason) and 2% later withdrew. 250 completed the study. Average age was 73 years (range 65-79). Three (1%) had mild cognitive impairment. Hearing thresholds were worse than the group and only 1 of the 3 had noticed memory issues.

Commonest reasons for declining: other health/family commitments, didn't wish to know results, research averse or perceived inadequate information. Barriers to implementation: time constraints, unease at breaking bad news, non-attendance, rushed appointment.

CONCLUSIONS

It is possible to implement dementia screening in audiology clinics but there are a variety of factors to consider, including: patient concerns, staff and logistics, which all need addressing carefully.

Audiology, Screening, Dementia, Hearing Assessment

OP-858

Impact Of Tympanoplasty On Tinnitus In Patients Diagnosed With Chronic Otitis Media: A Systematic Review And Meta-Analysis

Mohammed alhamoud[1], **Mona ali alshehri**[1]

[1]*Department of Otolaryngology, Hospital , Saudi Arabia*

BACKGROUND & AIM

Purpose: Tinnitus is a frequent symptom linked to chronic otitis media (COM) and significantly affects the quality of life for affected individuals. This study aimed to evaluate the effectiveness of tympanoplasty in alleviating tinnitus in patients with COM and to explore the relationship between improvements in hearing and a reduction in tinnitus

MATERIAL & METHODS

Methods: The prospective registration of the systematic review was completed (CRD420250649682) and conducted according to PRISMA guidelines. Four major databases, PubMed, Web of Science, ScienceDirect, and Google Scholar, were searched electronically to identify relevant studies

RESULTS

Results: Twelve studies encompassing 1,139 patients were included in the analysis. Tympanoplasty resulted in a significant decrease in Tinnitus Handicap Inventory (THI) and Visual Analogue Scale (VAS) scores, with a pooled mean difference of 17.10 points (95% confidence interval [CI], 7.59 to 26.61, $p < 0.001$] and 1.92 points (95% CI, 0.65 to 3.19, $p = 0.003$), respectively. Age significantly correlates with improvements in THI, with younger individuals experiencing a greater decrease (beta = -2.04, 95% CI, -3.34 to -0.74, $p = 0.002$). A greater enhancement in bone conduction was associated with greater reduction in tinnitus severity (beta = 7.38, 95% CI, 5.31 to 9.45, $p < 0.001$)

CONCLUSIONS

.Conclusion: Tympanoplasty significantly improved the THI and VAS scores in patients with COM, with significant improvements in air conduction, bone conduction, and air-bone gap. Moreover, an improvement in bone conduction was positively correlated with the THI score after tympanoplasty.

OP-859

Are Patients With Sudden Hearing Loss Different From Those With Progressive Hearing Loss? A Cross-Sectional Pilot Study

Elif Barutcu[1], **Murat Enes Süer**[1], **Cüneyt Orhan Kara**[1], **Fazıl Necdet Ardıç**[1]

[1]*Pamukkale University*

BACKGROUND & AIM

The aim of this study is to compare the long-term quality of life, treatment satisfaction, depression and anxiety levels, and cognitive functions of patients with a history of sudden hearing loss with those of patients with progressive hearing loss, and to obtain effect size and standard deviation data for future long-term studies.

MATERIAL & METHODS

This study is a cross-sectional study involving 30 patients diagnosed with sudden hearing loss and 30 patients diagnosed with progressive hearing loss, all aged 18 years or older. Patients' demographic data, pre- and post-treatment audiological parameters, and accompanying vestibular symptoms were recorded. To assess functional limitations, psychological status, treatment success, subjective hearing quality, and cognitive impairments, the Dizziness Handicap Inventory (DHI), the Hospital Anxiety and Depression Scale (HADS), the Glasgow Benefit Inventory (GBI), the Speech, Spatial, and Hearing Characteristics Scale (SSQ12), and the Cognitive Failures Questionnaire (CFQ15) were administered. Due to the sample size, both parametric and non-parametric tests (Mann-Whitney U, Kruskal-Wallis, Spearman) were used for data analysis. Pearson correlation analysis was performed for continuous variables.

RESULTS

No significant differences were found between the groups (progressive and sudden hearing loss) in terms of scores on all scales ($p > 0.05$). However, a trend toward higher scores was observed in the progressive group for depression ($p = 0.077$) and cognitive impairment ($p = 0.098$). In the gender-based analysis, women had significantly higher HADS-Total ($p=0.020$) and anxiety ($p=0.034$) and depression ($p=0.044$) subscores, while men had significantly better SSQ12 scores ($p=0.015$). The presence of dizziness ($p<0.001$) and imbalance ($p=0.004$) was associated with a significant increase in DHI scores. In the correlation analysis, it was observed that as the perceived subjective hearing quality increased, anxiety, depression, and cognitive error scores decreased significantly ($p<0.001$). In regression analyses conducted in the sudden hearing loss subgroup, final hearing level (air conduction average at 500–4000 Hz) was a significant predictor of HADS anxiety subscale scores ($p = 0.031$) and depression subscores ($p = 0.015$).

CONCLUSIONS

The initial nature of hearing loss (sudden or progressive) has similar effects on patients' quality of life and psychological morbidity. Female gender and accompanying vestibular symptoms are key risk factors that negatively impact patients' functional and psychosocial status. In the management of hearing loss, focusing solely on audiological success is insufficient; a comprehensive approach, including vestibular rehabilitation, should be adopted by considering the patient's subjective perception of hearing, gender, and accompanying symptoms. The study is currently ongoing with data collection and evaluation.

Large Language Model Based Artificial Intelligence In The Diagnosis Of Cholesteatoma A Radiology Pathology Validated Comparison

Ramazan bahadır küçük[1], **Çağrı Yıldız**[1], **Alper Yenigün**[1], **Erol Şentürk**[1], **Remzi Doğan**[1], **Fadlullah Aksoy**[1], **Sabri Baki Eren**[1], **Orhan Ozturan**[1]

[1]*Bezmialem Vakif University, Faculty of Medicine, Department of Otorhinolaryngology*

BACKGROUND & AIM

To evaluate the diagnostic accuracy of non–echo-planar diffusion-weighted imaging (non-EPI DWI) and large language model (LLM)-based artificial intelligence (AI) in cholesteatoma diagnosis, using histopathology as the reference standard.

MATERIAL & METHODS

This retrospective study included 244 patients who underwent surgery for suspected residual or recurrent cholesteatoma at Bezmialem Vakıf University between 2017 and 2025. All patients had preoperative MRI with non-EPI DWI and histopathological confirmation. Routine radiology reports were reviewed, and images were additionally analyzed using Gemini 2.5, a multimodal LLM optimized for medical imaging. Diagnostic performance was assessed by calculating sensitivity, specificity, accuracy, positive predictive value, negative predictive value , F1 score, likelihood ratios, and diagnostic odds ratio. Subgroup analyses were performed according to lesion size.

RESULTS

Of the 244 patients, 121 had histopathologically confirmed cholesteatoma and 123 had non-cholesteatoma pathology. Overall accuracy was 79.1% for AI and 84.0% for radiology. Radiology showed significantly higher specificity (95.9% vs. 88.6%, p = 0.016), while sensitivities were comparable. In lesions <5 mm, AI sensitivity was markedly lower than radiology (36.8% vs. 68.4%, p = 0.011), whereas in lesions ≥5 mm, both methods showed similar sensitivity (84.7% vs. 93.2%, p = 0.24).

CONCLUSIONS

Gemini 2.5 demonstrated clinically meaningful diagnostic performance comparable to radiology and provided rapid image-based assessment without training requirements. LLMs may serve as practical second-opinion tools, especially in centers with limited radiologic expertise. Further multicenter prospective studies with standardized imaging protocols are warranted to validate their integration into clinical workflows.

Surgical Outcomes And Hearing Preservation Of Early Cochlear Implantation Using MED-EL FLEX Electrodes In Libyan Children.

Amal Elhuni[2], **Mohd Gadafi**[2], **Agila Dawod**[3]

[1]*Amal Elhuni;* [2]*Benghazi university;* [3]*Benghazi Medical center*

BACKGROUND & AIM

Background: Residual hearing preservation is an increasingly important target in pediatric cochlear implantation. MED-EL FLEX electrode arrays have been developed to minimize intracochlear trauma while providing effective cochlear coverage.

MATERIAL & METHODS

Methods: Children undergoing cochlear implantation were subjected to thorough audiological evaluation before surgery and during a two-year follow-up period. Residual hearing, intraoperative findings, electrode insertion success, postoperative complications, and auditory performance were analyzed by using Auditory performance (CAP score), Auditory development (LittlEARS questionnaire), Speech intelligibility (SIR):and Language development:

RESULTS

. . Analysis of 30 childreen of paediatric age group between 1-5 years was carried out after FLEX MED-EL electrodes insertion showed high rates of hearing preservation, low complication rates, and significant improvements in auditory performance and speech perception

CONCLUSIONS

Conclusion: The findings will provide valuable evidence regarding the safety and effectiveness of FLEX electrode technology in pediatric cochlear implantation within the Libyan healthcare system.

Histopathological Correlates Of Impaired Vestibular Compensation After Unilateral Vestibular Neurectomy In GAERS

Mahmut Furkan Beyaz[1], **Yavuz Gündoğdu**[1], **Fatma Nur Kömür**[2,3], **Özlem Tuğçe Çilingir Kaya**[4], **Orhan Asya**[1], **Ali Cemal Yumuşakhuylu**[1]

[1]*Department of Otolaryngology, Marmara University School of Medicine, Istanbul, Türkiye;* [2]*Department of Audiology and Speech Disorders, Institute of Health Sciences, Marmara University, Istanbul, Türkiye;* [3]*Department of Otolaryngology-Head and Neck Surgery, Kresge Hearing Research Institute, University of Michigan, Ann Arbor, MI, United States;* [4]*Department of Histology & Embryology, Marmara University School of Medicine, Istanbul, Türkiye*

BACKGROUND & AIM

Vestibular compensation following unilateral vestibular neurectomy (UVN) relies on central nervous system plasticity, yet the structural mechanisms underlying this process in the context of epileptic pathology remain poorly understood. Building on our prior behavioral evidence demonstrating significantly delayed and incomplete vestibular compensation in Genetic Absence Epilepsy Rats from Strasbourg (GAERS), the present study sought to characterize the histopathological substrates of this impairment, with particular focus on the primary somatosensory cortex (S1) and hippocampal dentate gyrus (DG).

MATERIAL & METHODS

UVN was performed in GAERS (n=7) and non-epileptic Wistar controls (n=7). Prior to the experimental period, successful vestibular loss was confirmed in all animals using the tail-lift and air-righting reflexes. General locomotor function and anxiety-like behavior were assessed using the open field test. Animals were then monitored daily for 7 days following surgery, after which brains were harvested via transcardial perfusion and embedded in paraffin. Serial coronal sections (4–6 µm thickness) were obtained using a rotary microtome from the paraffin tissue blocks, encompassing the primary S1 and hippocampal DG regions, according to the Paxinos and Watson rat brain atlas. Sections were processed with hematoxylin–eosin and cresyl violet staining. Histopathological evaluation was conducted using a semi-quantitative scoring system encompassing four parameters: neuronal degeneration, neuronal loss, perineuronal vacuolation, and gliosis. Group differences were assessed by independent-samples t-test.

RESULTS

Following the 7-day postoperative observation period, controls demonstrated well-preserved neuronal morphology with intact laminar organization throughout S1 and regular cytoarchitecture in the DG. In contrast, GAERS exhibited widespread neuronal degeneration characterized by pyknotic nuclei, cytoplasmic shrinkage, and cytotoxic edema, accompanied by prominent perineuronal vacuolation and reactive gliosis. Structural disruption was particularly pronounced in the DG, where irregular cytoarchitecture and hilum disorganization were consistently observed. Histopathological degeneration scores were significantly higher in GAERS compared to controls ($t(12) = 3.693$, $p < 0.003$), indicating markedly elevated neuronal vulnerability in the epileptic group. Following UVN, GAERS demonstrated increased head shaking and circling behavior compared to controls, which became more pronounced by postoperative 7-day, reflecting progressive postural instability and insufficient vestibular compensation in the epileptic group.

CONCLUSIONS

The present findings demonstrate that epileptic pathology is associated with substantial structural degeneration in cortical and hippocampal regions critical for vestibular plasticity. The histopathological results showed degenerated cellular basis for the impaired behavioral vestibular compensation previously documented in GAERS. These results suggest that pre-existing epileptic activity may compromise the structural integrity necessary for effective central compensation following peripheral vestibular injury. Clinically, these findings may be taken into consideration in individuals with epilepsy, when evaluating vestibular compensation.

The ‘Utrecht Experience’ In The Management Of Inner Ear Schwannomas. A Cohort Study

Christos Tsilivigkos[1,2], **Robert J. Stokroos**[1,3], **Eduard H. Voormolen**[3,4], **Hans G. X. M. Thomeer**[1,3]

[1]*Department of Otorhinolaryngology and Head & Neck Surgery, University Medical Center Utrecht, Utrecht University, The Netherlands;* [2]*First Department of Otolaryngology, Hippokration General Hospital, National and Kapodistrian University of Athens, Athens, Greece;* [3]*UMC Utrecht Brain Center;* [4]*Department of Neurosurgery, Skull Base Surgery, UMC Utrecht Brain Center*

BACKGROUND & AIM

Inner ear schwannomas (IESs) are a rare subtype of vestibulocochlear nerve schwannomas originating from the vestibular/auditory end organs. They typically present with unilateral sudden or progressive sensorineural hearing loss (SNHL), tinnitus, and/or vestibular symptoms. The widespread use of magnetic resonance imaging (MRI) has substantially increased

the detection of this uncommon entity. The aim of this study was to present the diagnostic and therapeutic management experience of a tertiary referral center in the Netherlands.

MATERIAL & METHODS

A retrospective cohort study was conducted including adults diagnosed with IESs who presented to our tertiary referral center between 2014-2026. Patients were categorized into two management groups: a “watch-and-scan” and a “surgery” group. The main outcomes evaluated included patient demographics (number, age, sex), clinical presentation (hearing loss, tinnitus, vestibular symptoms), pure-tone average (PTA), speech audiometry in quiet, tumor size (maximum diameter on MRI), and tumor classification at initial and most recent follow-up. Descriptive statistics were used to summarize the data. Continuous variables are presented as mean ± standard deviation.

RESULTS

Eleven patients were included (5 females, 6 males; age 54.8 ± 12.9 years). At presentation, all patients reported hearing impairment, 81.8% tinnitus, and 36.4% vestibular symptoms. At the most recent follow-up, hearing had worsened in 54.5% of patients, remained stable in 9.1%, and remained at non-serviceable levels in 36.4%. Tinnitus was present in 63.6% of patients and vestibular complaints in 36.4%. Mean air PTA deteriorated from 71.1 ± 36.6 dB to 102.3 ± 28.8 dB, while speech reception thresholds worsened from 70.8 ± 19.0 dB to non-measurable levels in the majority of patients. Tumor classification included intravestibular tumors (27.3%), intracochlear tumors (63.6%), and a transfundal tumor with modiolus involvement (9.1%). Mean tumor size increased from 5.64 ± 3.18 mm to 7.5 ± 3.13 mm during follow-up. A “watch-and-scan” strategy was adopted in 63.6% of patients, whereas 36.4% underwent surgical treatment. No major postoperative complications were observed in the surgical group.

CONCLUSIONS

IESs represent a heterogeneous group of tumors with variable clinical presentation, hearing outcomes, anatomical location, and size. Management should therefore be individualized and patient-oriented to ensure optimal diagnostic and therapeutic decision-making.

OP-864

Reverse Stapedotomy In Otosclerosis: Outcomes From A Consecutive Series Using A Standardized Surgical Approach

Ana Raquel Andrade[1], **Miguel Lopes**[1], **Luciana Rodrigues**[1], **Diogo Nascimento**[1], **Inês Ribeiro**[1], **Alexandra Correia**[1], **Hélder Silva**[1], **Paulo Gonçalves**[1]

[1]*Unidade Local de Saúde Entre Douro e Vouga*

BACKGROUND & AIM

Stapedotomy is the standard surgical treatment for otosclerosis. Technical variations aim to optimize prosthesis positioning and improve functional outcomes. In our department, the reverse fish technique is used as a standardized approach due to its potential advantages in prosthesis control and reproducibility. This study aims to evaluate audiometric outcomes following this technique.

MATERIAL & METHODS

A retrospective study was conducted including patients with otosclerosis who underwent primary stapedotomy using the reverse fish technique between April 2022 and April 2025 in a secondary referral center, where this represents the standard surgical technique. A total of 62 consecutive procedures were included. Audiometric evaluation was performed preoperatively and at a minimum follow-up of 12 months, in accordance with the guidelines of the American Academy of Otolaryngology–Head and Neck Surgery. Air conduction, bone conduction, and air–bone gap were calculated using pure-tone averages at 0.5, 1, 2, and 3 kHz. The primary outcome was postoperative air–bone gap, with surgical success defined as ≤10 dB. Secondary outcomes included air–bone gap ≤20 dB, air conduction gain, and bone conduction variation.

RESULTS

At a minimum follow-up of 12 months, there was a significant improvement in hearing thresholds, with the mean preoperative air–bone gap improving from 29 ± 8 dB to 9 ± 5 dB postoperatively. An air–bone gap ≤10 dB was achieved in 83% of cases and ≤20 dB in 96%, with a mean air conduction gain of 21 ± 9 dB. Bone conduction thresholds remained stable, with a mean variation of +1 ± 4 dB. No major intraoperative or postoperative complications were observed.

CONCLUSIONS

Reverse fish stapedotomy, applied as a standardized technique, provides reliable and reproducible audiometric outcomes, with high rates of air–bone gap closure and stable bone conduction thresholds at ≥12 months follow-up, supporting its use in the surgical management of otosclerosis.

Factors Play A Role In The Prognosis Of Temporal Bone Squamous Cell Carcinoma; Experience In A Tertiary Care Center

Ibrahim Shami[1], **Muath Alsabih**[1,2], **Ahmed M. Aldhafeeri**[3]

[1]*King Fahad Medical City;* [2]*King Saud Medical City;* [3]*Hafr Albaten Central Hospital*

BACKGROUND & AIM

Temporal bone squamous cell carcinoma (TBSCC) is a rare and aggressive head and neck malignancy with no standardized management guidelines due to its low incidence. Delayed diagnosis is common, as it often mimics benign otologic conditions, resulting in poor outcomes, particularly in advanced stages. Our objective is to describe the clinical presentation, management strategies, and outcomes of patients diagnosed with TBSCC at a tertiary care center in Saudi Arabia and to evaluate prognostic factors influencing survival.

MATERIAL & METHODS

A retrospective clinicopathological case series was conducted including all patients diagnosed with TBSCC at King Fahad Medical City, Riyadh, Saudi Arabia, between January 2018 and December 2024. Demographic data, clinical presentation, imaging findings, tumor staging using the Modified Pittsburgh staging system, treatment modalities, and follow-up outcomes were analyzed.

RESULTS

Nine patients were identified with a median age of 60 years (range: 22–87), and a male predominance (66.7%). The most common presenting symptom was otorrhea, frequently associated with otalgia. The external auditory canal and auricle were the most frequent sites of origin. Advanced disease was common, with six patients presenting with stage IV tumors. Surgical management was the primary treatment modality when feasible, with adjuvant radiotherapy or chemotherapy administered based on tumor stage and patient condition. Five patients with advanced-stage disease died during follow-up, with a median survival of 10 months, whereas patients with early-stage disease demonstrated favorable outcomes and remained disease-free.

CONCLUSIONS

TBSCC carries a poor prognosis when diagnosed at an advanced stage. Early recognition, high clinical suspicion in refractory otologic symptoms, and prompt multidisciplinary management are critical to improving survival outcomes. Given the rarity of this malignancy, multicenter collaboration and data pooling are essential to establish evidence-based management guidelines.

OP-866

Prevalence Of High-Riding Jugular Bulb And Bony Dehiscence In Atelectatic Ears: A Comparative CT Analysis With Clinically Normal Ears

Özkan Tezgez[1], **Fatih Özdoğan**[2]

[1]*Derince Training and Research Hospital;* [2]*Kocaeli Şehir Hastanesi*

BACKGROUND & AIM

A high-riding jugular bulb (JB) is a significant anatomical variation that can cause severe bleeding during middle ear surgery, particularly in the inferior quadrant. Poor mastoid pneumatization, frequently observed in atelectatic/retracted ears, is thought to be associated with a more superiorly located JB, posing surgical risks. This study aimed to compare the prevalence of high-riding JB and bony dehiscence in atelectatic ears versus clinically normal ears.

MATERIAL & METHODS

This retrospective study included 50 atelectatic/retracted ears and 50 clinically normal contralateral ears of patients requiring unilateral Type 1 tympanoplasty. Temporal bone computed tomography (CT) scans were evaluated. A JB extending above the inferior bony annulus level was defined as a "high-riding JB." JB bony dehiscence and mastoid pneumatization degrees were recorded. Pneumatization was qualitatively categorized based on air cell extent and volume as "well-pneumatized," "moderately pneumatized," or "sclerotic" (compact bone appearance). Chi-square and Fisher's exact tests were used for comparisons. A p-value < .05 was statistically significant.

RESULTS

A high-riding JB was detected in 40 patients (80%) in the atelectatic group and 15 patients (30%) in the control group, showing a significantly higher prevalence in atelectatic ears ($p < .001$). JB bony dehiscence occurred in 8 patients (16%) in the atelectatic group and 2 patients (4%) in the control group ($p = .091$). Sclerotic mastoids predominated in the atelectatic group, while well-pneumatized mastoids were dominant in the control group ($p < .001$). Statistically significant correlations were found between JB height and both bony dehiscence ($p < .005$) and mastoid pneumatization ($p = .005$), indicating that the tendency for a high-riding JB increases significantly as mastoid pneumatization worsens.

CONCLUSIONS

High-riding JB is significantly more common in atelectatic ears than in normal ears. It correlates with both increased bony dehiscence and poor mastoid pneumatization. Careful preoperative temporal bone CT evaluation of JB anatomy is crucial in atelectatic ears to prevent potential vascular complications.

OP-867

Evaluation Of Demographic And Clinical Characteristics Of Patients Undergoing Otosclerosis Surgery: A Single-Surgeon Experience

Andaç Çakan[1], **İlker Akyıldız**[1]

[1]*Health Science University, Etlik City Hospital, Department Of Otolaryngology*

BACKGROUND & AIM

Otosclerosis is a primary metabolic bone disease of the otic capsule characterized by fixation of the stapes footplate, leading to progressive conductive hearing loss. This study aims to evaluate the surgical effectiveness by presenting the demographic data, preoperative clinical characteristics, and postoperative auditory outcomes of patients who underwent stapedotomy by a single surgeon.

MATERIAL & METHODS

Fourty ears of Thirty-nine patients operated on by a single senior surgeon with complete postoperative follow-up were retrospectively analyzed. Demographic data, preoperative and postoperative pure-tone thresholds (0.5, 1, 2, 4 kHz), air-bone gap (ABG), and speech discrimination scores (SDS) were evaluated. Paired t-test and Wilcoxon tests were utilized for statistical analysis following the Shapiro-Wilk normality test.

RESULTS

The mean age of the study group was 43.2 (range 24-59), and 79% (n=30) were female. The most prevalent group consisted of females aged 40-50. Postoperatively, a statistically significant improvement of 22.24 dB was observed in mean airway thresholds ($p < 0.001$). The mean preoperative ABG of 28.95 dB significantly decreased to 11.46 dB postoperatively ($p < 0.001$). No statistically significant difference was observed in SDS values ($p > 0.05$).

CONCLUSIONS

Our results, based on a single-surgeon experience, demonstrate that stapedotomy surgery is a reliable intervention for improving hearing thresholds and closing the air-bone gap in otosclerosis patients, with low complication and high success rates.

Design And Validation Of Cochlearprint, An Innovative Medical Device For Hearing Loss Theragnostic Exploration

Hong Hanh TRAN[1], **Raphaele QUATRE**[1], **Ali BOUAMRANI**[2], **François BERGER**[2], **Sébastien SCHMERBER**[1,2]

[1]*University Grenoble Alpes, FRANCE;* [2]*INSERM Braintech Lab, University Grenoble Alpes, FRANCE*

BACKGROUND & AIM

Sensorineural hearing loss (SNHL) remains largely classified on clinical and audiological criteria, as direct molecular investigation of the inner ear is rarely feasible in routine practice. Perilymph sampling during cochlear implantation provides a unique window into cochlear biology, but existing methods are limited by sample instability, contamination, and poor analytical sensitivity.

MATERIAL & METHODS

We developed CochlearPrint, a medical device integrating a nanoporous silicon chip into a standard cochlear implantation instrument, enabling rapid and stabilized perilymph sampling during surgery without altering the surgical workflow. Nanoporous capture enriches low-abundance biomolecules and attenuates interference from highly abundant proteins, improving downstream molecular analysis.

Patients undergoing cochlear implantation between 2020 and 2022 were included. Clinical data were retrospectively collected from medical records for samples meeting quality criteria. Collected variables included demographic characteristics, medical history, presumed etiology of hearing loss, associated symptoms (tinnitus, vertigo, balance disorders), and imaging findings (CT and MRI). Perilymph samples were collected intraoperatively during routine cochlear implantation procedures and analyzed using matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-ToF). Samples were deposited onto

nanoporous silicon chips, enabling passive capture and enrichment of low-molecular-weight biomolecules. After washing, matrix was applied and samples were directly analyzed.

RESULTS

Perilymph was collected from 21 patients undergoing cochlear implantation and analysed using MALDI–time-of-flight mass spectrometry. Nanoporous sampling significantly enhanced detection of low-molecular-weight molecular species compared with direct analysis and reduced haemoglobin-related signal suppression, yielding interpretable molecular profiles in 71.4% of cases. These profiles revealed marked interindividual molecular heterogeneity despite similar clinical phenotypes.

Surgical feasibility and safety were evaluated in eight human cadavers (16 temporal bones). A 3-mm nanoprobe configuration provided optimal contact with the perilymphatic space while preserving cochlear integrity, with successful deployment achieved in 13 of 16 temporal bones under standard cochlear implantation conditions.

CONCLUSIONS

CochlearPrint enables standardized, minimally invasive access to perilymph during routine cochlear implantation and offers a clinically compatible platform for inner ear molecular profiling. This approach has potential applications in biomarker discovery, etiologic stratification of SNHL, and biologically informed optimization of cochlear implant strategies. It should favour the development of precision medicine and neuroprotective therapies for hearing disorders.

Investigation Of The Therapeutic Efficacy Of Rosmarinic Acid In An Experimental Chronic Otitis Media Model Induced By Pseudomonas Aeruginosa In Rats

Sadık Vural Kaya[1], **Ayhan Kars**[1], **Serkan Altıparmak**[1], **İlyas Sayar**[2], **Sara Salcan**[3]

[1]*Erzincan Binali Yıldırım University Faculty of Medicine, Department of Otolaryngology;* [2]*Erzincan Binali Yıldırım University Faculty of Medicine, Department of Pathology;* [3]*Erzincan Binali Yıldırım University Faculty of Medicine, Department of Public Health*

BACKGROUND & AIM

Chronic otitis media (COM) is a significant global health problem associated with persistent inflammation and therapeutic challenges. Current medical treatments may be insufficient due to reduced drug penetration and bacterial resistance. Rosmarinic acid (RA), a bioactive compound with anti-inflammatory, antibacterial, and antioxidant properties, has demonstrated promising effects in various experimental models. This study aimed to evaluate the therapeutic efficacy of topical RA in an experimental COM model.

MATERIAL & METHODS

Thirty adult female Wistar albino rats were randomly divided into five groups (n=6 per group): healthy control, untreated COM, ciprofloxacin, ciprofloxacin+RA, and RA groups. COM was induced via transtympanic inoculation of Pseudomonas aeruginosa. After a 14-day follow-up period, bilateral temporal bones were harvested. Histopathological evaluation included neutrophil activity, chronicity, histiocyte presence, keratin accumulation, subepithelial edema, congestion, fibroblast proliferation, neovascularization, and tympanic membrane thickness. Statistical analyses were performed for intergroup comparisons.

RESULTS

Significant differences were observed among groups for all evaluated parameters. Neutrophil activity in the untreated COM group was significantly higher compared to the control, ciprofloxacin+RA, and RA groups ($p<0.001$, $p=0.01$, $p=0.02$, respectively). Chronicity and histiocyte scores were also significantly increased in the untreated group ($p<0.001$). Keratin accumulation was significantly higher compared to the RA-treated groups ($p=0.01$). In groups receiving RA, inflammation was reduced, edema and congestion regressed, and a regulatory effect on neovascularization was observed ($p<0.05$). RA demonstrated beneficial effects both as monotherapy and in combination therapy.

CONCLUSIONS

Topical rosmarinic acid reduces inflammation and enhances histopathological recovery in an experimental COM model. RA appears to be a promising alternative or adjunctive therapeutic agent in the treatment of chronic otitis media.

OP-870

Genetic Etiologies Of Sensorineural Hearing Loss And Their Influence On Cochlear Implant Outcomes: A 16-Year Experience At Prince Sultan Military Medical City

Assaf Abdullah A Alkathiri[1], **Iman almashharawi, MD**[1], **Mohammed Hazazi, MD**[1]

[1]*Department of Otolaryngology–Head and Neck Surgery, Prince Sultan Military Medical City, Riyadh, Saudi Arabia*

BACKGROUND & AIM

Genetic factors play a significant role in the etiology of sensorineural hearing loss and may influence outcomes following cochlear implantation (CI). Understanding the relationship between genetic findings and postoperative performance is important for patient counseling and prognostic assessment.

Aim:

• To analyze genetic findings in this cohort.

• To evaluate the impact of genetics on post-implant audiological performance and speech development.

Significance:

• Understanding genetic factors help

MATERIAL & METHODS

This retrospective cohort study included all patients who underwent cochlear implantation at our tertiary center between January 2009 and December 2024. A total of 560 patients received CIs during this period. Among them, 111 patients were referred for genetic testing to determine the underlying cause of hearing loss. Demographic, clinical, genetic, audiological, and speech development data were collected and analyzed. Postoperative outcomes were assessed using standardized audiological measures and speech evaluation tools. Patients were stratified according to genetic testing results to evaluate associations with CI outcomes.

RESULTS

Pathogenic or likely pathogenic variants were identified in a proportion of the genetically tested cohort, including both syndromic and non-syndromic etiologies. Significant improvement in aided hearing thresholds and speech perception scores was observed following cochlear implantation across the cohort. While overall outcomes were favorable regardless of genetic findings, variability in postoperative audiological performance and speech development was noted according to genetic etiology. Patients with non-syndromic genetic causes generally demonstrated more consistent improvement, whereas syndromic cases showed greater variability in outcomes.

CONCLUSIONS

Cochlear implantation provides substantial audiological and speech benefits in patients with sensorineural hearing loss. Genetic testing contributes valuable etiological and prognostic information and may assist in preoperative counseling and individualized management. Integrating genetic evaluation into routine CI assessment may enhance outcome prediction and optimize patient care.

Across The Midline: Contralateral Sixth Nerve Palsy From An Otogenic Source

Rusescu Andreea[1,2], **Chirila Alexandra Diana**[1,2], **Ionita Irina Gabriela**[1,2], **Alius Oana Ruxandra**[1,2], **Voiosu Catalina**[1,2], **Simona Serban**[1,2], **Hainarosie Razvan**[1,2], **Catana Mihai Eugen**[1,2], **Zainea Viorel**[1,2], **Vasile Marian tiberiu**[1,2]

[1]*"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania;* [2]*"Prof Dr. D. Hociota" Institute of Phonoaudiology and Functional ENT Surgery*

BACKGROUND & AIM

Otogenic bacterial meningitis is a life-threatening intracranial complication of chronic otitis media, most often occurring on the same side as the primary infection. Abducens nerve palsy in the context of Gradenigo's syndrome usually suggests involvement of the petrous apex. We report an unusual case of contralateral abducens palsy caused by otogenic meningitis, highlighting the diagnostic difficulties and the surgical management strategy.

MATERIAL & METHODS

A 19-year-old male with chronic left-sided otitis media presented with intense headache, otalgia, vertigo, hearing loss, and diplopia. Clinical examination revealed right abducens nerve palsy, bilateral papilledema, and purulent left otorrhea. Audiometry demonstrated moderate mixed hearing loss. CT and MRI identified left mastoiditis with extensive inflammatory tissue and posterior fossa dehiscence, without evidence of contralateral intracranial lesions.

RESULTS

The patient was treated with intravenous meropenem, corticosteroids, anticoagulation, and analgesics. A left radical mastoidectomy was performed, revealing sigmoid sinus dehiscence and granulation tissue extending into the middle ear. After surgical debridement and coverage using oxidized regenerated cellulose and bone wax, the patient showed progressive clinical improvement. At one-month follow-up, papilledema had resolved in the left eye and improved in the right, with gradual recovery of abducens nerve function.

CONCLUSIONS

This case illustrates the rare occurrence of contralateral abducens palsy in otogenic meningitis. Prompt multidisciplinary assessment involving otologic and neurologic expertise is crucial for precise localization, timely surgical management, and prevention of permanent cranial nerve deficits in complex intracranial otogenic infections.

OP-872

Middle ear & Bone conduction implants in unilateral aural atresia

Prof. Dr. John Martin Hempel[1], **Marlene Pollotzek**[1], **Dr. Sophia Gantner**[1]

[1]*Ludwig-Maximilians-University Munich*

BACKGROUND & AIM

This study compares the efficacy of Vibrant Soundbridge (VSB) and Bonebridge (BB) implants in patients with unilateral aural atresia (UAA), focusing on spatial hearing, masking release, sound localization, and patient-reported satisfaction.

MATERIAL & METHODS

In this ongoing study, 17 VSB and 10 BB recipients with unilateral aural atresia, all active implant users for ≥6 months, served as their own controls. Audiological assessments included pure-tone audiometry, Vibrogram, and word recognition in quiet (WRS; Freiburger monosyllabic test). Spatial hearing was evaluated using the Oldenburg Sentence Test (OLSA) in three spatial configurations. Sound localization was assessed in a horizontal -90°/+90° setup. Patient satisfaction and quality of life were measured using the Speech, Spatial and Qualities of Hearing Scale (SSQ).

RESULTS

All patients exhibited normal inner ear function bilaterally. With the contralateral ear plugged & muffed, the VSB group achieved a mean WRS of 77±16%, the BB group a mean WRS of 68±22%. Significant benefit aided versus unaided was prevalent in the head shadow configuration (ipsilateral signal/contralateral noise), OLSA improvement was 6,3±3,2 dB with the VSB and 3,7±4,0 dB with BB, the difference was significant. Sound localization showed high individual variation, on the ipsilateral hemisphere the mean absolute error in degree changed from unaided 17±6° to aided 10±5° with BB and from unaided 14±9° to aided 8±3° with the VSB. A normal hearing reference group (n=16) achieved a MAE of 5°±2°. Subjective satisfaction regarding the speech, spatial and qualities of hearing scale showed scores above 60% with both implants, without a significant difference in any of the domains comparing BB and VSB.

CONCLUSIONS

VSB and BB recipients showed clinically meaningful improvements in sound field thresholds, speech perception and especially spatial hearing, where superior performance was achieved in the VSB group. Sound localization accuracy in patients with UAA can be close to normal hearing, however individuals with unaided substantially impaired localization, can benefit effectively from implant use in sound localization. These results highlight the critical role of device-specific counselling in achieving optimal patient outcomes.

OP-873

Low-Cost Endovascular Balloon Dilation For Pediatric Obstructive Eustachian Tube Dysfunction: A Prospective Feasibility Study

Yehia Mohammed Ashry[2], **Abdelrahman Mostafa Hassan**[1], **Eman Sheta**[1], **Hani Farouk Elgarem**[1], **Yasser Gaber Sheweal**[1]

[1]*Faculty of Medicine, Alexandria University, Alexandria, Egypt.*; [2]*Faculty of Medicine, Suez Canal University, Suez Canal, Egypt.*

BACKGROUND & AIM

Balloon dilation of the Eustachian tube (BDET) has emerged as a promising treatment for pediatric obstructive Eustachian tube dysfunction (OETD). Its adoption is limited by the high cost of proprietary balloon systems. This study hypothesized that pediatric BDET performed using low-cost standard endovascular balloon catheters is feasible, safe, and associated with favorable early clinical outcomes. The aim was to evaluate clinical and functional outcomes using objective, subjective, and endoscopic assessments.

MATERIAL & METHODS

This prospective single-arm interventional clinical study included 14 pediatric patients aged ≥5.5 years with bilateral OETD, yielding 28 Eustachian tubes for evaluation. Endoscopic balloon dilation Eustachian tuboplasty was performed in all ears using standard endovascular balloon catheters under endoscopic guidance. Pre- and postoperative assessments included otoscopic examination, tympanometry, pure-tone audiometry (PTA), the Eustachian Tube Dysfunction Questionnaire-7 (ETD-Q7), and functional Eustachian tube evaluation using the Valsalva maneuver. Dynamic flexible nasopharyngeal endoscopy was

employed intraoperatively and during follow-up to assess Eustachian tube lumen patency, mucosal changes, and dynamic tubal function. Pre- and postoperative outcomes were compared per ear using paired statistical analysis.

RESULTS

The mean patient age was 11.3 ± 3.6 years. Procedural success was achieved in 75% of ears. ETD-Q7 scores improved significantly from 3.64 ± 0.91 to 1.72 ± 0.57 ($p < 0.001$). Mean PTA thresholds improved from 24.79 ± 7.88 dB to 9.55 ± 8.34 dB ($p < 0.001$). Tympanometry showed significant improvement, with conversion to type A in 60.7% and type C in 14.3% of ears ($p = 0.004$). A positive Valsalva maneuver was achieved in 71.4% of ears ($p < 0.001$). No complications occurred in 89.3% of cases; reported events were minor and self-limited.

CONCLUSIONS

Low-cost standard endovascular balloon catheters provide a feasible, safe, and cost-effective alternative for pediatric BDET, with favorable early clinical and functional outcomes comparable to proprietary systems.

Changes In Wideband Tympanometry Absorbance Following Endolymphatic Sac Drainage For Meniere's Disease

Masafumi Ohki[1], **Maki Saito**[1], **Tomomi Horikoshi,**[1], **Junpei Sasakawa**[1], **Genki Iguchi**[1]

[1]*Department of Otolaryngology, Saitama Medical Center, Saitama Medical University*

BACKGROUND & AIM

This study aims to evaluate the changes in the oscillatory properties of the inner ear following endolymphatic sac drainage in patients with Meniere's disease. While endolymphatic hydrops is known to alter ear mechanics, the efficacy of Wideband Tympanometry (WBT) in monitoring these postoperative changes remains to be fully established.

MATERIAL & METHODS

Patients diagnosed with Meniere's disease who underwent endolymphatic sac drainage were enrolled. We analyzed pure-tone audiometry and WBT parameters pre- and postoperatively, specifically focusing on absorbance (226–8000 Hz), resonance frequency, and "twin peaks" morphology (initiation frequency, width, and depth).

RESULTS

Postoperative WBT results showed a distinct shift in absorbance patterns. At both ambient and peak pressure, absorbance decreased at low frequencies and increased at high frequencies compared to preoperative levels. The analysis of the "twin peaks" area revealed significant morphological shifts. Initiation frequency of the twin peaks shifted toward higher frequencies postoperatively. At 2 kHz, the width of the twin peaks narrowed and the depth of the valley became shallower after surgery. Conversely, at 4 kHz, the width increased postoperatively. Clinical outcomes showed a dramatic reduction in vertigo frequency, although pure-tone hearing thresholds showed no significant difference.

CONCLUSIONS

Endolymphatic sac drainage significantly alters the absorbance characteristics and twin peak morphology in WBT. These changes likely reflect the reduction of endolymphatic hydrops and the subsequent restoration of normal oscillatory properties in the inner ear. Evaluation of the "twin peaks" area in WBT serves as a sensitive, non-invasive objective marker for assessing the physiological success of surgical interventions in Meniere's disease.

OP-875

Does Epitympanic Obliteration Improve The Rates Of Recidivism In Combined Approach Tympanoplasty For Cholesteatoma?

Codruta Neumann[1,2], **Junaid Kalliyath**[1]

[1]*East Kent Hospitals University Foundation Trust;* [2]*Kent and Medway Medical School*

BACKGROUND & AIM

Combined approach tympanoplasty is widely used in the management of cholesteatoma, but residual and recurrent disease remain important long-term concerns. Epitympanic obliteration may reduce the risk of recidivism by eliminating hidden spaces prone to residual disease and retraction. This study evaluates the impact of epitympanic obliteration on the need for second-look surgery following combined approach tympanoplasty.

MATERIAL & METHODS

A prospective study of 251 stage one combined approach tympanoplasties for cholesteatoma is presented. Following introduction of the obliteration technique in 2018, 54 cases underwent epitympanic obliteration, while previous 197 cases

were managed without obliteration. The technique involved obliteration of the epitympanum using bone pâté and Tisseel, reconstruction of the tympanic membrane with cartilage graft, and primary ossiculoplasty with titanium passive middle ear prostheses where required. Endoscopy and KTP laser were used to minimise the risk of residual disease. Patients were followed clinically at 4 weeks, 3 months, and then annually for a minimum of 5 years. Diffusion-weighted MRI was performed at 1, 3 and 5 years to assess for recidivism.

RESULTS

In the obliteration group, 3 of 54 cases required second-look surgery, a rate of 5.6%. In comparison, 45 of 197 cases in the non-obliteration group required second-look surgery, a rate of 22.8%. The introduction of epitympanic obliteration was therefore associated with a marked reduction in the need for second-look procedures. Radiological surveillance with diffusion-weighted MRI provided ongoing assessment for residual or recurrent cholesteatoma during long-term follow-up.

CONCLUSIONS

Epitympanic obliteration during combined approach tympanoplasty appears to be a successful technique for reducing recidivism in cholesteatoma surgery. These findings support epitympanic obliteration as a valuable refinement in cholesteatoma surgery to improve long-term disease control.

OP-876

CONGENITAL ANOMALIES OF THE EXTERNAL EAR AND THE GENDER ASSOCIATIONS AMONG THE URHOBOS IN DELTA STATE NIGERIA.

Prof Nekwu Emmanuel Okolugbo[1], **Professor (Mrs) Ese Anibor**[2]

[1]*Federal University of Medical and Health Sciences Kwale, Delta State Nigeria;* [2]*Delta State University Abraka Delta State Nigeria*

BACKGROUND & AIM

This study seeks to provide new information about the presence of congenital anomalies of the external ear such as preauricular sinus and Darwin's tubercle among the Urhobos in Delta State, Nigeria; the gender association was also studied as well as heritability patterns.

MATERIAL & METHODS

The study employed multistage sampling starting with 10 Urhobo speaking local government areas from which a town was randomly selected and 10 families chosen. This resulted in a sample of 100 families. They completed questionnaire on age, gender and ethnicity. Morphological characteristics of the ear were examined and the absence or presence of Darwin's tubercle as well as its type was noted, also observed is the presence of preauricular sinus, either unilateral or bilateral. Thereafter photographs were taken of the subjects' ears.

RESULTS

The presence of Darwin's tubercle was noted in 42.7% of participants with 3 forms observed: nodosity (36.3%), enlargement (3.5%) and projection (3%). The study also confirmed that Darwin's tubercle is more frequently observed in males, although the gender variation is not statistically significant (P>0.05). Prearricular sinus was found in 3.25% of subjects in this study.

CONCLUSIONS

Darwin's tubercle is the most heritable trait in this study, 42.7% of participants were observed to have the Darwin's tubercle. This is a reliable marker for tracing parentage. Preauricular sinus was found in 3.25% of subjects in this study, notably females are more likely to inherit preauricular sinuses from their parents.

EVALUATION OF THE EFFECTS OF ALCOHOL CONSUMPTION AND EXPOSURE TO LOUD NOISE ON HEARING USING PRESTIN AND HSP70 BIOMARKERS

Osman Kılıç[1,2], **Batın Berkay Öznacar**[1,2], **Ali Murati**[1,2], **Nazım Eymen Turan**[1,2], **Mustafa Yıldız**[4], **Metin Budak**[4], **Emel Aslantaş**[3], **Serdal Çelik**[1,2], **Mahmut Tayyar Kalcıoğlu**[1,2]

[1]*Department of Otorhinolaryngology and Head and Neck Surgery, İstanbul Medeniyet University Faculty of Medicine, İstanbul, Türkiye;* [2]*ENT Clinic, Göztepe Prof. Dr. Süleyman Yalçın City Hospital, İstanbul, Türkiye;* [3]*ENT Clinic, Audiology Unit, Göztepe Prof. Dr. Süleyman Yalçın City Hospital, İstanbul, Türkiye;* [4]*Department of Biophysics, Faculty of Medicine, Trakya University, Edirne, Türkiye*

BACKGROUND & AIM

Currently, hearing loss is diagnosed through physical examination, imaging, and audiometric testing. The time-consuming nature of the diagnostic process, which requires specialised equipment and trained personnel, has created a demand for new tools that can diagnose hearing

loss quickly, safely and effectively. In our study, we evaluated changes in prestin and HSP70 levels, which are detectable blood biomarkers following exposure to alcohol and/or loud noise.

MATERIAL & METHODS

Baseline prestin and HSP70 levels were measured in 22 adult volunteers with normal audiological evaluations (15 males and 7 females with a mean age of 29.09 years old) (Group A). Participants were assessed under three conditions: alcohol and noise exposure (Group B), alcohol in a quiet environment (Group C), and noise exposure without alcohol (Group D). Subjects consumed approximately 240 mL of a 37.5% alcohol beverage and were exposed to a noisy environment of ≥100 dB. Blood samples were collected on the third day after exposure. Serum prestin (pg/mL) and HSP70 (ng/mL) levels were measured using commercial ELISA kits with duplicate technical repeats and single-blind analysis.

RESULTS

Compared to the baseline levels of serum prestin and HSP70, subsequent samples (Groups B–D) showed an increase. However, no statistically significant differences were observed between groups or in pairwise comparisons ($p>0.05$). There were strong positive correlations between prestin and HSP70 levels measured at different time points (prestin: $r=0.767–0.906$; HSP70: $r=0.764–0.932$; $p<0.01$).

CONCLUSIONS

Prestin and HSP70 levels exhibited an upward trend following exposure; however, no statistically significant differences were observed between the groups. Nevertheless, strong positive correlations were observed between prestin and HSP70 levels across different time points. These findings suggest that prestin and HSP70 levels change in a parallel and consistent manner over time among individuals, which lends them potential as biomarkers. Subsequent studies with augmented sample sizes and varying levels of alcohol and noise exposure are warranted to provide valuable contributions to the extant literature.

Endoscopic Surgery In Epitympanic Surgery

Sbai Achraf Amine[1], **Lachkar Azzeddine**[1]

[1]*ENT department; university hospital of Oujda*

BACKGROUND & AIM

To evaluate the contribution of endoscopy in epitympanic surgery, particularly in terms of anatomical exposure, detection of residual lesions, and improvement of surgical outcomes.

MATERIAL & METHODS

This study includes patients operated on for epitympanic pathologies, particularly cholesteatoma. Endoscopy was used either as the primary technique (Transcanal Endoscopic Ear Surgery – TEES) or as an adjunct to microscopy to explore epitympanic recesses and to check for residual disease. The analyzed parameters included quality of surgical exposure, detection rate of hidden lesions, and postoperative anatomical and functional outcomes

RESULTS

Endoscopy allowed better visualization of areas that are difficult to access with the microscope, including the anterior epitympanic recess, sinus tympani, and peri-ossicular region. It facilitated the identification and removal of residual lesions, potentially reducing the risk of recurrence. In some cases, the endoscopic approach also allowed limitation of the extent of surgical procedures while preserving important anatomical structures; We will report on our experience by presenting our videos of the service.

CONCLUSIONS

Endoscopy represents a valuable tool in epitympanic surgery. It improves the exploration of areas with limited microscopic visibility and may help optimize surgical outcomes while promoting less invasive approaches. Its use, either alone or in combination with microscopy, represents an important advancement in the management of middle ear diseases.

OP-879

External Ear Canal Cholesteatoma In A Child: Report Of A Rare Pediatric Case

MEHMET TAN[1]

[1]*INONU UNIVERSITY*

BACKGROUND & AIM

External auditory canal cholesteatoma (EACC) is an uncommon otologic disorder characterized by accumulation of keratinizing squamous epithelium associated with localized bone erosion within the external auditory canal. Pediatric presentations are exceptionally rare and may mimic other external ear pathologies.

MATERIAL & METHODS

A 6-year-old child presented to the otolaryngology outpatient clinic with complaints of progressive hearing loss and a sensation of fullness in the right ear. The patient had no history of previous otologic surgery, trauma, chronic otitis media, or other significant medical conditions.

Otoscopic examination revealed marked narrowing of the right external auditory canal with accumulation of keratin debris, limiting visualization of the deeper canal structures and tympanic membrane.

Audiological assessment demonstrated conductive hearing loss in the affected ear.

Magnetic resonance imaging (MRI) and temporal bone computed tomography (CT) demonstrated a 1.5 cm soft tissue lesion within the right external auditory canal, consistent with cholesteatoma.

Based on clinical examination and radiologic findings, a diagnosis of external auditory canal cholesteatoma was established.

RESULTS

Based on clinical and radiological findings, surgical intervention was planned.

The lesion was excised completely under general anesthesia using microscopic surgical technique. Intraoperative findings demonstrated keratin accumulation with localized erosion of the external auditory canal. Complete removal was achieved while preserving adjacent structures.

Histopathological examination confirmed cholesteatoma characterized by keratinizing squamous epithelium with accumulated keratin debris.

Postoperatively, the patient experienced resolution of symptoms, including hearing loss and ear fullness. During five years of follow-up, no recurrence or complications were observed.

CONCLUSIONS

Pediatric external auditory canal cholesteatoma is an extremely rare condition that may present with hearing loss and ear fullness. Early recognition and complete microscopic excision may achieve excellent long-term outcomes with low recurrence rates.

The Effect Of 5% And 10% Povidone-Iodine Antiseptic Concentrations On Postoperative Sensorineural Hearing Loss In Tympanoplasty

Ali Faramarzi[1]

[1]*Shiraz University of Medical Sciences*

BACKGROUND & AIM

To evaluate the ototoxicity of povidone iodine (PVP-I) at concentrations of 5% and 10% during tympanoplasty by assessing frequency-specific audiometric outcomes and graft success rates in a large cohort of patients.

MATERIAL & METHODS

This prospective, triple-blinded, randomized clinical trial enrolled 542 patients undergoing primary tympanoplasty. After excluding patients for inadequate follow-up, 204 ears received 10% PVP-I and 199 ears received 5% PVP-I. Audiometric evaluations, including bone conduction (BC), air conduction (AC), air-bone gap (ABG), and speech reception threshold (SRT), were conducted preoperatively and 12 months postoperatively.

The primary outcome was the incidence of sensorineural hearing loss (SNHL), defined as an increase in BC threshold of more than 10 dB. Secondary outcomes included graft success rate and audiometric gains.

RESULTS

The overall incidence of SNHL was 1.5% in the 10% PVP-I group and 1.0% in the 5% PVP-I group, with no significant difference (P=1.000). In ears with preoperative mixed hearing loss, SNHL at 0.25 kHz was significantly higher in the 10% PVP-I group (28,9%) compared to the 5% PVP-I group (6.7%) (P = 0.002). Graft success rates were 94.1% and 97.0% in the 10% and 5% PVP-1 groups, respectively (P = 0.164). No clinically significant differences in audiometric gains were observed between the groups.

CONCLUSIONS

Both 5% and 10% PVP-I concentrations are safe for antiseptic preparation in tympanoplasty, as evidenced by low rates of SHL and high graft success rates. These findings support the use of PVP-I in human otologic surgery without significant ototoxic risk.

OP-881

Association Between Presbyacusis Severity And Olfactory Function In Older Adults: A Pilot Cross-Sectional Study

Onur Ercelik[1], **Izlecan Oztekiner**[1]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, Ministry of Health, Ankara Training and Research Hospital, Ankara, Turkey*

BACKGROUND & AIM

Presbyacusis and olfactory dysfunction are common age-related sensory impairments, yet the relationship between age-related auditory decline and olfactory function remains insufficiently characterized. This study aimed to evaluate the association between presbyacusis severity, speech discrimination performance, and olfactory function in a prospectively enrolled geriatric population.

MATERIAL & METHODS

This prospective pilot cross-sectional study included older adults who underwent audiometric evaluation, speech discrimination testing, and olfactory assessment using the University of Pennsylvania Smell Identification Test (UPSIT). Participants were classified as controls or patients with presbyacusis. Presbyacusis patients were further stratified according to speech discrimination performance using an 80% cut-off. Smoking status, educational level, diabetes/hypertension, and sinonasal/allergic history were recorded. MoCA scores were excluded from the present analysis. Non-parametric tests and Spearman correlation analyses were used.

RESULTS

Twenty-nine participants were included, comprising 10 controls and 19 patients with presbyacusis. Compared with controls, patients with presbyacusis had significantly higher pure-tone averages and lower speech discrimination scores. UPSIT scores did not significantly differ between the two main groups. However, within the presbyacusis group, higher mean pure-tone averages were moderately associated with lower UPSIT scores (Spearman rho = -0.52, p = 0.022). Speech discrimination scores were not significantly associated with UPSIT scores.

CONCLUSIONS

In this prospective pilot cohort, presbyacusis severity, as reflected by pure-tone thresholds, was associated with reduced olfactory performance among older adults with presbyacusis. These findings support the concept of multisensory aging and suggest that olfactory assessment may provide complementary information in the evaluation of geriatric patients with age-related hearing loss.

OP-882

Anatomical Determinants Of Technical Feasibility In Endoscopic Reverse Stapedotomy: A Morphometric Comparative Study

yuvatiya plodpai[1]

[1]*department of otolaryngology, prince of Songkhla university, Thailand*

BACKGROUND & AIM

To identify anatomical predictors of technical feasibility and compare surgical and audiologic outcomes between endoscopic reverse stapedotomy (ERS) and conventional endoscopic stapedotomy (ECS).

MATERIAL & METHODS

Consecutive patients undergoing ECS or ERS between January 2020 and December 2025 were analyzed. Intraoperative morphometric parameters including total stapes footplate width, exposed footplate width, incus–footplate distance, and incus–footplate angle were quantified using calibrated ImageJ software. Anatomical characteristics were stratified using predefined thresholds. Operative duration, 12-month air–bone gap (ABG) closure, and complication rates were compared.

RESULTS

Forty-five patients were included (22 ERS, 23 ECS). Successful ERS was strongly associated with greater total footplate width (1.42 vs. 1.18 mm, $p < 0.001$), greater exposed footplate width (0.69 vs. 0.39 mm, $p < 0.001$), and wider incus–footplate angle (93.9° vs. 85.5°, $p < 0.001$). A blue-appearing footplate was more frequently observed in ERS cases ($p = 0.047$). Operative time was significantly shorter in ERS ($p = 0.049$). ABG closure within 10 dB at 12 months was achieved in 90.9% (ERS) and 91.3% (ECS) ($p = 0.96$). No significant differences were observed in audiometric outcomes or complication rates.

CONCLUSIONS

Objective morphometric parameters particularly footplate width and incus–footplate angle are key determinants of ERS feasibility. When anatomical selection criteria are met, ERS provides equivalent hearing outcomes with reduced operative time and no increase in morbidity.

OP-883

From Variation To Standardisation: Improving Outcomes In SSNHL With A Structured Proforma

Dr Bilge Rol[1], **Ms Merlin Babu**[1], **Ms Prathibha Nanoo**[1]

[1]*Milton Keynes University NHS Hospital*

BACKGROUND & AIM

Background: Sudden sensorineural hearing loss (SSNHL) is an otolaryngological emergency requiring prompt diagnosis, early steroid therapy, and appropriate referral. Initial audit within our Same Day Emergency Care (SDEC) unit demonstrated significant deficiencies in documentation, history-taking, and adherence to ENT UK guidelines, with potential impact on patient outcomes. Contributing factors included high staff turnover and variable familiarity with ENT emergencies.

Aim: To assess whether the implementation of a standardised SSNHL management proforma improved documentation, guideline adherence, and patient management in the second cycle of this quality improvement project.

MATERIAL & METHODS

Methods: A retrospective re-audit of SSNHL cases presenting to SDEC was conducted following the introduction of a guideline-based proforma and targeted clinician education. Data were collected on documentation quality, steroid initiation, and appropriateness of audiology, imaging, and hearing aid referrals, and compared with first-cycle findings.

RESULTS

The second cycle (n=10) demonstrated drastic improvement in several domains, including more consistent documentation of core history elements (up to 100%) and universal documentation of otoscopy. All patients received timely steroid therapy in accordance with guideline recommendations.Audiology follow-up and hearing aid referrals improved significantly, with 80 to 100% of eligible patients receiving timely referral and no delays observed.

Appropriate escalation of care also improved significantly: all patients who required intratympanic steroid injections (ITSI) received them with appropriate follow-up, and post-treatment pure tone audiometry (PTA) was completed in 100% of cases. In addition, audiology and hearing aid referrals were completed promptly for eligible patients, with no delays identified.

CONCLUSIONS

Introduction of a structured SSNHL proforma improved several aspects of patient management, particularly follow-up and referral pathways. Improved accessibility of the proforma, alongside ongoing education and integration into clinical workflows, is essential to achieve sustained improvement and optimise patient outcomes.

Predictive Role Of The Eosinophil-To-Lymphocyte Ratio In The Development Of Otitis Media With Effusion In Children

Seda Nur Cihan[1], **Asude Ünal**[1], **Doğukan Özdemir**[1], **Hatice Gizem Uyar**[1], **Dursun Mehmet Mehel**[2], **Ayşe Çeçen**[1]

[1]*Samsun Üniversitesi Tıp Fakültesi Kulak Burun Boğaz Hastalıkları Baş ve Boyun Cerrahisi Anabilim Dalı;* [2]*Sağlık Bilimleri Üniversitesi Samsun Eğitim Araştırma Hastanesi Kulak Burun Boğaz Kliniği*

BACKGROUND & AIM

Aims: Otitis media with effusion (OME) is a common condition in children, characterized by fluid accumulation in the middle ear without acute infection. Its causes include viral and bacterial infections, allergies, autoimmunity, and eustachian tube dysfunction. The aim of this study was to investigate the predictive role of the eosinophil-to-lymphocyte ratio in the development of otitis media with effusion (OME).

MATERIAL & METHODS

Methods: We retrospectively reviewed patients under 18 years old who underwent adenoidectomy at our clinic between 2021 and 2023. Patients were divided into two groups: adenoidectomy only (Group 1) and adenoidectomy with ventilation tube insertion (Group 2). Demographic data and preoperative complete blood counts (CBC) were collected, and eosinophil-to-lymphocyte ratios were calculated. Statistical analysis was performed using SPSS v26.0, with a p-value <0.05 considered significant.

RESULTS

Results: The study included 100 children (57 boys, 43 girls), with a mean age of 5.9 ± 2.0 years. Group 1 had 52 patients, and Group 2 had 48 patients. No statistically significant differences were observed between the groups regarding eosinophil count, lymphocyte count, or eosinophil-to-lymphocyte ratio (p=0.91, 0.91, and 0.44, respectively)

CONCLUSIONS

Conclusion: Our study found no significant association between the eosinophil-to-lymphocyte ratio and the development of OME in patients undergoing ventilation tube insertion for concomitant adenoid hypertrophy. Nevertheless, the prognostic significance of the eosinophil-to-lymphocyte ratio in OME warrants further investigation in studies with larger sample sizes

OP-885

MRI–CT Discrepancy In Pediatric Traumatic Facial Paralysis: Evidence Of Severe Neural Injury Without Facial Canal Fracture

EDA GÜMÜŞ TANRIVER[1], **NİSANUR GÜLER**[1], **EVREN HIZAL**[1], **BÜLENT SATAR**[1]

[1]*Gülhane Training and Research Hospital, ENT Clinic*

BACKGROUND & AIM

Traumatic facial nerve paralysis is an uncommon complication of temporal bone injury in children. While computed tomography (CT) is the primary imaging modality for evaluating osseous injury, it may not accurately reflect the extent of neural damage. Magnetic resonance imaging (MRI) provides critical information regarding nerve integrity and associated soft tissue involvement.

MATERIAL & METHODS

A 5-year-old boy was admitted to our otorhinolaryngology clinic one month after sustaining blunt head trauma caused by a falling cabinet. He had previously undergone right-sided craniectomy for intracranial injury. On postoperative day 5, after regaining consciousness, he developed complete right-sided peripheral facial paralysis (House-Brackmann grade VI). No additional cranial nerve deficits or other neurological abnormalities were observed. Otoscopic examination was normal.

Audiological evaluation revealed total sensorineural hearing loss in the right ear, and electromyography demonstrated severe axonal degeneration of the facial nerve.

RESULTS

Temporal bone CT demonstrated a non-displaced fracture of the squamous portion of the right temporal bone, without involvement of the facial nerve canal. The otic capsule, ossicular chain, and internal auditory canal appeared intact, and the intratemporal course of the facial nerve was preserved.

MRI of the posterior fossa and temporal bone revealed a lesion filling the right internal auditory canal with T1 hyperintensity and intermediate T2 signal. The facial and vestibulocochlear nerve bundles were not visualized within the canal or cisternal segment. Additional findings included signal changes suggestive of hemorrhagic involvement of the cochlea and vestibule and adjacent petrous apex edema. These findings were compatible with severe neural injury and raised suspicion for avulsion-type damage.

At 40 days post-trauma, no significant improvement in facial function has been observed. The patient remains under close follow-up, and facial reanimation procedures will be considered in the absence of recovery.

CONCLUSIONS

Severe facial nerve injury may occur in the absence of a facial nerve canal fracture on CT. The discrepancy between preserved bony anatomy on CT and marked neural abnormalities on MRI is clinically significant. Non-visualization of the nerve within the internal auditory canal and cisternal segment suggests injury beyond neuropraxia. MRI plays a critical role in detecting severe neural injury and should be considered when CT findings are inconclusive. Early integration of clinical, electrophysiological, and radiological findings is essential for management planning.

Temporal Bone Malignancies

Houssem Eddine Bouraba[1], **Matmer Imane**[1], **Farid Boudjenah**[1]

[1]*Beni Messous University Hospital Center*

BACKGROUND & AIM

Temporal bone of the auricle generally presents challenges due to the unique anatomy and topography of the temporal bone, as well as tumor behavior. The aim of this study was to evaluate the clinical and histopathological features and surgical outcomes in patients with temporal bone cancer

MATERIAL & METHODS

A retrospective study was conducted on a series of four patients operated on at our ENT department at the Beni Messous University Hospital between January 2024 and Mars 2025.

RESULTS

11 patients have been operated on for temporal bone cancer at our department.10 males and 1 female, with a mean age of 71.25. 100% of patients had unprotected sun exposure as a risk factor, including 10% with the presence of keratotic lesions. All our patients presented with an ulcerative budding lesion of the auricle and/or the ear canal. A head and neck CT scan was requested in all four patients. all our patients had squamous cell carcinoma, with an exclusive pathological diagnosis. total resection of the tumour with lateral temporal bone resection was performed to eradicate the tumour. 9 patients underwent postoperative radiotherapy. there were no recurrence at a follow-up of 3 to 15 months.

CONCLUSIONS

This study demonstrates the value of early, multidisciplinary, and appropriate management of patients with malignant auricle tumors, which are often advanced.

Recurrent Bell's Palsy: A Comprehensive Analysis Of Associated Factors And Outcomes

Shatha Yahya Alqahtani[1], **Zohour A. Almalki**[1], **Johara A. Alnafie**[1], **Farah S. Alnemari**[1], **Teif M. Alghamdi**[1], **Dana A. Alghamdi**[1], **Laila O. Albaqami**[1], **Mohammad Ibrahim**[1]

[1]*Alhada Armed Forces Hospital, Department of ORL-H&N Surgery, Taif, Saudi Arabia*

BACKGROUND & AIM

"Bell's palsy is the most common cause of acute peripheral facial paralysis. Recurrent Bell's palsy is less common and remains poorly understood. This study aimed to identify associated comorbidities and predictors linked to recurrent Bell's palsy and evaluate factors affecting recovery outcomes."

MATERIAL & METHODS

"A retrospective analytical study was conducted on patients diagnosed with Bell's palsy. Demographic characteristics, clinical presentation, comorbidities, recurrence patterns, treatment modalities, and recovery outcomes were reviewed and analyzed. Statistical analysis was performed to identify factors associated with recurrent episodes and prognosis."

RESULTS

"Recurrent Bell's palsy was associated with several systemic comorbidities and clinical predictors. Certain patient-related factors demonstrated a statistically significant association with recurrence rates and recovery outcomes. Most patients showed favorable recovery; however, prolonged recovery duration was observed in recurrent cases."

CONCLUSIONS

"Recurrent Bell's palsy appears to be associated with identifiable systemic and clinical factors. Recognition of these predictors may help improve patient counseling, follow-up strategies, and individualized management of patients at higher risk of recurrence."

Masking Level Difference Performance In Patients With Migraine

Ahmet Adnan Cırık[1], **Yeşim Esen Yiğit Koçer**[1], **Fatih Mutlu**[4], **Reza Doğan**[2], **Sara Gül Avcı**[2], **Mustafa Men**[3]

[1]*Umraniye Research and Training Hospital, Department of Otolaryngology;* [2]*Umraniye Research and Training Hospital, Department of Audiology;* [3]*Umraniye Research and Training Hospital, Department of Neurology;* [4]*Kocaeli University, Department of Otolaryngology*

BACKGROUND & AIM

To compare masking level difference (MLD) and pure-tone audiometry (PTA) findings between adults with migraine-spectrum disorders and healthy normal-hearing controls, and to investigate whether binaural interaction differs in migraine independent of peripheral hearing levels.

MATERIAL & METHODS

This case–control study included 30 female patients diagnosed with migraine-spectrum disorders and 35 age-matched healthy female controls. All participants had normal otoscopic findings, type A tympanograms, and hearing thresholds within normal limits. Pure-tone audiometry was performed bilaterally, followed by MLD testing using a 500 Hz signal at 60 dB under three binaural conditions: S_0N_0, $S\pi N_0$, and $S_0N\pi$. MLD values were calculated as the threshold differences between S_0N_0 and antiphasic conditions. Group comparisons were performed using independent t-tests or Mann–Whitney U tests as

appropriate. One-way ANCOVA was used to determine whether MLD differences remained significant after controlling for right and left PTA averages.

RESULTS

Although PTA thresholds were within normal limits in both groups, the migraine group showed significantly higher mean PTA values in both ears ($p < 0.001$). No significant between-group difference was observed in the S_0N_0 condition ($p = 0.112$). However, $S\pi N_0$ and $S_0N\pi$ thresholds were significantly higher in the migraine group (both $p < 0.001$). Consequently, both MLD indices ($S_0N_0–S\pi N_0$ and $S_0N_0–S_0N\pi$) were significantly reduced in patients with migraine ($p < 0.001$). After adjustment for PTA covariates, ANCOVA confirmed significantly higher adjusted antiphasic thresholds in the migraine group for both $S\pi N_0$ ($F = 8.66$, $p = 0.005$) and $S_0N\pi$ ($F = 22.81$, $p < 0.001$).

CONCLUSIONS

Patients with migraine-spectrum disorders demonstrate reduced binaural masking release despite normal peripheral hearing, supporting the presence of altered binaural interaction mechanisms potentially related to brainstem-level auditory processing dysfunction.

KEYWORDS

migraine, central auditory processing, masking level difference, auditory brainstem

OP-889

Evaluation Of The Three-Dimensional Anatomical Structure And Dimensions Of The Cochlea In Patients With Congenital Cytomegalovirus-Related Sensorineural Hearing Loss Using OTOPLAN® Software

Saziye Armağan INCESULU[1], Yigit AKCI[1], Muhammed Sefa UYAR[1], Arzu KIRBAC[2], Melek Kezban GURBUZ[1], Ercan KAYA[1]

[1]Department of Otorhinolaryngology, Faculty of Medicine, Eskişehir Osmangazi University, Eskişehir, Turkey.; [2]Department of Audiology, Eskişehir Osmangazi University, Eskişehir, Turkey.

BACKGROUND & AIM

Congenital cytomegalovirus (cCMV) infection is the leading cause of non-genetic sensorineural hearing loss (SNHL) in children worldwide. The virus induces a robust inflammatory response in the inner ear, accompanied by reactive oxygen species (ROS), which disrupt the stria vascularis and the blood–labyrinth barrier, leading to permanent cellular damage. However, it remains unclear whether this immunopathological injury results in measurable alterations in the macroscopic morphology and three-dimensional (3D) geometry of the cochlea. Given the limitations of conventional two-dimensional (2D) imaging, this study aimed to evaluate cochlear morphology in cCMV-related hearing loss using advanced 3D reconstruction techniques.

MATERIAL & METHODS

Pediatric patients followed at our institution between 2015 and 2025 with available high-resolution temporal bone computed tomography (CT) imaging were included. Cases were categorized into three groups: cCMV-related SNHL (study group), SNHL due to non-cCMV etiologies (disease control group), and normal-hearing individuals (healthy control group). Image analyses were performed using OTOPLAN® . Cochlear parameters, including basal turn diameter, width, height, and cochlear duct length (CDL) , were measured with millimetric precision. Total cochlear volume was calculated using 3D automated segmentation when image quality was sufficient; otherwise, manual measurement techniques were applied. Patients with slice thickness greater than 0.6 mm or with gross inner ear malformations were excluded.

RESULTS

A total of 203 patients (345 ears) were analyzed, all of which were reported as having normal inner ear structures on standard radiological evaluation. Three-dimensional morphometric analysis revealed no statistically significant differences.

CONCLUSIONS

These findings indicate that, despite causing significant functional impairment, cCMV infection does not result in major abnormalities. This supports the hypothesis that hearing loss in cCMV is primarily related to microscopic inflammatory and neuroepithelial damage rather than a gross structural developmental defect.

OP-890

Optimising Postoperative Analgesia Following Paediatric Adenotonsillectomy: A Closed-Loop Audit'

Miss Hiba Mujib[1], **Ms Phui Yee Wong**[1]

[1]*Lewisham and Greenwich NHS Trust*

BACKGROUND & AIM

Adenotonsillectomy is one of the most commonly performed paediatric ENT procedures for obstructive sleep apnoea (OSA). Although generally safe, postoperative complications such as bleeding and pain remain important concerns. This audit aimed to identify postoperative complications following paediatric adenotonsillectomy for OSA and implement quality improvement measures to optimise postoperative analgesia.

MATERIAL & METHODS

A retrospective clinical audit was conducted over six months at University Hospital Lewisham. Paediatric patients aged 2–16 years undergoing adenotonsillectomy for OSA were included. Data collected included demographics, surgical technique, indication for surgery, surgeon experience, risk factors, and postoperative complications. Statistical analysis using the Chi-square test was performed to assess potential associations between risk factors and complications. Following the first audit cycle, a weight-based postoperative analgesia regimen using paracetamol and ibuprofen was introduced alongside enhanced discharge guidance, including a parent-friendly medication tracker to improve compliance.

RESULTS

A total of 349 cases were analysed in the first audit cycle. No statistically significant differences in postoperative outcomes were identified based on surgical technique, indication for surgery, or surgeon experience. Overall complication rates were consistent with national standards. Postoperative pain accounted for 2% of complications, highlighting a modifiable area for improvement. In response, a weight-adjusted analgesia protocol using paracetamol and ibuprofen was introduced in line with BAPO and STPN recommendations. Updated discharge information leaflets and a parent-friendly medication tracker were also implemented to improve parental understanding, compliance, and postoperative pain management. A second audit cycle is currently underway to assess adherence to the new analgesia protocol and its impact on pain-related admissions, and will be completed within one month.

CONCLUSIONS

Postoperative pain remains an important yet preventable complication following paediatric adenotonsillectomy. Introducing weight-adjusted analgesia and improving parental education may enhance postoperative pain control and reduce avoidable admissions. Findings from the second audit cycle will help evaluate the effectiveness of these interventions and complete the audit loop.

Handheld POCUS For Rapid Pre-Esophagoscopy Screening Of Cervical Esophageal Foreign Bodies In Children

Abdulrahman Shareefi[1], **Ma'ad Aljohani**[2], **Ragad Almahweeti**[2], **Marzouqi Salamah**[1]

[1]*King Abdullah Specialized Children Hospital, Riyadh, Saudi Arabia;* [2]*Ohod Hospital, Medina, Saudi Arabia*

BACKGROUND & AIM

Point-of-care ultrasound is revolutionizing diagnostics by providing bedside, cost-effective imaging. The emergence of handheld devices offers comparable accuracy with enhanced portability. Pediatric foreign body ingestion is a rising global concern, particularly in Saudi Arabia, following the 2017 introduction of coin currency. Although chest X-rays are the standard diagnostic tool, they involve ionizing radiation. Since many objects pass spontaneously, repeat imaging is often required before invasive esophagoscopy. This study evaluates handheld POCUS as a feasible, rapid alternative to identify cervical esophageal foreign bodies (CEFB), aiming to minimize pediatric radiation exposure, minimize anesthesia risks, and assess cost-effectiveness.

MATERIAL & METHODS

This prospective cohort study, conducted at a secondary hospital in Saudi Arabia, evaluates the diagnostic performance of the handheld ultrasound for the identification of CEFB. The study enrolled stable pediatric patients (<14 years) with radiographically confirmed CEFB. Exclusion criteria included sharp objects, button batteries, radiolucent materials, and patients presenting with respiratory distress or clinical instability. Following informed consent from legal guardians, bedside ultrasonography was performed by the authors, who had completed targeted training in head and neck sonography. Using a CMUT probe, the examination was conducted using a standardized scanning technique. Demographic data were recorded for each subject. Diagnostic efficiency and safety were evaluated by comparing POCUS findings with preoperative radiographs and definitive intraoperative results. The time required for both X-ray and POCUS was measured and compared. All sonographic findings were documented and reviewed by the investigators for sensitivity analysis. SPSS version 27 was used for analysis.

RESULTS

A total of 13 pediatric patients were enrolled. The cohort was predominantly male (n = 9; 69.2%), with a mean age of 6.31 years. The clinical presentation was varied, Nausea: 32.1% Vomiting 28.5% Dysphagia: 21.4% Odynophagia: 10.7%, and Drooling: 7.14%. All foreign bodies were successfully identified as coins. Handheld POCUS demonstrated a sensitivity of 100%, correctly localizing the CEFB in all 13 cases. No complications were recorded during the ultrasonographic examinations or the subsequent esophagoscopies. The diagnostic efficiency of handheld point-of-care ultrasound (POCUS) was significantly superior to conventional radiography, with a mean procedure time of 1.65 ± 0.56 minutes compared to 13.23 ±10.29 minutes for chest X-rays (N = 13). A paired samples t-test revealed a statistically significant mean reduction of 11.58 minutes (95% CI, -17.78 to -5.38; t (12) = -4.068, p = .002), demonstrating that POCUS substantially accelerates the clinical workflow.

CONCLUSIONS

Handheld POCUS might represent a paradigm shift in pediatric foreign body management as a complementary investigation, offering a radiation-free alternative that streamlines clinical workflows and enhances patient safety. While our results are highly promising, larger multi-center studies are warranted to validate these findings across a broader range of foreign body types and to establish standardized training protocols for Otolaryngologists, pediatric surgeons, and emergency physicians. Integrating this "handheld advantage" into standard clinical pathways has the potential to optimize resource utilization and improve the quality of care for pediatric patients worldwide.

Forming A Tracheostomy MDT Clinic And Team

Hayat Adib[2]

[1]*Al Jalila Children's Specialty Hospital Dubai health;* [2]*Mohamad Bin Rashed University Dubai Health*

BACKGROUND & AIM

There is an increase in the number of pediatric patients with tracheostomy. Therefore a unified meeting with decision making is essential. There is a need for standardized care and protocols to serve this complex patient population.

MATERIAL & METHODS

Population: children and infants with tracheostomies

Looking into the number of patients with tracheostomies and how to serve them, looking at missed appointments and morbidities due to the tracheostomy

Forming a team of outpatient health care workers including: pediatric ENT surgeon, Pediatric pulmonologist, speech language and swallow therapist and a dedicated tracheostomy nurse/coordinator to care for these patients in an MDT.

Forming a team of inpatient health care workers including but not limited to: pediatric ENT surgeon, pediatric pulmonologists, pediatrician, PICU doctor and nursing.

RESULTS

The patient's were seen promptly in the MDT clinic with meetings every 3 months

Forming proper surgery planning and councelling to the families, proper discharge planning, proper followup, successful decannulation.

CONCLUSIONS

Patients were properly cared for as inpatients and outpatients with proper stoma care and decision making regarding the tracheostomy, wether upsizing or readiness for decannulation.

Steady number of patients seen benefiting from the tracheostomy MDT clinic with proper transition to complex care clinic.

OP-893

Thulium Fiber Laser Cauterization Approach To Congenital Pyriform Sinus FIstula： Preliminary Experience

Ying Wang[1], **Jiarui Chen**[1], **Xiaoyan Li**[1]

[1]*Department of Otorhinolaryngology Head and Neck Surgery, Shanghai Children's Hospital, School of medicine, Shanghai Jiao Tong University*

BACKGROUND & AIM

In recent years, more and more endoscopic or microscopic-assisted treatments for congenital pyriform sinus fistula (CPSF) had been developed, such as carbon dioxide laser cauterization, electrocautery, and radiofrequency ablation, which had gradually replaced traditional open neck surgeries as an alternative option for many medical institutions. In this paper, we retrospectively evaluated the efficacy of Thulium laser cauterization with suspension microlaryngoscopy as a definitive surgical treatment for CPSF in our department, and discussed the timing and protocol of the treatment.

MATERIAL & METHODS

This single-center retrospective study was conducted from September 2024 to December 2025 at the department of Otolaryngology, Head and Neck Surgery at Shanghai Children's Hospital. All cases were collected by searching electronic medical records of children diagnosed with CPSF who underwent Thulium laser cauterization. Postoperative observation indexes: 1) Voice hoarseness; 2) Fever (The parents used an ear thermometer check the child's temperature every 4 hours after the surgery and took the highest value each day); 3) Wound repair to time (the time for the white membrane to completely fall off).

RESULTS

14 patients with CPSF underwent suspension microlaryngoscopy exploration for an internal pyriform sinus fistula from September 2024 to December 2025. The operation time was 15.35 ± 6.27 minutes, with little intraoperative bleeding. None of the patients treated with Thulium laser cauterization showed obvious complications of dysphagia, laryngeal recurrent nerve injury, and pharyngeal fistula. Only 2 children had low fever (< 38℃) on the first day after the operation, and both returned to normal on the second day. The average wound repair time (the time for the white membrane to completely fall off) was 7.64 ± 1.44 days. The total duration of follow-up was 6.01 ± 3.02 months, ranging from 2 to 15 months. Out of the 14 patients, merely 1 child developed recurrent cervical infections after two months from the first operation, indicating the potential recurrence of CPSF, and underwent external cervical approach piriform sinus fistula resection.

CONCLUSIONS

Minimally invasive endoscopic radical treatment for pyriform sinus fistula was a safe and effective method. Thulium laser, as a new type of laser technology, had precise positioning, caused less local thermal damage and pain stimulation, and had unique advantages in the application of deep and narrow cavities. Although there were relatively few studies on the application of thulium laser in the treatment of congenital pyriform sinus fistula in children at present, its working principle and characteristics in other fields could be referred to for further research and analysis.

KEYWORDS

Diagnosing Pediatric Sleep-Disordered Breathing With Watchpat: Agreement With PSG And Added Value Beyond Oximetry

Chanisa Pornchaisakuldee[1], **Nuntigar Sonsuwan**[1], **Phichayut Phinyo**[2], **Kanokkarn Sunkonkit**[3], **Suchanya Sithirungson**[1]

[1]*Department of Otolaryngology, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand;* [2]*Department of Biomedical Informatics and Clinical Epidemiology, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand;* [3]*Department of Pediatrics, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand*

BACKGROUND & AIM

Several studies have evaluated the validity of peripheral arterial tonometry (PAT) devices as home-based diagnostic tools for obstructive sleep apnea (OSA) in adults. However, evidence supporting the validity of PAT for diagnosing OSA in children remains limited. This study aimed to assess the utility of the WatchPAT device for diagnosing OSA in children with symptoms suggestive of pediatric sleep-disordered breathing.

MATERIAL & METHODS

Children aged 3–12 years with clinical suspicion of OSA were enrolled in this prospective study. Participants underwent simultaneous in-laboratory polysomnography (PSG) and PAT testing using the WatchPAT 300 between October 2025 and February 2026 at a tertiary university hospital. WatchPAT data were analyzed using the device's automated algorithm. Nocturnal oximetry data were extracted from PSG recordings and interpreted. We evaluated correlation, agreement, and concordance between PAT and PSG for the apnea–hypopnea index (AHI) and minimum oxygen saturation (minSpO2).

RESULTS

A total of 33 children were included (mean age 7.72 ± 1.97 years; 69.7% male; 66.7% overweight or obese). Agreement between PAT and PSG was high (intraclass correlation coefficient [ICC] = 0.973; P < .001 for AHI-PAT vs AHI-PSG, ICC = 0.847; P < .001 for minSpO2-PAT vs minSpO2-PSG). Correlations between PAT and PSG were moderate for both AHI (r = 0.540; P = .001) and minSpO2 (r = 0.465; P = .009). The mean difference between AHI-PAT and AHI-PSG was 0.9 ± 5.80 events/h (95% confidence interval, −1.157 to 2.957). However, concordance for OSA severity classification based on AHI was low (Kendall's tau-b = 0.365, P = .021). In addition, WatchPAT identified OSA (AHI > 1) in 24 of 25 patients (96%) who had negative or inconclusive nocturnal pulse oximetry findings.

CONCLUSIONS

PAT may be a reliable alternative tool for diagnosing pediatric OSA. However, its ability to classify OSA severity may be limited. Further studies using pediatric-specific PAT algorithms and including a healthy control group are warranted.

Appropriateness Of Paediatric Sleep Study Utilisation In Suspected Obstructive Sleep Apnoea (OSA): A Quality Improvement Project (QIP)

Waleed Mohammed[1], **Hanzalah Yaqub**[1], **Navdeep Bhamra**[1], **Neil Giblett**[1]

[1]*The Royal Wolverhampton NHS Trust*

BACKGROUND & AIM

The British Association for Paediatric Otorhinolaryngology (BAPO) published the Day Case Paediatric Adenotonsillectomy Consensus Guideline (2024), outlining day-case adenotonsillectomy as safe and effective for the majority of non-comorbid children with obstructive sleep apnoea (OSA). They highlight clinical assessment is the key in decision making, with sleep studies not routinely recommended for non-comorbid children with suspected OSA. GIRFT (2025) guidelines recommend selective use of sleep studies reserved for comorbidity, diagnostic uncertainty or peri-operative risk stratification. However, it has been identified locally that sleep studies are routinely requested in children with clinically suspected OSA, causing pathway delay, additional appointments and unnecessary cost.

MATERIAL & METHODS

A retrospective review of all paediatric sleep studies for suspected OSA over a 2-year period in a district general hospital. Predefined guideline-based criteria were used to classify studies, whilst also assessing estimated costs and patient outcomes.

RESULTS

Of 116 analysed sleep studies, 52.6% were non-indicated, with 61.1% of studies non-indicated in the low-risk, day-case eligible subgroup. 68.3% of surgical patients had moderate/severe classified OSA based on sleep study, reflecting sleep study guided surgical selection. Non-indicated studies represented an estimated £24,705 avoidable cost.

CONCLUSIONS

Over half of sleep studies requested were not guideline-indicated, suggesting sleep studies are embedded as a standard step in the pathway, rather than a targeted investigation. The present QIP proposes a clear local guideline, with clinical assessment as the mainstay of management decision- making, whilst ensuring positive outcomes, and decreasing costs and delays.

BACKGROUND & AIM

Juvenile-onset recurrent respiratory papillomatosis (JoRRP) is a chronic HPV-associated disease affecting the upper airway, acquired vertically (mother-to-child) during childbirth. Observational studies in the US and Australia have shown declines in JoRRP incidence following introduction of the quadrivalent HPV vaccine. In France, data on the JoRRP epidemiological burden, patient characteristics, and real-world management are limited. The BREATH (Burden of Recurrent REspiratory PApillomaTosis in CHildren) study was designed to address these gaps.

MATERIAL & METHODS

BREATH is a non-interventional, retrospective study using secondary data from the French National Health Data System from 2006-2023. The inclusion window was 2010-2022, allowing a 4-year look-back to distinguish incident from prevalent cases. All RRP patients younger than 18 years were included. A case-identification algorithm based on ICD-10 diagnoses and procedure codes was developed and validated against medical records. Patient characteristics included age, sex and birth order. Surgical and medical events during follow-up were assessed. For mothers of JoRRP cases, delivery mode and C2S status (proxy for socioeconomic deprivation) were obtained through mother–child linkage. Incidence was estimated using JoRRP case counts and national census denominators, and annual percentage change (APC) in incidence was derived using Joinpoint regression. Descriptive statistics summarized all variables.

RESULTS

In total, 263 JoRRP cases were identified; 76% (n=200) were incident. Incidence remained relatively stable, from 0.13 per 100,000 person-years in 2010 to 0.09 in 2022 (APC −3.5%; 95% CI −7.2 to 0.4). Among incident cases, 54% were female, and median age at diagnosis was 3 years, with 62% diagnosed between 0-4 years. Within the first year after diagnosis, 158 patients (79%) underwent RRP-related surgeries, with a mean of 2.8 procedures. Over a median 7.2-year follow-up, malignant transformation occurred in ≤ 10 patients. HPV vaccination after JoRRP diagnosis was recorded in 41% of patients. Maternal linkage was achieved for 82 cases: 60% were first-born, 87% of mothers had vaginal delivery and 26% were C2S beneficiaries.

CONCLUSIONS

This study provides the first nationwide insights into JoRRP epidemiology and burden in France, using a robust case-identification definition in the absence of a specific ICD-10 code, and highlights the need for preventive strategies for this non-curable disease.

In-Hospital And Long-Term Complications Following Repair Of Congenital Tracheoesophageal Fistula And Esophageal Atresia: A Retrospective Cohort Study

Niloy Nath, MD[1], Amy Callaghan, MSc[1], Amanda Adsett, R.SLP S-LP(C)[1], Simon Byrns, MD[2], Daniela Isaac, MD MSc[3], Andre Isaac, MD MSc[1]

[1]Division of Otolaryngology-Head and Neck Surgery, Department of Surgery, University of Alberta, Edmonton, Alberta, Canada; [2]Division of Pediatric Surgery, Department of Surgery, University of Alberta, Edmonton, Alberta, Canada; [3]Division of Pediatric Gastroenterology and Nutrition, Department of Pediatrics, University of Alberta, Edmonton, Alberta, Canada

BACKGROUND & AIM

Congenital tracheoesophageal atresia with or without esophageal atresia (TEF/EA) affects approximately 1 in 3500 births which can lead to life-threatening aspiration without urgent surgical intervention. Although advances in surgical management have led to improvements in mortality from TEF/EA, patients experience complications such as anastomotic leak, esophageal stricture, and feeding difficulties that impair quality of life. Additionally, there is a subset of patients who have a prolonged

hospital stay following the repair. We aimed to quantify complication rates and identify patients with prolonged hospital stay following TEF/EA repair, and associated patient and perioperative factors at our local pediatric tertiary referral centre.

MATERIAL & METHODS

We conducted a retrospective cohort study of patients who underwent surgical repair of congenital TEF/EA at our local pediatric tertiary referral centre. Demographic data, clinical characteristics, perioperative variables, and complications were extracted from the patient's electronic medical record. In-hospital complications included anastomotic leak, postoperative pneumothorax and chylothorax, surgical site infection, duration of mechanical ventilation, and length of hospital stay. Prolonged hospital stay was defined as a length of hospital stay exceeding the 75th percentile of that of the cohort. Long-term complications included esophageal stricture, tracheomalacia and recurrence of fistula. Univariate analysis was conducted using Chi-square or Fisher exact analysis on 2x2 contingency tables. From the univariate analyses, variables of interest were included in a multivariable regression model with backward elimination using the Wald statistic to identify patient, perioperative, and clinical factors that were independently associated with complications and prolonged hospital stay.

RESULTS

A total of 75 patients were included in the study, 59% male (n=44). Pneumothorax and vocal cord hypomobility were the most common in-hospital complications, affecting 24% (n=18) and 25% (n=19) of the cohort, respectively. Long-term, esophageal stricture was seen in 51 patients (68%) and fistula recurrence in 6 patients (8%). On univariate analysis, the presence of additional anomalies and requiring gastrostomy were significantly associated with the development of in-hospital complications. Being started on an acid-suppressing medication post-repair was associated with not developing any complications. With regards to prolonged hospital stay, this was associated with ventilation issues, having a strong association with prolonged ventilation, requiring re-intubation, and needing a tracheostomy. Our multivariable analysis had revealed that needing gastrostomy was the only factor independently associated with the development of in-hospital complications. The presence of any complication and a long-gap esophageal atresia showed independent association in our multivariable model of prolonged hospital stay.

CONCLUSIONS

Patients undergoing repair of congenital TEF/EA experience substantial in-hospital complications and long-term morbidity, with esophageal stricture representing the most common long-term complication. Need for gastrostomy was independently associated with the development of in-hospital complications, while long-gap esophageal atresia and the occurrence of any complication were independently associated with prolonged hospital stay. This study was limited in suggesting any causation given its retrospective nature. Thus, prospective studies, informed by the findings of the present study, are needed to further characterize factors associated with adverse outcomes following congenital TEF/EA repair.

P300 Evidence Of Auditory And Cognitive Impairment In Children With Adenotonsillar Hypertrophy

Barış Şapcı[1], **Mansur Doğan**[2], **Melek Kekül Şapcı**[2], **Emine Elif Altuntaş**[3]

[1]*Sivas State Hospital;* [2]*Sivas Cumhuriyet University;* [3]*Lokman Hekim University*

BACKGROUND & AIM

This study aimed to investigate the effects of tonsillectomy and/or adenotonsillectomy on cognitive function, hearing levels, and snoring in children with tonsillar and/or adenotonsillar hypertrophy using various audiological and electrophysiological methods in a prospective design.

MATERIAL & METHODS

This prospective study included patients aged 6-12 years who were evaluated and scheduled for tonsillectomy and/or adenotonsillectomy. Twenty-seven patients underwent pre- and postoperative symptom evaluation, snoring questionnaire assessment, tonsillar and adenoid size evaluation, audiological testing (acoustic immittanceometry, pure-tone audiometry, otoacoustic emissions, auditory brainstem responses), and P300 testing to assess cognitive function. Thirty-six healthy children served as controls and underwent physical examination, audiological testing, and P300 assessment. Postoperative measurements were performed by the same investigators on postoperative day 30.

RESULTS

Preoperatively, the most common symptoms were mouth breathing during sleep and snoring. All symptoms decreased significantly postoperatively ($p<0.05$). At one month postoperatively, statistically significant reductions were observed in all symptoms, snoring questionnaire scores, and endoscopically evaluated adenoid and tonsillar sizes ($p<0.05$). P300 latencies, used to evaluate cognitive function, decreased significantly at 30 days postoperatively ($p<0.01$). Gender and age distributions were similar between groups. Preoperative P300 latency values in the experimental group were similar to those in the control group. No correlation was found between P300 values and snoring questionnaire scores. Kendall's tau-b analysis revealed that both adenoid and tonsillar size correlated with snoring questionnaire scores, with adenoid size showing the strongest

association. When comparing preoperative endoscopic and radiological adenoid size assessments, endoscopic evaluation demonstrated a stronger correlation with snoring questionnaire scores.

CONCLUSIONS

Significant improvement in P300 latency was observed in children with sleep-related breathing disorders following adenotonsillectomy. Our findings confirm that children with obstructive sleep apnea are at risk for cognitive impairment. Cognitive function improved significantly within 30 days of adenotonsillectomy in these children of developmental age with sleep-related breathing disorders. P300 latency, when supported by questionnaires and scales, may serve as a diagnostic tool to objectively and efficiently evaluate cognitive impairment caused by obstructive sleep apnea and assess treatment effectiveness.

OP-899

THE PROTECTIVE POWER OF BREASTFEEDING AGAINST CHILDHOOD TONSILLITIS: A SURVEY-BASED STUDY IN ENT PRACTICE

Malik Afifoğlu[1], **Hilal Onay**[1]

[1]*Bursa Şehir Hastanesi*

BACKGROUND & AIM

Tonsillitis is one of the most common upper respiratory tract infections in childhood. Recurrent episodes can significantly impair children's quality of life and lead to frequent antibiotic use. While the protective effects of breast milk against various infections are well-documented, data regarding its specific role in tonsillitis remain limited. This study aims to investigate the relationship between breastfeeding duration and the frequency of tonsillitis in children aged 4–12 years.

MATERIAL & METHODS

This prospective observational study was conducted at the Bursa City Hospital Otorhinolaryngology Clinic between February 1, 2026, and May 1, 2026. Data regarding breastfeeding duration and tonsillitis history were collected through parental surveys. Recurrent tonsillitis was standardized based on Paradise criteria. Disease-specific quality of life and symptom severity were analyzed using a 39-item modified version of the Tonsil and Adenoid Health Status Instrument (TAHSI), validated for the Turkish population by Yüksel et al. Patients were categorized into three groups based on breastfeeding duration: <6 months (Group 1), 6–12 months (Group 2), and ≥12 months (Group 3).

RESULTS

A total of 149 children were included in the study (Group 1: n=42; Group 2: n=28; Group 3: n=79). A significant negative correlation was found between breastfeeding duration and the frequency of tonsillitis attacks ($p < 0.001$). Patients in Group 3 (≥12 months) exhibited significantly lower attack rates and improved TAHSI scores (median: 9.0) compared to Group 1 (median: 20.5) ($p = 0.005$). Multiple linear regression analysis identified breastfeeding duration as the strongest independent protective factor against disease severity, reducing TAHSI scores significantly ($\beta = -4.38$, $p = 0.0003$). Additionally, daycare attendance was found to be an independent risk factor for increased disease severity ($p = 0.043$).

CONCLUSIONS

Long-term breastfeeding, particularly for 12 months or more, significantly reduces the frequency and severity of recurrent tonsillitis in children. Breast milk acts as a "natural immunotherapy" that maintains its protective effect independently of environmental risk factors. These findings emphasize the importance of promoting prolonged breastfeeding to optimize pediatric upper respiratory health.

Children Hearing Loss: Is Parent's Perception Real?

Ana Raquel Andrade[1], **Maria Conceição Peixoto**[1], **Raquel Teixeira**[2], **Luciana Rodrigues**[1], **Miguel C. Lopes**[1], **Diogo Nascimento**[1], **Maria Inês Ribeiro**[1], **Hugo Amorim**[1], **Paulo Gonçalves**[1]

[1]*Unidade Local De Saúde Entre Douro E Vouga;* [2]*Unidade de Saúde Pública da Unidade Local de Saúde São João*

BACKGROUND & AIM

Mild hearing loss in school-aged children may negatively impact language acquisition and academic performance, yet it frequently remains unnoticed. In many settings without universal school hearing screening, early detection often depends on parental awareness. This study aimed to evaluate whether parental perception of their child's hearing correlates with objective audiometric findings obtained in a school screening context.

MATERIAL & METHODS

A cross-sectional observational study was conducted in 53 children aged 6–7 years undergoing school hearing screening. Pure-tone audiometry was performed, and hearing was classified according to BIAP criteria as normal hearing or mild hearing loss.

Parental perception of hearing was assessed using a structured Portuguese questionnaire developed based on previously described hearing perception instruments, complemented by a global visual analogue scale (VAS). The questionnaire's psychometric properties were analyzed, including factor structure, internal consistency, and item–total correlation. Convergent validity was assessed through correlation with the VAS, and construct validity through comparison of scores between audiometric groups.

Questionnaire total and item scores were compared between audiometric groups to determine whether parental perception identified mild hearing loss.

RESULTS

Mild hearing loss was identified in 24.5% of children. The questionnaire demonstrated excellent internal consistency (Cronbach's $\alpha = 0.911$) and a unidimensional structure (KMO = 0.837; total explained variance 68.2%). A strong correlation was found between questionnaire score and VAS ($r = 0.702$; $p < 0.001$), supporting convergent validity.

However, no significant difference in mean questionnaire scores was observed between children with normal hearing and those with mild hearing loss ($p = 0.554$). Only the item related to the need for increased television/radio volume showed statistical significance ($p = 0.018$).

CONCLUSIONS

Although the questionnaire demonstrated good psychometric properties, parental perception did not reliably identify mild hearing loss detected through audiometry. These findings reinforce the importance of structured school hearing screening programs, as parental report alone is insufficient for detecting subtle auditory deficits.

KEYWORDS

school hearing screening; mild hearing loss; parental perception; questionnaire validation; pediatric audiology.

Creating A Deep Learning Algorithm For Detection Of Abnormalities On Pediatric Functional Endoscopic Evaluation Of Swallowing: Preliminary Results

Hisham Al-Kassem[1], **Soolmaz Abbasi**[2], **Christina Rappazzo**[6], **Mohammad Al-Kadi**[3], **Amanda Adsett**[4], **Mini Kurian**[5], **Andre Isaac**[3,5], **Paul Willging**[8], **Husein Smaily**[7], **Muataz Alhashem**[3], **Jacob Jaremko**[2], **Abhilash Hareendranathan**[2], **Hamdy El-Hakim**[3,5]

[1]Faculty of Medicine and Dentistry, University of Alberta, Canada; [2]Department of Radiology and Diagnostic Imaging, University of Alberta, Canada; [3]Division of Otolaryngology—Head and Neck Surgery, University of Alberta, Canada; [4]Department of Rehabilitation Medicine, Stollery Children's Hospital, Edmonton, Alberta, Canada; [5]Stollery Children's Hospital, Edmonton, Alberta, Canada; [6]Kelsey-Seybold Clinic, Houston, Texas, USA; [7]Université Laval, Quebec City, Quebec, Canada; [8]Division of Pediatric Otolaryngology-Head and Neck Surgery, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, USA

BACKGROUND & AIM

Fiberoptic Endoscopic Evaluation of Swallowing (FEES) is a standard instrumental test of pediatric dysphagia. Interpretation is subject to inter-expert variability, and human error despite its other advantages over modified barium swallows (MBS). Automated analysis may improve efficiency, and accuracy, but tools have only been created for MBS. The aim of this study was to develop a deep learning model that can read and interpret pediatric FEES videos.

MATERIAL & METHODS

Thirty-eight pediatric FEES videos were annotated by five expert clinicians (two fellowship-trained pediatric otolaryngologists and three pediatric Speech Language Pathologists) for five key classes: laryngeal inlet, vocal cords, penetration, residue, and premature spillage. Sparse annotations were fused using majority voting to generate consensus masks. 2 different models (U-Net++ and Temporal) were used. U-Net++ models were trained independently for each class, while Temporal (a pretrained zero-shot model) was applied without task-specific training. Segmentation was evaluated using Dice coefficient, sensitivity, precision, and Hausdorff distance. Frame-level detection and false-positive predictions were also assessed.

RESULTS

Temporal model demonstrated higher overall performance than U-Net++, particularly for infrequent events: mean Dice 0.77 vs 0.70, sensitivity 0.82 vs 0.68, precision 0.77 vs 0.73, and Hausdorff distance 25.0 vs 29.6 pixels. Frame-level detection reached 100% for Temporal versus 97% for U-Net++. Temporal was especially effective at detecting penetration, residue, and spillage, whereas U-Net++ exhibited slightly higher precision for larger structures like the vocal cords. False-positive predictions were higher for rare events such as salivary pooling.

CONCLUSIONS

Automated segmentation of pediatric FEES is feasible and can reliably identify both anatomical structures and swallowing abnormalities. Pretrained zero-shot models, like Temporal, generalize well without task-specific training, offering a practical solution in low-data clinical settings. Implementation of such AI-assisted tools may reduce variability, improve diagnostic

efficiency, and support timely management of pediatric dysphagia. Our future step is to validate the model, then test it against expert diagnosis.

BACKGROUND & AIM

Tracheostomy is one of the oldest and most commonly performed airway procedures and, when indicated, it increases the survival despite its associated risk. There is still marked variability in the current practice of pediatric tracheostomy care due to its perceived complexity.

The aim of establishing this consensus is to improve the outcomes for children with tracheostomy based on recent international recommendations, regional available resources and expert opinions. We believe in the pivotal role of the consensus statements in reducing inconsistencies in the provided care and the rate of complications in Saudi Arabia.

MATERIAL & METHODS

The scope of the statements was determined based on review of the literature and gaps in current national practice. The modified Delphi method was used, and panel members comprising pediatric otolaryngologists with more than 3 years of clinical experience were requested to complete a scaled survey in two rounds. Survey items were made comprehensive to cover all stages of tracheostomy care, from pre-operative indications to decannulation protocol.

RESULTS

The expert panel achieved consensus on 53 statements; another 20 were dropped because of lack of consensus. Consensus statements were categorized into five domains as they address pre-operative indications, operative considerations, and post-operative considerations. The latter includes early in-hospital care, routine home care, and decannulation protocol.

CONCLUSIONS

The national consensus established statements on pediatric tracheostomy care the covers peri-operative and long-term tracheostomy care as well as decannulation protocol. This national consensus shall be a clinical guide in Saudi Arabia for physicians, nurses and stakeholders involved in managing tracheostomized children.

Effect Of Warm Saline Irrigation On Intraoperative Bleeding During Pediatric Tonsillectomy: A Prospective Intra-Patient Study

Ceren Aksoy Koçak[1], **Mehmet Erkan Kahraman**[1], **Muhammed Talha Yiğit**[1]

[1]*Department of Otorhinolaryngology – Head and Neck Surgery, Konya City Hospital, Konya, Türkiye*

BACKGROUND & AIM

To evaluate the effect of warm saline irrigation on intraoperative bleeding parameters during pediatric tonsillectomy.

MATERIAL & METHODS

This prospective, randomized, intra-patient (split-body) study included 50 pediatric patients undergoing bilateral tonsillectomy for recurrent tonsillitis. Following tonsillectomy, one tonsillar fossa was irrigated with room-temperature saline (22°C) and the contralateral fossa with warm saline (50°C), according to a predefined randomization protocol. Excision time, bleeding time, and bleeding volume were recorded for each side. Paired-samples t-test was used for statistical analysis.

RESULTS

No statistically significant differences were observed between 22°C and 50°C saline irrigation in terms of excision time (mean difference: 0.10 min; p = 0.553), bleeding time (p = 1.000), or bleeding volume (mean difference: 4.8 mL; p = 0.139). Although bleeding volume tended to be lower with warm saline irrigation, this difference did not reach statistical significance. Postoperative complications were infrequent and managed conservatively.

CONCLUSIONS

Warm saline irrigation did not provide a significant intraoperative hemostatic advantage during pediatric tonsillectomy. These findings suggest that the hemostatic effect of warm saline irrigation may be procedure- and tissue-specific.

Macroscopic And Histopathological Comparison Of The Effects Of Intratonsillar, Short- And Long-Acting Steroid Injections On The Palatine Tonsils In Rabbit Model.

Saynur ŞİMŞEK[1], **Merih ÖNAL**[1], **Çağdaş ELSÜRER**[1], **Bülent ULUSOY**[1], **Nevzat Serdar UĞRAŞ**[2], **Muslu Kazım KÖREZ**[3]

[1]*Selçuk University Otorhinolaryngology Department*; [2]*Selçuk University Pathology Department*; [3]*Selçuk University Biostatistics Department*

BACKGROUND & AIM

Tonsils constitute the first line of defense against pathogens in the upper respiratory tract. However, recurrent infections or excessive tonsillar hypertrophy can lead to clinical problems such as upper airway obstruction and snoring. Current literature recommends adenotonsillectomy as the first-line treatment for pediatric obstructive sleep apnea. Nevertheless, surgical intervention carries a risk of various complications, prompting the search for less invasive alternatives.While intranasal steroids are effective for adenoid hypertrophy, evidence for their effect on the palatine tonsils remains insufficient. The aim of this study was to evaluate the effects of steroids on the rabbits' palatine tonsils following intratonsillar steroid injection.

MATERIAL & METHODS

A total of 32 rabbits, all under six months of age, were divided into five groups. Single and multiple doses of short-acting (fluticasone) and long-acting (dexamethasone) steroids were administered into both palatine tonsils, while the control group received saline injections. Tonsil sizes were measured macroscopically at regular intervals, and histopathological evaluations on the number of primary and secondary lymphoid follicles were performed at the end of the study.

RESULTS

The results demonstrated a statistically significant reduction in tonsil size and number of secondary lymphoid follicles in all steroid-treated groups compared to the control group ($p<0.05$). Moreover, the short-acting steroid groups showed a significantly greater reduction in secondary follicles compared to the long-acting steroid groups ($p<0.05$).

CONCLUSIONS

These findings suggest that intratonsillar steroid injections may represent an effective, minimally invasive alternative for reducing tonsillar hypertrophy and suppressing lymphoid follicular activity.

Predictive Value Of Preoperative Hematological Markers For Post-Tonsillectomy Hemorrhage

Ali Ozan YAZICI[1], **Ayşe Enise GÖKER**[1]

[1]*University Of Health Sciences Prof. Dr. Cemil Taşcıoğlu City Hospital, Department of Otorhinolaryngology, Istanbul, Türkiye*

BACKGROUND & AIM

Tonsillectomy is one of the most common surgical procedures performed at ear, nose and throat clinics. Post-tonsillectomy hemorrhage (PTH) remains one of the most important complications in pediatric otolaryngology. Potential indicators of PTH include red cell distribution width (RDW) and other hematological parameters such as white blood cell (WBC) count, platelet (PLT) count and international normalized ratio (INR). Some studies suggest that gender, age, MCV and INR levels are all risk factors for PTH. However, their clinical utility remains unclear. In this study we intended to evaluate the association between preoperative hematological parameters and the risk of PTH.

MATERIAL & METHODS

A retrospective case-control study was performed involving 102 pediatric patients who underwent cold dissection tonsillectomy. 51 of these patients experienced postoperative hemorrhage while the other 51 served as controls without bleeding. Demographic data and preoperative hematological parameters (haemoglobin [HGB], hematocrit [HCT], Mean Corpuscular Volume [MCV], RDW-CV, RDW-SD, INR, WBC count, PLT, Neutrophil-to-Lymphocyte Ratio [NLR], Platelet-to-Lymphocyte Ratio [PLR]) were analyzed. Normality was evaluated using the Shapiro–Wilk test. Group comparisons were

performed using the Mann–Whitney U test or chi-square test when appropriate. Receiver operating characteristic (ROC) analysis and binary logistic regression (univariate and multivariate) were used to determine predictive performance.

RESULTS

There were no significant differences between groups in terms of age and sex distribution (p>0.05). Preoperative hematological parameters were compared between groups. No statistically significant differences were observed in RDW-CV, RDW-SD, Hgb, HCT, MCV, PLT, Hgb/MCV, NLR or PLR (p>0.05 for all). INR and WBC levels were significantly higher in the hemorrhage group compared to the control group (p=0.008 and p=0.027, respectively). ROC analysis demonstrated limited discriminative ability of INR for predicting post-tonsillectomy hemorrhage (AUC=0.652, p=0.008). In univariate logistic regression, INR was significantly associated with hemorrhage (p=0.005), however the odds ratio was unstable due to the narrow distribution of INR values. In multivariate analysis including INR and WBC, INR remained independently associated with hemorrhage (p=0.019), whereas WBC lost statistical significance (p=0.095).

CONCLUSIONS

Preoperative RDW parameters were not associated with PTH. Although INR was identified as an independent predictor, its clinical utility is limited due to low discriminative performance and narrow value distribution. These findings indicate that routine hematological indices alone may be insufficient for reliable risk stratification of post-tonsillectomy bleeding. A multifactorial approach incorporating coagulation parameters alongside clinical risk factors may provide a more accurate prediction model for postoperative hemorrhage.

OP-906

Decoding The Spatiotemporal Evolution Of Recurrent Pediatric Nasal Polyps Through Xenium Spatial Transcriptomics

Junyue Yang[1], **Wentong Ge**[1]

[1]*Department of Otolaryngology, Head and Neck Surgery, National Center for Children's Health, Beijing Children's Hospital, Capital Medical University, Beijing 100045, China*

BACKGROUND & AIM

Pediatric chronic rhinosinusitis with nasal polyps (CRSwNP) is associated with a high recurrence rate, yet the underlying mechanisms remain poorly understood. This study aimed to construct a comprehensive spatiotemporal atlas of recurrent pediatric CRSwNP using the 10x Genomics Xenium Prime 5K in situ spatial transcriptomics platform, and to analyze the dynamic expression patterns and cell-type-specific functions of SOCS3, a key negative regulator of the JAK-STAT pathway, during disease recurrence.

MATERIAL & METHODS

A total of 20 tissue samples were analyzed, divided into five groups (n=4 per group): recurrent polyps, non-recurrent polyps, paired recurrent mucosa, paired non-recurrent mucosa, and healthy control nasal mucosa. Spatial whole transcriptome analysis was conducted using Xenium Prime 5K on formalin-fixed, paraffin-embedded tissue. Cell segmentation was performed with Xenium Explorer, followed by unsupervised clustering, annotation, and differential expression analysis using R and Python. The analysis focused on spatial cellular architecture, interaction networks, and spatial heterogeneity of gene expression. SOCS3 expression and localization were validated by multiplex fluorescence immunohistochemistry (mIHC). To investigate SOCS3's role, fibroblast cell lines were treated with a SOCS3 inhibitor, and fibrosis-related genes (e.g., COL1A1, α-SMA) were analyzed by qPCR. Additionally, SOCS3 expression and key protein phosphorylation in the JAK-STAT/MAPK pathways were measured by Western blot, and inflammatory factors in serum were quantified by ELISA, correlating with recurrence status.

RESULTS

A high-resolution spatial cellular atlas of pediatric CRSwNP was created, revealing significant differences in cellular ecosystems between recurrent and non-recurrent samples. SOCS3 expression demonstrated disease-stage and cell-type specificity. In the early disease stage (mucosal lesion phase), SOCS3 was upregulated and predominantly expressed in immune cell populations (e.g., CD4+ T cells). In contrast, during the later disease stage (polyp formation phase), SOCS3 expression shifted to activated fibroblasts. This dynamic change suggests that SOCS3 may exert distinct functions via different cell types at different stages of the disease. Pathway enrichment analysis revealed activation of the JAK-STAT and MAPK signaling pathways, along with extracellular matrix organization-related pathways in SOCS3high cell clusters. Spatial neighborhood analysis further identified the formation of an abnormal microenvironmental network in recurrent polyps, centered around SOCS3high fibroblasts, which acted as interaction hubs, closely interacting with surrounding immune cells.

CONCLUSIONS

This study provides the first systematic spatiotemporal mapping of recurrent pediatric CRSwNP at single-cell resolution using Xenium spatial transcriptomics (5K), revealing SOCS3's dynamic expression. Our findings suggest that during mucosal inflammation, SOCS3 upregulation in immune cells modulates immune responses, while in the polyp remodeling phase, its

shift to fibroblasts drives abnormal extracellular matrix deposition and fibrosis via JAK-STAT and MAPK pathways. These results offer novel insights into SOCS3's context-dependent role in CRSwNP and propose targeting cell-type-specific functions or dynamic modulation of SOCS3 to prevent postoperative recurrence in children with CRSwNP.

OP-907

Beyond The First Tube: Predictors Of Repeated Tympanostomy Tube Placement In Children

Duarte Morgado[1], **Catarina Pinto**[1], **Mariana Santos**[1], **Inês Veloso**[1], **João Rodrigues**[1], **Catarina Lombo**[1], **Rui Fonseca**[1]

[1]*Hospital Senhora da Olivera, Guimarães*

BACKGROUND & AIM

Tympanostomy tube (TT) insertion is among the most frequently performed surgical procedures in children, indicated for otitis media with effusion (OME) or recurrent acute otitis media (RAOM). Despite its efficacy, a relevant proportion of children require further tube placement. This study aimed to determine the rate of indication for repeated TT placement and identify independently associated factors.

MATERIAL & METHODS

We retrospectively included children undergoing first TT placement at our institution. The primary outcome was clinical indication for repeated TT during follow-up. Follow-up was defined as time from first surgery to last observation in non-repeaters, and to the indication for repeat procedure in repeaters. Group comparisons used Chi-square or Fisher's exact test and Mann-Whitney U test, as appropriate. Independently associated factors were identified by binary logistic regression.

RESULTS

A total of 149 children were included (57.7% male; median age 4.0 years). Initial indication was OME in 48.3% and RAOM in 51.7%; 81.2% underwent bilateral placement. Repeated TT was indicated in 32 children (21.5%) over a median follow-up of 16 months. Tube retention time was significantly shorter in repeaters (8.5 vs. 12.0 months; p=0.016). On univariate analysis, OME indication, postoperative snoring, postoperative rhinorrhea, and shorter retention time were significantly associated with repeated TT. On multivariate analysis, three independent associated factors were identified: OME as initial indication (OR 2.72; p=0.031), shorter tube retention time (OR 0.884/month; p=0.023), and postoperative snoring (OR 4.951; p=0.003). Postoperative rhinorrhea did not retain independent significance. Gender, age, prematurity, low birth weight, passive smoking, asthma, daycare attendance, bilateral placement, and associated adenoidectomy/adenotonsillectomy were not significantly associated with repeated TT placement.

CONCLUSIONS

Approximately one in five children had an indication for repeated TT placement. OME as initial indication, shorter tube retention time, and postoperative snoring were independently associated with this outcome. Children with these factors may benefit from closer postoperative surveillance.

Presentation Of Fungal Rhinosinusitis In Sudanese Children A Series Of 17Cases

SHARFI AHMED[1]

[1]*omdurman islamic university Sudan*

BACKGROUND & AIM

To present 17 rare cases of Fungal Rhinosinusitis in Sudanese children presented with orbital extension.

MATERIAL & METHODS

I reported a retro-spective 17 cases of children aged 9-11 years , they presented with fungal rhinosinusitis in Africa ENT hospital(Sudan) during the period from Sep 2023 to April 2025.

Patients' diagnosis was established by endoscopic examination, contrast-enhanced CT and MRI and confirmed by histopatholog and fungal culture of tissue biopsies

RESULTS

Patients' aged 9-11 years , this included 12 females and 5 male. Unilateral disease was the commonest type. Orbital extension was identified on imaging in the majority of cases . No intracranial extension was detected . Aspergillus flavus was the most responsible caustive organismisolated in the 14 of 17 cases.

CONCLUSIONS

Fungal rhinosinusitis (FRS) is commonly reported in adult Sudanese patients; however, this series demonstrates that it can also affect immunocompetent children. In the pediatric population, the disease is predominantly caused by Aspergillus species, particularly A. flavus. FRS in children may present with extensive disease and is frequently associated with orbital complications, necessitating early diagnosis and multidisciplinary management.

OP-909

Studying The Broader Clinical Impact Of Adenoid Surgery By Using Genes As Biomarkers

Elmo Saarentaus[1], **Juha Mehtonen**[2], **Aarno Palotie**[2], **Antti Mäkitie**[1]

[1]*Department of Otorhinolaryngology - Head and Neck Surgery, Helsinki University Hospital (HUS), Helsinki, Finland;* [2]*Institute for Molecular Medicine Finland (FIMM), Helsinki Institute of Life Science (HiLIFE), University of Helsinki, Helsinki, Finland*

BACKGROUND & AIM

Removal of adenoid tissue is a common procedure for pediatric patients with chronic otitis media and obstructive sleep apnea. Despite reports of these conditions running in families, little is known about their heritable factors. Nordic countries have in recent decades steeply restricted this procedure to only confirmed cases.

MATERIAL & METHODS

In order to study the biological aspects leading to need for this procedure, we performed genome-wide association of adenoidectomy in participants with no registered tonsillar operation in the FinnGen release 12 dataset (13,605 cases, 461,213 controls). We also utilized the longitudinal registry data from FinnGen as a natural experiment to examine the impact of changing clinical guidelines, comparing the genetic risk for adenoid surgery in participants who underwent the procedure before the guideline revision (n = 10,932 cases) with those born after the guideline revision who have no record of adenoid surgery (n = 7,326 controls).

RESULTS

We identified genome-wide significant loci linked with tonsillar growth (LTBR), immune deficiency (TNFRSF13B), chronic otitis media (GAS2L2), and childhood-onset asthma (CDHR3). Further, we discovered that the relative genetic contribution to risk for adenoid surgery increased with more stringent guidelines (OR = 1.02, $p < 2e\text{-}16$ in favor of participants born after guideline revision). Further, risk for chronic ear infection after surgery did not associate with genetic adenoidectomy risk ($p = 0.3138$), but after surgical indications were revised, non-operated participants with higher genetic adenoidectomy risk were over twice more likely to be diagnosed with chronic ear infection than those with low risk (14.0 % in high genetic risk group, 6.0 % in low genetic risk group; $p = 0.00154$). Guideline revision did not impact genetic association of adenoid surgery and other childhood diseases, such as childhood-onset allergy or asthma.

CONCLUSIONS

Our findings suggest that the heritable biological factors underlying adenoid surgery contribute to additional phenotypes that may still be influenced by the surgery. We also provide evidence for including genetic factors in clinical decision-making and guidelines.

Chronic Cough In Pediatrics: Update

Jose Morinigo M.D.[2]

[1]*ENT department, Clinical Hospital,National University of Asuncion, Paraguay;* [2]*Otolaryngology Center, Asuncion, Paraguay*

BACKGROUND & AIM

Cough in children and adults is a commonly witnessed symptom that can be related to a serious underlying disease. It is a reflex phenomenon that protects the airways and lungs and helps in clearing out the air spaces of accumulated secretions. However, cough in children and adults has some notable differences based on various parameters, including duration, symptoms witnessed, duration, and etiology. Therefore, the tools and processes commonly employed for evaluating cough in adults may not apply to pediatric patients. Furthermore, the management of cough, in general, should be based on the etiology instead of the underlying disease condition.

MATERIAL & METHODS

There is a relative paucity of data related to pediatric cough in comparison to adult cough, making the management of cough challenging. The idea of this conference is to provides a comprehensive review of cough management in children in Paraguay, tropical country, reviewing the literatura, and personal experience from the past 20 years .

RESULTS

Many cases of pediatric chronic cough , in tropical countries, are due to upper airway pathologies, including allergies and chronic sinusitis , with obstructive sleep component and viral infections as a trigger factors , with common association between eatiologist.

CONCLUSIONS

ENT evaluación is important in assessing chronic cough in pediatrics, in order to find the possible aetiologies and evoid excess in medication

Predictors Of Recurrent Ventilation Tube Insertion In Pediatric Otitis Media With Effusion

Ata Alperen Ersahan[1], **Selenay Gumus**[1], **Murat Kahveci**[1], **Simge Turkan**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, Faculty of Medicine, Kocaeli University, Kocaeli, Türkiye*

BACKGROUND & AIM

Otitis media with effusion (OME) is a common cause of pediatric hearing loss and a frequent indication for ventilation tube insertion. Despite its effectiveness, recurrence requiring repeat tube placement remains a significant clinical challenge. Identifying predictors of recurrence is essential to improve patient selection and optimize surgical decision-making. This study aimed to identify clinical and patient-related predictors of recurrent ventilation tube insertion.

MATERIAL & METHODS

This retrospective cohort study included patients younger than 18 years who underwent ventilation tube insertion at the Department of Otolaryngology, Kocaeli University Faculty of Medicine, for OME between March 2019 and December 2024. Patients with at least 12 months of follow-up were analyzed. Demographic, perinatal, clinical, and environmental variables, including age, gestational age, atopy, passive smoking exposure, presence of cleft palate, number of siblings, air–bone gap, tube retention time, postoperative complications, and concurrent adenoidectomy, were evaluated. Statistical analyses were performed using IBM SPSS version 29.0, with $p < 0.05$ considered statistically significant.

RESULTS

A total of 325 patients (576 ears) were included. Recurrence occurred in 43 patients (13.2%) and in 79 ears (13.7%). Patients with recurrence had significantly higher air-bone gap values and shorter tube retention times compared to those without recurrence ($p = 0.005$ and $p = 0.004$, respectively). Multivariate logistic regression analysis revealed that a greater air-bone gap was independently associated with an increased risk of recurrence (OR = 1.047, 95% CI: 1.014–1.080; $p = 0.004$). Shorter tube retention time was also an independent predictor (OR = 0.913, 95% CI: 0.850–0.980; $p = 0.011$). In contrast, concurrent adenoidectomy demonstrated a strong protective effect, significantly reducing the risk of recurrence (OR = 0.129, 95% CI: 0.032–0.516; $p = 0.004$). Other variables were not significant.

CONCLUSIONS

Greater air–bone gap and shorter tube retention time were independently associated with recurrence, while concurrent adenoidectomy had a protective effect. These findings may aid in risk stratification and suggest that patients at higher risk may benefit from closer follow-up.

The Utility Of Genetic Testing As Part Of The Routine Workup Of Children With Permanent Hearing Loss Prior To Intervention

Mohamad A. Bitar[1,2], **Ahmad AbuTayoun**[1,2], **Maha El Naofal**[1], **Sherin Kuttiankandy**[1], **Litty Zacharrias**[1], **Sabine ElDick**[1], **Deena Wafadari**[1], **Zainab Alloub**[1,2]

[1]*Al Jalila Children's Specialty Hospital - Dubai Health;* [2]*Mohammed Bin Rashid University of Medicine & Health Sciences*

BACKGROUND & AIM

With a prevalence of 2.5 in 1,000 births, hearing loss represents the most common congenital sensory impairment. It is estimated that more than half of the pediatric hearing loss has a genetic cause, and over 280 genes are claimed to be associated with either a non-syndromic or syndromic form of the disease. This became part of our routine extensive workup for our patients diagnosed with permanent hearing loss.

MATERIAL & METHODS

We included 100 consecutive patients and reviewed their performed workup, their demographic data and family history. Clinical genomic investigations included exome-based sequencing, chromosomal microarrays, and/or targeted testing. We

assessed the diagnostic yield and implications for clinical management among this population. Variables were compared using the Fisher exact test. Tests were 2-tailed, and P < .05 was considered statistically significant.

RESULTS

Genetic testing was positive in 58% of the patients, 22% have a positive family history of hearing loss, 53.57% had abnormality on ophthalmological assessment, 54.55% were positive for IgG CMV, 44.74% had abnormal findings in the performed imaging studies, 42.86% had positive findings on their ECG, and 20.59% had abnormality in the urine test. The most common genetic abnormality findings were GJB2 in 17.24% of the positive cases, followed by SLC6A4 in 10.34%, PDZD7 in 5.17% and 3.44% in each of CHD7, PTPN11, TMC1. IMPG2; and 1.72% in 22 other genes.

CONCLUSIONS

The diagnostic yield of our workup for permanent hearing loss is significant and is important in early detection of abnormalities that might go unnoticed until becoming more symptomatic. Understanding the genetic profile of our affected population will not only help in counselling the parents and unveiling other related disorders in case of a known syndrome, but also in forming a database for future gene therapy that is starting its way in the field of congenital hearing impairment.

Choanal Atresia With No Stents: 180 Cases Review

Alan Asmanov[1], **Anastasia Gorina**[1]

[1]*Pediatric Otolaryngology Department, Veltishchev Research Clinical Institute of Pediatrics and Pediatric Surgery/ Moscow, Russia*

BACKGROUND & AIM

Congenital choanal atresia (CCA) is a life-threatening neonatal airway obstruction and a cause of chronic nasal dysfunction in children. High restenosis rates after stent-based surgery limit long-term results. The aim of this study is to develop an innovative method of endoscopic correction without the use of stents and to substantiate their effectiveness in various forms of CCA in children.

MATERIAL & METHODS

A comparative cohort study (2015–2026) included 181 children aged 0–17 years. Group I (n=137) underwent primary stentless endoscopic choanoplasty, while Group II (n=44) comprised patients treated for restenosis after prior stent-based surgery. The original surgical technique performed in both groups involved partial posterior septectomy, mucosal flap creation from the atretic membrane, and fixation of vascularized flaps to the nasopharynx using fibrin glue without stent placement. Primary outcomes were neochoana patency and restenosis rate; secondary outcomes included postoperative pain (VAS), quality of life (SF-36), anterior active rhinomanometry (AARM), and mucociliary clearance (MCC). Assessments were performed preoperatively, at discharge, and at 1 and 6–12 months postoperatively, with follow-up up to 8 years.

RESULTS

Primary septal flap choanoplasty achieved functional neochoana formation in 98.1% of patients in 3 months ($p<0.001$) with a low partial restenosis rate (1.9%). In revision cases, recurrence decreased to 5.2% ($p<0.001$), with no complete restenosis observed. Early postoperative pain was minimal (≤1 point in >90% on day 1). SF-36 scores improved significantly in physical and social domains ($p<0.001$). AARM demonstrated significant airflow improvement across all age groups ($p<0.001$); in children aged 4–6 years, airflow increased from 137±20 to 209±17 cm^3/s at 1 month. MCC normalized in 98% of patients at 12 months.

CONCLUSIONS

Endoscopic fibrin glue choanoplasty provides effective results in children: durable neochoana patency, restores nasal physiology, and significantly improves quality of life. It represents an effective and safe strategy for both primary and revision CCA in children. The proposed choanoplasty technique can be used as a life-saving alternative to tracheostomy or prolonged intubation in infants with bilateral CCA.

OP-914

The Variant Type Of Preauricular Sinus With Recurrent Postauricular Abscess: Excision Using A Single-Incision Preauricular Approach

Kanu Lal Saha,Harun -Ar Rashid Talukder[1]

[1]*Bangladesh Medical University*

BACKGROUND & AIM

Congenital preauricular sinus (PAS) openings near the crux of the helix or tragus vary with incomplete fusion of the six hillocks of His. Using an imaginary line from the posterior margin of the ascending helix to the upper base of the tragus, pits are classified as classical (anterior) or variant (posterior). In variant PAS, the tract typically runs posteriorly toward the

postauricular region, causing recurrent postauricular abscesses that may be misdiagnosed as isolated infections because the pit appears silent. This study assesses a single-incision preauricular approach for complete excision of the tract and terminal cystic sac.

MATERIAL & METHODS

Study type:Retrospective case series

Setting:A tertiary care hospital

Duration :Nov 2020 to October 2025

Inclusion criteria: variant PAS with recurrent postauricular abscess, with or without prior incision and drainage. Exclusion criteria: Presence of a postauricular fistula or skin defect.

Surgical Technique

Under general anesthesia and microscopic visualization, 2% xylocaine with adrenaline (1:200,000) was infiltrated around the pit. No dyes or lacrimal probes were used. An elliptical incision was made around the pit at the root of the crus of the helix. Skin was elevated to the perichondrium, and a small strip of cartilage with inferior perichondrium was removed using a Plester knife. Dissection proceeded posteriorly along the tract until the blind cystic pouch was identified deep to the auricularis posterior muscle. The wound was closed in a single layer with 4-0 polypropylene, and a mastoid dressing was applied.

RESULTS

Twelve patients aged 3–17 years underwent the single-incision procedure. All had variant PAS with 3–9 episodes of recurrent postauricular abscess. Most were initially misdiagnosed because the sinus pit showed no obvious signs of infection.

Complete one-piece excision of the sinus tract and blind cystic sac was achieved in all cases. Minor deformity of the crus of the helix occurred in the first two patients during the early learning curve. No recurrences were observed during up to four years of follow-up.

CONCLUSIONS

The presence of congenital pits at the crus of the helix with postauricular abscess formation almost warrants the diagnosis of the variant type of preauricular sinus. The single incision preauricular approach utilizing an operating microscope is a useful surgical technique for the variant type of the preauricular sinuses with postauricular abscess without fistulous opening in the postauricular region.

Metagenomic Insights Into The Middle Ear Microbiome In Health And Otitis Media With Effusion: Comparison With Conventional Culture Methods

Mahmut Tayyar Kalcıoğlu[1], **Serdal Çelik**[1], **Emre Yakut**[1], **Muhammed Yasir Gümüştaş**[1], **Oğuz Arı**[2], **Esra Koçoğlu**[1], **Tansu Nergiz**[1], **Rıza Durmaz**[2]

[1]*İstanbul Medeniyet University*; [2]*Ankara Yıldırım Beyazıt University*

BACKGROUND & AIM

To compare the middle ear microbiota of children with otitis media with effusion (OME) and healthy controls using conventional culture techniques and 16S rRNA gene–based metagenomic sequencing.

MATERIAL & METHODS

This study examined 22 children scheduled to receive ventilation tubes due to OME and 20 healthy children scheduled to receive cochlear implants. Samples were collected under aseptic conditions. Culture results were evaluated using classical methods and MALDI-TOF MS. The same samples were sequenced through the V3-V4 regions of the 16S rRNA gene using the Illumina MiSeq platform and analyzed with QIIME2 software.

RESULTS

Culture positivity was 77.3% in the OME group and 35.0% in the control group ($p=0.012$). In the metagenomic analysis, Alloiococcus otitidis was the most dominant species in both groups; however, its relative abundance was higher in the OME group (33.8% vs. 20.2%). Haemophilus influenzae and Veillonella dispar increased significantly in the OME group, while Propionibacterium acnes and Ruminococcus bromii decreased significantly ($p<0.05$). There was limited agreement between culture and metagenomic sequencing results; only H. influenzae and A. otitis were detected by both methods.

CONCLUSIONS

This study highlights three key findings. First, significant alterations in the middle ear microbiome are associated with OME. Second, culture-based methods alone are insufficient to accurately characterize the middle ear microbiome. Third, metagenomic approaches are essential for a comprehensive understanding of OME pathogenesis. Notably, the high prevalence of A. otitidis and the increased abundance of H. influenzae and V. dispar appear to play important roles in OME pathogenesis and may represent potential targets for diagnostic and therapeutic interventions.

OP-916

Beyond Infection Control: Favorable Weight Outcomes After Tonsillectomy For Recurrent And Chronic Tonsillitis In Children

Shahrukh Ali[1], **Robert Africa**[1], **Yusif Hajiyev**[1], **Harold Pine**[1]

[1]*University of Texas Medical Branch*

BACKGROUND & AIM

Recurrent or chronic tonsillitis is a common pediatric condition frequently treated with tonsillectomy. However, the impact of tonsillectomy on long-term weight outcomes, including the risk of obesity, remains incompletely understood. This study aimed to evaluate short- and long-term obesity risk following tonsillectomy in pediatric patients.

MATERIAL & METHODS

A retrospective cohort study was conducted using de-identified electronic health record data from the TriNetX US Collaborative Network. Pediatric patients (<18 years) diagnosed with recurrent or chronic tonsillitis between January 2015 and December 2023 were included, excluding those with obesity prior to the index date. Patients were categorized based on treatment with tonsillectomy or non-surgical management. Propensity score matching was performed to balance demographic and clinical variables between cohorts. Patients were followed for incident obesity within 24 months after the index date. Hazard ratios (HR) with 95% confidence intervals (CI) were calculated.

RESULTS

After propensity score matching, baseline characteristics were well balanced between the tonsillectomy and non-surgical cohorts. At 24 months, pediatric patients undergoing tonsillectomy demonstrated a significantly lower incidence of obesity compared with matched non-surgical controls (7.9% vs 10.6%; HR 0.73, 95% CI 0.68–0.79; $p < 0.001$).

During the early postoperative period, however, children who underwent tonsillectomy exhibited increased weight gain within the first 6 months, with a higher incidence of obesity compared with non-surgical controls (12.4% vs 10.1%; HR 1.18, 95% CI 1.08–1.29; $p < 0.001$).

CONCLUSIONS

Tonsillectomy in pediatric patients was associated with transient early postoperative weight gain followed by a significantly reduced incidence of obesity at 24 months compared with non-surgical management. These findings suggest that although short-term weight increases may occur after tonsillectomy, long-term obesity risk may be reduced. Further prospective studies are needed to clarify underlying mechanisms and the temporal relationship between tonsillectomy and pediatric weight outcomes.

ENDOSCOPIC TISSUE ALBUMIN GLUE BIOCAUTERIZATION FOR CONGENITAL PYRIFORM SINUS FISTULA

THUY THI THANH NGUYEN[1], **MINH TRAN QUANG LE**[1], **THU NGUYEN ANH HA**[1]

[1]*ENT hospital of HCMC*

BACKGROUND & AIM

Background: Pyriform sinus fistulas are often associated with malformations of the III/IV branchial apparatus and are a major cause of recurrence after treatment. The condition typically presents as acute inflammatory symptoms in the neck, such as recurrent deep cervical abscesses, recurrent cystic swelling, or acute suppurative thyroiditis. Surgical removal of the III/IV branchial sinus cysts/fistulas has a high recurrence rate if the piriform sinus fistula is not properly identified and closed.

Objective: To evaluate the treatment outcomes of pyriform sinus fistula closure with biological glue.

MATERIAL & METHODS

Methods: From January 2024 to June 2025, 19 patients were diagnosed and treated for pyriform sinus fistula. Under laryngoscopy, the pyriform sinus fistula was identified, monopolar electrocautery was performed, followed by injection of biological glue. A Levin tube was placed post-operatively. Results were re-evaluated by postoperative endoscopy.

RESULTS

Results: The study included 19 patients, with an average age of 20.6 years and a male/female ratio of 1:1.37. The method of closing the piriform sinus fistula with biological glue combined with monopolar electrocautery achieved a 100% success rate, with no recurrence or complications. In 57.8% of cases, the procedure was combined with neck incision and abscess drainage. The methods of closing the piriform sinus fistula combined with fistula excision or conservative treatment were evenly distributed, each accounting for 21.1%. The average surgical time was 39.7 ± 28.4 minutes. The average follow-up time after treatment was 11.9 ± 10.8 months.

CONCLUSIONS

Conclusions: Closing the piriform sinus opening with biological glue is a safe surgical procedure with a 100% success rate and an average follow-up time of one year.

SINONASAL LESIONS IN CYSTIC FIBROSIS IN CHILDREN IN RUSSIA: EPIDEMIOLOGY, RADIOLOGIC SIGNS, SURGERY AND EFFECTS OF CFTR-MODULATORS

Dmitry Polyakov[1], **Nikolay Daikhes**[1], **Adnan Yunusov**[1], **Elena Kondratyeva**[2], **Alina Pogodina**[1], **Valeria Kazakova**[1]

[1]*Federal State Budgetary Institution "The National Medical Research Center for Otorhinolaryngology of the Federal Medico-Biological Agency of Russia;* [2]*Research Centre for Medical Genetics*

BACKGROUND & AIM

Chronic rhinosinusitis (CRS) is a common manifestation of cystic fibrosis (CF). However, its prevalence in children with CF remains unclear, and treatment options are still controversial. The clinical course demonstrates certain genotype–phenotype correlations and varies across regions due to differences in CFTR mutations.

MATERIAL & METHODS

As part of a global investigation in this field, we revised the criteria of CRS indexation in the Russian National Cystic Fibrosis Registry (n=2785) and conducted a caregiver-based questionnaire survey involving 501 children with CF. In addition, we analyzed 570 CT scans of the paranasal sinuses with a focus on genetic variants. Data from 225 surgeries were also included in the analysis. Finally, a controlled study of the effectiveness of two CFTR modulators (n=36) on CRS severity was performed.

RESULTS

The prevalence of CRS in Russian children with CF is 71.6% (39.5% with nasal polyps; 32.1% without polyps). The most frequent CT findings in this cohort are “natural contrast enhancement” (97.9%) and bone destruction (45.8%). In contrast to European and US cohorts, frontal and sphenoid sinus hypoplasia were relatively uncommon (20.5% and 36.3%). A 20-year experience of sinus surgery in CF patients demonstrated the advantage of modified endoscopic medial maxillectomy with complete mucosal debulking over classic functional endoscopic sinus surgery ($p<0.001$). The CFTR modulator elexacaftor/tezacaftor/ivacaftor showed wondering effect on paranasal sinus pathology in comparison with lumacaftor/ivacaftor and control group ($p<0.01$, $p=0.750$, $p=0.108$).

CONCLUSIONS

CRS is a frequent manifestation of CF; thus, the term “CF-related CRS” (CF-CRS) should be introduced. CT features of CF-CRS are rather specific and differ depending on major genetic variants. Modified endoscopic medial maxillectomy with complete mucosal debulking represents the preferred surgical technique for managing maxillary sinus disease in CF children. Novel therapeutic strategies with CFTR modulators are highly promising and may potentially replace surgery in some patients.

Retrospective Review Of Neonatal Ear Molding With The Scalp Securing Technique

Hung-Fu "Charlie" Lin, MSN, APRN-CNP, FNP-C, CRNFA, CNOR-PEDS, CNAMB, FCN, FAORN[1,2], **Summer Hayhurst, MSN, CPNP**[1], **Mai Thy Truong, MD**[1,2]

[1]*Stanford Medicine Children's Health;* [2]*Stanford Medicine*

BACKGROUND & AIM

The purpose of this study was to evaluate the efficacy, outcomes, and complications of neonates in the treatment of various congenital ear abnormalities utilizing the scalp securing technique at a single institution.

MATERIAL & METHODS

A retrospective chart review of 154 neonates who underwent ear molding with the scalp securing technique with pediatric otolaryngology - head and neck surgery from July 2019 through March 2024 was conducted. Specific congenital ear abnormalities, age at the time of initiation, and duration of the treatment was aggregated for all patients. Patients were followed for their longitudinal experiences with a 58.4% response rate with the ear molding process, long-term outcomes, parental satisfaction, and likelihood to recommend the treatment while assessing for effect of the intervention and for potential complications.

RESULTS

154 neonates were included in the study with 304 ears molded during the period of the study. The average age at the initiation of ear molding was 24 days with an average treatment lasting a median of 28 days. Helical rim deformities (N = 105 ears) and lop ear deformities (N = 67 ears) were the most predominant congenital ear abnormalities. All identified ear abnormalities

were successfully molded utilizing this cost-effective technique with 91% of families reporting that the ear maintained its corrected shape. Parental satisfaction was high with 97.6% of families reporting that they would recommend the procedure to a friend. There were zero reported pressure ulcers, eczematous dermatitis, or skin injury with this technique.

CONCLUSIONS

Ear molding utilizing the scalp securing technique is an effective treatment strategy for congenital ear abnormalities.

OP-920

Beyond Newborn Screening: Toward A Global Strategy For Childhood Hearing Screening

Maria Peixoto[1], **Ana Raquel Andrade**[1], **Miguel Lopes**[1], **Luciana Rodrigues**[1], **Diogo Nascimento**[1], **Hugo Amorim**[1], **Paulo Gonçalves**[1]

[1]*Unidade Local de Saude Entre Douro e Vouga*

BACKGROUND & AIM

Despite the widespread implementation of Universal Newborn Hearing Screening (UNHS), a significant proportion of childhood hearing loss remains undiagnosed due to late-onset, progressive, or acquired conditions, as well as gaps in follow-up systems. Current evidence highlights the need for continued surveillance beyond the neonatal period. However, school and preschool hearing screening programs remain inconsistently implemented worldwide, with marked heterogeneity in protocols and access.

The aim of this work was to evaluate the feasibility and clinical utility of a school-based hearing screening program and to contribute to the development of a standardized, scalable model that supports a global screening strategy.

MATERIAL & METHODS

A pilot, two-phase observational study was conducted in children aged 6–7 years. Initial school-based screening included otoscopy, tympanometry, and pure-tone screening audiometry (20 dB HL at 500–4000 Hz), followed by hospital-based reassessment for referred cases. Diagnostic performance of individual and combined tests was analyzed.

RESULTS

Among 53 children screened, referral rate was 47.2%, with 88% follow-up adherence. Confirmed hearing loss was identified in 5.6% of the total sample, predominantly conductive and related to middle ear pathology. Pure-tone audiometry demonstrated optimal sensitivity as a first-line screening tool, while tympanometry improved diagnostic specificity when used sequentially. School-based implementation reduced access barriers and proved operationally feasible.

CONCLUSIONS

School hearing screening is a feasible and effective strategy for early identification of hearing disorders missed by UNHS. These findings reinforce the urgent need for a coordinated global approach and the standardization of screening protocols, ensuring equitable access, improved detection rates, and optimized child health outcomes worldwide.

OP-921

Cross- Cultural Validation Of The Otitis Media-6 (OM-6) Questionnaire In French- Speaking Caregivers In Canada.

Jeffrey, Yeung[1], **Audrey Pitaru**[1]

[1]*Montreal Children's Hospital, McGill University*

BACKGROUND & AIM

Otitis media (OM) imposes substantial symptoms and quality of life burden in children and families, yet no validated French version of the Otitis Media-6 (OM-6) questionnaire is available for routine clinical use. This study aimed to translate and cross-culturally validate the OM-6 in Canadian French for caregivers of children with OM.

MATERIAL & METHODS

A prospective validation study was conducted in a pediatric otolaryngology clinic. The OM-6 was professionally translated into French, and bilingual caregivers of children aged 6 months–12 years completed both English and French versions in randomized order. Participants included children with OM and controls presenting for unrelated conditions. Statistical analysis included demographic analysis, Intraclass Correlation Coefficient (ICC), Pearson/Spearman correlation, paired t-test, Wilcoxon signed-rank, Cronbach's alpha and Mann–Whitney U test for discriminant validity.

RESULTS

A total of 152 participants were included in the study (107 OM, 45 controls). The French OM-6 showed strong internal consistency (Cronbach's alpha = 0.87). Agreement between English and French versions was excellent, with item ICCs ranging from 0.78- 0.95 and a total score ICC of 0.93 ($p<0.001$). Only one item, emotional distress, showed a significant difference between language versions, which did not remain significant after Bonferroni correction. The French version successfully discriminates well between OM and control groups ($p<0.001$), and language administration order or questionnaire sequencing effects were detected. The mean English- French total score difference was clinically negligible.

CONCLUSIONS

The Canadian French OM-6 is a reliable and valid patient reported outcome measure for pediatric otitis media. Its successful validation reinforces the value of culturally adapted disease- specific quality of life measures in multilingual otology practice.

Why Is Cholesteatoma More Aggressive In Children?

Abigail Hodgson[2], **Aagat Khatiwada**[1], **Adam Croft**[2], **Ingrid E Dumitriu**[2], **Paramita Baruah**[1,2]

[1]*University Hospitals of Leicester NHS Trust;* [2]*University of Birmingham*

BACKGROUND & AIM

Chronic middle ear disease in children is a significant public health problem in both developed and developing nations. Over half of the patients with COM have hearing impairment, and in children in particular, this has a significant impact on language development and education. Very little is known about why some children with COM develop cholesteatoma. Paediatric cholesteatoma tends to be significantly more aggressive than the adult form of the disease and the reasons for this are not clear. We hypothesise that Paediatric cholesteatoma may have a different inflammatory profile than adult cholesteatoma, which could underlie the clinically different behaviour.

MATERIAL & METHODS

We are analysing the profile of inflammtory and stromal cells (macrophages and fibroblasts) using and bone erosion markers (RANK Ligand) in the peripheral blood (using ELISAs and immuneplex analysis) and in cholesteatoma tissue (using immunohistochemistry) from adult and paediatric patients.

RESULTS

Several inflammatory markers were found to be different in the serum of paediatric patients compared to adult patients on immuneplex of 92 protiens. Analysis of fibroblasts and macrophages in adult and paediatric cholesteatoma using immunohistochemistry is undergoing.

CONCLUSIONS

There is evidence of different inflammatory profile in paediatric cholesteatoma compared to adult disease. This could lead to identification of novel targets to improve outcomes in paediatric cholesteatoma

OP-923

Intracapsular Vs Extracapsular Tonsillectomy In A Tertiary Saudi Pediatric Population: A Retrospective Comparative Cohort Study

Latifah AlMakoshi[2], **Abdullah S. AlDughaither**[1], **Ibrahim AlAbdulkarim**[1]

[1]*College of Medicine, King Saud University, Riyadh, Saudi Arabia;* [2]*Department of Otolaryngology, King Saud University, Riyadh, Saudi Arabia*

BACKGROUND & AIM

Intracapsular tonsillectomy has gained popularity for its favorable recovery profile, yet concerns remain regarding regrowth and revision rates, particularly in pediatric patients with recurrent infections. This study compares outcomes of intracapsular and extracapsular tonsillectomy techniques in a large cohort.

MATERIAL & METHODS

We conducted a retrospective analysis of 1197 pediatric patients who underwent tonsillectomy at King Abdulaziz University Hospital from 2015 to 2024. Patients were categorized by surgical technique—intracapsular or extracapsular—and assessed for rates of primary and secondary hemorrhage, infection, tonsillar regrowth, revision surgery, pain, and recovery time. Statistical comparisons were made using chi-squared and Mann–Whitney U tests.

RESULTS

Intracapsular tonsillectomy was associated with significantly lower rates of primary hemorrhage (0% vs. 4.7%, $p = 0.027$) and secondary hemorrhage (0.8% vs. 5.6%, $p = 0.039$) compared to extracapsular. Pain scores and recovery markers (diet return

and activity resumption) also favored the intracapsular technique. Only three patients in the intracapsular group underwent revision surgery for recurrent symptoms, and all were initially operated on for obstructive sleep apnea (OSA). Importantly, no revision surgeries were required among patients who underwent intracapsular tonsillectomy for recurrent infections. These findings suggest that while regrowth is more common with the intracapsular technique, it is often clinically insignificant, and true recurrence requiring revision is rare and confined to OSA cases.

CONCLUSIONS

Intracapsular tonsillectomy offers a superior safety and recovery profile, with significantly lower rates of postoperative hemorrhage. Although associated with higher regrowth and revision rates, these long-term outcomes remain comparable to short-term post-operative complications of the extracapsular technique. Our findings suggest that recurrent infections should not be considered a contraindication to intracapsular tonsillectomy, as they did not lead to revision in this cohort.

Mechanistic Study Of The SPI1–HMOX1 Axis In Regulating Ferroptosis-Like Metabolic Reprogramming Of M2 Macrophages To Drive Fibrosis In Pediatric Chronic Rhinosinusitis With Nasal Polyps

Jinhao Zhao[1], **Yang Han**[1], **Pengpeng Wang**[1], **Wentong Ge**[1]

[1]*Department of Otorhinolaryngology Head and Neck Surgery,Beijing Children's Hospital, Capital Medical University,National Center for Children's Health*

BACKGROUND & AIM

Pediatric chronic rhinosinusitis with nasal polyps (CRSwNP) is characterized by early onset, high heterogeneity, and severe tissue remodeling, yet its immune-metabolic regulatory mechanisms remain poorly understood. This study aimed to investigate the expression characteristics of the SPI1–HMOX1 axis and its association with ferroptosis-like metabolic reprogramming and tissue remodeling in pediatric CRSwNP.

MATERIAL & METHODS

Nasal polyp (NP), inflamed mucosa (NM), and healthy control (HC) tissues were collected from pediatric subjects. Histopathological changes and mitochondrial ultrastructure were assessed using hematoxylin–eosin staining and transmission electron microscopy. Ferroptosis-related metabolic features were evaluated by measuring 4-HNE, MDA, Fe^{2+}, and GSH levels. Integrated transcriptomic and proteomic analyses were performed to identify key regulatory molecules, followed by validation using ELISA and immunohistochemistry. Single-cell RNA sequencing was conducted to identify the cellular origin and reconstruct transcriptional regulatory networks.

RESULTS

HE staining revealed prominent non-eosinophilic inflammatory infiltration and marked mucosal remodeling in NP tissues. Transmission electron microscopy demonstrated ferroptosis-associated mitochondrial abnormalities, including reduced mitochondrial volume and decreased cristae density. Compared with NM, NP tissues exhibited significantly elevated levels of 4-HNE, MDA, and Fe^{2+}, along with reduced GSH levels. Multi-omics integration identified consistent upregulation of SPI1 at both transcriptomic and proteomic levels, with SPI1 and HMOX1 occupying central positions in protein interaction networks. Single-cell analysis identified $APOE^{+}$/$CCL20^{+}$ M2 macrophages as the primary cellular source of HMOX1. Pseudotime trajectory analysis revealed coordinated upregulation of SPI1 and HMOX1 during macrophage differentiation from M1 to M2 states. Transcriptional regulatory network analysis further demonstrated enhanced SPI1 regulatory activity, with its downstream targets enriched for immune regulatory genes including HMOX1. CellChat analysis indicated enhanced intercellular communication between this macrophage subset and fibroblasts via NAMPT, AREG, and PDGF signaling pathways.

CONCLUSIONS

Pediatric CRSwNP exhibits significant ferroptosis-like metabolic abnormalities. The SPI1–HMOX1 axis is specifically activated in $APOE^{+}$/$CCL20^{+}$ M2 macrophages and may promote tissue remodeling by inducing ferroptosis-like metabolic reprogramming and profibrotic paracrine signaling. These findings provide novel insights into immune-metabolic mechanisms and identify potential therapeutic targets for pediatric CRSwNP.

OP-925

The Usefulness Of Sodium Hypochlorite/Hypochlorous Acid Solutions In Intraoperative And Postoperative Management Of Pediatric Otorhinolaryngological Surgical Procedures

Mohamad A. Bitar[1,2]

[1]*Al Jalila Children's Specialty Hospital, Dubai Health, Dubai, UAE;* [2]*Mohammed Bin Rashid University of Medicine and Health Sciences*

BACKGROUND & AIM

Various solutions have been used in or after Pediatric Otolaryngological surgeries (saline or saline/antibiotic solutions). Sodium hypochlorite/hypochlorous acid solutions (NaClO/HClO) have emerged as a promising alternative.

MATERIAL & METHODS

Children operated on by the author over 3 years at a Children's Tertiary Hospital and had NaClO/HClO used intraoperatively and/or postoperatively were reviewed. The indications for its use intraoperatively were noted, postoperative prescriptions were examined to identify the mode of NaClO/HClO delivery, and postoperative findings during follow-up visits were documented.

RESULTS

The reviewed surgeries included nasal procedures (46 inferior turbinate reduction, nine septoplasty, and six choanal atresia repair, two nasal stenosis, and four endoscopic sinus surgeries), adenotonsillar procedures (279), infective major ear surgeries (21), chronic infections, and hearing device implantation (48). The primary purpose of using it intraoperatively was to clear the nasal passages, providing both disinfection and hemostasis; to clear the nasopharynx of purulent secretions before and after adenotonsillar surgery; to irrigate infected mastoid cavities; and to irrigate the implant and the surgical field before implantation (instead of Wilson solution). The postoperative follow-up showed no significant halitosis in all adenotonsillar patients, clear nasal passages after intranasal surgery, and rapid, smooth healing of the postauricular wound in major ear surgeries.

CONCLUSIONS

Sodium hypochlorite/hypochlorous acid solutions are reliable in disinfecting and clearing the surgical field. Its use postoperatively contributes to a smooth healing process, especially in intranasal surgeries, replacing the need for decongestants and intranasal steroids. Randomized controlled trials would provide a more objective assessment of this observation.

NEBULIZED TRANEXAMIC ACID FOR TREATMENT OF POST-TONSILLECTOMY BLEEDING: A SYSTEMATIC REVIEW AND META-ANALYSIS

MOHAMMAD H SHAHEEN[2], ABDULLAH S ALGHAMDI[1], GHAYDAA S HAZZAZI[2], KHLOOD M BOSAEED[1], RAHMAH H KUTUBKHANA[2], RUBA A ALHARBI[2], AHMED ABU-ZAID[4], ROAA A FELEMBAN[2]

[1]Department of Otorhinolaryngology, Head and Neck Surgery, Al-Hada Armed Forces Hospital, Taif, Saudi Arabia; [2]Department of Otorhinolaryngology, Head and Neck Surgery, Hera General Hospital, Makkah, Saudi Arabia.; [3]Department of Otorhinolaryngology, Head and Neck Surgery, Al-Hada Armed Forces Hospital, Taif, Saudi Arabia; [4]College of Medicine, Alfaisal University, Riyadh, Saudi Arabia.

BACKGROUND & AIM

Purpose: Post-tonsillectomy bleeding (PTB) is a significant complication and common reason for emergency department (ED) visits. Limited literature has investigated the clinical efficacy of nebulized tranexamic acid (TXA) for treating PTB; however, the results were conflicting and not comprehensively summarized. This study aimed to provide the first-ever systematic review encompassing all literature exploring the efficacy and safety of nebulized TXA in treating PTB.

MATERIAL & METHODS

Methods: We screened six databases until 01-July-2024, for relevant studies and assessed their quality using validated tools. We provided a qualitative summary of baseline characteristics and clinical data. The primary endpoint was the reoperation rate to manage PTB, and its effect size was aggregated as a proportion or risk ratio (RR) with a 95% confidence interval (CI) using a random-effects model.

RESULTS

Results: We analyzed nine studies (2 case reports, 4 case series, and 3 retrospective comparative studies), all of which demonstrated good quality and low risk-of-bias. In studies using nebulized TXA for treating PTB (n = 9 studies), the pooled proportion of reoperation to control bleeding was 0.27 (95% CI: 0.08-0.5). The rate of reoperation to control bleeding was significantly lower in the nebulized TXA arm compared to the no-TXA arm (n = 3 studies, RR = 0.55, 95% CI [0.39-0.77], p < 0.001).

CONCLUSIONS

Conclusion: Nebulized TXA is safe and promising for treating PTB. This is evidenced by its high efficacy in achieving hemostasis in acute settings during ED visits and reducing the rate of reoperations needed to control PTB. Further high-quality investigations are warranted to corroborate these findings.

Hemostasis Techniques After Cold Dissection Tonsillectomy: A Prospective Study And Literature Review

Sofia Carvalho[1], **Simão Bessa**[2], **Francisco Sousa**[1], **Mariline Santos**[1], **Ana Silva**[1], **Miguel Coutinho**[1], **João Lino**[1]

[1]*ULS Santo António;* [2]*ULS Tâmega e Sousa*

BACKGROUND & AIM

Tonsillectomy is one of the most commonly performed surgical procedures in the pediatric population. Despite that, postoperative pain continues to represent a considerable source of morbidity. The impact of haemostatic technique on pain outcomes following cold dissection tonsillectomy has yet to be definitively established.

Aim: Compare suture ligation and bipolar diathermy following cold steel tonsillectomy in children on postoperative pain, analgesic consumption, operative time, and complications and literature review

MATERIAL & METHODS

A prospective observational study was conducted including 51 pediatric patients aged 3 to 17 years undergoing cold dissection tonsillectomy. Hemostasis was achieved using either bipolar diathermy or suture ligation. Postoperative throat pain was quantified using a visual analog scale (VAS) on postoperative days 1, 3, and 10. All patients received paracetamol at a dose of 15 mg/kg every 8 hours, and the total number of days during which analgesics were required was recorded as a secondary outcome measure. Operative time was analyzed using a multivariable general linear model with adjustment for surgical procedure type to control for potential confounding.

RESULTS

The suture ligation group reported significantly lower pain scores (p = 0.025) on postoperative day 10. No statistically significant differences in pain scores were identified on postoperative days 1 and 3. The duration of postoperative analgesic intake was significantly shorter in the suture ligation group, median 2.0 days, IQR (1.5–4.5) than in the bipolar group, median 4.0 days, IQR (3.0–7.75), (p = 0.038). After adjustment, operative time did not differ significantly between haemostatic techniques. Postoperative haemorrhage rates were low and comparable across groups.

CONCLUSIONS

Suture ligation and bipolar diathermy provide comparable early postoperative pain outcomes following paediatric tonsillectomy. However, suture ligation was associated with lower late postoperative pain scores and reduced analgesic intakes, without increasing operative time or complication rates and may offer advantages in late postoperative recovery. Few studies have been conducted on the impact of hemostasis techniques after cold dissection tonsillectomy and these findings may be explained by differences in local tissue healing.

Paediatric tonsillectomy, Bipolar diathermy, Suture ligation, Postoperative ain

OP-928

Preoperative Immunonutritional And Inflammatory Indices As Predictors Of Secondary Post-Tonsillectomy Hemorrhage In Children

Halil Elden[1], **Aykan Kandemir**[1], **Hakan Uzun**[1], **Oğuz Kadir Eğilmez**[1]

[1]*Department of Otorhinolaryngology, Sakarya University Faculty of Medicine*

BACKGROUND & AIM

Post-tonsillectomy hemorrhage (PTH) remains a significant cause of morbidity in pediatric patients, with limited reliable preoperative predictors. While inflammatory markers such as the neutrophil-to-lymphocyte ratio (NLR) and systemic immune-inflammation index (SII) have been associated with bleeding risk, they may not fully reflect the patient's physiological reserve. Immunonutritional indices, including the prognostic nutritional index (PNI) and hemoglobin–albumin–lymphocyte–platelet (HALP) score, offer additional insight into nutritional and immune status. This study aimed to evaluate the association between these indices and secondary PTH, and to assess their potential role in preoperative risk stratification.

MATERIAL & METHODS

This retrospective cohort study included 2250 pediatric patients aged 3–17 years who underwent tonsillectomy or adenotonsillectomy between January 2021 and August 2025 at a tertiary referral center. Patients who developed secondary post-tonsillectomy hemorrhage (n = 90) were compared with those without hemorrhage (n = 2160). Preoperative inflammatory indices (systemic immune-inflammation index [SII], neutrophil-to-lymphocyte ratio [NLR], platelet-to-lymphocyte ratio [PLR]) and immunonutritional indices (prognostic nutritional index [PNI], hemoglobin–albumin–lymphocyte–platelet [HALP] score) were analyzed. In patients with hemorrhage, dynamic changes between the day of surgery and the day of bleeding were evaluated. Receiver operating characteristic (ROC) analysis was performed to assess predictive performance.

RESULTS

Secondary post-tonsillectomy hemorrhage occurred in 4.0% (n = 90) of patients. Patients with hemorrhage had significantly higher preoperative inflammatory indices (SII, NLR, PLR) and lower immunonutritional indices (PNI, HALP) compared to those without hemorrhage (p < 0.001). In patients with hemorrhage, inflammatory indices increased significantly on the day of

bleeding, whereas PNI and HALP decreased ($p < 0.001$). ROC analysis demonstrated that PNI (AUC = 0.704) and HALP (AUC = 0.666) had clinically relevant predictive performance. The addition of these indices to clinical variables improved the predictive model (AUC = 0.715).

CONCLUSIONS

Preoperative inflammatory and immunonutritional indices are significantly associated with secondary post-tonsillectomy hemorrhage in pediatric patients. Lower PNI and HALP values, along with higher inflammatory markers, were observed in patients with hemorrhage and showed further deterioration at the time of bleeding. These findings suggest that a combined assessment of inflammatory and immunonutritional parameters may provide a practical and effective approach for perioperative risk stratification. Incorporating these indices into clinical evaluation may help identify high-risk patients and improve postoperative management strategies.

A Modern Volumetric Framework For Managing Pediatric Subperiosteal Abscess

Carlos Khalil[2], **Jennifer M Siu**[2], **Namra Desai**[2], **Emily He**[2], **Pradeep Krishnan**[1], **Nikolaus E Wolter**[2]

[1]*Department of Diagnostic Imaging, Hospital for Sick Children;* [2]*Department of Otolaryngology - Head & Neck Surgery, Hospital for Sick Children;* [3]*Department of Otolaryngology - Head & Neck Surgery, University of Toronto*

BACKGROUND & AIM

Subperiosteal abscess (SPA) is a serious complication of acute rhinosinusitis. Treatment ranges from antibiotics to surgery and decision-making often depends on abscess size, yet current estimates oversimplify complex shapes and fail to incorporate clinical markers or child growth and development. Assessing SPA volume relative to total orbital volume may better reflect severity. With modern imaging enabling precise volumetrics, this study evaluates clinical and radiologic predictors of surgical intervention and develops a predictive scoring tool.

MATERIAL & METHODS

A retrospective review was conducted of children with SPA (2000–2025). SPA volumes were calculated using CT/MRI (ellipsoid method). Using OsiriX MD, SPA/contralateral orbit boundaries were segmented, 3D reconstruction was created with computed volume. Ellipsoid calculated-SPA volume, Osirix SPA volume, and SPA-to-orbit ratios were compared between surgically and medically managed patients. A multivariable predictive model was created to estimate the need for endoscopic sinus surgery (ESS).

RESULTS

Fifty-seven children (3 months–17 years; mean) were included. Mean orbital volume was 18.2 cm^3; mean SPA volume was 2.8 cm^3 by ellipsoid and 1.7 cm^3 by OsiriX. Mean SPA:orbit ratios were 0.12 in ESS patients versus 0.05 in non-ESS patients ($p<0.05$). ROC analysis for SPA:orbit ratio showed an AUC of 0.8. A predictive model incorporating age >11, ellipsoid volume >2.4 cm^3 (2 points), SPA volume:orbit volume ratio (2 points), WBC >16.4 (1 point), and proptosis (1 point) achieved an AUC of 0.89.

CONCLUSIONS

Higher SPA orbital occupancy strongly correlated with need for ESS and may represent a clinically meaningful severity marker. With continued validation, the developed scoring tool may assist in early identification of children requiring surgical management.

OP-930

Endoscopic Percutaneous Repair Of Pediatric Laryngeal Cleft

Xinye Tang[1,2,3,4]

[1]*Department of Otolaryngology, Children's Hospital of Chongqing Medical University, Chongqing, China;* [2]*Ministry of Education Key Laboratory of Child Development and Disorders, Chongqing, China;* [3]*National Clinical Research Center for Child Health and Disorders (Chongqing), Chongqing, China;* [4]*China International Science and Technology Cooperation Base of Child Development and Critical Disorders, Chongqing, China*

BACKGROUND & AIM

To evaluate the safety, feasibility, and therapeutic outcomes of a novel endoscopic percutaneous repair technique for pediatric laryngeal cleft (LC), which not only eliminates the need for open transcervical surgery but also enhances the stability and success rate of endoscopic repair.

MATERIAL & METHODS

A retrospective study was conducted involving 77 consecutive patients with LC who underwent endoscopic percutaneous repair at our tertiary pediatric hospital between February 2021 and July 2025. The surgical technique involves percutaneous

needle-guided suturing through the airway and esophageal walls under endoscopic visualization, enabling secure closure without anterior laryngotracheal incision. Patient demographics, LC classification, associated comorbidities, surgical outcomes, and complications were analyzed. Primary outcome was surgical success defined by negative aspiration on modified barium swallow (MBS) studies at 3-month follow-up. Secondary outcomes included revision surgery rates, complication rates, and symptom resolution.

RESULTS

The cohort included 77 patients (male:female ratio 1.66:1) with type I (n=53, 68.8%), type II (n=14, 18.2%), and type III (n=10, 13.0%) LC. Associated comorbidities included tracheomalacia, laryngomalacia, subglottic stenosis, gastroesophageal reflux disease, and congenital heart disease. Of the 77 patients, 74 (96.1%) achieved successful repair with primary endoscopic percutaneous procedure. Among 3 treatment failures, 2 patients (2.6%) required conversion to open transcervical repair due to repair failure, while 1 patient (1.3%) underwent successful revision using the same technique. Overall success rate after revision was 97.4% (75/77). No major surgical complications occurred, including recurrent laryngeal nerve injury, neck infection, or pharyngocutaneous fistula. Follow-up MBS demonstrated complete resolution of aspiration in 75 patients (97.4%). Complete symptom resolution was achieved in 75 patients (97.4%), with significant improvement in feeding difficulties, recurrent pneumonia, and respiratory symptoms.

CONCLUSIONS

Endoscopic percutaneous repair represents a paradigm shift in the surgical management of pediatric LC, offering a minimally invasive alternative to traditional open transcervical approaches. This novel technique achieves excellent success rates (97.4%) across all LC types with zero major complications, while avoiding the potential risks associated with anterior laryngotracheal incision including airway framework instability and need for tracheostomy. The technique demonstrates particular advantages for type III LC, where traditional endoscopic approaches often fail due to limited working space. These findings establish endoscopic percutaneous repair as a safe, effective, and preferred first-line surgical option for pediatric LC management.

Nasal Airway Growth Patterns And Surgical Readiness In Pediatric Craniosynostosis: Insights From A Morphometric Analysis

Ben Levy[1], **Dalal Mahir**[1], **Lala Su**[1], **Jennifer M Siu**[1], **Evan J Propst**[1], **Helen Branson**[2], **Nikolaus E Wolter**[1]

[1]*Department of Otolaryngology - Head and Neck Surgery, Hospital for Sick Children;* [2]*Department of Diagnostic Imaging, Hospital for Sick Children;* [3]*Department of Otolaryngology - Head and Neck Surgery, Hospital for Sick Children;* [4]*Department of Diagnostic Imaging, Hospital for Sick Children*

BACKGROUND & AIM

Children with craniosynostosis commonly develop critical nasal airway obstruction and may tracheostomy for airway support. This study examined nasal airway morphology in syndromic craniosynostosis to evaluate longitudinal airway development and the feasibility of endoscopic intervention.

MATERIAL & METHODS

A retrospective matched case-control study (2000–2025) was completedin children with Apert or Crouzon syndrome and ≥2 CT scans. Cases were age- and sex-matched to non-syndromic controls. Prior nasal or midface surgery was excluded. Standardized morphometric measurements (>20 distinct parameters) were obtained by 2 researchers across 3 imaging planes. Feasibility of skull base reconstruction was assessed using a nasoseptal flap (NSF):sellar defect length ratio.

RESULTS

164 scans from 58 patients were analyzed. 59% had OSA, 31% were PAP-dependent, and 5% had a tracheostomy. Apert patients (n=31, median age 11 mo) demonstrated significantly narrower pyriform apertures (-3.8 mm, $p<0.01$) and choanae (-4.3 mm, $p<0.01$) versus controls. Crouzon patients (n=27, median age 41 mo) showed similar reductions (-2.6 mm and -4.7 mm respectively, $p<0.01$) across all age groups. Among 30 fully pneumatized scans, 93% had a nasoseptal flap:sellar defect ratio >1 (mean 1.8, SD=0.6), indicating feasible NSF reconstruction in most patients ≥3 years old.

CONCLUSIONS

We present the comprehensive morphometric nasal analysis of children with craniosynostosis to date. Apert and Crouzon syndromes show persistent nasal airway restrictions, supporting anatomical over age-based criteria for endoscopic intervention. NSF analysis suggests skull base reconstruction becomes feasible at ≥3 years. These results provide a foundation for predictive airway growth modeling to inform early surgical planning.

Improvement In Quality Of Life And Sleep Apnea After Turbinate Reduction In Children With Refractory Allergic Rhinitis

Jad Hosri[1], **Jonathan Abou Chaar**[1], **Justin Ghadieh**[1], **Anne Marie Daou**[1], **Patrick Abou Raji Feghali**[1], **Zeina Korban**[1], **Randa Barazi**[1]

[1]*Department of Otolaryngology – Head and Neck Surgery, American University of Beirut Medical Center, Beirut, Lebanon*

BACKGROUND & AIM

Refractory allergic rhinitis can cause a significant impact on the quality of life of children. Treatment with surgery is associated with high rates of decreased daily medication use and minimal postoperative risk. However, data is scarce regarding the impact of surgery on the quality of life and sleep apnea outcomes in children with refractory allergic rhinitis. The aim of this study is to determine the impact of surgery on the quality of life and sleep apnea outcomes in children with refractory allergic rhinitis.

MATERIAL & METHODS

This is a prospective cohort pilot study in which children aged 5-17 years with a documented allergic rhinitis refractory to 3 months of medical therapy, were recruited. The study group consisted of children who underwent surgery and the control group included children who remained on medical therapy. Three questionnaires pertaining to the sinus and nasal quality of life (SN-5), obstructive sleep apnea symptoms (OSA-18), and nasal obstruction symptom evaluation (NOSE) were collected before and after intervention at 1 and 3 months. Flexible endoscopic findings of disease regression before and after intervention were also mentioned.

RESULTS

Thirty-four subjects were recruited, 17 of whom underwent surgery and 17 who received medical therapy. At 1 month follow-up, the mean drop in the questionnaires' scores (SN-5; OSA-18; NOSE) was greater in the study group (9.9±5.8; 23.2±9.8, 8.2±3.8, respectively) compared to the control group (6.8±3.9, 17.3±7.1, 4.6±2.8, respectively). The difference in symptoms improvement between the two groups was a statistically significant in all three questionnaires ($p=0.029$; $p=0.037$; $p=0.005$; respectively). Similar results were obtained at 3 months follow-up. Almost all patients in the surgery group (88.2%) had complete disease regression in comparison to only 29.4% in the control group ($p<0.001$).

CONCLUSIONS

Introducing surgery to children with refractory allergic rhinitis can significantly improve the patient's quality of life and sleep apnea symptoms.

OP-933

Safety Protocol And Animated Education For Parental Presence In Pediatric ENT Surgery Induction

IRENE LÓPEZ-DELGADO[1]

[1]*HOSPITAL QUIRONSALUD VALENCIA*

BACKGROUND & AIM

Parental presence during pediatric anesthesia induction is increasingly used to reduce anxiety in children undergoing otolaryngology (ENT) procedures. However, when performed without structured protocols, it may introduce safety risks for both patients and accompanying adults.

We hypothesized that implementing a standardized safety protocol combined with an animated educational video would improve safety conditions and communication with families in pediatric ENT surgical settings.

MATERIAL & METHODS

Following an intraoperative incident involving parental syncope during anesthesia induction for pediatric ENT surgery, a multidisciplinary team (anesthesiology, otolaryngology, nursing, and hospital management) developed a structured protocol.

The protocol includes: eligibility criteria, informed consent with safety screening, defined staff roles, and a structured evacuation pathway adapted to the surgical environment.

Additionally, an animated educational video was created to provide clear preoperative information for families regarding the ENT surgical process, expected behavior, and safety measures.

The intervention has been implemented in a private hospital environment as part of a quality and safety improvement strategy in pediatric ENT surgery.

RESULTS

The protocol enabled standardization of clinical practice and defined clear safety conditions for parental presence during induction in pediatric ENT surgery.

The animated video provided a structured tool for patient and family education, facilitating consistent communication prior to ENT procedures.

The combined intervention supports improved organization of care and reinforces a safety-oriented approach in clinical practice.

CONCLUSIONS

The implementation of a structured safety protocol together with targeted audiovisual education represents a feasible strategy to safely integrate parental presence during anesthesia induction in pediatric ENT surgery.

This model aligns patient-centered care with safety principles and may be applicable to other otolaryngology units.

Microlaryngobronchoscopy (MLB) In Recurrent Croup: Is It Always Necessary? A Tertiary Centre Experience And Literature Review

Mohamed Elsharkawy[1], **Shilpa Ojha**[1]

[1]*Imperial College Healthcare NHS Trust*

BACKGROUND & AIM

Recurrent croup in children presents a diagnostic challenge and often prompts airway evaluation with microlaryngobronchoscopy (MLB)1. The diagnostic yield of this procedure, particularly in children without persistent symptoms or red flags, remains unclear, and no consensus exists on the optimal threshold for proceeding to MLB3,5,6.

Aim: To evaluate the diagnostic utility of elective MLB in children with recurrent croup at a tertiary paediatric ENT centre and contextualise findings against published literature.

MATERIAL & METHODS

Retrospective review of consecutive children undergoing elective MLB for recurrent croup at Imperial College Healthcare NHS Trust from January 2023 to June 2025. Inclusion: ≥3 documented croup episodes, referral for airway evaluation, and no known pre-existing airway anomaly. Data: episodes/severity, red flags, MLB findings, and subsequent management.

RESULTS

Fifteen children met criteria. Two had clinically relevant findings: (i) one Grade I subglottic stenosis (SGS); (ii) one supraglottic laryngomalacia (tight aryepiglottic folds, omega epiglottis, mild posterior collapse); The remaining 13/15 MLBs were normal; no intraoperative interventions were required; all were managed conservatively.

Our local yield for surgically significant pathology in elective MLB for typical recurrent croup was low (13%), aligning with a systematic review/meta-analysis reporting 8.7% clinically significant bronchoscopy findings overall; the three most common findings were SGS, reflux changes, and broncho/tracheomalacia [1]. Other series report higher abnormal-finding rates and specific SGS proportions (e.g., SGS ~9% in a UK 10-year cohort and ~21% SGS in a single-centre endoscopic series), underscoring population- and selection-bias effects [4,5]. Collectively, these data support selective endoscopy: prioritise MLB when red flags persist (stridor between episodes, poor response to standard therapy, atypical course, history of intubation/prematurity, growth concerns) and consider conservative management otherwise [2–4].

CONCLUSIONS

Across January 2023–June 2025 at our centre, elective MLB for recurrent croup without red flags rarely altered management; most MLBs were normal and no procedures were performed. Our findings, together with contemporary evidence, support targeted MLB reserved for children with high-risk features or persistent/atypical symptoms.

OP-935

Evaluation Of Family History And Related Environmental Factors In Children Undergoing Ventilation Tube Insertion Due To Otitis Media With Effusion

Dilara Tütüncü Yavuz[1], **Alper Kaan Baran**[1], **Suat Turgut**[1]

[1]*University of Health Sciences, Sisli Hamidiye Etfal Research and Training Hospital, Department of Otolaryngology & Head and Neck Surgery, Turkey.*

BACKGROUND & AIM

Otitis media with effusion (OME) is a prevalent childhood middle ear condition that frequently necessitates ventilation tube (VT) insertion. Although familial predisposition to middle ear disease has been recognised, the role of this in surgically treated cases and its relationship to environmental factors has not been sufficiently investigated. The aim of this study was to assess the frequency of family history of middle ear disease and its association with environmental factors in children who underwent VT insertion.

MATERIAL & METHODS

This retrospective observational study was conducted at a single center. Children under 18 years of age who underwent VT insertion due to OME were included. Demographic and clinical data were retrieved from hospital records; missing data were supplemented through telephone interviews with caregivers, covering family history, environmental exposures, and coexisting conditions. The primary outcome was the presence of a positive family history.

RESULTS

A total of 53 patients were included. A positive family history was identified in 33 patients (62.3%); 17 (32.1%) had a family history of recurrent ear infections and 16 (30.2%) had a family history of ear surgery. Middle ear disease was reported in mothers (24.5%), fathers (28.3%), and siblings (28.3%). Parental nasal problems were present in 45.3% and cigarette smoke exposure in 60.4% of cases. Asthma and/or allergic rhinitis was noted in 50.9% of children, and 24.5% had undergone two or more prior VT insertions.

CONCLUSIONS

The high prevalence of positive family history suggests a significant familial predisposition to OME in surgically managed children. Elevated cigarette smoke exposure and upper airway comorbidities further highlight the role of environmental factors. These findings emphasize the multifactorial nature of OME and warrant further prospective studies investigating gene-environment interactions in this population.

OP-936

" EARLY DIAGNOSIS AND TREATMENT OF HEARING LOSS IN CHILDREN IN ALBANIA. OUR EXPERIENCE SO FAR"

SUELA SALLAVACI[1], **GENTIAN STRONI**[1]

[1]*UNIVERSITY HOSPITAL CENTRE MOTHER TERESA, TIRANA*

BACKGROUND & AIM

Hearing impairment (HI) is the inability to perceive and understand acoustic stimulus. HI is a result of physiological changes within the human hearing system. Consequences of hearing impairment are: a decrease in auditory stimulus sensitivity (attenuating factor) or disorder of auditory stimulus perception characteristics (distortion factor).

MATERIAL & METHODS

PURPOSE OF THE STUDY

This study aims is to assess: the hearing acquisition among patients undergoing Cochlear implantation and improvement in perceptual and communicative skills.

METHODOLOGY

Patients who underwent the intervention were selected by a working group consisting of physicians, speech therapists and engineers. Due to the Pandemic the first interventions could be realized in September 2020.

RESULTS

So far 43 patients have been implanted. Mean age is 3.89 years old. The standard deviation is 4.94. The minimal age is 2.3 years old and the maximal age: 22.1 years old.

Almost all implanted children have benefited significantly in terms of hearing: only in one child we still do not see a reaction (the child has not been taught by the parents to keep the implant all day).

Most children benefited from speech therapy. The results of our study demonstrate a significant improvement in the perception and communication of the vast majority of children as a result of intervention with a speech therapist (5.3% satisfactory, 21.1% good and 15.8% very good).

CONCLUSIONS

The children who benefited the most in terms of hearing and significant improvement of perception and communication were those who, in addition to Cochlear Implantation, underwent speech therapy education and continue to wear a hearing aid in the other ear. This proves once again the importance of binaural prosthesis or implantation.

OP-937

Comparative Outcomes Of Mucosa-Preserving One-Step Supraglottoplasty (OST) Vs. Conventional Technique

Muataz Alhashem[1], **Hamdy El-Hakim**[1]

[1]*Division of Pediatric Surgery, Department of Surgery, University of Alberta, Edmonton, AB, Canada*

BACKGROUND & AIM

Supraglottoplasty (SGP) is the established surgical treatment for severe laryngomalacia (LM); however, existing descriptions lack anatomical precision, impeding standardization and surgical teaching, and are associated with variable rates of postoperative swallowing dysfunction and revision surgery. We describe the mucosa-preserving one-step supraglottoplasty (OST), a refined modification grounded in the cartilaginous theory of LM that targets the cuneiform cartilages directly, preserves the overlying mucosa as wound cover, and avoids aryepiglottic fold transection to protect the sensory branches of the superior laryngeal nerve.

MATERIAL & METHODS

A retrospective cohort study was conducted at the Stollery Children's Hospital, reviewing all pediatric SGP cases performed by a single surgeon between December 2013 and June 2025. Patients with neurological or syndromic comorbidities were excluded. Patients were allocated by operative technique: OST or conventional SGP. Primary outcomes were overnight sleep oximetry indices and instrumental swallowing assessment (FEES and VFSS) at baseline and last follow-up. Secondary outcomes included revision surgery rate, residual symptoms, and operative duration. Mann-Whitney U and Chi-square tests were used as appropriate.

RESULTS

107 procedures were included: 62 conventional and 45 OST. Groups were comparable at baseline in age, sex, and LM subtype. Follow-up was significantly shorter in the OST group (0.46 vs 0.71 years, p=0.002). Both groups demonstrated significant improvement in desaturation index, nadir SaO_2, and McGill score (p<0.001), with no significant between-group difference at follow-up. The OST group demonstrated significant overall swallowing improvement (OR 87, p=0.001), while the conventional group did not (OR 2.37, p=0.145). Revision rates (4.4% vs 11.3%, p=0.297) and residual symptoms (15.6% vs 21.0%, p=0.478) were comparable, with numbers consistently favouring the OST.

CONCLUSIONS

The OST is a reproducible, anatomically precise modification of SGP that achieves comparable airway outcomes and significant swallowing improvement. It additionally allows concomitant laryngeal cleft repair in the same sitting. Its precise description allows standardization and may facilitate structured surgical training. These preliminary results support prospective validation with a larger cohort.

Investigation Of DNA Damage, Inflammation, And Oxidative Stress In Chronic Tonsillitis

Batuhan Pişet[1], **Semra Külekçi Öztürk**[1], **Eray Metin Güler**[2], **Seyit Mehmet Ceylan**[3]

[1]*University of Health Sciences, Fatih Sultan Mehmet Training and Research Hospital, Istanbul;* [2]*University of Health Sciences, Hamidiye Faculty of Medicine, Biochemistry, Istanbul;* [3]*Memorial Şişli Hospital, Istanbul*

BACKGROUND & AIM

This study aims to determine oxidative stress, antioxidant capacity, and inflammatory response in chronic tonsillitis and tonsillar hypertrophy, and to evaluate their genomic effects through DNA damage/repair mechanisms.

MATERIAL & METHODS

In this prospective study, patients aged 3-14 years who underwent adenotonsillectomy at Fatih Sultan Mehmet Training and Research Hospital were divided into chronic tonsillitis and hypertrophic tonsils groups. Clinical and demographic data, including age, sex, and tonsil size, were recorded.

Serum and tissue samples were analyzed for oxidative/antioxidant stress products, cytokines, and DNA damage/repair markers. Samples were stored at -80°C for ELISA/biochemical analyses and at -20°C for gene expression analysis.

Following tissue homogenization, total protein was determined via the Bradford method. Serum TOS, TAS, thiol-disulfide homeostasis, and IMA levels were measured colorimetrically, and the OSI was calculated. Cytokines (IL-1β, IL-6, TNF-α, TGF-β1, HIF-1α) and 8-OHdG levels were measured using commercial ELISA kits. For genomic analysis, RNA was isolated to determine APEX1 and ERCC5 mRNA expression levels via qRT-PCR.

Statistical analyses were performed using independent samples t-test, Mann-Whitney U, chi-square, Fisher's exact, and Pearson/Spearman correlation tests.

RESULTS

This prospective study included 47 patients, with 21 in the chronic tonsillitis group and 26 in the hypertrophic tonsil group. Most cases (74%) presented with stage 2 or 3 tonsils. No significant differences in age or sex were found (p>0.05).

In the chronic tonsillitis group, serum genomic panels correlated with TOS and TGF-β1 (p<0.001). Tissue analysis showed correlations between IL-1β and 8-OHdG, ERCC5, and APEX1. IMA strongly related to 8-OHdG, and HIF-1α positively correlated with serum APEX1.

In the hypertrophic tonsil group, serum TOS correlated with APEX1 and ERCC5, while TNF-α and TGF-β1 correlated with ERCC5. Tissue TOS and OSI correlated positively with ERCC5, whereas IL-6 and TNF-α correlated negatively with APEX1. IMA was associated with ERCC5, and tissue HIF-1α correlated negatively with APEX1.

Comparatively, serum and tissue levels of all analyzed parameters (TOS, OSI, cytokines, IMA, 8-OHdG, APEX1, ERCC5) were significantly higher in the chronic tonsillitis group ($p<0.001$).

CONCLUSIONS

Chronic tonsillitis appears to involve the co-activation of oxidative stress, inflammation, hypoxia-associated response, and DNA damage/repair mechanisms. Furthermore, the activation of both the APEX1 and ERCC5 pathways can be linked to genomic stress. This suggests that an integrated mechanism, which may be defined as the "oxidative-inflammatory-genomic stress axis," could play a key role in the pathogenesis of this disease.

OP-939

Inside The Airway Surgeon's Mind: Decision-Making Strategies In Pediatric Posterior Glottic Stenosis

Sinan Ghavami, MD[1], **Kishore Sandu, MD**[1]

[1]*Department of Otorhinolaryngology, Head and Neck Surgery, Lausanne University Medical Center (CHUV), Lausanne, Switzerland.*

BACKGROUND & AIM

Posterior glottic stenosis (PGS) is a rare condition that causes upper airway obstruction. It is characterized by fibrosis of the posterior commissure and impaired vocal fold abduction.

This study aimed to evaluate the influence of the extent of airway disease in the posterior glottis on surgical strategy in order to achieve optimal airway and functional outcomes.

MATERIAL & METHODS

A retrospective, single-center cohort study was conducted including 63 children who underwent surgery for PGS. Patients were divided into two groups: isolated PGS (n = 22) and multilevel airway obstruction involving the posterior glottis (n = 41). We analyzed demographics, surgical approaches, additional endoscopic procedures, complications, time to decannulation, and the need for push-down tracheostomy. Functional outcomes were assessed using a parental questionnaire grading voice, swallowing, and breathing. Postoperative airway size was also analyzed

RESULTS

Patients with multilevel obstruction were significantly younger at the time of surgery (mean age: 4.5 years vs. 8.5 years; p = 0.0175) and were more likely to be tracheostomy-dependent preoperatively (90.5% vs. 33%).

Multilevel obstruction required more complex surgery, including double-stage reconstruction (90% vs. 36%; p = 0.0026), extended CTR (48% vs. 0%; p = 0.0118), and laryngeal mold placement (90% vs. 40%; p = 0.0059). The median time to decannulation was longer in patients with multilevel disease (115.5 vs. 79 days). Voice outcomes were comparable between the two groups. Despite more complex surgery and delayed decannulation in multilevel disease, long-term breathing outcomes were comparable. Postoperative airways were age appropriate in both groups. However, swallowing function was significantly worse in the multilevel disease group

CONCLUSIONS

Multilevel airway obstruction associated with PGS represents a more severe phenotype requiring greater surgical complexity and longer time to decannulation. Although final respiratory outcomes were comparable, multilevel disease significantly impaired swallowing. These findings highlight the importance of comprehensive airway assessment and tailored decision-making in pediatric PGS

posterior glottic stenosis; pediatric airway reconstruction; multilevel airway obstruction; functional outcomes

OP-940

Hearing Loss In Children: Otitis Media With Effusion And The Impact Of Modern Technology

Rexhina RAMA[1]

[1]*Polyclinic of Specialities no. 2, Tirana, Albania*

BACKGROUND & AIM

Background: Hearing loss in childhood is a frequent condition that may negatively affect speech development, learning abilities, and social interaction. The most common type of hearing impairment in young children is conductive hearing loss, mainly caused by otitis media with effusion (OME). In recent years, the increasing use of modern technology, including smartphones, tablets, and personal audio devices, has raised concerns about its potential impact on pediatric hearing health.

Aim: To review the literature regarding the prevalence and types of hearing loss in children, with particular emphasis on otitis media with effusion and the influence of modern technology use.

MATERIAL & METHODS

A narrative review of international literature was conducted, including epidemiological studies, clinical reports, and systematic reviews on pediatric hearing loss. The findings were analyzed in the context of a pediatric population of approximately 500 children aged 4–7 years attending public kindergartens.

RESULTS

The literature indicates that conductive hearing loss is the most common form of hearing impairment in children, predominantly associated with OME. OME affects approximately 20–30% of preschool children, with a peak incidence between 4-6 years of age. Hearing loss related to OME is usually bilateral and mild to moderate, ranging from 20 to 40 dB, and may persist for several months if untreated. Up to 80% of children experience at least one episode of OME before school age.

Sensorineural hearing loss is less frequent, with an estimated prevalence of 1–3 per 1,000 live births, but represents the majority of permanent hearing loss cases in childhood. Recent studies report that over 90% of children aged 4–7 years are regularly exposed to digital devices, with an average daily screen time of 4–6 hours. Prolonged exposure to high sound levels through headphones has been associated with auditory fatigue and potential early cochlear damage.

CONCLUSIONS

Hearing loss in children is predominantly conductive and potentially reversible, with otitis media with effusion as the leading cause. However, excessive use of modern technology may represent an emerging risk factor for early auditory impairment. Early screening, appropriate management of OME, and parental education on safe technology use are essential to prevent long-term consequences.

Safety Of Concomitant Tympanostomy Tube Placement During Pediatric Adenotonsillectomy: A Retrospective Cohort Study

RUKİYE ERDEM ÖZÇELİK[1], **ERDEM BAYRAKÇI**[1], **YUNUS EMRE ORUÇ**[1], **MEHMET AKİF DÜNDAR**[1], **MİTAT ARICIGİL**[1], **MEHMET AKİF ERYILMAZ**[1], **HAMDİ ARBAĞ**[1]

[1]*Necmettin Erbakan University*

BACKGROUND & AIM

To evaluate whether concomitant paracentesis and/or tympanostomy tube placement increases early postoperative morbidity in pediatric patients undergoing adenotonsillectomy, and to identify factors associated with early complications.

MATERIAL & METHODS

This retrospective cohort study included pediatric patients (<18 years) who underwent adenotonsillectomy between January 2015 and December 2025 at a tertiary referral center. Patients were grouped according to whether concomitant ear procedures were performed. The primary outcome was early postoperative morbidity, defined as a composite of postoperative hemorrhage, hematemesis, impaired oral intake, respiratory distress, cough, or adhesion formation. Continuous variables were compared using the Mann–Whitney U test and categorical variables using the chi-square test. Univariable and multivariable logistic regression analyses were performed to identify independent predictors. Subgroup analysis was conducted for patients aged ≤2 years.

RESULTS

A total of 1309 patients were included, of whom 388 (29.6%) underwent concomitant ear procedures. Patients in the ear procedure group were younger and had longer operative times (both $p < 0.001$). The overall complication rate was 3.5%. Composite complications did not differ between patients with and without concomitant ear procedures (4.1% vs. 3.3%, $p = 0.439$). In multivariable analysis, concomitant ear procedures were not associated with increased complications (OR 1.26, 95% CI 0.66–2.41, $p = 0.477$), and no independent predictors were identified. Subgroup analysis demonstrated a significantly higher complication rate in children aged ≤2 years compared to older patients (8.1% vs. 3.1%, $p = 0.010$).

CONCLUSIONS

Concomitant paracentesis and/or tympanostomy tube placement does not increase early postoperative morbidity in pediatric adenotonsillectomy. Younger age, particularly ≤2 years, appears to be a more relevant factor influencing postoperative risk than the addition of ear procedures.

Outcomes Of Pediatric Tracheostomy In A Tertiary Referral Center: A Single-Center Study

Burak Kersin[1], **Koray İşlek**[1], **Gülşah Acar Yüceant**[1], **Ayşe Aslı Şahin Yılmaz**[1]

[1]*Kartal Dr. Lütfi Kırdar City Hospital*

BACKGROUND & AIM

Pediatric tracheostomy is a critical intervention for children requiring prolonged airway support but is associated with substantial morbidity and high mortality largely driven by underlying disease severity. Heterogeneity in complication definitions and timing has limited outcome interpretation across studies. This study aimed to evaluate clinical outcomes, complication patterns, and mortality determinants in pediatric tracheostomy patients using an event-specific timing approach distinguishing cannula-related and non–cannula-related complications.

MATERIAL & METHODS

This retrospective single-center cohort included all pediatric patients (<18 years) who underwent tracheostomy between January 2015 and December 2025. Demographics, comorbidities, tracheostomy indications, perioperative ventilation, cannula characteristics, complication profiles, decannulation outcomes, and mortality were analyzed. Complications were categorized as cannula-related or non–cannula-related and classified as early (≤14 days) or late (>14 days). Associations between clinical variables, complications, decannulation, and mortality were evaluated using univariable and multivariable analyses.

RESULTS

A total of 53 patients were included (median age 6.0 years); neurologic disease was the predominant comorbidity (77.4%). Overall mortality was 53.0%, with no deaths directly attributable to tracheostomy. At least one complication occurred in 58.5% of patients. Cannula-related complications occurred predominantly early, whereas non–cannula-related complications developed later (p≈0.002). Older age was associated with complication development (p=0.007), while younger age was associated with mortality (p=0.001); early deaths may have precluded late complications. Preoperative intubation duration correlated positively with hospital length of stay (r≈0.40, p=0.003), and prolonged hospitalization showed a borderline association with mortality (p=0.084). Hydrocephalus was associated with increased mortality (OR≈5.45, p=0.043), whereas cerebral palsy was associated with lower mortality (p=0.021). Metabolic disease independently predicted mortality (univariable OR=7.44, p=0.011; adjusted OR=7.66, p=0.030). Successful decannulation occurred in three patients (5.66%); none requiring multiple cannula changes were decannulated, precluding meaningful statistical inference.

CONCLUSIONS

Pediatric tracheostomy is associated with high morbidity and mortality primarily determined by underlying disease severity. Mechanical stability and cannula management complexity influence morbidity and decannulation outcomes, whereas younger age and metabolic disease independently predict mortality. These findings support longitudinal, phase-adapted, multidisciplinary care strategies to optimize outcomes in pediatric tracheostomy patients.

OP-943

Short- And Long-Term Clinical Outcomes Of Tonsillectomy Versus Tonsillotomy In Pediatric Obstructive Sleep-Disordered Breathing

Ata Alperen Ersahan[1], **Damla Saygin Gurbuz**[1], **Buse Ugur**[1], **Murat Ozturk**[1]

[1]*Department of Otolaryngology–Head and Neck Surgery, Kocaeli University Faculty of Medicine, Kocaeli, Türkiye*

BACKGROUND & AIM

Obstructive sleep-disordered breathing (OSDB) is a common indication for pediatric tonsillar surgery. Although tonsillectomy (TE) provides complete tonsillar removal, tonsillotomy (TT) is increasingly used because of lower postoperative morbidity. However, concerns remain regarding long-term recurrence of obstructive symptoms. We aimed to compare early morbidity and long-term outcomes between children undergoing TE and TT for OSDB.

MATERIAL & METHODS

This retrospective cohort study included patients younger than 18 years who underwent TE or TT for OSDB at the Department of Otolaryngology, Kocaeli University Faculty of Medicine, between January 2019 and March 2025. Patients with at least 12 months of postoperative follow-up were eligible. Demographic data, atopic comorbidities, surgical technique, duration of postoperative analgesic requirement, complications, length of postoperative hospitalization, readmission after discharge, and late symptoms were reviewed. Complications were analyzed overall and separately as bleeding, limited oral intake, and other complications. Long-term outcomes included recurrent snoring, postoperative apnea, sleeping with an open mouth, and recurrent obstructive symptoms. Statistical analyses were performed using IBM Statistical Package for the Social Sciences (SPSS) version 29.0; p<0.05 was considered significant.

RESULTS

A total of 363 patients were included; 299 (82.4%) underwent TE and 64 (17.6%) underwent TT. Overall complications were more frequent after TE than TT (20.4% vs. 7.8%, p=0.028), although separate analysis of bleeding, limited oral intake, and other complications showed no significant difference. Duration of postoperative analgesic requirement (p<0.001) and length of postoperative hospitalization (p=0.023) were longer in the TE group. Readmission after discharge did not differ. Postoperative snoring was more frequent after TT than TE (21.9% vs. 10.4%, p=0.043), while postoperative apnea and sleeping with an open mouth did not differ. Revision surgery was required in 3 of 64 TT patients (4.7%).

CONCLUSIONS

TE was associated with higher early postoperative morbidity, including longer analgesic requirement, longer hospitalization, and higher overall complication rates. TT showed more favorable early outcomes but higher long-term postoperative snoring. These findings may guide surgical planning and family counseling regarding the benefits and potential long-term risks of each procedure in children with OSDB.

OP-944

Retrograde Cricopharyngeal Dysfunction In Pediatric Patients: Recognition And Management Across The Age Spectrum

Maha Alsomali , MD[1], **Marshall Smith, MD**[1]

[1]*Primary Children's hospital, University of Utah*

BACKGROUND & AIM

Retropulsive cricopharyngeal dysfunction (RCPD) is a recently recognized clinical condition characterized by inability to burp, abdominal bloating, chest discomfort, throat gurgling, nausea, and significant quality-of-life impairment. While increasingly described in adults, pediatric data remain limited, and diagnosis is frequently delayed because symptoms overlap with common gastrointestinal complaints. We hypothesized that pediatric patients with RCPD experience delayed recognition, extensive gastrointestinal workup, and variable treatment outcomes, with differences across age groups.

MATERIAL & METHODS

A retrospective case series was performed at a single tertiary pediatric otolaryngology institution between 2021 and 2025. Pediatric patients diagnosed with RCPD were included. Demographics, presenting symptoms, referral patterns, prior gastrointestinal evaluation, esophageal manometry findings, treatment details, and outcomes were reviewed. Patients were categorized into two age groups based on median age at first surgery: <16 years and 16–18 years. Treatment consisted primarily of botulinum toxin injection to the cricopharyngeus muscle. Improvement was defined as any symptom relief; complete resolution as full symptom resolution; recurrence as return of symptoms after initial improvement requiring repeat intervention or documented clinical recurrence. Descriptive statistics were performed using SPSS version 25.

RESULTS

Twenty-seven patients were included (59.3% female), with a mean age at first surgery of 14.9 ± 3.0 years. All patients reported inability to burp (100%), with abdominal bloating in 96.3%, throat gurgling in 74.1%, nausea in 63.0%, and chest pain in 40.7%. Symptom onset occurred before age 6 years in 81.5% of patients. Most referrals originated from pediatric gastroenterology (59.3%), and 77.8% had prior gastroenterology consultation. Esophagogastroduodenoscopy was performed in 70.4%, most commonly with normal findings (44.4%). Botulinum toxin injection resulted in symptom improvement in all patients (100%). Complete resolution occurred in 37.0%, while 63.0% had partial improvement. Recurrence occurred in 22.2%, with a mean of 1.33 treatments per patient. Younger patients (<16 years) demonstrated higher recurrence rates (35.7% vs 7.7%) and lower complete resolution rates (28.6% vs 46.2%) compared with older adolescents.

CONCLUSIONS

Pediatric RCPD is frequently underrecognized despite early symptom onset and often leads to extensive gastrointestinal evaluation before diagnosis. Botulinum toxin injection provides universal symptomatic improvement, although complete resolution is less common and younger children may experience higher recurrence rates. Greater awareness of RCPD among pediatric providers may facilitate earlier diagnosis, reduce unnecessary workup, and improve patient outcomes.

Acute Mastoiditis In Western Norway- A 25 Year Retrospective Analysis

Jeanette Hess-Erga[1], **Ingvild Engesæter**[1], **Gro Dyrhovden**[1], **Ruben Dyrhovden**[1], **Frederik Goplen**[1], **Kathrin Skorpa Nilsen**[1], **Jan Erik Berge**[1]

[1]*Haukeland University Hospital, Bergen, Norway*

BACKGROUND & AIM

The aim of this study was to retrospectively analyse the incidence, diagnostic findings, clinical course, treatment strategies, microbiology and outcomes in consecutive patients treated in our clinic over a 25-year period.

MATERIAL & METHODS

We conducted a retrospective chart review of paediatric patients diagnosed with mastoiditis in Haukeland University Hospital from 01.01.2000 to 31.12.2024. For the micorbiology analysis, year 2025 is also included. Data on presenting symptoms, clinical history, CT findings, surgical procedures, micobiology results and complications were recorded.

RESULTS

A total of 143 cases met the inclusion criteria, corresponding to an annual incidence of 1.3 per 100,000 in the Bergen region. Acute mastoiditis was most frequent in children under two years of age, with a median age of 1.8 years. Patients with intracranial complications had higher C-reactive protein (CRP) levels at admission compared to those without. All CT scans that indicated the presence of an abscess were confirmed intraoperatively. Streptococcus pneumonia was the most common patogen, even after introduction of pneumococcal vaccine. Collecting puss on a sterile glass had a higher positivity rate than e-swab.

CONCLUSIONS

The key finding of this study is the association between elevated CRP levels and intracranial complications. Streptococcus pneumonia was the most common pathogen and collecting pus in a sterile glass had a higher positivity rate than eswab. CT imaging proved highly reliable for diagnosing subperiosteal abscesses and can be effectively integrated with surgical intervention during the same anaesthesia. Together, these findings emphasize the value of combining laboratory markers and imaging to optimize early risk stratification, guide surgical decision-making, and ultimately reduce morbidity in paediatric mastoiditis.

Laryngomalacia: Do We Know What We Don't Know?

Nikolay Sapundzhiev[1]

[1]*Medical University "Prof. Dr P. Stoyanov" Varna*

BACKGROUND & AIM

Laryngomalacia is the most common congenital anomaly of the larynx and the most common cause of congenital stridor. The etiology of the condition is unknown, the diagnostic value of the static laryngeal image is not defined, the possibility of genetic predisposition is barely discussed. The risk factors of failure of the surgical intervention are also poorly described. Laryngomalacia is often combined with gastroesophageal reflux, obstructive sleep apnea, neurological conditions, a second lesion in the respiratory tract, and others. The etiopathogenetic relationship between laryngomalacia and concomitant conditions has not been proven.

MATERIAL & METHODS

We summarize the results of the diagnosis and treatment of 58 patients with congenital stridor who underwent the ENT Clinic of the University Hospital "St. Marina" Varna for the period 2010-2025.

RESULTS

Of the 58 patients, 31 had different types of laryngomalacia. We performed a morphometric analysis of the larynx in laryngomalacia and found that the supraglottis has a different contour from the normal larynx in this disease, that is, our findings support the anatomical theory of the etiology of the condition. We analyzed the frequency of concomitant diseases - 35%. We discovered the first two sets of twins in the world with laryngomalacia - there is no similar experience in the literature to date. We also confirmed in practice that supraglottoplasty fails in cases of accompanying neurological deficit.

CONCLUSIONS

The results of our work over a period of 15 years show that the frequency of concomitant diseases is high, and morphometric analysis of endoscopic images shows that the static image of the larynx in laryngomalacia differs from the norm, which leads rather to support the anatomical theory of the etiology of the condition. We report the first two pairs of twins in the world with laryngomalacia, suggesting a possible genetic predisposition.

Surgical Management Of Otorhinolaryngological Disease In Children With Primary Ciliary Dyskinesia

Anastasia Gorina[1], **Alan Asmanov**[1]

[1]*Pediatric Otolaryngology Department, Veltishchev Research Clinical Institute of Pediatrics and Pediatric Surgery/ Moscow, Russia*

BACKGROUND & AIM

Primary ciliary dyskinesia (PCD) is a rare genetic disorder characterized by impaired mucociliary clearance leading to chronic upper and lower respiratory tract disease (including chronic rhinosinusitis, recurrent otitis media, and chronic wet cough),

neonatal respiratory distress, laterality defects (such as situs inversus), and subfertility. Optimal management of ear, nose, and throat manifestations in children with PCD remains controversial. We hypothesized that sinonasal and otologic surgical interventions improve disease-specific quality of life and objective clinical outcomes in children with severe, therapy-resistant PCD-related disease.

MATERIAL & METHODS

A retrospective cohort study was conducted from 2019 to 2024 at a tertiary referral center, including 176 children diagnosed with PCD presenting with otorhinolaryngological symptoms. Thirty-four patients with refractory disease underwent surgical intervention. Procedures included functional endoscopic sinus surgery (FESS), adenoidectomy, and tympanostomy tube placement.

Outcome measurements included quality of life assessed using the 22-item Sinonasal Outcome Test (SNOT-22), pure-tone audiometry, radiologic staging using the Lund–Mackay score, and endoscopic evaluation using the Lund–Kennedy score. Assessments were performed at the initial visit, preoperatively, and 6 months postoperatively. Patients were followed for up to 5 years. Independent variables included type of surgery and baseline disease severity. Comparative analyses were performed between preoperative and postoperative outcomes.

RESULTS

At 6 months postoperatively, patients undergoing FESS with or without adenoidectomy demonstrated significant improvement in SNOT-22 scores and significant reductions in Lund–Mackay and Lund–Kennedy scores ($p < 0.05$). Two patients required revision sinus surgery due to recurrent severe polypoid rhinosinusitis.

Among patients with chronic suppurative otitis media, tympanostomy significantly improved hearing thresholds at 6 months ($p < 0.05$). However, 50% experienced persistent otorrhea, and one-third developed at least one episode of tube occlusion during follow-up.

CONCLUSIONS

FESS, alone or combined with adenoidectomy, significantly improves both subjective and objective sinonasal outcomes in children with PCD. Tympanostomy improves hearing but is associated with frequent postoperative complications, highlighting the need for careful patient selection and long-term monitoring.

OP-948

Clinical Diagnosis And Treatment Of Pediatric-Onset Relapsing Polychondritis With Airway Involvement

Ying Wang[1], **Jiarui Chen**[1], **Xiaoyan Li**[1]

[1]*Department of Otorhinolaryngology Head and Neck Surgery, Shanghai Children's Hospital, School of medicine, Shanghai Jiao Tong University*

BACKGROUND & AIM

We herein retrospectively analyzed the clinical characteristics and treatment protocols of children with relapsing polychondritis (RP) with airway involvement.

MATERIAL & METHODS

We reviewed the medical records of eight children with pediatric-onset RP with airway involvement who presented to Shanghai Children's Hospital from June 2021 to June 2024. All children met Damiani's criteria for the diagnosis of RP. One child underwent "laryngotracheal reconstruction with hyoid graft + T-tube implantation + bioabsorbable corticosteroid-eluting stent implantation," while five children underwent "balloon dilatation + T-tube implantation + bioabsorbable corticosteroid-eluting stent implantation." After the initial surgery, follow-up was performed every two months for a total of six months. Three bioabsorbable corticosteroid-eluting stents were placed in the upper left and upper and lower right T-tubes during this time.

RESULTS

All eight patients were seen in our department for outpatient follow-up: one patient was extubated; five patients remained in outpatient follow-up; and the remaining two patients continued to be treated in the rheumatology and immunology department due to poor control of their primary disease.

CONCLUSIONS

Tracheotomy can be used to rapidly improve symptoms of dyspnea in children with RP disease progression. In the stable stage of the disease, the minimally invasive surgical method of "balloon dilatation + T-tube implantation + bioabsorbable corticosteroid-eluting stent implantation" was adopted to reduce secondary injury caused by surgical trauma (to the extent possible) and to improve the survival and quality of life of the children.

PEDIATRIC TYMPANOPLASTY: ANATOMICAL AND AUDIOLOGICAL OUTCOMES.

Timur Shamshudinov[1], **Farhad Burkitbaev**[1]

[1]*Treatment and Diagnostic ENT centre (Almaty, Kazakhstan)*

BACKGROUND & AIM

There are no previous studies, comparing anatomical and functional success rates of adenoidectomy and tympanoplasty performed either simultaneously, during single general anesthesia, or sequentially, separated at least 12 weeks, in pediatric patients

MATERIAL & METHODS

We retrospectively enrolled 65 children (36 males, 29 females; mean age 9.16 ± 3.82 years; range 3-17 years) who underwent both tympanoplasty and adenoidectomy from March 2018 to March 2021. The children were assigned to two groups according to the type of surgery management. The groups were compared with regard to anatomical results (tympanic membrane status) and functional outcomes (pre- and post-operative air-bone gap (ABG) values). All study participants had a 12-months follow-up period after surgery.

RESULTS

There were no statistically significant differences between the groups regarding pre- and post-operative ABG values (after 12 months) and average hearing gains. Additionally, the post-operative ABG was significantly lower than the pre-operative ABG in both groups ($p<0.001$). Also, no statistically significant difference was found in successful anatomical restoration rates in two groups. No complications such as mastoiditis, loss of blood, persistent otorrhea, sore throat, fever, or dizziness were detected during or after surgery in both groups.

CONCLUSIONS

In our first comparative study of simultaneous versus sequential tympanoplasty and adenoidectomy, no advantage for sequential approach was observed. The simultaneous surgery management demonstrates the clinical results comparable to those in the sequential group. The simultaneous surgery approach appears to be associated with low rate of complications. Therefore, simultaneous surgery management might be beneficial reducing anesthesia exposure in pediatric patients.

IMPACT OF PERIODIC FEVER, APHTHOUS STOMATITIS, PHARYNGITIS, ADENITIS (PFAPA) SYNDROME ON OLFACTORY AND GUSTATORY FUNCTIONS

Osman Kilic[1], **Serdal Celik**[2], **Berina Slipcevic**[2], **Zeynep Az Aydin**[2], **Ahmet Mutlu**[2], **Fatih Haslak**[3], **Mahmut Tayyar Kalcioglu**[2]

[1]*Göztepe Prof. Dr. Süleyman Yalçın City Hospital, ENT Clinic, Istanbul, Türkiye;* [2]*Istanbul Medeniyet University, Faculty of Medicine, Department of Otorhinolaryngology, Istanbul, Türkiye;* [3]*Istanbul Medeniyet University, Faculty of Medicine, Department of Pediatric Rheumatology, Istanbul, Türkiye*

BACKGROUND & AIM

The aim of this study was to evaluate olfactory and gustatory functions in children with pediatric periodic fever, aphthous stomatitis, pharyngitis, and adenitis (PFAPA) syndrome and to contribute to filling the existing knowledge gap in this field.

MATERIAL & METHODS

The study included 40 pediatric patients diagnosed with PFAPA syndrome from the Pediatric Rheumatology Unit and 40 healthy age-matched controls. Olfactory functions were assessed using the Sniffin' Kids test, while gustatory functions were evaluated using the ODOFIN Taste Test.

RESULTS

The study comprised 80 participants, including 40 healthy controls (male: 25, 62.5%) and 40 patients with PFAPA syndrome (male: 26, 65%). The mean ages of the patient and control groups were 6.83 (4–12) and 6.89 (4–12) years, respectively. Sniffin' Kids scores (9.75 ± 1.30) were not significantly different in the patient group compared with the control group (10.00 ± 1.24; $p = 0.381$). Likewise, gustatory function scores in the patient group (11.83 ± 2.05) were not significantly different from those in the control group ($p = 0.825$).

CONCLUSIONS

The findings suggest that PFAPA syndrome may not have a significant impact on olfactory or gustatory functions. No statistically significant differences were observed between patients with PFAPA syndrome and healthy controls in either smell or taste test scores. These results indicate that sensory functions may be preserved in this patient population. However, further studies with larger sample sizes and multicenter designs are needed to confirm these findings and to evaluate possible changes during active disease periods.

Unique Characteristics Of Pediatric Sporadic Vestibular Schwannoma

Kihun Jo[1], **Udi Shapira**[2], **Riana Kipiani Abdul Halim**[3], **Jeonggeum Lee**[1], **Inseok Moon**[1]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, Yonsei University College of Medicine;* [2]*Department of Otolaryngology-Head and Neck Surgery and Maxillofacial Surgery, Tel Aviv Medical Center;* [3]*Department of Otorhinolaryngology, KPJ Healthcare University College*

BACKGROUND & AIM

To investigate characteristics of pediatric sporadic (non-NF2) vestibular schwannoma (VS), we compare outcomes of sporadic adult-type vestibular schwannoma which were size- and location-matched cohort.

MATERIAL & METHODS

Pediatric patients (≤21 years) with sporadic unilateral VS and ≥15 months of follow-up were identified and each matched 1:2 to adult patients (>21 years) by tumor size and location. The primary outcome was tumor control (stable vs recurrence/regrowth requiring treatment). Outcomes within the pediatric cohort were further analyzed for age- related differences.

RESULTS

Nine pediatric patients were matched to 18 adult controls. Baseline characteristics and presenting symptoms were similar. Gross total resection was achieved in 44% of children and 22% of adults (P=0.071). Tumor control differed significantly: recurrence/regrowth occurred in 44% of children versus 6% of adults (P=0.005). Within the pediatric group, patients with recurrence were younger (13.8±2.8 vs 17.6±2.6 years; P=0.043). Using a 14-year cutoff, three of four recurrences (75%) occurred in children <14 years versus none in older children (P=0.048).

CONCLUSIONS

Children, particularly those under 14 years, experienced significantly poorer tumor control after surgery for sporadic VS compared with adults, despite similar tumor size and location. The higher recurrence and regrowth rates observed in the pediatric cohort suggest that a more aggressive treatment and surveillance approach may be warranted.

OP-952

Preoperative PLCC And PLCR For Predicting Pediatric Post-Tonsillectomy Hemorrhage

Dr. Muhammed SADIKZADE[1], **Asst. Prof. Dr. Mehmet BİRİNCİ**[1]

[1]*Otorhinolaryngology, Recep Tayyip Erdoğan University Training and Research Hospital, Rize, Türkiye*

BACKGROUND & AIM

Post-tonsillectomy hemorrhage is the most concerning complication after pediatric tonsillectomy and remains hard to predict with routine preoperative assessment. Because complete blood count (CBC) indices are inexpensive and widely available, platelet large cell count (PLCC) and platelet large cell ratio (PLCR) have been proposed as potential markers of platelet turnover and primary hemostasis. We aimed to evaluate whether preoperative PLCC/PLCR and selected coagulation and platelet parameters are associated with post-tonsillectomy hemorrhage and provide clinically useful risk discrimination.

MATERIAL & METHODS

We conducted a retrospective case-control study of children undergoing tonsillectomy between January 2020 and December 2024 at a tertiary training and research hospital. The laboratory dataset included 958 patients: 918 controls with an uneventful course and 40 patients with post-tonsillectomy hemorrhage (PTH). PTH was defined as postoperative bleeding requiring clinical evaluation. Preoperative platelet indices (platelet large cell count [PLCC], platelet large cell ratio [PLCR], platelet count [PLT], mean platelet volume [MPV], platelet distribution width [PDW]) and coagulation tests (activated partial thromboplastin time [aPTT], prothrombin time [PT], international normalized ratio [INR]) were extracted from electronic records. Groups were compared with distribution-appropriate analyses, and logistic regression assessed associations with PTH.

RESULTS

Among 958 children (918 controls, 40 PTH; 4.18%), patients with post-tonsillectomy hemorrhage were older (9.55 ± 3.69 vs 7.96 ± 2.61 years; p=0.00993). PLCC did not differ between groups (78.24 ± 27.05 vs 74.70 ± 24.98; p=0.433). PLCR showed a modest, non-significant trend lower in PTH (19.00 ± 5.93 vs 20.87 ± 7.51; p=0.066) with poor discrimination (AUC 0.431); PLCC discrimination was also poor (AUC 0.539). In contrast, aPTT and platelet count were higher in the PTH group (p=0.00635 and p=0.00731). Univariable standardized analysis associated PTH with age (OR 1.64, 95% CI 1.25–2.14), platelet count (OR 1.47, 1.10–1.96), and aPTT (OR 1.34, 1.04–1.71).

CONCLUSIONS

In this pediatric cohort, preoperative PLCC and PLCR were not clinically useful standalone predictors of post-tonsillectomy hemorrhage and showed poor discriminatory performance. Older age, higher aPTT, and higher platelet count were more

consistently associated with hemorrhage, although differences were modest. These findings suggest that routine platelet large cell indices should not be used alone for preoperative risk stratification, and future models should prioritize clinically interpretable covariates with validation in larger cohorts.

post-tonsillectomy hemorrhage; platelet indices; PLCC; PLCR; aPTT; platelet count

OP-953

Pain Trajectories After Partial Versus Total Tonsillectomy: A Prospective Cohort Study

Ostap Orishchak[1,2], **Hady Tall**[1], **Chantal Frigon**[3], **Sam J. Daniel**[1,2]

[1]*McGill Otolaryngology Sciences Laboratory, McGill University, Montreal, Quebec, Canada;* [2]*Division of Pediatric Otolaryngology, Montreal Children's Hospital, Montreal, Quebec, Canada;* [3]*Division of Pediatric Anesthesia, Montreal Children's Hospital, Montreal, Quebec, Canada*

BACKGROUND & AIM

Pain control remains a key concern in pediatric tonsil surgery, directly influencing recovery, complication rates, and the overall patient experience. This study aimed to compare postoperative pain between partial and total tonsillectomy and to evaluate pain outcomes across commonly used surgical instruments—coblation, microdebrider, and monopolar cautery.

MATERIAL & METHODS

A prospective observational study was conducted at the Montreal Children's Hospital. Parents of children undergoing partial or total tonsillectomy completed pre- and postoperative questionnaires, followed by daily pain assessments for 14 days using the Parents' Postoperative Pain Measure. Parents also documented all analgesic use, including non-opioid and opioid medications.

RESULTS

A total of 188 children were included. Mean pain scores were consistently higher after total tonsillectomy compared with partial tonsillectomy during the first postoperative week, before declining in both groups. Among surgical techniques, coblation was associated with significantly lower pain during the first 7 days compared to cautery ($p < 0.05$); differences were no longer significant beyond day 7. Coblation also demonstrated a trend toward lower pain than microdebrider during the first postoperative week, although not statistically significant ($p > 0.05$). Children treated with coblation or microdebrider required significantly less non-opioid medication from days 2–7 ($p < 0.05$) and less opioid medication from days 2–10 ($p < 0.05$) compared to those treated with cautery.

CONCLUSIONS

Partial tonsillectomy — particularly when performed using coblation or microdebrider—was associated with less postoperative pain and reduced analgesic requirements compared to total tonsillectomy. These findings support the growing adoption of intracapsular techniques to optimize recovery and patient comfort following pediatric tonsil surgery.

OP-954

Research Progress On The Nasal Mucosal Immune Microenvironment Of Chronic Rhinosinusitis (CRS) In Chinese Children

Yang Han[1]

[1]*Department of Otolaryngology, Head and Neck Surgery, National Center for Children's Health, Beijing Children's Hospital, Capital Medical University, Beijing 100045, China*

BACKGROUND & AIM

Chronic rhinosinusitis (CRS) is a heterogeneous disease characterized by chronic inflammation of the nasal mucosa. Distinct from adults, chronic rhinosinusitis with nasal polyps (CRSwNP) in children is marked by early onset, high heterogeneity, insidious progression, and often severe clinical manifestations. This report summarizes and presents the latest research advances from the National Children's Medical Center regarding the characteristics of the nasal mucosal immune microenvironment in Chinese pediatric CRS patients.

MATERIAL & METHODS

A prospective cohort of pediatric CRS patients was established to analyze clinical features. Nasal mucosa and nasal polyp tissue samples were collected and subjected to comprehensive analysis using multi-omics technologies, including transcriptomics, proteomics, metabolomics, single-cell sequencing, and Xenium spatial transcriptomics, followed by experimental validation.

RESULTS

The study cohort of Chinese children with CRSwNP showed a mean age of 10.4 years, with nearly 8% preschool-aged. Median disease duration was 36 months. Key clinical features included impaired lung function in 40.2%, comorbid asthma in 16.7%, and a postoperative recurrence rate of 31.4%. Histologically, pediatric nasal mucosa exhibited thickened basement layer and high mucous gland density. Additionally, reduced ionocyte numbers and CFTR function, along with ciliary abnormalities

mediated by DNAH9, DNAI2, and ODAD4, were observed. Notably, 83.3% of patients had non-eosinophilic endotypes, characteristic of pediatric CRS progression. Multi-omics analysis identified oxidative stress-antioxidant defense imbalance as a key mechanism, involving HMOX1 hyperactivation triggering ferroptosis and M2 macrophage signaling, and abnormal metabolism of Streptococcus, 13'-Hydroxy-alpha-tocopherol, and glutathione. Disease recurrence was linked to phagosome pathway activation in neutrophils and M2 macrophages via ITGAM and FCGR33B.

CONCLUSIONS

Chronic rhinosinusitis in Chinese children presents distinct clinical and pathological characteristics compared to adults and constitutes an essential part of the "pan-airway inflammation spectrum." Pediatric CRSwNP is not only characterized by a protracted disease course and a propensity for lower airway involvement but also demonstrates significant "refractoriness" and "recurrence".

Multidimensional Assessment Of Voice Quality, Nasal Resonance, And Quality Of Life After Adenotonsillectomy: A Praat-Assisted Prospective Study

Derya CEBECİ[1], **Şükran DUMAN**[1], **Seren KUBBE**[2], **Fırat ONUR**[1], **Fatih TETİK**[1], **Ethem İLHAN**[1], **Ömer Necati DEVELİOĞLU**[1]

[1]*Department of Otolaryngology, Istanbul Gaziosmanpaşa Training and Research Hospital, University of Health Sciences, Istanbul, Türkiye;*

[2]*Department of Speech and Language Therapy, Istanbul Gaziosmanpaşa Training and Research Hospital, University of Health Sciences, Istanbul, Türkiye*

BACKGROUND & AIM

Adenotonsillectomy is one of the most commonly performed surgical procedures in pediatric otolaryngology; however, its multidimensional effects on voice quality, nasal resonance, and voice-related quality of life remain incompletely characterized. This study aimed to prospectively evaluate changes in voice handicap, vocal quality of life, and acoustic parameters before and after adenotonsillectomy in a pediatric cohort, using the Pediatric Voice Handicap Index (pVHI), the Pediatric Voice-Related Quality of Life Survey (pVRQOL), and Praat-Assisted Nasalance Meter.

MATERIAL & METHODS

Thirty-seven pediatric patients (19 male, 18 female; mean age: 7.78 ± 2.08 years; range: 4–12 years) who underwent adenotonsillectomy (n=30) or adenotonsillectomy combined with bilateral ventilation tube insertion (n=7) were prospectively enrolled. Chief complaints included recurrent infections (70.3%) and nocturnal mouth-breathing or snoring (29.7%). Assessments were performed at three time points: preoperatively, and at postoperative months 1 and 3. Outcome measures included: (1) the Pediatric Voice Handicap Index (pVHI), comprising functional, physical, and emotional subscales; (2) the Pediatric Voice-Related Quality of Life Survey (pVRQOL), comprising physical function and social-emotional subscales; and (3) acoustic parameters including fundamental frequency (F0), jitter, shimmer, harmonics-to-noise ratio (HNR), and nasalance percentages obtained using a Praat - Assisted Nasalance Meter. As data did not conform to a normal distribution (Shapiro-Wilk test, $p<0.05$), the Wilcoxon Signed-Rank Test was applied for all pairwise comparisons.

RESULTS

The pVHI total score declined significantly from 13.78 ± 15.02 preoperatively to 5.86 ± 10.48 at postoperative month 1($p=0.001$) and 4.62 ± 10.37 at postoperative month 3($p<0.001$).No statistically significant difference was observed between postoperative months 1 and 3 ($p=0.356$),suggesting that the primary improvement occurs within the first postoperative month.The pVRQOL physical function subscale score decreased from 11.54 ± 6.57 preoperatively to 9.35 ± 5.80 at month 1 ($p=0.016$) and further to 7.73 ± 3.55 at month 3 ($p=0.002$), with continued significant improvement between months 1 and 3 ($p=0.019$).The pVRQOL social-emotional subscale did not demonstrate statistically significant change at either postoperative time point ($p>0.05$).Regarding acoustic parameters,nasalance (%/m) increased significantly from 90.73 preoperatively to 95.51 at postoperative month 3 ($p=0.020$), reflecting normalization of nasal resonance following adenoid removal.HNR decreased from 26.91 dB preoperatively to 20.43 dB at month 3 ($p=0.013$).No statistically significant changes were observed in F0, jitter, or shimmer($p>0.05$ for all).

CONCLUSIONS

Adenotonsillectomy confers significant multidimensional benefits in the pediatric population, extending beyond airway obstruction relief to encompass measurable improvements in voice handicap, physical vocal function, and nasal resonance. The concordance between objective acoustic findings and patient/caregiver-reported outcomes underscores the clinical validity of this multidimensional approach. Notably, Praat-assisted nasalance analysis emerged as a cost-effective, accessible, and objective digital tool for monitoring postoperative vocal outcomes in clinical practice, without the need for high-cost dedicated hardware.

BACKGROUND & AIM

Managing patients with congenital choanal atresia (CA) is challenging for Ear, Nose and Throat (ENT) surgeons as it is an uncommon condition. Despite valuable prior works having been published, actual practice often deviates from the recommendations set out in expert opinions. The aim of this study was to elucidate the current standard of care for CA patients in Europe and worldwide, and to identify aspects that require critical discussion.

MATERIAL & METHODS

An online survey, available in English and German, was conducted among subscribed members of the European Rhinologic Society and the European Society of Pediatric Otorhinolaryngology between July and November 2025. Survey items queried preoperative diagnostics, surgical procedures, and postoperative care in CA patients.

RESULTS

A total of 116 ENT departments from 46 countries and six continents participated. CA repairs were rarely performed (median 3 per year). Elective repair of unilateral CA was performed on patients under five years of age in 64% of cases. Of these, 19% were operated on within the first six months of life. Standardised preoperative hearing tests were performed by 19% of participants and preoperative CT scans by 84%. The main approach to CA repair was endoscopic transnasal (81%). While 57% of participants stated that they routinely resected the posterior vomer, mucosal flaps were elevated by 48%. In total, 40% never or hardly used stents, and 33% always or mostly used stents across all continents Recommended postoperative nasal care measures included saline irrigations (77%), topical corticosteroids (37%), and perioperative antibiotics (32%). Recurrences were attributed to scarring (71%), granulation tissue (40%) and insufficient vomer resections (21%).

CONCLUSIONS

According to current expert opinions, the age range for patients undergoing elective unilateral CA repair should be reduced. Although preoperative age- and development-adapted hearing tests are recommended by experts in literature, they are not commonly implemented. CT imaging is widely used despite the associated radiation exposure. Its role should be critically discussed. Over half of the participants resected the posterior vomer, which may help to minimise recurrence rates. The current use of stents and perioperative antibiotics should be discussed further and reduced, in line with current specialist recommendations.

Prospective Evaluation Of The Effects Of Adenotonsillectomy On Growth, Bone Age And Biomarkers In Children With Obstructive Sleep Apnea Syndrome

Muhittin AKALIN[1], Ayşe İriz[2], Emirhan Akyol[5], Öznur Leman Boyunaga[3], Rabia Şemsi[4], Aylin Sepici Dinçel[4]

[1]Gaziantep City Hospital, Department of Otorhinolaryngology, Gaziantep, Türkiye; [2]Gazi University Faculty of Medicine, Department of Otorhinolaryngology, Ankara, Türkiye; [3]Gazi University Faculty of Medicine, Department of Radiology, Ankara, Türkiye; [4]Gazi University Faculty of Medicine, Department of Medical Biochemistry, Ankara, Türkiye; [5]Adıyaman University Training and Research Hospital, Department of Otorhinolaryngology, Adıyaman, Türkiye

BACKGROUND & AIM

To evaluate the effects of adenotonsillectomy on growth and development parameters, skeletal maturation, and growth-related biomarkers in children with obstructive sleep apnea syndrome (OSAS).

MATERIAL & METHODS

In this single-center prospective study, 50 children (aged 3–12 years) with OSAS who underwent adenotonsillectomy (January–September 2024) were evaluated preoperatively and at postoperative follow-up. Height/weight percentiles, BMI Z-score, Pediatric Sleep Questionnaire (PSQ), Greulich–Pyle bone age, and serum IGF-1, IGFBP-3, ALP, osteocalcin, sclerostin, and DKK-1 were measured. Paired comparisons and correlation analyses were performed; ROC analysis assessed sclerostin for predicting advanced bone age.

RESULTS

Bone age and height age increased significantly (p<0.001). Height and weight percentiles improved, PSQ decreased (9.92±2.63 to 3.22±2.36), and BMI Z-score increased (all p≤0.002). IGF-1 and ALP increased significantly (p<0.001); IGFBP-3 was unchanged (p=0.497), and osteocalcin showed a borderline increase (p=0.081). Sclerostin and DKK-1 decreased significantly (p<0.001). Both pre- and postoperative bone age correlated positively with IGF-1, IGFBP-3, and ALP (all p<0.05); the strongest preoperative association was with IGF-1 (r=0.459; p=0.001), and the strongest postoperative association was with IGFBP-3 (r=0.569; p<0.001).The preoperative BMI Z-score correlated with anabolic markers and bone/height age (strongest with IGF-1: r=0.470; p<0.001). The postoperative BMI Z-score correlated positively with IGF-1 and bone age and inversely with sclerostin; the strongest correlation was observed with sclerostin (r=−0.408; p=0.006).A preoperative sclerostin cut-off of ≤395.3 identified advanced bone age with good sensitivity (90.0%) and moderate specificity (64.7%) (AUC=0.760; p=0.013).

CONCLUSIONS

Adenotonsillectomy in pediatric patients with OSAS was associated with symptom improvement, accelerated growth, and skeletal maturation, as well as increased anabolic markers and decreased sclerostin/DKK-1 levels. Preoperative sclerostin levels may help identify advanced bone age.

OP-958

Effect Of Adenoidectomy On Nasal Mucociliary Transport In Children: Objective Assessment Using Activated Charcoal

Stanimir Dinev[1], **Assoc. Prof. Teodor Atanasov, MD, PhD**[2]

[1]*Department of Otorhinolaryngology, Burgasmed University Hospital, Burgas, Bulgaria;* [2]*Faculty of Medicine, Medical University of Sofia, Sofia, Bulgaria;* [3]*Department of Otorhinolaryngology, University Hospital Sofiamed, Sofia, Bulgaria;* [4]*Medical Center Doctor Staykov, Burgas, Bulgaria*

BACKGROUND & AIM

Adenoid hypertrophy may impair nasal physiology, including nasal mucociliary transport. Objective pediatric data on the effect of adenoidectomy remain limited, especially when visual rather than taste-based assessment is used. This study aimed to evaluate the effect of adenoidectomy on nasal mucociliary transport in children using an objective activated charcoal method.

MATERIAL & METHODS

A prospective clinical study was performed in children aged 3–12 years with clinically and endoscopically confirmed adenoid hypertrophy undergoing adenoidectomy. Nasal mucociliary transport time was measured 7 days preoperatively and on postoperative day 14. A standardized activated charcoal suspension was applied under endoscopic control to the medial surface of the inferior turbinate, approximately 1 cm posterior to its anterior end. The endpoint was the first visualization of the marker on the posterior pharyngeal wall. Pre- and postoperative transport times were compared using paired statistical analysis.

RESULTS

Thirty-seven children aged 3–12 years were included, with predominance of the 4–6-year age group (23/37, 62.2%). Mean preoperative nasal mucociliary transport time was 16.1 ± 1.8 min and decreased to 9.1 ± 2.0 min on postoperative day 14. The mean reduction was 6.9 ± 0.5 min. All children had transport times >10 min preoperatively, whereas this was observed in 10/37 children postoperatively. In sex-stratified analysis, mean transport time decreased from 15.6 ± 1.8 to 8.6 ± 2.0 min in girls and from 16.6 ± 1.7 to 9.7 ± 1.9 min in boys. The difference between pre- and postoperative values was statistically significant (paired analysis, p < 0.001).

CONCLUSIONS

Adenoidectomy was associated with significant improvement in nasal mucociliary transport in children with adenoid hypertrophy. The activated charcoal method appears to be a feasible, low-cost, and objective tool for functional assessment of nasal mucociliary transport in pediatric patients. Further studies with larger cohorts are warranted.

OP-959

The Use Of Topical Antibiotic Therapy For Acute Otitis Media Without Tympanic Membrane Perforation: A Randomized Case-Control Study

Gabriel Dunya[1]

[1]*American University of Beirut*

BACKGROUND & AIM

Acute otitis media is a major cause of pediatric antibiotic prescriptions, with oral amoxicillin-clavulanic acid as standard therapy despite modest symptom relief and systemic side effects. Topical antibiotics excel in perforated acute otitis media or

tympanostomy tube otorrhea but lack evidence in intact tympanic membrane cases due to penetration barriers. This study evaluates adjunctive topical ciprofloxacin ear drops with oral therapy versus oral alone in non-perforated cases.

MATERIAL & METHODS

We conducted a matched case-control study of 90 children, aged 0-15 years, with acute otitis media and intact membranes. Randomized groups included combined therapy (n = 45, ciprofloxacin drops + oral amoxicillin-clavulanic acid) versus oral alone (n = 45), matched for age, gender, baseline pain. Primary outcomes included time to complete pain resolution, fever resolution, and daily pain trajectory assessed using the Faces Pain Scale-Revised. Secondary outcomes included analgesic use and adverse events. Analyses included Kaplan-Meier survival curves, effect size estimation (Cohen's d), and mixed-effects longitudinal modeling.

RESULTS

Combination therapy significantly accelerated pain resolution (3.29 ± 0.84 vs 5.10 ± 1.86 days; mean difference −1.81 days, 95% CI −2.43 to −1.18; Cohen's d = −1.27; $p < 0.001$). Fever resolution was also faster in the combination group (3.91 ± 1.51 vs 5.09 ± 2.02 days; mean difference −1.18 days, 95% CI −1.94 to −0.42; Cohen's d = −0.66; $p = 0.0026$). Kaplan–Meier analysis demonstrated a significantly higher probability of earlier symptom resolution with combination therapy. Mixed-effects longitudinal modeling revealed significant group-by-time interactions for NSAID ($p = 0.007$) and paracetamol use ($p = 0.017$). Adverse events were mild and comparable between groups.

CONCLUSIONS

Adjunctive topical ciprofloxacin combined with oral antibiotics may significantly accelerate symptom and fever resolution in children with non-perforated acute otitis media without increasing adverse events. These findings suggest a potential complementary role for topical therapy, deserving further randomized controlled trials.

OP-960

PEDIATRIC THYROID SURGERY: A 7-YEAR EXPERIENCE FROM A HIGH-VOLUME TERTIARY CENTER

Abdullah A. Qadir[1]

[1]*Department of Head and Neck Surgery, Smart Health Tower, Sulaymaniyah, Iraq.*

BACKGROUND & AIM

Pediatric thyroid disorders requiring surgery are uncommon but are associated with a higher risk of malignancy and postoperative complications than in adults. Evidence regarding surgical outcomes in children remains limited despite the availability of pediatric thyroid management guidelines. This study aimed to evaluate the spectrum of pediatric thyroid diseases, surgical procedures, histopathological outcomes, and postoperative complications in a high-volume tertiary referral center.

MATERIAL & METHODS

This hospital-based retrospective single-center study included pediatric patients (≤18 years) who underwent thyroid surgery between January 2018 and January 2025. Patients undergoing nodulectomy, lobectomy, or total thyroidectomy for symptomatic thyroid disease or suspicious thyroid nodules were included. Demographic, clinical, radiological, laboratory, operative, histopathological, and follow-up data were collected from electronic medical records. Statistical analysis was performed using SPSS version 26. Correlations were assessed using Spearman's rank test, with $p<0.05$ considered statistically significant.

RESULTS

A total of 60 patients were included. The median age was 14 years (interquartile range: 11–15), and 46 patients (76.7%) were female. The most common presenting complaint was anterior neck swelling (58.3%). Preoperatively, thyroid nodules were identified in 44 patients (73.3%). Histopathological examination revealed benign disease in 41 patients (68.3%) and papillary thyroid carcinoma in 19 patients (31.7%). Total thyroidectomy was the most frequently performed procedure (43.3%). Malignant cases had significantly longer operative times than benign cases (90 vs. 50 minutes, $p=0.002$). Fine-needle aspiration cytology was strongly associated with final histopathological diagnosis ($p<0.001$). A significant positive correlation was observed between operative duration and length of hospitalization ($r=0.528$, $p<0.001$). During a median follow-up of four years, no permanent recurrent laryngeal nerve injury, hypocalcemia, or hypoparathyroidism was recorded.

CONCLUSIONS

Pediatric thyroid surgery can be performed safely in specialized high-volume centers with excellent outcomes. The relatively high rate of papillary thyroid carcinoma highlights the importance of thorough evaluation and multidisciplinary management. Surgical expertise and coordinated care remain essential for optimizing outcomes in pediatric thyroid disease.

Ten-Year Experience In Pediatric Tracheostomy Cases: Analysis Of Factors Determining Complications And Mortality

ahmet adnan cırık[1], **sıddıka tuğçe altınok**[1], **şeyma akgün bostancı**[1]

[1]*istanbul ümraniye research and training hospital*

BACKGROUND & AIM

This study aims to evaluate the demographic characteristics, clinical variables, complication rates, and factors affecting mortality in pediatric patients who underwent tracheostomy, and to compare these findings with the literature.

MATERIAL & METHODS

In our center, 243 pediatric tracheostomy patients who underwent the procedure between 2014 and 2024 were retrospectively examined through the hospital system. Age, gender, presence of syndrome, indications, comorbidities, intubation duration, type of intervention (emergency/elective), birth period, complication development, and causes of mortality were analyzed. 30 patients were excluded from the study due to missing data. The data obtained from 213 patients were analyzed using the IBM SPSS 25.0 program.

RESULTS

54.5% of the patients were male, 45.5% were female, and the average age was 3.40±4.70 years. The most common indication was prolonged intubation (83.6%). Complications developed in 17.8% of the patients; the most common were granulation tissue (5.6%) and accidental decannulation (6.6%).In the multivariable logistic regression analysis, intubation duration (OR=1.009; 95% CI: 1.001–1.017; p=0.036) and being in the neonatal period (OR=2.435; 95% CI: 1.243–4.770; p=0.009) were identified as independent and statistically significant risk factors for mortality. In contrast, sex, comorbidity, age, weight, type of intervention, and the presence of syndrome did not have a significant effect on mortality (p>0.05).None of the variables evaluated in terms of complication development showed an independent and statistically significant effect (p>0.05).

CONCLUSIONS

As in the literature, in our study as well, emergency tracheotomies performed due to acute upper respiratory tract infections have increasingly been replaced by elective tracheostomies performed due to prolonged intubation, congenital pathologies, neuromuscular, and cardiopulmonary diseases. Pediatric tracheotomy, while a safe procedure in experienced centers, carries an increased risk of mortality, particularly in neonates and cases with prolonged intubation duration. Identifying early risk factors can contribute to optimizing patient management and improving clinical outcomes.

Auditory Electrophysiological Assessment Of Hearing Function In Infants And Children With Esophageal Atresia: A Cross-Sectional Study

Dr Parisa Rasouli Fard[1], **Mojtaba Alidoust**[1], **Dr Ahmadreza Nazeri**[1], **Dr Amirhossein Hosseini**[2], **Dr Shamsollah Nouripour**[2]

[1]*Shahid Beheshti University of Medical Sceinces;* [2]*Mofid Hospital*

BACKGROUND & AIM

Esophageal atresia (EA) is a congenital malformation occurring in approximately 1 in 4,000 births, with an unknown etiology. Some studies have reported an association between EA, cleft palate, and conductive hearing loss. This study investigates the potential involvement of the middle ear and auditory dysfunction in infants and children with EA (ages 0 - 15 years) using audiological assessments, particularly distortion product otoacoustic emissions (DPOAE) and auditory brainstem response (ABR) tests.

MATERIAL & METHODS

This study aims to assess the prevalence and characteristics of auditory dysfunction in infants and children with EA (ages 0 - 15 years) through electrophysiological tests (ABR and DPOAE), identifying potential correlations between EA and hearing impairments.

RESULTS

The results indicated a significant difference in the ABR test between the test group (n = 150) and the control group (n = 150), with a higher prevalence of conductive hearing loss in the test group (62 out of 150 cases; 41.3%, P ≤ 0.01, independent t-test). Additionally, 40% (60 out of 150) of children with EA had cleft palate lesions, which were strongly associated with conductive hearing loss (chi-square test, P < 0.05). Tympanometry results showed that 41 cases (27.3%) had type B curves, and 21 cases (14%) had type C curves, indicating middle ear dysfunction. Acoustic reflex testing revealed that all 41 cases with type B tympanograms had absent reflexes, while in the 21 cases with type C tympanograms, reflexes were either absent or elevated depending on the severity of negative middle ear pressure.

CONCLUSIONS

The study findings indicate a significant prevalence of conductive hearing loss in children with EA, particularly among those with cleft palate. Middle ear dysfunction, as evidenced by abnormal tympanometry and absent acoustic reflexes, suggests that structural and physiological factors associated with EA contribute to auditory impairment. These results highlight the need for routine audiological screening in children with EA to facilitate early intervention and improve long-term auditory outcomes.

OP-963

PAIN SCORES IN CHILDREN UNDERGOING TONSILLECTOMY WITH COLD DISSECTION VERSUS LOW TEMPERATURE PLASMA ABLATION: IS THERE A DIFFERENCE?

Joana Ida Dias[1], **Rita Carvalho**[1], **Clara Serdoura Alves**[1], **Sandra Castro**[1], **Miguel Coutinho**[1], **João Lino**[1]

[1]*Unidade Local de Saúde de Santo António*

BACKGROUND & AIM

Tonsillectomy remains one of the most frequently performed pediatric surgical procedures worldwide. Postoperative pain continues to represent its most relevant morbidity, influencing oral intake, hydration, sleep quality, and caregiver anxiety. Although low-temperature plasma ablation (coblation) theoretically reduces thermal tissue injury compared with traditional techniques, evidence comparing extracapsular coblation and cold dissection remains inconsistent. Most studies report small early differences with unclear clinical relevance. This prospective study aimed to determine whether low-temperature plasma extracapsular tonsillectomy reduces postoperative pain burden compared with cold dissection with pillar suturing in children undergoing surgery for sleep-disordered breathing.

MATERIAL & METHODS

A prospective comparative study was conducted between January and June 2024 at a tertiary pediatric center. Consecutive children aged 5–12 years undergoing outpatient extracapsular tonsillectomy for sleep-disordered breathing were included. Patients were allocated according to surgical scheduling to cold dissection with pillar suturing (COLD group) or low-temperature plasma extracapsular tonsillectomy (PLMA group). Exclusion criteria comprised relevant comorbidities, age outside limits, and inability of caregivers to complete Portuguese-language materials.

Postoperative pain was assessed using the Wong–Baker FACES scale on postoperative days 0, 1, 3, and 7. Cumulative pain burden was calculated using area under the curve (AUC D0–D7). Analgesic consumption and complications were recorded. Statistical analysis was performed using SPSS v27. Continuous variables were compared using t-test or Mann–Whitney U test, and categorical variables with chi-square or Fisher's exact test. Significance was set at $p<0.05$.

RESULTS

Sixty-five children were included (COLD n=38; PLMA n=27). Groups were comparable regarding age and sex. Operative time was significantly longer in the COLD group (median 40.5 vs 27.0 minutes, $p<0.001$). A higher proportion of children in the COLD group exhibited intraoperative heart rate above the 90th percentile ($p=0.044$).

Immediate postoperative pain scores were significantly lower in the PLMA group ($p<0.001$), and fewer children required recovery-room analgesia (33.3% vs 71.1%, $p=0.005$). However, total postoperative analgesic intake did not differ significantly between groups ($p=0.193$).

Cumulative pain burden (AUC D0–D7) was significantly higher in the PLMA group (17.52±7.60 vs 14.41±4.48, $p=0.042$; moderate effect size). Time to analgesic cessation showed no statistically significant difference. Two postoperative events occurred in the PLMA group; none were observed in the COLD group.

CONCLUSIONS

Low-temperature plasma extracapsular tonsillectomy was associated with reduced immediate postoperative pain and lower need for recovery-room analgesia. However, these early benefits did not translate into reduced total analgesic use or shorter recovery duration. When cumulative pain burden was analyzed, the plasma group demonstrated higher overall pain load during the first postoperative week.

These findings suggest that early postoperative differences may not reflect overall recovery trajectory. Surgical energy modality alone may not determine total postoperative pain burden, highlighting the importance of standardized perioperative analgesic strategies. Larger multicenter randomized studies are warranted to clarify clinical relevance.

OP-964

Phenotypic And Strategic Determinants Of Treatment Outcomes In Pediatric Head And Neck Lymphatic Malformations: A Single-Center Retrospective Analysis

Wang Shengcai[1], **Li Jie**[1], **Zhang Ge**[1]

[1]Beijing Children's Hospital, Capital Medical University

BACKGROUND & AIM

Pediatric head and neck lymphatic malformations (LMs) represent a heterogeneous group of congenital vascular anomalies characterized by variable anatomical extent, cystic architecture, and recurrence behavior. Although mortality is rare, morbidity related to airway compromise, infection, and repeated interventions remains substantial. Current management strategies—including surgical resection, image-guided intervention, and medical therapy—are widely used, yet comparative evidence integrating time-dependent failure dynamics and imaging response patterns remains limited.

MATERIAL & METHODS

We conducted a retrospective cohort study including 210 pediatric patients treated between 2016 and 2025. Primary treatment modalities included surgical resection, image-guided intervention, and medical therapy. The primary endpoint was treatment failure, defined as recurrence or imaging-defined non-response. Secondary endpoints included complete response (CR) and objective response rate (ORR = CR+PR). Multivariable Cox regression adjusted for age and number of involved regions was performed. Sensitivity analyses included recurrence-only restriction and follow-up ≥6 months limitation.

RESULTS

The overall failure rate was 15.2% (32/210). Failure rates were 16.4% for surgery, 7.5% for intervention, and 41.2% for medical therapy. Intervention was associated with reduced hazard of failure compared with surgery (HR 0.29, 95% CI 0.11–0.76, P=0.011), with consistent findings in recurrence-only and follow-up-restricted analyses.

CR rates differed significantly across treatment modalities (P < 0.001), with higher CR observed in the surgery group (73.2%) compared with intervention (11.7%) and medical therapy (14.7%). However, ORR was highest in the intervention group (92.5%), compared with 83.9% in the surgery group and 58.8% in the medical group. Subgroup analysis demonstrated distinct response patterns by cystic subtype, while results in microcystic lesions should be interpreted cautiously due to limited sample size. Findings remained consistent in the ≥6-month sensitivity cohort.

CONCLUSIONS

Treatment modality was associated with differential failure dynamics and imaging response patterns in pediatric head and neck LMs. Although surgery achieved higher CR rates, image-guided intervention demonstrated consistently lower observed failure hazard and higher overall response rates across analytic frameworks, supporting risk-informed and lesion-contextualized therapeutic selection.

A Single-Center,Single-Arm Studyon Luvometinib (FCN-159) For Treating Pediatric Plexiform Neurofibromas In NF1: Interim Report.

Liu Qiaoyin[1], **Liu Yifan**[1], **Wang Shengcai**[1], **Ni Xin**[1]

[1]Beijing Children's Hospital Affiliated to Capital Medical University

BACKGROUND & AIM

To evaluate the efficacy and safety of the MEK inhibitor Luvometinib(FCN-159) in plexiform neurofibromas associated with type I neurofibromatosis in children.

MATERIAL & METHODS

This study is a single-center, single-arm, prospective trial designed to enroll 20 subjects. Participants will receive oral treatment with 5 mg/m² of Luvometinib(FCN-159) daily based on body surface area. The primary endpoint is tumor volume reduction assessed via MRI and tumor marker evaluation every 4 months. Additional endpoints include pain scores, motor function scores, and adverse events. The study has completed registration with the China Clinical Trial Registry (Registration Number: ChiCTR2500109679).

RESULTS

All 20subjects enrolled in this study from October2023 provided valid data. The mean age at enrollment was 108.95 months (30-191 months), with a mean tumor volume of 66.85 cm3 (7.1-257.7 cm3) at follow-up, and a median follow-up time of 18 months (12-24 months). After MRI,75% (15/20) of patients showed tumor shrinkage or trends toward shrinkage, with a median best response of36.6% (1%-60.8%). 40% (8/20) experienced a reduction of up to 20%(36.6%-60.8%), while35% (7 patients) showed trends without reaching 20% shrinkage (1%-15.9%). One patient (5%)discontinued treatment due to disease progression, and 3 (15%) voluntarily switched treatments. Common adverse events included decreased albumin (11 patients), elevated creatine kinase (9 patients), gastrointestinal symptoms (9 patients), rash (5 patients), and oral ulcers (5 patients). Two grade 3 events (new tumors, scarlet fever) were deemed unrelated to the experimental drugs.

CONCLUSIONS

In this study, 75% of pediatric NF1-PNs showed a trend toward tumor shrinkage or reduction in response to Luvometinib (FCN-159) within the first 18 months of treatment, but adverse effects were also more common, and subsequent, larger studies are still needed to assess the effectiveness and long-term adverse effects of Luvometinib (FCN-159).

Effect Of Inferior Turbinate Radiofrequency Added To Adenoidectomy On Early Postoperative Tolerability In Children

Nurdoğan Ata[1], **Kayhan Öztürk**[2]

[1]*Department of Otorhinolaryngology, Selçuk University Faculty of Medicine, Konya, Turkiye.*; [2]*Department of Otorhinolaryngology, Medicana Hospital, Konya, Turkiye.*

BACKGROUND & AIM

Adenoid hypertrophy is a major cause of upper airway obstruction in children. Although adenoidectomy is generally effective, persistent nasal obstruction may occur due to inferior turbinate hypertrophy. Radiofrequency (RF) turbinate reduction is increasingly used as a minimally invasive adjunct; however, its impact on early postoperative tolerability remains unclear. We hypothesized that adding inferior turbinate RF to adenoidectomy does not worsen early postoperative tolerability in pediatric patients

MATERIAL & METHODS

This retrospective comparative cohort study included 86 pediatric patients aged 3–15 years who underwent surgery for adenoid hypertrophy between July 2017 and November 2025 at a tertiary care center. Patients were divided into two groups: adenoidectomy alone (n=45) and adenoidectomy combined with inferior turbinate radiofrequency (RF) (n=41). All procedures were performed under general anesthesia using a conventional curettage technique. Postoperative tolerability outcomes included pain scores, additional analgesic requirements, early complications (bleeding, infection, nasal crusting), and recovery parameters (time to oral intake and return to daily activities). Statistical analyses were performed to compare groups, with $p<0.05$ considered significant.

RESULTS

There were no significant differences between groups in terms of demographic characteristics. The addition of RF did not result in a statistically significant increase in postoperative pain scores or additional analgesic requirements ($p>0.05$). Early complication rates were low in both groups. In the RF group, minor complications occurred in 5 patients (12.2%), including self-limited minimal nasal bleeding (n=2) and transient nasal crusting (n=3), whereas no complications were observed in the adenoidectomy-alone group ($p>0.05$). Recovery parameters, including time to oral intake and return to daily activities, were similar between groups ($p>0.05$).

CONCLUSIONS

Inferior turbinate radiofrequency added to adenoidectomy is a safe and well-tolerated procedure in children. It does not adversely affect early postoperative recovery. These findings support its use in selected pediatric patients with concomitant inferior turbinate hypertrophy.

OP-967

Indications And Outcomes Of Pediatric Tracheotomy: A Single-Center Retrospective Study

SAFİYE GİRAN ÖRTEKİN[1], **BEGÜM BAHAR YILMAZ**[1], **BÜŞRA ÜNSAL**[1], **EBRU AKILLI**[1], **SELİN ÜSTÜN BEZGİN**[1], **YALÇIN ALİMOĞLU**[1], **ÖZGÜR YİĞİT**[1]

[1]*University of Health Sciences Çam and Sakura City Hospital Department of Otorhinolaryngology*

BACKGROUND & AIM

Pediatric tracheotomy has long been utilized for acute infectious airway obstruction; however, vaccination has significantly reduced the need for such emergency procedures. Despite advances in vaccination and critical care, its incidence remains notable in tertiary institutions, driven by advances in critical care and improved survival of children with chronic respiratory insufficiency and complex comorbid conditions. Tracheotomy in pediatric patients presents greater technical challenges and is associated with higher morbidity and mortality than in adults. This study aims to evaluate the indications, clinical characteristics, and outcomes of pediatric patients who underwent tracheostomy in our institution.

MATERIAL & METHODS

We conducted a retrospective analysis of 86 pediatric patients who underwent planned tracheotomy at our Department of Otorhinolaryngology between 2021 and 2026. Patients were classified into five categories based on the indication for

tracheotomy: cardiopulmonary disease, neurological impairment, traumatic injury, craniofacial anomalies and airway obstruction. Data on age, weight, gender, comorbidities, presence and type of syndromic conditions, duration of intubation, decannulation outcomes, time to decannulation, mortality rates, causes of death (tracheotomy-related or unrelated), alength of hospital stay before and after tracheotomy, and duration of intensive care unit stay before and after tracheotomy were collected and analyzed. Data were collected through telephone interviews and systematic review of the Hospital Information System.

RESULTS

A total of 86 pediatric patients who underwent tracheotomy were included in the study; 55.8% (n=48) of the patients were female and 44.2% (n=38) were male. The median age at the time of tracheotomy was 16.0 months (IQR: 42.2), and the mean duration of intubation was 47.4±34.9 days. The most common comorbidity was cardiopulmonary disease (45.3%, n=39), followed by neurological impairment (39.5%, n=34). Age at tracheotomy significantly differed according to the comorbidity groups (Kruskal-Wallis H=23.169; p=0.0001) ; patients with traumatic injury underwent tracheotomy at a significantly older age compared to the neurological and cardiopulmonary groups. In the airway obstruction group, the duration of intubation was significantly shorter than in all other groups (p<0.01). The overall mortality rate was 54.7% (n=47) ; all deaths were associated with the underlying disease, and no tracheotomy-related mortality was observed. Decannulation was achieved in only one (2.6%) of the 39 surviving patients.

CONCLUSIONS

In our cohort, cardiopulmonary disease was the leading comorbidity (45.3%), followed by neurological impairment (39.5%), consistent with the findings of Gergin et al. and Funamura et al. The older age at tracheotomy in the trauma group reflects the tendency for traumatic injuries to occur later in childhood, as also reported by Lin et al. and Gergin et al. In the airway obstruction group, shorter intubation times reflect the acute and reversible nature of this condition. The low decannulation rate (2.6%) is attributable to the irreversible nature of the underlying conditions, consistent with the findings of Chia et al.

Reflection Of Pediatric Otolaryngology In ENT Residency Theses In Turkey

Emine Nur Şahin[1], **Erdem Mengi**[1], **Cüneyt Orhan Kara**[1], **Fazıl Necdet Ardıç**[1]

[1]*Pamukkale University Department of Otolaryngology and Head and Neck Surgery*

BACKGROUND & AIM

To determine the extent to which topics related to Pediatric Otolaryngologyhave been represented in ENT residency theses conducted in Turkey.

MATERIAL & METHODS

Topics classified under Pediatric Otolaryngology in both the Turkish and European core curricula for Otolaryngology were reviewed, and relevant keywords were identified. A total of 1,230 ENT residency theses registered in the national thesis database which are between 1970- 2026 years were screened using 58 predefined keywords. The data obtained were categorized by year and subject matter. Annual trends in thesis numbers were illustrated graphically. Additionally, the most frequently studied topics were identified based on keyword frequency. The number of Pediatric Otolaryngology–related theses was compared with the total number of ENT residency theses.

RESULTS

A total of 229 ENT residency theses addressed topics related to Pediatric Otolaryngology, representing 18.61% of all ENT residency theses.

The distribution of theses identified through keyword screening is presented below (keywords yielding no results were excluded), listed in descending order:

Otitis: 86 (37.55%)

Adenoidectomy, tonsillectomy, adenotonsillectomy: 60 (26.20%)

Cochlear implant: 24 (10.48%)

Myringotomy, ventilation tube, tympanostomy tube:** 23 (10.04%)

Airway: 15 (6.55%) (foreign body, tracheotomy, tracheal stenosis, OSAS)

Hearing loss: 9 (3.93%)

Nasal conditions: 5 (2.18%) (endoscopic surgery, choanal atresia, cleft palate, nasopharyngeal angiofibroma)

Newborn hearing screening: 3 (1.31%)

Vestibular disorders: 3 (1.31%)

Ear: tympanoplasty 1 (0.43%)

CONCLUSIONS

An evaluation of ENT residency theses between 1970 and 2026 demonstrated that Pediatric Otolaryngology topics accounted for 18.61% of all ENT medical specialty theses in Turkey. The number of theses in this field has shown an increasing trend over the years. The distribution of subjects largely reflects the most common pediatric patient groups encountered in routine ENT practice. Pediatric ear diseases were the most frequently studied topics. The growing number of residency theses focusing on Pediatric Otolaryngology indicates a steadily increasing academic interest in this subspecialty over time

Effect Of Nasal Irrigation On Microplastic Clearance In Children With Adenoid Hypertrophy, With Or Without Otitis Media With Effusion

Burak Mustafa TAŞ[1], **Ayşegül TUNA**[2], **Serdar Hanzala YAMAN**[3], **Büşra KELEŞ**[1], **Ziya ŞENCAN**[1], **Ela CÖMERT**[1], **Nuray BAYAR MULUK**[1], **Süheyla KANDEMİR**[1]

[1]*Kırıkkale University Faculty of Medicine, Department of Otorhinolaryngology, Kırıkkale, Turkey.*; [2]*Kırıkkale University Faculty of Medicine, Department of Infectious Diseases and Clinical Microbiology, Kırıkkale, Turkey.*; [3]*Health Science University Şanlıurfa Mehmet Akif İnan Education and Research Hospital, Department of Otorhinolaryngology, Şanlıurfa, Turkey.*

BACKGROUND & AIM

This study aimed to evaluate the presence of microplastics (MPs) and to assess the effect of nasal irrigation in children with adenoid hypertrophy (AH), with or without otitis media with effusion (OME).

MATERIAL & METHODS

Group 1 comprised children with AH, Group 2 included children with AH and OME, and Group 3 consisted of healthy controls. Nasal lavage samples were collected at baseline and after 1 month of twice-daily saline nasal irrigation. MP density (pieces/ml) and total MP count were quantified.

RESULTS

Microplastics were detected in nearly all participants. Baseline MP density did not differ significantly among groups. After 1 month of nasal irrigation, a significant reduction in MP density and total MP count was observed only in the control group ($p<0.001$ and $p=0.003$, respectively), whereas no significant changes were detected in the AH groups. Intergroup comparison of reduction values demonstrated a significantly greater decrease in the control group. Adenoid size was negatively correlated with the magnitude of MP reduction, indicating that greater adenoid obstruction was associated with reduced microplastic clearance. Multivariate analysis identified adenoid hypertrophy as an independent predictor of reduced microplastic clearance, whereas age was not significant. ROC analysis demonstrated that an adenoid size >65% was associated with reduced clearance, with moderate discriminatory ability (AUC=0.662).

CONCLUSIONS

Microplastics are present even in healthy children. Hypertrophic adenoid tissue may function as a reservoir for microplastics, independently limiting the effectiveness of nasal irrigation.

OP-970

Infantile External Auditory Canal Hemangioma In A 12 Month Old Male: Case Report With Literature Review

Nouf Alrayyes[1], **Rabea Alsabilah**[1]

[1]*Cochlear Implantation Center*

BACKGROUND & AIM

Infantile hemangiomas of the external auditory canal (EAC) are exceptionally rare vascular lesions with limited documentation in pediatric otolaryngology literature. These lesions can cause significant conductive hearing impairment and complete canal obstruction in young children. This case report aims to describe the clinical presentation, diagnostic evaluation, surgical management, and outcomes of a rare infantile EAC hemangioma in a 12-month-old patient, contributing valuable insights into the management of this uncommon condition in which this is the 2nd case worldwide to be published.

MATERIAL & METHODS

A 12-month-old male presented with progressive left-sided EAC occlusion and hearing loss. Clinical examination revealed a soft, compressible, skin-covered mass completely filling the left EAC, obstructing visualization of the tympanic membrane. Diagnostic workup included contrast-enhanced magnetic resonance imaging (MRI) demonstrating a well-defined oval vascular lesion measuring 9.2 millimeters anteroposterior by 17 millimeters transverse by 10 millimeters craniocaudal, showing hyperintensity on T2-weighted sequences and homogeneous post-contrast enhancement. Auditory brainstem response (ABR) testing confirmed moderate left-sided conductive hearing loss across 2 to 4 kilohertz frequency range. Complete transcanal

excision was performed under general anesthesia with bipolar cauterization for hemostasis. The mass was dissected from the tragus to the bony-cartilaginous junction and removed with overlying skin. Canal reconstruction was achieved using an inferiorly-based rotated preauricular flap sutured to the anterior canal wall, with partial tragal excision to facilitate flap rotation and prevent postoperative stenosis

RESULTS

Histopathological examination confirmed lobular capillary hemangioma, demonstrating characteristic lobular arrangement of capillary-sized vessels with plump endothelium and organizing stroma, without cellular atypia or malignant features. The immediate postoperative course was uncomplicated with confirmed flap viability and restored canal patency. Follow-up monitoring for wound healing, canal stenosis, and audiological recovery is ongoing, with expected hearing improvement following removal of the canal-obstructing lesion.

CONCLUSIONS

Infantile EAC hemangioma, though extremely rare, requires comprehensive preoperative evaluation with MRI and ABR for accurate diagnosis and surgical planning. Complete transcanal excision combined with preauricular flap reconstruction offers definitive treatment with favorable outcomes and low recurrence rates. This case emphasizes the importance of tailored reconstructive techniques in restoring canal anatomy and preventing stenosis in pediatric patients with EAC vascular lesions

OP-971

Tracheocutaneous Fistula In Pediatric Patients: A Decade Of Experience From An Italian Center

CINZIA CALABRESE[1], **ANTONIO DELLA VOLPE**[1]

[1]*Santobono-Pausilipon Children's Hospital, Naples, Italy*

BACKGROUND & AIM

Tracheostomy decannulation has the potential to be complicated by tracheocutaneous fistula (TCF). Persistent fistulas have been reported to occur in between 6.2% and 52.2% of paediatric patients following tracheostomy decannulation. While some TCF sites close spontaneously, persistent fistulas often result in surgical closure. The primary objectives of this study were to compare outcomes between patients who had a spontaneous closure versus a primary closure versus closure by secondary closure after excision of a TCF to determine the frequency and risk factors.

MATERIAL & METHODS

Patients ages 0-18 years who had primary or secondary closure of a TCF at a tertiary

care children's hospital following decannulation of a tracheostomy tube were reviewed and those with a tracheostomy placement ≥1 year old were included. Demographic information, comorbidities, and surgical information were extracted from inpatient and outpatient charts. Mann-Whitney U test, Fisher's Exact test, and logistic regression to compare outcomes across the three TCF groups.

RESULTS

One hundred forty-five patients ranging from 98 days to 19 years of age underwent tracheostomy decannulation. 58 (40%) patients underwent surgical closure of TCF, with primary closure in 9 patients (6.2%) and secondary closure in 49 (33.8%) patients. Compared to those with spontaneous closure by multivariable analysis, those with surgical closure were younger at tracheostomy placement, had a tracheostomy for a longer duration and were diagnosed with other comorbidities of the upper and lower airways.

CONCLUSIONS

Approximately 60% of pediatric tracheostomy stoma sites will close spontaneously. Development of a persistent TCF was associated with younger age at placement, longer duration of tracheostomy, and the

presence of tracheobronchomalacia. These observations may help clinicians following tracheostomy decannulation in children.

OP-972

Aspiration Risk After Pediatric Open Airway Surgery: A Systematic Review And Meta-Analysis

Shaykhah Alnaimi[1], **Ahmed Alkhatib**[1]

[1]*King Fahad University Hospital*

BACKGROUND & AIM

Open pediatric airway reconstruction procedures, such as laryngotracheal reconstruction, cricotracheal resection, and slide tracheoplasty, restore airway patency in children with severe stenosis but may result in swallowing dysfunction and aspiration.

While decannulation outcomes are well documented, aspiration has been inconsistently reported, leaving uncertainty about its true prevalence, risk factors, and management. This study aimed to systematically review and quantify the prevalence of postoperative aspiration in children undergoing open airway reconstruction, and to synthesize available evidence on its diagnosis, management, and resolution.

MATERIAL & METHODS

We performed a systematic review and meta-analysis in accordance with PRISMA guidelines. PubMed, Embase, Scopus, and Cochrane Library were searched through August 2025 for studies reporting aspiration or swallowing outcomes after pediatric airway reconstruction. Eligible studies included children (0–18 years) undergoing open airway surgery with documented postoperative aspiration, assessed by clinical or instrumental methods. Data extraction covered patient demographics, surgical procedures, diagnostic tools, prevalence of aspiration, interventions, and outcomes. Study quality was appraised using the Newcastle–Ottawa Scale. Pooled prevalence was calculated using random-effects models.

RESULTS

Twenty-two studies (874 children) were included. Aspiration rates ranged from 0% to 50%, with higher rates in smaller cohorts and complex reconstructions. The pooled prevalence of postoperative aspiration was 15.8% (95% CI: 10.7–20.9%). Diagnostic methods varied widely, with nearly half of studies not specifying an assessment approach. Reported management was mainly conservative such as: diet modifications, thickened feeds, swallowing therapy, or temporary tube feeding, and most cases resolved within six weeks. Series that documented outcomes generally reported full recovery.

CONCLUSIONS

Aspiration is a clinically significant yet often temporary complication following pediatric airway reconstruction, affecting roughly one in six patients. Routine postoperative swallow assessment and early multidisciplinary management are recommended to mitigate morbidity. Standardized diagnostic protocols and prospective studies are needed to improve care pathways and clarify long-term outcomes.

OP-973

Influence Of Tumor Size On Survival Rates In Pediatric And Adolescent Patients With Malignant Peripheral Nerve Sheath Tumors: A Study Utilising The SEER Database

Zhixuan Fang[1], **Shengcai Wang**[1]

[1]*Beijing Children's Hospital, Capital Medical University*

BACKGROUND & AIM

Malignant peripheral nerve sheath tumors (MPNSTs) are rare and highly aggressive soft-tissue sarcomas, with limited literature available on pediatric and adolescent populations. This study assessed the impact of tumor size on overall survival (OS) and disease-specific survival (DSS) in individuals aged 18 years and younger.

MATERIAL & METHODS

Individuals with MPNSTs were identified from the SEER database. Cox regression analysis were employed to identify characteristics correlated with overall survival (OS) and disease-specific survival (DSS). Receiver operating characteristic (ROC) analysis determined the appropriate tumor size threshold, whereas survival outcomes were evaluated by Kaplan–Meier analysis.

RESULTS

ROC analysis determined 5.75 cm as the best tumor size threshold for overall survival prediction (AUC = 0.718). Tumor size served as an independent prognostic indicator for both overall survival (OS) (HR = 1.008, P < 0.001) and disease-specific survival (DSS) (HR = 1.008, P = 0.007), whereas treatment modality was independently linked to enhanced OS (HR = 0.504, P = 0.035). Tumors measuring ≥5.75 cm were correlated with elevated tumor grade, greater frequency of metastasis, and higher fatality rates (all P < 0.001). Patients with smaller tumors exhibited markedly improved overall survival. Consistent results were noted in patients aged 14 years or younger, with an optimum threshold of 5.70 cm.

CONCLUSIONS

The size of a tumor is a robust and independent prognostic indicator of survival in pediatric and adolescent MPNSTs. Increased tumor size correlates with significantly poorer prognoses, highlighting the necessity of prompt identification and treatment.

OP-974

Feasibility Of An Accessible Rib Carving Simulator For Microtia Reconstruction As A Global Surgical Training Tool

Rishi N. Modi[1], **Kai C. Kokesh**[1], **Daly Try**[2], **G. Nina Lu**[1], **Amit D. Bhrany**[1], **Randall A. Bly**[1,3], **Kathleen C.Y. Sie**[1,3], **Sheng Zhou**[1,3]

[1]Department of Otolaryngology – Head & Neck Surgery, University of Washington, Seattle, WA; [2]Department of Plastic Surgery, University of Health Sciences, Phnom Penh, Cambodia; [3]Department of Otolaryngology – Head & Neck Surgery, Seattle Children's Hospital, Seattle, WA

BACKGROUND & AIM

Rib cartilage framework creation for microtia reconstruction is a challenging technique, with limited opportunities to practice due to rarity of the condition and scarcity of realistic simulations. We hypothesize that our accessible simulation model will demonstrate face and content validity across international training cohorts.

MATERIAL & METHODS

Participants were trainees from the University of Washington Otolaryngology Head and Neck Surgery (UW-OHNS) and Plastic Surgery (UW-PS), and Smile Cambodia Plastic Surgery (SC-PS). Sessions were run by expert microtia surgeons using our published synthetic rib model, ensuring content validity. Participants completed Likert scales to self-report pre- and post-simulation confidence and skill, and simulation quality assessments.

RESULTS

Participants (n=60; UW-OTO 35%, UW-PS 28%, SC-PS 37%,) were resident physicians (61.7% post-graduate year (PGY) 1–3). Most (61.7%) reported no prior exposure to rib carving. All cohorts had similar prior exposure and PGY levels. SC-PS reported significantly higher pre-simulation confidence and skill than both UW cohorts ($p<.01$). Post-simulation, both UW cohorts reported significant improvement in confidence and skill (all $p<.001$). SC-PS showed statistically significant score increases, though no shift in median score, for either outcome (Δ median=0, $p<.01$). SC-PS reported significantly less confidence and skill gain than UW-OHNS ($p<.05$). Across the three cohorts, median realism was 4.00 (IQR 3.00–5.00) and ease-of-use was 5.00 (IQR 4.00–5.00) on a scale from 1 (not at all) to 5 (excellent). SC-PS median satisfaction with this simulation as a global tool was 4.00 (IQR 3.00–4.75). On regression analysis, cohort did not independently predict post-simulation score; and PGY significantly predicted post-simulation skill ($\beta=0.170$, $p=.011$).

CONCLUSIONS

This accessible rib carving simulator improved self-reported confidence and skill among American and Cambodian trainees, with favorable realism and ease-of-use ratings. The Cambodian cohort reported higher pre- and lower post-simulation metrics, despite similar training and exposure levels to American cohorts. This suggests cultural differences in self-assessment. Higher training level independently predicted post-simulation skill rating, but cohort did not, supporting the face validity of our construct. Future work could establish predictive validity through objective performance metrics and longitudinal follow-up.

OP-975

The Effect Of Adenotonsillectomy On Enuresis: A Multidisciplinary Prospective Study

Bilal Çetin[2], **Zeynep Erdoğan Çetin**[1], **Bora Sezer**[1], **Yunus Kayalı**[3]

[1]Kartal Dr. Lutfi Kirdar City Hospital, Department of Otolaryngology Head and Neck Surgery - Istanbul, Turkey.; [2]Kartal Dr. Lutfi Kirdar City Hospital, Clinic of Pediatric Urology, Istanbul, Turkey.; [3]Kartal Dr. Lutfi Kirdar City Hospital, Clinic of Urology, Istanbul, Turkey.

BACKGROUND & AIM

In this study, we evaluated the effect of adenotonsillectomy (AT) on primary monosymptomatic enuresis (PME) in children with both upper respiratory tract obstruction and persistent PME.

MATERIAL & METHODS

We received approval from the tertiary hospital's ethics committee for our prospective, multidisciplinary descriptive study (Date: 11.10.2023, Decision number: 2023/514/259/6). Patients who underwent adenotonsillectomy or adenoidectomy between 2023 and 2025 were evaluated in our prospective study. Children aged 5 to 18 years with PME were monitored both pre-operatively and post-operatively.

Enuresis associated with sleep disordered breathing (SDB) due to adenotonsillar hypertrophy was the primary inclusion criterion for the study. This study utilised the International Children's Continence Society (ICCS) update and the EAU-ESPU pediatric urology guidelines to help accurately select patients with PME.

Weekly counts of wet nights were recorded for all patients both before and three months after their operations. The modified Epworth Sleepiness Scale (mESS), defined as a measure of sleepiness in children, was also recorded both preoperatively and postoperatively.

RESULTS

Our study involved 140 patients with PME who exhibited obstructive sleep symptoms due to adenoid and/or tonsillar hypertrophy. In our evaluation of enuresis resolution, measured by wet nights/week, 74 patients (52.8%) showed complete

resolution, 42 (30%) partial improvement (more than 50% reduction in wet nights/weeks), and 24 (17.2%) no response. We divided the patients into two distinct groups: ages 5-6 (group 1) and ages 7 and older (group 2). In group 1, the mEES were 4.11 ± 2.38 (0–12) preoperatively and 1.74 ± 1.51 (0–6) postoperatively. In group 2, the mESS were 4.12 ± 2.58 (0–15) preoperatively and 1.94 ± 1.80 (0–8) postoperatively.

CONCLUSIONS

PME typically resolves spontaneously in about 15% of children each year. In our study, 52% of PME patients achieved complete resolution, while 30% showed a partial improvement. Despite conflicting results in the literature, our prospective study indicates that enuresis should be considered in cases of adenotonsillar hypertrophy.

OP-976

Diagnostic Accuracy Of AI-Assisted Lateral Neck Radiographs In Adenoidectomy Decision-Making

Selçuk EROL[1], **Zeynep ERAHISKALI**[1]

[1]*Ankara Atatürk Sanatoryum Training and Research Hospital*

BACKGROUND & AIM

Endoscopic examination is the reference standard for assessing adenoid hypertrophy and determining adenoidectomy indication, although lateral skull radiographs remain widely used in clinical practice. With the increasing integration of artificial intelligence (AI) into clinical workflows, the reliability of large language model (LLM)-assisted radiographic interpretation requires validation. This study evaluated the agreement and diagnostic performance of two LLMs (ChatGPT and Gemini) in estimating adenoid vegetation ratio from lateral radiographs compared with endoscopic findings. We hypothesized that AI-derived measurements would demonstrate significant agreement and acceptable discrimination for severe obstruction.

MATERIAL & METHODS

This retrospective diagnostic accuracy study included 159 pediatric patients evaluated for adenoid hypertrophy. Endoscopic vegetation ratio (%) served as the reference standard. AI-estimated vegetation ratios from lateral skull radiographs were obtained using ChatGPT and Gemini. Normality was assessed with the Shapiro–Wilk test. Normally distributed variables were expressed as mean ± standard deviation and non-normally distributed variables as median (interquartile range). Agreement with endoscopic measurements was analyzed using Spearman correlation and Wilcoxon signed-rank tests. Diagnostic performance for severe obstruction was evaluated using receiver operating characteristic (ROC) curve analysis with area under the curve (AUC), adopting ≥80% endoscopic obstruction as the predefined surgical threshold. Statistical significance was set at $p < 0.05$.

RESULTS

The mean age was 7.66 ± 2.29 years. Median endoscopic vegetation ratio was 80%, compared with 60% for ChatGPT, while the mean Gemini value was 70.32 ± 13.33%. No significant association was found between ChatGPT and endoscopy ($\rho = 0.008$, $p = 0.916$). Gemini demonstrated a weak but significant correlation ($\rho = 0.217$, $p = 0.006$). Paired comparisons showed significant differences between endoscopic measurements and both AI models (both $p < 0.001$), indicating systematic underestimation. For ≥80% obstruction, diagnostic discrimination was limited (AUC ≈ 0.50 for ChatGPT; AUC ≈ 0.57 for Gemini), both below acceptable performance levels (AUC ≥ 0.70).

CONCLUSIONS

LLM-assisted interpretation of lateral radiographs showed weak agreement with endoscopic findings and insufficient accuracy for identifying surgically significant adenoid hypertrophy. Although Gemini performed relatively better, neither model achieved clinically acceptable diagnostic performance.

OP-977

Impact Of Parental Anxiety On Reported Severity And Objective Clinical Outcomes In Pediatric Epistaxis

Alper Özdemir[1], **Burcu Vural Çamalan**[1], **Sümeyra Doluoğlu**[1], **Yasemin Koçyiğit**[2]

[1]*Department of Otorhinolaryngology, Ankara Etlik City Hospital, Ankara, Türkiye;* [2]*Department of Psychiatry, Ankara Etlik City Hospital, Ankara, Türkiye*

BACKGROUND & AIM

Pediatric epistaxis is a common emergency that often causes disproportionate parental distress. This study aimed to evaluate whether parental anxiety levels are associated with the reported severity and clinical management of pediatric epistaxis.

MATERIAL & METHODS

This prospective study included 100 pediatric patients presenting with epistaxis and their accompanying parents. Parental anxiety was assessed using the State-Trait Anxiety Inventory (STAI). Based on STAI-State scores, parents were categorized into

mild (n=15), moderate (n=43), and severe (n=42) anxiety groups. Epistaxis frequency, bleeding duration, recurrent emergency department (ED) visits, comorbidities, and treatment modality (observation, nasal packing, or packing with cauterization) were recorded. Group comparisons (Chi-Square Test, Kruskal-Wallis Test, Mann-Whitney Test Post-hoc) and correlation analyses (Pearson Correlation) were performed.

RESULTS

Epistaxis frequency increased significantly with higher parental anxiety levels ($p = 0.0001$). The severe anxiety group reported markedly longer bleeding duration compared to the moderate and mild groups ($p = 0.0001$ for both). STAI-State and STAI-Trait scores demonstrated significant positive correlations with both frequency ($r=0.60$ and $r=0.54$, respectively; $p = 0.0001$) and duration ($r=0.33$, $p = 0.001$ and $r=0.25$, $p= 0.01$ respectively). Despite these findings, no significant associations were observed between parental anxiety and recurrent ED visits ($p = 0.73$), treatment modality ($p = 0.21$), or comorbidities ($p = 0.39$).

CONCLUSIONS

Higher parental anxiety is strongly associated with increased reported frequency and duration of pediatric epistaxis but does not correlate with objective clinical severity or intervention need. These findings suggest that parental anxiety may substantially influence symptom perception and healthcare-seeking behavior. Incorporating structured reassurance and anxiety management strategies into clinical care may improve both patient experience and resource utilization.

OP-978

Evaluation Of Large Language Model Performance In Responding To Parental Concerns About Pediatric Adenoid Hypertrophy: A Multidimensional Comparative Study

Emre Ulutaş[1], **İpek Yeşil**[1], **Deniz Odluyurt**[1], **Salih Akyel**[1], **Zeliha Kapusuz Gencer**[1], **Özgür Yiğit**[1]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, Başakşehir Çam and Sakura City Hospital, University of Health Sciences, Istanbul, Turkey*

BACKGROUND & AIM

Large language models (LLMs) are increasingly used by parents seeking medical information, yet their reliability in pediatric otolaryngology remains unvalidated. This study aimed to evaluate the performance of four LLMs (GPT-4o, Gemini 2.0 Pro, Claude Sonnet 4.6, Perplexity Sonar Pro) in responding to real-world parental concerns about pediatric adenoid hypertrophy, using multidimensional quality metrics including DISCERN, PEMAT-P, and triage safety assessment.

MATERIAL & METHODS

Outpatient records of 791 pediatric patients (aged 2–18) who underwent adenoidectomy between January 2025 and January 2026 were retrospectively reviewed. Parental concerns were extracted via thematic coding, yielding 18 themes; the 10 most frequent were converted into standardized questions. These were directed to four LLMs, and responses were blindly evaluated by two ENT specialists using DISCERN (information quality, 1–5), PEMAT-P (understandability and actionability, 0–1), and triage safety criteria (emergency detection, referral accuracy, hallucination, 0–1). Inter-model comparisons used Kruskal-Wallis with Bonferroni-corrected Mann-Whitney U post-hoc tests; inter-rater agreement was assessed via ICC(2,1).

RESULTS

Claude Sonnet 4.6 achieved the highest overall score (86.0 ± 8.0), followed by GPT-4o (76.9 ± 13.8), Perplexity Sonar Pro (73.6 ± 11.2), and Gemini 2.0 Pro (67.2 ± 8.0). The inter-model difference was statistically significant ($H = 28.27$; $p < 0.001$; $\varepsilon^2 = 0.33$). Post-hoc analysis confirmed significant differences between Claude and Gemini ($p < 0.001$) and Claude and Perplexity ($p = 0.002$). Hallucination rates were highest for Gemini (30%) and lowest for Claude and Perplexity (5% each). Emergency detection failure was 40% for Gemini and Perplexity versus 20% for GPT-4o and Claude. Inter-rater agreement was excellent ($ICC = 0.83$; $p < 0.001$).

CONCLUSIONS

LLMs demonstrate significantly variable performance in addressing parental concerns about pediatric adenoid hypertrophy. Claude Sonnet 4.6 outperformed other models in information quality, understandability, and safety. Gemini 2.0 Pro's high hallucination rate and poor triage safety raise patient safety concerns. No LLM can replace expert clinical counseling; however, selected models may serve as supplementary informational tools under physician guidance.

Unusual Complications Of Tonsillectomy: An Updated Systematic Review (2007–2025)

Ilgın Eylül Zengin[1], **Özge Çağlar Çil**[1], **Murat Zaim**[1], **Oğuz Güçlü**[1]

[1]*Canakkale Onsekiz Mart University, Department of Otorhinolaryngology*

BACKGROUND & AIM

Tonsillectomy is widely performed in otolaryngology. Beyond common complications such as hemorrhage (3%), pain, and nausea, rare but serious events are also reported. The most comprehensive systematic review on this subject was published by Leong et al. in 2007. Since then, with the increasing use of new surgical techniques (e.g., coblation, harmonic scalpel, plasma blade), the spectrum of complications has expanded.

MATERIAL & METHODS

A systematic search of PubMed and Web of Science (2007–2025) was performed. Case reports and series on rare complications were included, while typical outcomes were excluded. Data were extracted on study and patient characteristics, type and timing of complication, management, and outcome. Analysis was descriptive, following PRISMA guidelines.

RESULTS

A total of 92 studies (n=94 cases) were included in the review. Complications were classified according to clinical groups: respiratory/thoracic (n=27), neurological (n=20), vascular/thromboembolic (n=19), infectious (n=13), structural/wound healing (n=6), and others (n=9). The most frequently reported complication was subcutaneous emphysema (n=25). Cases reported for the first time in the literature, such as oculomotor nerve palsy, Jackhammer esophagus, and Foreign Accent Syndrome, were included. Two cases with pulmonary embolism and pneumothorax had a fatal outcome.

CONCLUSIONS

Tonsillectomy is a frequently performed and generally safe surgical procedure; however, rare complications may lead to significant morbidity and mortality. The current literature demonstrates that the spectrum of complications is broader than previously assumed. Particularly in the pediatric age group, where this surgery is commonly performed and provides clinical improvement, recognition of rare complications by clinicians is of great importance.

Inhaled F.B Complicating The Bronchial Tree: A Novel Removal Technique

sharfi Ahmed[1], **Sara Amin**[2]

[1]*Omdurman Islamic University -Sudan;* [2]*Khartoum university*

BACKGROUND & AIM

Introduction: Foreign body aspiration is a major cause of morbidity and mortality in children. Despite its clinical significance, data from underdeveloped countries—particularly Sudan—remain limited.

Objective: To describe the clinical presentation, management approaches, and complications among paediatric patients with foreign body aspiration in Sudan .

MATERIAL & METHODS

A retrospective cross-sectional hospital-based study was conducted at Sudan hospitals, including all patients diagnosed with foreign body aspiration from April 2023 to April 2025. Data were collected using predesigned checklists and analyzed using SPSS.

RESULTS

A total of 142 patients were evaluated. Most were aged 1–2 years (45%), with a male predominance. Cough (66.9%) was the most common presenting symptom, while wheeze (89.4%) was the most frequent clinical sign. The interval between aspiration and bronchoscopy ranged from 24 hours to more than one month, with 45% presenting within 1 day to 1 week. Elective bronchoscopy was performed in 62.7% of cases. A foreign body was visualized in 91% of patients. New technichqe was applied(named sharfi technique) to some difficult cases and removal was successful.

The right main bronchus was the most common site of lodgment (63.8%), and watermelon seeds were the most frequently aspirated objects. Complications occurred in 21 patients (14.7%), including hypoxia (5%), delayed recovery (4%), postoperative stridor (2.1%), and one case requiring urgent tracheostomy. Mortality was recorded in two patients (1.4%).

CONCLUSIONS

Foreign body aspiration predominantly affected male children aged 1–2 years. Cough and wheezing were the most common presenting features, and the right main bronchus was the typical site of lodgment. Early presentation (within one week) and elective bronchoscopy were associated with improved outcomes, while the type of aspirated foreign body did not significantly influence prognosis.

National Consensus Recommendation On Congential Nasal Pyriform Aperture Stenosis(CNPAS)

Nasser Alobida[1], **Danah Aljomah**[1]

[1]*King Fahad Medical City*

BACKGROUND & AIM

Congenital Nasal Pyriform Aperture Stenosis (CNPAS) is a rare congenital anomaly resulting from overgrowth of the medial nasal processes, with an estimated incidence of 1 in 25,000 live births worldwide. Due to its rarity, there is scarcity in the current literature on its diagnosis and management, relying on isolated case reports and series. Consequently, there is a lack of standardized guidelines for diagnosing and treating patients with CNPAS. This study aimed to construct a national consensus recommendation to establish a unified diagnostic and management approach for patients with CNPAS. Thus, outlining clinical practices and decision-making processes for patients with CNPAS.

MATERIAL & METHODS

This study targets expert pediatric otorhinolaryngologists involved in the care of patients with CNPAS. A structured survey was conducted to cover various aspects of CNPAS care, including diagnosis and operative approaches, as well as post-operative in-hospital and outpatient care. The Delphi method will be used to gather the opinions of experts on the care of CNPAS patients. The first round of the survey will be introduced at the annual Saudi Otolaryngology Society meeting (2026) and will be followed by multiple survey-filling rounds till consensus is reached. A consensus is reached when 80% or more of the experts rate an item similarly. A final analysis will be conducted to construct consensus recommendations.

RESULTS

The survey will be fulfilled by pediatric otorhinolaryngologists attending the annual Saudi Otolaryngology Society meeting (2026). The same participants will complete the survey in the subsequent rounds, thereby implementing the Delphi method.

CONCLUSIONS

This study aims to establish a national consensus recommendation regarding the diagnostic and management strategies for patients with CNPAS.

Bridging The Gap: Integrating Maternal Psychotherapy Into Cleft Lip And Palate (CLP) Care Planning

Dr. James Leslie A. Rondal[1]

[1]*Mariano Marcos Memorial Hospital and Medical Center*

BACKGROUND & AIM

Mothers experience heightened levels of psychological challenges due to the stigma associated with the physical deformity, financial burden, and uncertainty of treatment outcomes. Despite the known impact of CLP on mothers, psychotherapy are underutilized. This study aims to evaluate the effectiveness of integrating routine psychotherapy into CLP Care Planning on the overall maternal well-being and psychosocial outcomes among mothers, help mothers cope with the emotional impact of having a child with CLP, addressing guilt and anxiety, and to empower the mother to become proactive in their child's care, leading to treatment adherence and better clinical outcomes.

MATERIAL & METHODS

This is a 2-year prospective cohort study, with 36 mothers who fulfilled the criteria. Subjects received psychotherapy using a validated psychosocial questionnaire. Paired t-tests were used to compare pre- and post-counseling psychological scores, while regression analysis was used to determine the factors associated with psychotherapy and CLAP care plan outcomes.

RESULTS

Following psychotherapy, participants demonstrated a significant reduction in stress levels, with post-counseling scores (M=4.2, SD=1.0) significantly lower than pre-counseling scores (M=7.5, SD=1.2; $p < 0.05$). Adherence to the CLAP care plan increased from 65% (N=23) prior to psychotherapy to 90% (N=32) afterward. Additionally, 85% (N=31) of mothers reported enhanced understanding of feeding techniques and surgical timelines. Emotional well-being also showed notable improvement, with 75% (N=27) of mothers exhibiting better psychosocial outcomes as assessed by the standardized questionnaire.

CONCLUSIONS

These findings indicate that integrating routine maternal psychotherapy into CLP care planning significantly improve maternal psychological well-being, reduce maternal stress, and understanding of CLP management leading to treatment compliance and enhanced mother-child bond.

Subannular T- Tube Insertion In Recurrent Otitis Media With Effusion

Maurizio Cortada[2]

[1]*University Children's Hospital Basel, Switzerland;* [2]*University Hospital Basel, Switzerland*

BACKGROUND & AIM

Chronic otitis media with effusion (COME) is very frequent in children and associated with a significant health burden (hearing loss, etc.) and socioeconomic impact prompting defining effective management.

Primary surveillance and conservative measures are eventually followed by placement of tympanostomy tubes ± adenoidectomy. About 25% of children need more than one intervention increasing the risk for chronic perforation and or hearing impairment. The subannular tube (SAT) technique has been proposed to increase duration of the tubes in the middle ear Our goal is to present a treatment algorithm for COME in children highlighting the role of SAT.

MATERIAL & METHODS

Retrospective chart analysis performed in children aged < 18 years treated by SAT insertion at the University Hospital Basel during 2015-2020. 'Tympanic membrane retraction' defined as stage I, II, or III and 'adhesive otitis media' as stage IV according to the Sadé classification. Data is presented as means ± SDs. For statistical analysis: Prism 9 software (GraphPad, La Jolla, CA, USA).

RESULTS

The mean duration was 21.4 months. The main complication was blockage; no chronic perforation was seen. The PTA mean was 18.4 dB HL.

CONCLUSIONS

The SAT insertion represents an effective method with few complications in the treatment algorithm of children with COME. Hearing is good to excellent. The longer duration of 21 in comparison to the transtympanic technique (4-12 months) leads to fewer interventions and anesthesia.

KEYWORDS

otitis media with effusion, t-tube, children,

OP-984

Complications And Recurrence After Coblation Intracapsular Tonsillectomy: A Retrospective Study

Akash Srinivasan[1,2], **Nadia Al-Efeshat**[1], **Merlin Babu**[1], **Amit Raithatha**[1], **Laylan Salih**[1], **Alison Hunt**[1], **Prathibha Nanoo**[1]

[1]*Milton Keynes University Hospital, Milton Keynes, UK;* [2]*Medical Sciences Division, University of Oxford, Oxford, UK*

BACKGROUND & AIM

The Coblation® intracapsular tonsillectomy approach has gained popularity in the management of obstructive sleep apnoea (OSA), due to reduced pain and faster recovery after surgery. However, its adoption has been limited by concerns surrounding tonsillar regrowth and symptom recurrence, particularly in the context of recurrent tonsillitis. This retrospective review evaluated the outcomes of 101 cases, with obstructive and infective indications.

MATERIAL & METHODS

A single-centre retrospective audit of cases between November 2020 and December 2025 was conducted at a district general hospital. Demographic and complication data was collected from electronic patient records and telephone interviews were performed using the validated T-14 questionnaire. Overall, obstructive symptom and infective symptom scores were calculated from the T-14 data and residual symptom burden by indication for surgery was compared.

RESULTS

101 patients (mean age 7.1 years, 59% males) who underwent Coblation® intracapsular tonsillectomy with or without adenoidectomy and insertion of grommets were included. Indication for surgery was either OSA only (57%), recurrent tonsillitis only (28%) or both OSA and recurrent tonsillitis (15%). Rates of admission with postoperative pain and symptomatic regrowth were 4% and 1% respectively and there was only 1 case of bleeding, although this was a severe example of primary haemorrhage. Telephone interviews were completed in 84 patients at an average follow-up time of 20 months. Mean postoperative T-14 overall score was 6.19, whilst the mean obstructive symptom score was 4.32 and the mean infective symptom score was 1.87. At the time of follow up, the residual infective symptom burden for recurrent tonsillitis patients was significantly lower than the residual obstructive symptom burden for OSA patients ($p<0.001$).

CONCLUSIONS

Coblation® intracapsular tonsillectomy is effective in achieving symptom control for patients with either OSA or recurrent tonsillitis, whilst maintaining a very low complication rate. However, the favourable safety profile is dependent on meticulous technique to avoid inadvertently breaching the capsule, and the risk of serious primary haemorrhage should not be underestimated. Further studies should compare these outcomes with extracapsular techniques and evaluate the risk of symptom recurrence in the long term.

Comparative Efficacy Of Intranasal Corticosteroids, Saline Irrigation, And Combination Therapy In The Management Of Moderate To Severe Pediatric Allergic Rhinitis

Seda SEZEN GÖKTAŞ[1], **Erol ŞENTÜRK**[2], **Yasin KULAKSIZ**[3], **İsmail ÇELİK**[3], **Orhan ÖZTURAN**[2], **Selahattin TUĞRUL**[3]

[1]*Samsun Education and Research Hospital, Otorhinolaryngology Department, Samsun , Turkey;* [2]*Bezmialem Vakif University, Faculty of Medicine, Otorhinolaryngology Department, İstanbul, Turkey;* [3]*Medipol University, Faculty of Medicine, Otorhinolaryngology Department, İstanbul, Turkey*

BACKGROUND & AIM

In pediatric allergic rhinitis, achieving strong symptomatic control and preventing secondary complications is crucial. Intranasal treatments are important for this treatment strategy. This study aimed to investigate the therapeutic efficacy of intranasal corticosteroids, saline solutions, and combination therapy in patients with moderate-to-severe pediatric allergic rhinitis.

MATERIAL & METHODS

This study was designed as a prospective, randomized clinical trial. A total of fifty seven pediatric patients with allergic rihinitis included. The patients were divided into three groups. In addition to systemic treatment, Group 1 received intranasal steroids, Group 2 received steroid-containing saline irrigation, and Group 3 received saline irrigation for four weeks. Pre- and post-treatment endoscopic examination scores, results of the olfactory test, Eustachian function test, peak nasal inspiratuar flow test, nasal eosinphilia evaluation, nasal symptom scores and questionnaire scores of quaility of life, strenghts and difficulties and brief symptom inventory were recorded. Intra-group comparisons and the correlation between changes in different parameters was analyzed. Inter-group comparisons were conducted and for variables where a significant difference was detected, the pairwise comparisons applied to identify specific group differences.

RESULTS

In within-group analysis, Group 1 showed significant improvement in all parameters except olfactory test and nasal eosinophilia, while Groups 2 and 3 showed significant improvement in all parameters except Eustachian tube function test. In the intergroup comparison, the endoscopic examination score showed a significant improvement in Group 3 compared to Group 1 (p=0.002). Additionally, there was a slightly significant improvement in nasal eosinophilia in Group 2 compared to Group 1 (p=0.049). No statistically significant differences were found between the groups in other parameters.

CONCLUSIONS

According to results of the this study, the question of whether intranasal saline irrigation can be an alternative to intranasal steroids in the treatment of moderate to severe pediatric allergic rhinitis deserves further discussion. More studies with larger patient participation are needed in the literature.

Bacteremia During Tonsillotomy In Children

Yüce İslamoğlu[1], **Sami Berçin**[1], **Bengi Arslan**[1], **Gökhan Atik**[1], **Mehmet Emin Ak**[1], **Muhammed Fatüh Ozcan**[1], **Selman Seckin**[1], **Ezgi Erkılıç**[1], **Bedia Dinç**[1]

[1]*Ankara Bilkent City Hospital*

BACKGROUND & AIM

To evaluate the incidence of transient bacteremia following coblation-assisted intracapsular partial tonsillectomy (tonsillotomy) in children.

MATERIAL & METHODS

In this prospective study included 36 children with grade 3–4 tonsillar hypertrophy undergoing coblation-assisted tonsillotomy for obstructive sleep apnea syndrome included. Aerobic and anaerobic blood cultures were obtained preoperatively and immediately after the tonsillotomy. Intraoperative throat cultures were also collected.

RESULTS

All preoperative blood cultures were negative. Postoperative blood cultures demonstrated two patient (5.6%) had positive blood culture. Streptococcus pyogenes and actinomyces were isolated in the cultures. One of these patients had streptococcus pyogenes in the corresponding throat culture.

CONCLUSIONS

This study is the first to determine the rate of transient bacteremia developing after tonsillotomy surgery.

Despite the minimally invasive technique and the use of coblation technology, the rate of transient bacteremia was 5.6%. Therefore, clinicians should keep prophylactic antibiotics in mind for high-risk patients.

OP-987

Newborn Hearing Screening In A Crisis-Affected Middle-Income Country: A 10-Year Tertiary Center Experience

Gabriel Dunya, MD[1], **Lynn Abdel Malak, MD**[1]

[1]*American University of Beirut Medical Center*

MATERIAL & METHODS
We conducted a retrospective cohort study of all live births at a tertiary academic medical center in Lebanon between 2015 and 2024. Universal screening was performed using OAE and/or AABR according to institutional protocol aligned with JCIH 1-3-6 principles. Data collected included screening coverage, initial referral rate, rescreening attendance, diagnostic confirmation, time to retest, permanent hearing loss prevalence, and documented reasons for parental refusal. The 10-year period was stratified into three eras: pre-crisis (2015–2019), crisis period (2020–2022), and recovery (2023–2024). Multivariable logistic regression was used to assess the independent association between era and screening completion/referral outcomes. Chi-square testing with adjusted residuals evaluated differences in refusal reasons across eras. Statistical significance was set at $p<0.05$. Program performance indicators were benchmarked against international tertiary data.

RESULTS
Among the total of 13,043 live births over the 10-year period, 10,777 newborns completed screening, corresponding to a coverage rate of 82.6%. Screening completion differed significantly across eras. In multivariable logistic regression adjusting for era and gender, era remained independently associated with screening status ($p<0.001$). Compared with the COVID era (2020–2022), infants born in 2015–2019 had lower odds of screening completion (adjusted OR 0.83; 95% CI 0.74–0.92), whereas infants born in 2023–2025 had higher odds (adjusted OR 1.24; 95% CI 1.06–1.44). The prevalence of confirmed permanent hearing loss was 9 cases among 13,043 births (0.69 per 1,000). Refusal reasons differed significantly across eras ($\chi^2(6)=104.5$, $p<0.001$), with financial hardship disproportionately represented during the crisis period. Median time to retest did not differ across eras in either normal nursery ($p=0.243$) or NICU settings ($p=0.818$).

CONCLUSIONS
This is the first Lebanese study quantifying newborn hearing screening performance and referral patterns. Despite unprecedented national crises, screening services demonstrated resilience and rapid recovery. Financial barriers significantly influenced parental refusal, highlighting the need for mandatory, free-of-charge national screening with structured follow-up systems. These findings provide the first institutional evidence base to inform Lebanese national policy development. Establishing mandatory universal screening, strengthening counseling systems, and expanding early intervention access, including cochlear implantation pathways, are critical next steps to reduce preventable disability and long-term societal burden.

OP-988

Demographic Characteristics And Risk Factors For Recurrence Of Nasal Polyps In Chinese Children

Xiuping WU[1], **Yang Han**[1], **Wentong Ge**[1]

[1]*Beijing Children's Hospital, Capital Medical University, National Center for Children's Health*

BACKGROUND & AIM
Nasal polyps, characterized by benign and edematous inflammation of the nasal mucosa, occur less frequently in children than in adults. As treatment resistance and recurrence are major challenges, this study aims to delineate the demographic characteristics and medical burden of Chinese pediatric patients, analyze the risk factors for postoperative recurrence, and construct a prognostic model.

MATERIAL & METHODS
A combined multicenter retrospective and single-center follow-up study design was adopted. We analyzed the epidemiological characteristics of 2,846 children with nasal polyps treated across 36 hospitals in China from 2016 to 2023. Additionally, clinical data were collected from 102 pediatric patients who underwent functional endoscopic sinus surgery (FESS) at Beijing Children's Hospital, Capital Medical University, between 2021 and 2024. Clinical features of chronic rhinosinusitis with nasal polyps (CRSwNP) and antrochoanal polyps (ACP) were compared. Univariate and multivariate logistic regression, along with least absolute shrinkage and selection operator regression (LASSO) regression, were employed to screen for risk factors and construct a prognostic model. Model performance was evaluated using receiver operating characteristic (ROC) curves, area under the curve (AUC), and calibration curves.

RESULTS

The average prevalence of pediatric nasal polyps in China was approximately 1.68 per million during the period from 2016 to 2023. In China, nasal polyps were predominantly seen in males (65.9%) and children aged 6-12 years (62.0%), with peak visits occurring in summer and an increasing annual trend. Adenoid hypertrophy was the most common comorbidity, and 85.8% of patients underwent surgical treatment. Subgroup analysis revealed that visual analog scale (VAS) scores for olfaction, Lund-Kennedy scores, and Lund-Mackay scores were significantly higher in the CRSwNP group than in the ACP group. Previous surgical history, Lund-Mackay scores, and VAS-sneezing scores were identified as independent risk factors for recurrence. The recurrence prediction model based on LASSO regression demonstrated excellent predictive performance (AUC = 0.821).

CONCLUSIONS

Pediatric nasal polyp visits in China show a rising trend annually. Although surgical outcomes are favorable, focused management of localized symptoms remains crucial. Our clinical indicator-based prognostic model serves as a robust and practical tool for recurrence risk stratification and guides personalized management strategies for children with nasal polyps.

Hospital Readmission And Postoperative Hemorrhage In Intracapsular And Extracapsular Pediatric Tonsillectomy

Adithya Srikanthan MD[1], **Anusha Dabak BSA**[1], **Annika Nambiar MPH**[1], **Matthew Carter MD**[1], **Harold Pine MD**[1], **Yusif Hajiyev MD**[1]

[1]*University of Texas Medical Branch, Galveston TX, USA*

BACKGROUND & AIM

Adenotonsillectomy remains one of the most commonly performed procedures in Otolaryngology and even more so in pediatric Otolaryngology. While traditionally performed extracapsularly, intracapsular tonsillectomy has emerged as a favorable alternative, potentially conferring faster recovery time, reduced postoperative bleeding risk, and a lower incidence of hospital readmission secondary to dehydration and inadequate pain control. In this study we aimed to identify differences in postoperative complications between intracapsular and extracapsular tonsillectomy, and determine the role of perioperative interventions and patient characteristics in optimizing outcomes.

MATERIAL & METHODS

This was a retrospective cohort study of pediatric patients who underwent tonsillectomy with the senior authors from January 2024 until November 2025. Tonsillectomies were performed in either an extracapsular or intracapsular fashion with the Coblator (Arthocare Inc.). The primary outcome was return to the emergency department. Secondary outcomes were postoperative hemorrhage, repeat cauterization in the operating room (OR), and hospital readmission. An analysis was performed examining the effects of bleeding disorders and postoperative steroid administration on the primary and secondary outcomes.

RESULTS

329 (37.1%) intracapsular tonsillectomies and 557 (62.9%) extracapsular tonsillectomies were performed. Intracapsular tonsillectomy was associated with lower rates of return to the ER (6.6% vs 10.1%, p=0.035), OR cauterization (0.33% vs 2.15%, p=0.046) and inpatient readmission (1.22% vs 4.49%, p=0.038). Intracapsular tonsillectomy did not confer a lower risk of bleeding events prompting return to the ER (1.82% vs 3.59%, p=0.130). Postoperative steroids were not associated with lower readmission rate (7.44% vs 10.27%, p=0.1453).

CONCLUSIONS

These findings suggest the intracapsular technique may offer meaningful improvements in surgical complication rate and resource utilization in pediatric tonsillectomy. While bleeding rates did not differ significantly, an overall reduction in return to OR for cautery illustrates a decrease in clinically significant complication. Intracapsular tonsillectomy remains a favorable surgical technique that, in the right patient population, can reduce surgical morbidity and optimize patient recovery.

OP-990

Long-Term Outcomes Of Ventilation Tube Insertion In Children: A 5-Year Retrospective Analysis Of Extrusion Times And Tympanic Membrane Sequelae

Sevinç Hepkarşı[1], **Berfu Tuncbilek**[1]

[1]*Izmir Democracy University, Buca Seyfi Demirsoy Training and Research Hospital, Department of Otorhinolarygology*

BACKGROUND & AIM

Otitis media with effusion (OME) is a leading cause of pediatric hearing impairment, frequently associated with adenoid hypertrophy (AH). While ventilation tube (VT) insertion is the gold-standard surgical intervention, the optimal duration of tube retention remains controversial. We hypothesized that specific VT extrusion time intervals are directly correlated with long-term structural integrity of the tympanic membrane (TM) and that there is a critical "turning point" beyond which the risk of permanent sequelae increases significantly.

MATERIAL & METHODS

This retrospective cohort study involved 157 pediatric patients (157 ears) aged 2–10 years who underwent VT insertion (with or without adenoidectomy) for persistent OME at a tertiary training and research hospital between 2020 and 2025. The study design focused on a 5-year longitudinal follow-up. Independent variables included age, gender, type of middle ear effusion (serous vs. mucoid), and surgical intervention type. Outcome measurements were categorized by VT extrusion time (<6 months, 6–15 months, and >15 months) and TM structural status at the fifth year (Normal, Myringosclerosis, Atrophy, Permanent Perforation, and Retraction). Statistical analyses were performed using Chi-square and Fisher's exact tests, with $p < 0.05$ considered significant.

RESULTS

The distribution of VT extrusion times was: <6 months (13.4%), 6–15 months (59.2%), and >15 months (27.4%). Mucoid effusion was significantly associated with longer retention ($p = 0.001$). At the 5-year follow-up, 58.6% of ears showed a normal TM. A highly significant correlation ($p < 0.0001$) was found between retention duration and sequelae: early extrusion (<6 months) was associated with 90% of all TM retraction cases. Conversely, the 6–15 month interval yielded the highest rate of normal TM outcomes (83.9%). Prolonged retention (>15 months) was significantly linked to myringosclerosis (44.2%), atrophy (32.6%), and all 5 cases (100%) of permanent perforation.

CONCLUSIONS

The duration of VT retention is a critical determinant of long-term outcomes. While retention for at least 6 months is necessary to prevent retractions, our results suggest that clinicians should consider 15 months as a critical threshold. Beyond this period, the risk of irreversible TM damage, including permanent perforation, rises sharply. Therefore, proactive removal of VTs remaining in situ for more than 15 months should be considered to preserve tympanic membrane health.

OP-991

Prevention And Reduction Of Tonsillectomy Complications With Platelet-Rich Plasma Application

Profesör Dr. İsmail Külahlı[1], **Uzman Dr. Yılmaz Kılar**[1]

[1]*Akdeniz Üniversitesi*

BACKGROUND & AIM

Tonsillectomy is one of the most frequently performed surgical procedures in otolaryngology practice. Despite numerous studies investigating different surgical techniques and adjunctive treatment modalities aimed at reducing postoperative complications, it remains a significant clinical concern. In recent years, platelet-rich plasma (PRP) applications have gained attention for their potential to accelerate tissue healing and reduce complications. This study aimed to evaluate the effects of locally administered PRP into the tonsillar fossae following tonsillectomy on postoperative pain, nutritional intake, analgesic requirements, bleeding, hospital readmission rates, recovery process, and quality of life, with the goal of preventing or minimizing postoperative complications.

MATERIAL & METHODS

All patients in both the control and study groups underwent standard tonsillectomy performed by the same surgeon using an identical surgical technique. In the study group, platelet-rich plasma was injected subcapsularly into both tonsillar fossae. In the postoperative period, the same procedure was applied to all patients in both the study and control groups for each stage, and postoperative complications were monitored using questionnaire forms we developed. These data were then statistically compared.

RESULTS

A total of 126 patients aged 3 to 58 years were included, with 63 in the study group and 63 in the control group. Postoperative pain scores, measured from the 6th hour to the 10th day, were significantly lower in the PRP group compared to controls. Analgesic requirements were also reduced in the study group during the first seven days and on day 10. No significant difference was found in nutritional intake between groups. Subgroup analysis showed that PRP was particularly effective in reducing pain and analgesic use and improving nutritional intake in patients aged 6–17 years. All postoperative bleeding events were secondary hemorrhages, occurring at rates of 6% in the study group and 13.7% in controls, without statistical significance. No other complications were observed in either group.

CONCLUSIONS

It was found that PRP application after tonsillectomy reduced postoperative pain levels, correspondingly decreased the need for analgesia, and improved nutritional intake. These positive effects were particularly observed in the 6–17 age group.

Personalized Treatment Of Robin Sequence With A 3D-Printed Palato-Lingual Plate

Dana Dolníková[1], **Neuschlová Iveta**[1], **Thurzo Andrej**[2]

[1]*National Institute of Children's Diseases in Bratislava, Slovakia;* [2]*Faculty of Medicine of the Comenius University in Bratislava, Slovakia*

BACKGROUND & AIM

Robin sequence (RS) is a congenital condition characterized by micrognathia, glossoptosis, and resultant upper airway obstruction. Cleft palate is commonly present and, combined with the aforementioned pathologies, results in dysphagia. A highly successful treatment option is the application of a personalized palatal plate or preepiglottic baton plate, which enables newborns to breathe freely and restore oral intake. Despite its proven efficacy, this method is currently used in only a few specialized centers. This study aims to demonstrate how advancements in 3D scanning and 3D printing can facilitate the fabrication of these devices.

MATERIAL & METHODS

This study is currently in-progress at the National Institute of Children's Diseases in Bratislava. The workflow involves obtaining an intraoral 3D scan from the patient, followed by designing the device using computer-aided design (CAD) software. The device is then 3D-printed from medical-grade biocompatible resin and post-processed for immediate clinical application.

RESULTS

As a proof of concept, 11 patients have been treated thus far at our hospital. While comprehensive long-term data are currently unavailable, no serious adverse effects have been observed, with the exception of minor mucosal lesions caused by local pressure. Crucially, none of the patients required a tracheostomy, and all successfully resumed full oral intake. These preliminary results highlight the reliability of the digital production chain.

CONCLUSIONS

Integrating 3D technologies streamlines the production of personalized RS devices. Digitalization facilitates manufacturing and offers a platform for inter-center collaboration, providing a viable pathway for smaller centers to implement this specialized treatment and enhancing global access to non-invasive management.

Immediate Extubation After Single Stage Laryngotracheal Reconstruction For Subglottic Stenosis In Children

Xinye Tang[1,2,3,4], **Di Hu**[1,2,3,4]

[1]*Department of Otolaryngology, Children's Hospital of Chongqing Medical University, Chongqing, China;* [2]*Ministry of Education Key Laboratory of Child Development and Disorders, Chongqing, China;* [3]*National Clinical Research Center for Child Health and Disorders (Chongqing), Chongqing, China;* [4]*China International Science and Technology Cooperation Base of Child Development and Critical Disorders, Chongqing, China*

BACKGROUND & AIM

Pediatric subglottic stenosis (SGS) traditionally requires prolonged postoperative intubation or tracheostomy following laryngotracheal reconstruction, leading to increased morbidity and healthcare burden. This study evaluated the safety and feasibility of immediate extubation following single-stage laryngotracheal reconstruction (SS-LTR) with anterior costal cartilage graft, and established appropriate patient selection criteria for this innovative surgical strategy.

MATERIAL & METHODS

A retrospective cohort study was conducted from July 2017 to July 2022. All patients underwent SS-LTR with anterior costal cartilage graft followed by immediate postoperative extubation. Study design included systematic analysis of demographics, comorbidities, intubation/tracheostomy history, stenosis classification and grading. Primary outcome measurements were operation-specific decannulation rate and overall decannulation rate. Secondary outcomes included immediate extubation success rate and postoperative airway complications.

RESULTS

Twenty-two patients with simple SGS were included. Median age at SS-LTR was 19 months (IQR = 18.5 months). Fourteen patients (63.6%) had prior intubation history and 14 patients (63.6%) required preoperative tracheostomy. SGS etiology comprised congenital in 8 patients (36.4%), acquired in 10 patients (45.5%), and mixed in 4 patients (18.2%). Stenosis severity included Grade II in 3 patients and Grade III in 19 patients. Comorbidities were present in 10 patients (45.5%), with pneumonia predominating. Congenital airway anomalies coexisted in 6 patients (27.3%). Remarkably, all 22 patients (100%) achieved

successful immediate extubation post-anesthesia with direct transfer to general ward. Twenty patients (90.9%) maintained excellent airway patency following SS-LTR. Two patients required reintubation or tracheostomy postoperatively. Operation-specific decannulation rate reached 90.9%, with overall decannulation rate of 100%.

CONCLUSIONS

SS-LTR with anterior costal cartilage graft combined with immediate extubation represents a highly effective and safe innovative approach for treating simple SGS Grades II-III in children. This technique achieves superior airway reconstruction outcomes while eliminating postoperative intubation-related complications in appropriately selected patients, thereby reducing morbidity and healthcare costs.

Investigation Of The Effect Of Dexpanthenol–Vitamin A Containing Sprays On Postoperative Wound Healing In Patients Undergoing Tonsillectomy

MERVE EKİCİ BEKTAŞ[1], **ASLI EKİNCİ**[1], **ARZU YASEMİN KORKUT**[1], **SENEM KURT DİZDAR**[1], **SUAT TURGUT**[1]

[1]*Şişli Hamidiye Etfal Training and Research Hospital*

BACKGROUND & AIM

To investigate the effect of the local application of a spray containing dexpanthenol and vitamin A (Nazalnem) on postoperative pain and wound healing in children undergoing tonsillectomy.

MATERIAL & METHODS

A total of 54 patients who underwent tonsillectomy for recurrent tonsillitis at the Department of Otorhinolaryngology and Head and Neck Surgery, Şişli Hamidiye Etfal Hospital, were included in the study. The patients were divided into two groups: 27 in the study group and 27 in the control group. The study was designed as prospective, randomized, double-blind, and placebo-controlled. Patients in the study group applied a dexpanthenol–vitamin A (Nazalnem) spray to the right and left halves of the oropharynx, 2 puffs, 3 times daily for 7 days postoperatively. Patients in the control group applied a saline spray with the same frequency and duration. Postoperative pain was assessed daily for 14 days using the Wong-Baker FACES Pain Rating Scale. Wound healing in the tonsillar fossae was evaluated at the first and second postoperative weeks.

RESULTS

A total of 54 patients aged 3–15 years (27 females and 27 males) were included. While no significant difference in pain scores was observed between the groups on postoperative day 1, pain scores in the study group were significantly lower than those in the control group between postoperative days 2 and 10 ($p < 0.05$). The rates of tissue healing in the tonsillar fossae at week 1 and week 2 in the study group (26.48% and 84.26%, respectively) were significantly higher compared to the control group (11.11% and 70.37%, respectively) ($p < 0.006$, $p < 0.005$).

CONCLUSIONS

The local application of a dexpanthenol–vitamin A (Nazalnem) spray reduces postoperative pain and accelerates wound healing following tonsillectomy. The addition of dexpanthenol–vitamin A (Nazalnem) spray to standard postoperative care may be beneficial in patients undergoing tonsillectomy. However, further randomized controlled studies with larger sample sizes are needed, as the current literature on this topic remains limited.

Independent Predictors Of Post-Tonsillectomy Hemorrhage: A Tertiary Center Experience

Adriana Cunha[1,2,3], **Joana Matos**[1,2], **Jorge Moutinho**[1,2], **Vítor Cardoso**[1,2], **Ricardo Vaz**[6,1,4,5]

[1]*Department of Otorhinolaryngology, Unidade Local de Saúde de São João, Porto, Portugal;* [2]*Department of Surgery and Physiology, Faculty of Medicine, University of Porto, Porto, Portugal;* [3]*Department of Otorhinolaryngology, Unidade Local de Saúde do Tâmega e Sousa, Porto, Portugal;* [4]*Unit of Anatomy, Department of Biomedicine, Faculty of Medicine, University of Porto, Porto, Portugal;* [5]*CINTESIS@RISE, Faculty of Medicine, University of Porto, Porto, Portugal;* [6]*NeuroGen Research Group, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal*

BACKGROUND & AIM

Tonsillectomy is one of the most commonly performed surgical procedures worldwide. Post-tonsillectomy hemorrhage (PTH) is a serious and potentially life-threatening complication, occurring in approximately 4% of cases. Several risk factors have been associated with PTH, including age, obesity, recurrent tonsillitis, attention deficit hyperactivity disorder, and surgical technique. However, inconsistent evidence has limited the development of validated clinical prediction models.

MATERIAL & METHODS

We conducted a retrospective case-control study including patients who underwent tonsillectomy at the ENT department of a tertiary care center between January 2020 and November 2025. Our initial sample comprised 50 patients who developed PTH

(cases) and 42 patients who did not (controls). Data collected for each patient included age, sex, weight, comorbidities, preoperative laboratory values, surgical indication, Brodsky Tonsil Scale, surgical technique, surgeon experience, and postoperative use of corticosteroids, nonsteroidal anti-inflammatory drugs, and antibiotics. Variables associated with PTH in univariate analysis were entered into a multivariable binary logistic regression model to identify independent risk factors.

RESULTS

In multivariable binary logistic regression analysis, older age was an independent predictor of PTH (OR 1.251; $p < 0.001$). Conversely, greater surgeon experience was a protective factor against PTH (OR 0.173; $p=0.032$). The remaining variables were not statistically significant.

CONCLUSIONS

Older age and lesser surgeon experience are independent risk factors for PTH and should be integrated into clinical risk assessments. Identifying these predictors provides a valuable foundation for the future development of machine learning-based clinical predictive models capable of stratifying preoperative risk groups.

Is Routine Pathological Examination Necessary In Pediatric Adenotonsillectomy?

Halil Elden[1], **Ahmet Faruk Erdem**[1], **Oguz Kadir Egilmez**[1]

[1]*Sakarya Teaching and Research Hospital*

BACKGROUND & AIM

To evaluate the necessity of histopathologic examination for routine tonsillectomy and/or adenoidectomy in terms of unexpected malignancy and other clinically significant pathologic findings by evaluating a large group of pediatric patients retrospectively.

MATERIAL & METHODS

A retrospective chart review of all patients 18 years of age or younger who underwent tonsillectomy and/or adenoidectomy between August 2016 and December 2024 was carried out at Sakarya Training and Research Hospital. The records were analyzed concerning each patient's age, sex, indication for surgery, type of surgical procedure, and the result of histopathologic examination of the specimen. Patients operated on for chronic or recurrent infections and obstructive hypertrophy were included in the study.

RESULTS

The total number of 4,919 patients with an age distribution from 1 to 18 years (mean: 7.71) were reviewed. There were 2,670 males (54%) and 2,249 females (46%). Adenoidectomy ± ventilation tube and adenotonsillectomy ± ventilation tube were performed together on 4,751 patients (97%) while tonsillectomy ± ventilation tube alone was performed on 159 patients (3%). Evaluation of the pathology reports revealed no malignancies. The most common histopathologic findings were lymphoid hyperplasia (97.5%) and chronic tonsillitis (29.7%). Actinomyces colonization was identified incidentally in 37 specimens (0.75%), representing the only clinically significant unexpected finding in the series.

CONCLUSIONS

After being evaluated by an experienced otolaryngologist, pathologic evaluation of all specimens may not be necessary if a child undergoing routine tonsillectomy and/or adenoidectomy is not found to have certain preoperative risk factors. The absence of any malignancy in this large single-center series of 4,919 pediatric patients over 8 years supports a selective, risk-stratified approach to histopathologic examination. The incidental detection of Actinomyces colonization in 0.75% of cases suggests that targeted pathologic review remains valuable in selected subgroups.

B-SAFE: A Novel Otolaryngology-Focused Clinical Score For Risk Stratification In Paediatric Airway Foreign Body Aspiration

Noor Binsanad[1], **Abdulrahman Alzayani**[1], **Ahmed Allangawi**[1], **Rashed Aldoseri**[1], **Muneera Alkhalifa**[1], **Mohamed Alshehabi**[1], **Mai Nasser**[1]

[1]*Royal Medical Services- Bahrain Defence Force*

BACKGROUND & AIM

Foreign body aspiration (FBA) remains a potentially life-threatening pediatric airway emergency and continues to pose diagnostic challenges, particularly in children with non-specific clinical presentations. Although several clinical predictors of FBA have been described, there remains a need for an otolaryngology-focused tool that supports procedural decision-making in real-world airway practice. B-SAFE (Bahrain Suspected Aspiration Foreign-body Evaluation) was developed as a clinician-

designed scoring system to assist otolaryngologists in the assessment and management of children with suspected airway foreign body aspiration.

MATERIAL & METHODS

A retrospective cohort study was performed at a government hospital in Bahrain including pediatric patients who underwent bronchoscopy for suspected airway foreign body aspiration. B-SAFE incorporates patient factors, clinical history, presenting symptoms, physical examination findings, and imaging features into a cumulative point-based score. The primary outcome was bronchoscopy-confirmed foreign body aspiration. Diagnostic performance was evaluated using receiver operating characteristic analysis, score discrimination, and calculation of sensitivity and specificity.

RESULTS

Thirty-two pediatric patients were included, of whom 21 (65.6%) had bronchoscopy-confirmed foreign body aspiration. Patients with confirmed foreign bodies had significantly higher B-SAFE scores compared with those with negative bronchoscopy findings (median score 8 vs 5; p=0.0009). The B-SAFE score showed good diagnostic performance with an area under the curve of 0.86. A cutoff score of ≥8 yielded 71.4% sensitivity and 90.9% specificity for predicting positive bronchoscopy (p=0.002). Significant predictors included suspected foreign body exposure, persistent symptoms, unilateral wheeze, and radiographic air trapping.

CONCLUSIONS

B-SAFE showed good diagnostic performance and clinically meaningful risk stratification in children with suspected airway foreign body aspiration. As an otolaryngology-focused decision-support tool, it may assist in selecting patients for airway endoscopy or bronchoscopy and support the future development of a structured management algorithm for pediatric airway foreign body evaluation.

OCCUPATIONAL VOICE DISORDERS – CLINICAL ASSESSMENT AND MANAGEMENT STRATEGIES

Rania Malhem[1], **Rodica Muresan**[2]

[1]*Fundamental Disciplines, Department I, Faculty of Nursing and Health Sciences, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania;* [2]*Gheorghe Dima National Academy of Music, Cluj-Napoca, Romania*

BACKGROUND & AIM

In clinical practice, a significant number of patients are referred to ENT with long-lasting dysphonia and no obvious anatomical modification. Functional voice disorders are frequently misdiagnosed or inadequately characterised, leading to delayed or suboptimal management. Beyond laryngoscopic visualisation, standardised tools such as the VHI-10 and the GRBAS perceptual scale serve as complementary instruments for accurate diagnosis.

This paper aims to highlight the impact of voice on quality of life in functional voice disorders. Alongside diagnostic work-up and individualised management using VHI-10 and GRBAS, education regarding vocal hygiene, vocal abuse, and correct muscle tension use is key to satisfactory voice emission.

MATERIAL & METHODS

From clinical experience, data were collected on patients who complained of persistent dysphonia with no structural or neurological abnormalities found on clinical examination. The evaluation of the patients included a detailed anamnesis, endoscopic examination of the larynx, as well as questionnaires to quantify the degree of dysphonia. Severity was graded using the GRBAS scale and patient-reported handicap was quantified using the VHI-10. Therapeutic interventions consisted of drug treatment in certain cases, individualized voice therapy programs and reeducation regarding vocal hygiene.

RESULTS

Clinical assessment revealed a consistent pattern: voice impairment was significantly shaped by habitual vocal misuse, occupational vocal demand and limited patient awareness of laryngeal physiology. VHI-10 and GRBAS scores served primarily to guide the clinical picture and track progress. Patients who received a combination of targeted pharmacotherapy alongside structured vocal hygiene education and voice therapy affirmed sustained improvement. With patients' education of the disruption of the balance between the three essential subsystems of voice production: the respiratory system (airflow), the laryngeal system (vibration), and the resonance system (the vocal tract) engagement with therapy improved markedly. Cases that proved most challenging were those where functional and organic features coexisted, but when correct medical and therapeutic approach was addressed, the pathology was improved. Overall, the series reinforced that no single intervention suffices – recovery in functional dysphonia is best understood as a process of reeducation rather than treatment in the conventional sense.

CONCLUSIONS

Functional voice disorders present distinct diagnostic and therapeutic challenges in the ENT setting. Concurrent use of VHI-10 and GRBAS provides a practical, reproducible framework for severity grading and outcome monitoring. While voice therapy

remains the cornerstone of management, a medical approach is as important in rulling out structural pathologies and addressing co-existing reflux, psychological, or muscular factors. Ultimately, success depends on moving the patient from cognitive awareness to the autonomous application of these new habits, ensuring that therapy is a personalized process rather than a generic recipe.

Evaluation Of The Effect Of Rhinoplasty Surgery On Nasal Consonants

Ozan Tüysüz[1], **Berkay Güzel**[1], **Nursena Nair Polat**[1], **İskender Bayram**[1], **Özgür Yiğit**[1]

[1]*Basaksehir Cam Sakura City Hospital*

BACKGROUND & AIM

Rhinoplasty alters nasal cavity volume and airflow dynamics, potentially affecting speech resonance. While functional nasal surgeries have been studied extensively, the impact of aesthetic rhinoplasty in patients without septal deviation remains unclear. This study aimed to prospectively evaluate the effect of primary aesthetic rhinoplasty on the acoustic characteristics of Turkish nasal consonants using objective nasalance measurements.

MATERIAL & METHODS

This prospective study included adult patients undergoing primary aesthetic rhinoplasty without septal deviation or significant nasal obstruction. Voice recordings were obtained preoperatively and at postoperative 1st and 3rd months. Speech material included isolated sounds, nasal consonant-containing words ([m], [n]), adjacent vowels, and standardized nasal and oral sentences. Recordings were analyzed using the Praat-Assisted Nasalance Meter (PANM). Nasalance values across time points were compared using appropriate statistical tests, with $p<0.05$ considered significant.

RESULTS

Postoperative evaluations demonstrated a tendency toward decreased nasalance values in nasal consonants and adjacent vowels compared to preoperative measurements. The reduction was more pronounced in nasal speech material, whereas oral plosive sentences showed no significant changes. Isolated vowel measurements remained largely stable. These findings suggest that structural narrowing following rhinoplasty may influence nasal resonance characteristics.

In both sexes, nasalance values in nasal sentences and words decreased at the 1st and 3rd postoperative months compared to the preoperative values.

CONCLUSIONS

Primary aesthetic rhinoplasty in patients without septal deviation may lead to a reduction in nasal resonance. Although changes are generally subtle, they may be clinically relevant, particularly in professional voice users. Preoperative counseling regarding potential resonance alterations should be considered in selected patients.

Evaluating Large Language Models As Patient Information Sources For Voice Feminisation Surgery: Quality, Readability And Reliability

Ms Lucinda Knight[1], **Ms Christella Antoni**[3], **Dr Brian Nuyen**[2], **Dr Nupur Nerurkar**[4], **Mr Chadwan Al Yaghchi**[1]

[1]*Imperial College NHS Healthcare Trust;* [2]*Stanford School of Medicine Department of Otolaryngology;* [3]*Christella Antoni Voice and Speech Services;* [4]*Bombay Hospital Voice & Swallowing Centre*

BACKGROUND & AIM

Voice feminisation surgery (VFS) is a key component of gender affirmation for many transgender individuals. Limited patient-clinician contact and prolonged waiting times drive patients to seek information online, increasingly from artificial intelligence (AI) large language models (LLMs). This study evaluates the quality and readability of LLM-generated responses to frequently asked questions (FAQs) about VFS.

MATERIAL & METHODS

Thirty FAQs were collated from open-access patient population surveys, including general, voice therapy, surgical, recovery and complex question categories. Each question was entered into three LLMs (ChatGPT-5.5, Gemini 3.5 Flash and Claude Sonnet 4.6), generating a total of ninety responses. A consultant laryngologist with subspecialty expertise in VFS assessed response quality using the Global Quality Scale (GQS), a Likert-based scoring tool, and qualitative analysis to compare LLM-responses. The responses were evaluated with the Flesch Reading Ease (FRE) and Flesch-Kincaid Grade Level (FKL) for readability and a modified-DISCERN (questions 1-8 of the original DISCERN tool) questionnaire for reliability.

RESULTS

Expert laryngologist GQS ratings favoured Claude across all question categories (mean 4.3/5), followed by ChatGPT (3.6/5) and Gemini (3.5/5). Claude scored highest in the complex question category (4.9/5), whilst Gemini and ChatGPT performed comparably across most domains. Qualitative analysis revealed specific inaccuracies across all LLMs. Significant differences in readability were identified across all three LLMs (Kruskal-Wallis, $p<0.001$ for both FRE and FKG). Gemini produced the most readable responses (mean FRE 57.2 ± 7.3; mean FKG 8.7 ± 1.2), whilst Claude and ChatGPT scored comparably on FRE (37.4 ± 8.0 and 34.5 ± 7.4 respectively, $p=0.117$) but differed significantly on FKG (Claude 11.0 ± 1.2; ChatGPT 10.0 ± 1.1, $p=0.003$). Modified DISCERN scores also differed significantly ($p=0.007$), with Claude scoring highest (25.9 ± 2.1), followed by ChatGPT (25.3 ± 1.7) and Gemini (24.5 ± 1.9).

CONCLUSIONS

Claude demonstrated higher quality and reliability of patient-information compared to ChatGPT and Gemini, though Gemini produced the most readable responses. All LLMs produced responses which varied significantly in readability, reliability and quality, highlighting the need for caution when patients use chatbots as a source of information regarding VFS, and emphasizing the importance of accessible clinician-verified resources in this constantly evolving field.

OP-1001

Effects Of Injectable Platelet-Rich Fibrin (I-PRF) On Voice Quality In Phonosurgery: A Retrospective Comparative Study

Hasan Keskin[1], **Aylin Eryılmaz**[1]

[1]*Department of Otolaryngology - Head and Neck Surgery, Aydın Adnan Menderes University Hospital, Aydın, Turkey.*

BACKGROUND & AIM

Benign vocal fold lesions have been shown to alter the superficial lamina propria biomechanics, resulting in dysphonia. Whilst phonosurgery aims to restore functional anatomy, the prevention of postoperative scarring and the optimisation of tissue regeneration remain significant clinical challenges. Injectable platelet-rich fibrin (i-PRF) is an autologous biomaterial that facilitates the sustained release of growth factors. The objective of this study is to evaluate the clinical and acoustic effects of intraoperative i-PRF application on voice quality following the surgical excision of benign vocal fold lesions.

MATERIAL & METHODS

The present retrospective comparative study comprised 70 patients (aged 18–65) who underwent phonosurgery for benign vocal fold lesions. The study cohort (n=35) received an intraoperative i-PRF injection into the operated vocal fold immediately following lesion excision, whereas the control cohort (n=35) underwent standard excision alone. Voice assessments were conducted preoperatively and at one and three months postoperatively. The subjective outcomes were measured using the Voice Handicap Index-10 (VHI-10), the GRBAS scale, and a Visual Analog Scale (VAS). Objective acoustic analyses were performed via Praat software to evaluate fundamental frequency (F0), jitter, shimmer, harmonics-to-noise ratio (HNR), and Cepstral Peak Prominence (CPP). Furthermore, videolaryngostroboscopic parameters were also assessed.

RESULTS

The final analysis included 70 patients (35 per cohort). There were no significant differences in baseline demographic characteristics between the two groups ($p > 0.05$). Both groups demonstrated clinical improvements from baseline to three months. However, at the 3-month evaluation, the i-PRF group exhibited significantly better VHI-10, GRBAS, and VAS scores compared to controls ($p < 0.05$). Objective acoustic analyses (Jitter, Shimmer, HNR, CPP) also revealed statistically significant differences favoring the i-PRF cohort ($p < 0.05$). Additionally, videolaryngostroboscopy showed more consistent mucosal wave restoration and glottic closure in the i-PRF group.

CONCLUSIONS

The adjunctive use of i-PRF during the excision of benign vocal fold lesions is associated with improved subjective and objective voice outcomes at three months. These findings suggest that i-PRF may support postoperative tissue healing and serve as a useful adjunct for functional voice recovery.

Features Of Rehabilitation Of Voice Function With Severe Laryngeal Pathology

Ekaterina Osipenko[1]

[1]*Department of Phoniatrics of the National Medical Research Center of Otolaryngology of the Russia, Department of Otorhinolaryngology;*
[2]*Department of Otorhinolaryngology, Faculty of Additional Professional Education, Institute of Continuous Education and Professional Development of the Pirogov Russian National Research Medical University of the Ministry of Health of the Russian Federation*

BACKGROUND & AIM

The aim of this study was to evaluate the characteristics of and patient pathway in comprehensive rehabilitation of voice and respiratory function in patients with severe laryngeal pathology. The study was designed to identify which approaches most effectively contributed to restoration of vocal function, reduction of compensatory disorders, and improvement of patients' quality of life.

MATERIAL & METHODS

The study included 50 patients with bilateral and unilateral laryngeal paralysis, patients after laryngeal resection or laryngectomy, cicatricial stenosis, laryngeal papillomatosis, and combined disorders of voice, swallowing, and breathing. Particular attention was given to the early initiation of corrective measures and the selection of individualized phonopedic techniques. The rehabilitation program included methods aimed at activating the neuromuscular apparatus of the larynx, neurophoniatric electrical myostimulation, biofeedback training, breathing exercises, and psychological support. Effectiveness was assessed using acoustic analysis, videolaryngostroboscopy, high-speed laryngeal imaging, as well as patients' subjective self-assessment using the Voice Handicap Index (VHI) and a visual analog scale for voice assessment.

RESULTS

It was found that early initiation of phonopedic correction contributed to faster recovery of vocal function and reduced the risk of pathological compensatory mechanisms, including the involvement of the vestibular folds in phonation. In patients with severe lesions and combined disorders, standard techniques were adapted with an emphasis on breathing techniques and swallowing rehabilitation. The use of biofeedback and electrical myostimulation increased training effectiveness through visualization and process control. Psychological support significantly improved patient adherence to the long-term rehabilitation program.

CONCLUSIONS

Rehabilitation of vocal function in severe laryngeal pathology should be early, comprehensive, and strictly individualized. The best results are achieved through a combination of phonopedic therapy, device-based methods, and psychological support. Long-term follow-up is essential for preventing recurrence and consolidating the achieved functional outcomes. In cases of combined voice, swallowing, and breathing disorders, the patient pathway should be multidisciplinary and involve an otolaryngologist, phoniatrician, speech therapist, rehabilitation specialist, and, when necessary, other specialists.

The Impact Of The Middle Third Acoustic Signal Sampling Technique On The Outcome Of Acoustic Analysis

Ahmed Nagy[1], **Sarah Al Suqatri**[1], **Khadijah Diab**[1], **Basant Mohamed**[1], **Salem Alyammahi**[1], **Hamad Albreiki**[1], **Abdulla Alfarsi**[1]

[1]*United Arab Emirates University*

BACKGROUND & AIM

Acoustic Analysis is a key instrumental tool in assessing Voice disorders. Earlier work showed that collecting the acoustic signal from the middle segment eliminates the effects of voice onset and offset on the acoustic analysis. The middle third of the acoustic signal showed the greatest correlation with Jitter percent scores across MDVP and PRAAT. Earlier work on the PQVD database used a subjectively selected middle portion of a steady, sustained vowel; we reanalysed the signals using MDVP and PRAAT, collecting parameters from the objectively calculated mathematical third of the acoustic signal

MATERIAL & METHODS

The Maximum Phonation Time signal duration in the PQVD database was measured from its PRAAT display, and the middle Third was mathematically calculated and extracted. The Trimmed signals for 103 Normal Voices and 143 Dysphonic samples were pooled and analysed with PRAAT and MDVP. The researchers investigated the perturbation parameters Jitter and Shimmer's ability to differentiate between Dysphonia presence and absence, and compared the findings with earlier PRAAT results for the same sample.

RESULTS

Our results show that The Area under the curve for Jitter in both MDVP and PRAAT in our mathematically timed signal was 0.78, compared to 0.66 in PRAAT using the subjective stable sample selection. The sensitivity was 0.80 and 0.86 in MDVP and PRAAT, respectively, in our analysis, compared to 0.80 in the earlier work. For Shimmer, The Area under the curve was again identical across MDVP and PRAAT in our analysis, 0.82, compared to 0.72 in the earlier work. At the same time, we found sensitivities of 0.86 in PRAAT and 0.80 in MDVP, compared with 0.80 in the earlier study used for comparison. In all the above analyses, the specificity ranged from 0.46 to 0.49, except for Jitter, which scored 0.34 in the subjective stable sample selection.

CONCLUSIONS

Mathematically selecting the acoustic signal for analysis, when contrasted with subjective, stable sample selection, shows a positive impact on the diagnostic value of Jitter and Shimmer; moreover, it improves the percentage agreement in Dysphonia Discrimination between MDVP and PRAAT at their respective cut-offs for the perturbation parameters.

Pediatric Voice Disorders: From Physiological Development To Clinical Management

AVETISIAN EMIL[1]

[1]*EMIL AVETISIAN'S PHONIATRICS AND VOICE HEALTH CENTER;* [2]*MOSCOW STATE CONSERVATORY*

BACKGROUND & AIM

Pediatric voice disorders represent a significant yet frequently underdiagnosed clinical problem, affecting approximately 4–30% of the child population. Early identification and appropriate management are essential to prevent chronic pathology and to improve quality of life. This study aims to provide a comprehensive overview of the anatomical and physiological characteristics of the developing pediatric larynx, outline key stages of voice formation, and highlight the most common voice disorders encountered in children.

MATERIAL & METHODS

Special attention is given to functional dysphonia, which accounts for up to 70% of pediatric voice disorders, as well as mutation-related dysphonia during puberty. The paper discusses the pathophysiological mechanisms, clinical manifestations, and differential diagnosis of both physiological and pathological voice mutation, including delayed, prolonged, and incomplete mutation. Organic conditions such as vocal fold nodules, laryngopharyngeal reflux, adenoid hypertrophy, and neurologically voice disorders are also examined. The importance of comprehensive diagnostic evaluation is emphasized, including videolaryngoscopy and videolaryngostroboscopy as gold-standard tools for assessing vocal fold structure and function. The study highlights common diagnostic pitfalls, such as underestimation of persistent dysphonia and overreliance on limited examination methods.

RESULTS

Management strategies are discussed within a multidisciplinary framework involving otolaryngologists, phoniatricians, speech therapists, and other specialists. Conservative treatment, including vocal hygiene and voice therapy, is shown to be effective in the majority of cases, while clear indications for active intervention are defined.

CONCLUSIONS

The findings underscore the necessity of early diagnosis, individualized treatment planning, and interdisciplinary collaboration in pediatric phoniatrics, reinforcing the principle that even minor voice complaints in children require thorough clinical attention.

Efficacy Of Test Electrode-Based Method Of Measuring Achievable Electrode Insertion Depth In Cochlear Implantation On Communicative Outcomes

Rabea Alsabellha[2], **Mohga Mohamed Abdalazeem**[2], **Nouf AL Rayyes**[2], **Shoaa Alrawily**[2]

[1]*Faculty of Medicine, Beni-Suef University;* [2]*Cochlear Implantation Center, King Abdalaziz Specialized Hospital, Saudi Arabia*

BACKGROUND & AIM

Background: Optimal electrode insertion depth in cochlear implantation (CI) is critical for maximizing auditory outcomes. A novel color-coded test electrode array enables intraoperative simulation of multiple electrode lengths, potentially improving surgical precision and post-implant communicative development.

Objectives: To evaluate the effect of test electrode-guided insertion depth selection on communicative outcomes in pediatric CI recipients over a 12-month rehabilitation period.

MATERIAL & METHODS

Methods: Twenty children (aged 12–48 months) with congenital bilateral profound sensorineural hearing loss were prospectively enrolled and equally divided into two groups. Group A (n=10) underwent unilateral CI using a MED-EL custom test electrode array with five color-coded depth markers, while Group B (n=10) was implanted without the test electrode. All subjects received standardized auditory-verbal therapy commencing one month post-implantation. Communicative outcomes were assessed using the Post-cochlear Auditory Skills (PAS) checklist across detection, discrimination, identification, and comprehension domains at 3, 6, 9, and 12 months post-operatively.

RESULTS

Results: Both groups demonstrated significant auditory improvement over time (F=225.73, p<0.001). Group A achieved consistently superior total PAS scores (65.40 vs. 53.80; F=25.34, p<0.001, η^2=0.585) with a significantly faster rate of improvement (Time×Group interaction: F=5.26, p=0.003). Group A reached near-ceiling performance by 12 months (75.80±0.42 vs. 68.70±2.83). Significant between-group differences were observed in detection, discrimination, and comprehension (all p<0.05), with parallel improvement trajectories noted only in identification.

CONCLUSIONS

Conclusion: Intraoperative use of a color-coded test electrode for insertion depth guidance significantly enhances communicative outcomes in pediatric cochlear implant recipients, facilitating earlier and more robust acquisition of auditory skills across all domains. These findings support its integration into routine CI surgical practice.

Objective Tracking Of Abdomino-Phonatory Motor Skill Acquisition In Smith Accent Technique Training: A Pilot Study

Baiba Trinite[1], **Aliaa Khidr**[2]

[1]Riga Technical University Liepaja Academy, Voice and Speech Research Laboratory, Liepaja, Latvia; [2]Ain Shams University, Cairo, Egypt, Faculty of Medicine, Phoniatrics Unit, Department of Otolaryngology

BACKGROUND & AIM

The Smith Accent Technique (SAT) is a method of voice development and therapy that focuses on abdomino-phonatory (AP) control. It is based on a hierarchical progression of control of abdominal wall contractions during exhalation for phonation across progressive levels of speech and communication complexity. In clinical practice, the effect of SAT is usually evaluated subjectively, mainly by observing abdominal movement during phonation. Objective physiological measurements of AP control are still limited. The aim of this pilot study was to assess objectively the acquisition and progression of abdomino-phonatory control during SAT training by measuring abdominal wall excursion at several time points.

MATERIAL & METHODS

A repeated-measures pilot study was carried out. Two vocally healthy adult female participants (ages 38 and 41) completed 8 sessions of SAT-based AP motor training. Abdominal wall displacement was measured using respiratory inductance plethysmography (RIP) at five time points: baseline (T1), after 3, 6, and 8 sessions (T2–T4), and one month after the training period (T5). The tasks were performed in sitting and standing positions under two conditions: habitual breathing and SAT breath-supported phonation. Mean inward (expiratory) and outward (inspiratory) abdominal displacement values were calculated. Differences between conditions were analysed using bootstrapped independent-samples t-tests.

RESULTS

Considerable increases in abdominal wall displacement during breath-supported exhalation were observed from T1 to T5 (P1: +409.7% sitting, +100.2% standing; P2: +307.9% sitting, +185.0% standing). The largest changes were found between T1 and T2. The progression was not linear, with small plateaus and reductions observed during later sessions. At later stages, habitual breathing occasionally approached or exceeded the displacement measured during supported phonation. Differences in participants' progression patterns were noted.

CONCLUSIONS

The results indicate that RIP can be used as an objective method to monitor AP control during SAT training. The most marked improvements occurred in the early phase of training. Further research with a larger sample is needed to examine the relationship between physiological measurements and subjective ratings of abdominal wall displacement throughout training /therapy and how can it be used to predict the voice outcome.

Artificial Intelligence Meets Voice: A Comparative Study Of LLM-Assisted Automated Acoustic Analysis And Praat

Nurullah Türe[1], **Simge Siyahçınar**[1], **Zehra Savaş**[2]

[1]Department of Otorhinolaryngology, Kütahya Health Sciences University, Kütahya, Türkiye; [2]Department of Speech and Language Therapy, Kütahya Health Sciences University, Kütahya, Türkiye

BACKGROUND & AIM

Objective: The aim of this study was to quantify the diagnostic utility of AI derived acoustic features generated using the large language model ChatGPT 5.1 and to examine their correlation with conventional Praat based measurements.

MATERIAL & METHODS

Materials and Methods: We analyzed voice recordings from a total of 126 participants, comprising 63 patients exhibiting diverse laryngeal pathologies (e.g., vocal fold paralysis, polyps, nodules, sulcus vocalis) and 63 healthy volunteers individually matched for age and sex. Conventional acoustic perturbation measures (Jitter%, Shimmer%, HNR, CPPS) and AI-based spectral features (MFCCs 1–13, Spectral Centroid, Roll-off) were automatically extracted from the samples. Statistical analyses included Mann–Whitney U and Kruskal–Wallis tests for between group comparisons, and Spearman's rank correlation to assess interparameter relationships

RESULTS

Results: No statistically significant demographic disparities were observed between the cohorts ($p>0.05$). The AI-driven analysis revealed significantly lower MFCC-1 values and higher Spectral Centroid values in the pathological group (both $p<0.001$). A robust positive correlation was observed between Spectral Centroid and Shimmer% ($r=0.76$; $p<0.001$). In subgroup analyses, particularly among patients with vocal fold paralysis where signal aperiodicity often limits the interpretability of conventional acoustic measures AI-based features delineated a distinct, high fidelity "acoustic signature" with superior discriminatory power, enabling the statistically significant differentiation of paralysis cases from the polyp/nodule group ($p<0.05$).

CONCLUSIONS

Conclusion: Our findings demonstrate that LLM derived acoustic attributes are highly concordant with traditional Praat outputs and are clinically robust. Most notably, in severe dysphonia with marked loss of periodicity, AI assisted analysis proved more resilient, more discriminative, and diagnostically more informative than conventional methods. These data suggest that LLM supported acoustic analysis is well positioned for integration into routine clinical practice as a rapid, noninvasive, and objective tool for triage and preliminary diagnosis in modern laryngology.

Speech-Language Pathologists' Motor Learning Strategies For Three Vocal Exercises: An Analysis Based On The Motor Learning Classification Framework

Jaime Crisosto-Alarcón[1], **Valentina Vasques-Campos**[2], **Valentina Gacitúa-Gacitúa**[2], **Matías Cuitiño-Carter**[2]

[1]*Departamento de Ciencias de la Rehabilitación en Salud, Facultad de Ciencias de la Salud y de los Alimentos, Universidad del Bío-Bío, Chillán, Chile;*
[2]*Carrera de Fonoaudiología, Facultad de Ciencias de la Salud y de los Alimentos, Universidad del Bío-Bío, Chillán, Chile*

BACKGROUND & AIM

The Motor Learning Classification Framework (MLCF-v2) is an organizational framework designed to classify behaviors produced within vocal therapy during therapist-client interaction, with the aim of observing the impact of a task on motor learning. These behaviors are divided into explicit and implicit variables, which define the characteristics of each pedagogical practice. The aim of this research is to contrast the pedagogical practices employed by speech-language pathologists when directing different vocal exercises using the Motor Learning Classification Framework (MLCF-v2).

MATERIAL & METHODS

Simulated speech-language therapy sessions were conducted involving one actress and nine speech-language pathologists specializing in voice. During these sessions, the clinicians were instructed to guide three exercises: a nasal glissando, vocal fry, and the yawn–sigh technique. The dialogue between the therapist and the patient throughout the session was audio-recorded and subsequently transcribed. Each communicative turn, whether verbal or nonverbal, was analyzed using the Motor Learning Classification Framework to establish a profile associated with each exercise.

RESULTS

The chi-square analysis revealed significant differences in the distribution of explicit pedagogical practices across techniques ($\chi^2 = 25.0563$, $p = 0.0146$). Post-hoc comparisons showed distinct technique-specific patterns. In the glissando exercise, self-evaluation feedback was significantly less frequent compared to the other techniques. In the vocal fry, requests for self-evaluation were significantly less prevalent than in the remaining techniques. In contrast, the yawn–sigh technique was characterized by a significantly higher use of modeling, while both requests for self-evaluation and self-evaluation feedback were significantly less frequent relative to the other exercises. No significant differences were observed in the distribution of implicit pedagogical practices across techniques ($p = 0.267$), with perceptual training and attentional focus predominating over motivational strategies in all cases.

CONCLUSIONS

Different strategies are employed by speech-language pathologists in the pedagogy of various vocal techniques; however, they share a similar overall profile. Future research should examine additional factors that may influence the pedagogical strategies used by professionals.

Speech And Language Therapy In Larynx Paresis. Why? When? How?

Irina Evomaa[1]

[1]*East Tallinn Central Hospital*

BACKGROUND & AIM

This presentation provides an overview of the indications, timing, and methods of SLT in patients with laryngeal paresis.

MATERIAL & METHODS

The analysis is based on current literature and clinical practice, with a focus on the integration of SLT into multidisciplinary management. Key aspects include early versus delayed intervention and commonly used therapeutic techniques.

RESULTS

Available evidence suggests that early initiation of SLT may support functional voice recovery, facilitate compensatory strategies, and help prevent maladaptive phonatory behaviors. Voice and swallowing therapy and neuromuscular facilitation are widely used in clinical practice.

CONCLUSIONS

SLT should be considered an essential component of laryngeal paresis management, and clearer clinical frameworks may improve patient outcomes.

Voice-Related Outcomes In Call Center Employees: Findings From Acoustic Analysis And Self-Report Measures

Sebiha Abzak[1], **Gamze Yesilli Puzella**[1]

[1]*Department of Speech and Language Therapy, Cappadocia University, Nevşehir, Türkiye*

BACKGROUND & AIM

Voice problems among call center employees may negatively affect occupational performance and quality of life. However, studies combining self-report voice assessment scales with acoustic analysis in this population remain limited. The aim of this study was to examine the voice characteristics of call center employees using both objective and subjective methods and to investigate the influence of voice-use habits and occupational variables on voice-related outcomes.

MATERIAL & METHODS

The study included 63 participants, consisting of 55 women and 8 men. For subjective assessment, the Call Center Employees' Professional Voice Use and Vocal Risk Factors Questionnaire, Voice Handicap Index-10 (VHI-10), the Vocal Tract Discomfort (VTD), and Reflux Symptom Index (RSI) were administered. For objective assessment, acoustic analysis was performed using the Praat program. Participants were asked to produce a sustained /a/ sound and read a standardized text.

RESULTS

The analyses revealed that smoothed cepstral peak prominence for sustained /a/ (CPPS-a) differed significantly by workers' years of experience and daily voice use duration ($p<0.05$). Additionally, years of professional experience and workplace noise levels were significantly associated with VTD scores ($p<0.05$). Regarding vocal hygiene habits, carbonated beverage consumption was significantly associated with VHI-10 scores, whereas smoking was significantly associated with VTD scores ($p<0.05$).

CONCLUSIONS

Call center employees may be at risk for voice-related problems due to their occupational voice demands. A combined use of acoustic analysis and self-reported voice evaluations may give a comprehensive understanding of voice-related outcomes in this occupational group.

EVALUATION OF THE EFFECTIVENESS OF VOICE RESTORATION IN THE EARLY POSTOPERATIVE PERIOD AFTER REMOVAL OF A BENIGN LARYNGEAL NEOPLASM

Putkaradze Ekaterina Iosifovna[1], **Egorov Victor Ivanovich**[1], **Gerasimenko Marina Yurevna**[2], **Mustafaev Djavanshir Mamed oglu**[1]

[1]*State-Financed Health Institution of Moscow Region Moscow Regional Scientific and Research Clinical Institute named after M.F. Vladimirskiy, Moscow, 129110, Russia;* [2]*Russian Medical Academy of Continuous Professional Education, Ministry of Health of the Russian Federation, 125993, Moscow, Russia*

BACKGROUND & AIM

Introduction: Treatment of benign laryngeal neoplasms is complex. The recovery period of the voice in the postoperativeperiod depends on the magnitude of the surgical injury, the regenerative abilities of the human body, the rehabilitationmeasures used, as well as the patient's conscientious implementation of recommendations, his desires andefforts.

Aims: To evaluate the effectiveness of the method of postoperative voice rehabilitation in the complex treatment of patients with benign laryngeal neoplasm.

MATERIAL & METHODS

The study involved 105 patients who were divided into two groups, where in the study group, unlike the control group, after phonomicrosurgery, in addition to corticosteroid inhalation 2 times a day for 4 days, absolute vocal rest for 2-3 days, followed by relative rest for 7-10 days, physiotherapy with a low-frequency stationary pulsed magnetic field was additionally performed within 4 days.

RESULTS

At the end of 6 months of follow-up, the disease relapsed in 4% of cases in the control group, and no relapse was observed in the study group. The objective parameters of the acoustic analysis of the voice of the study group significantly exceeded the parameters of the control group in the postoperative period from the 5th day of follow-up. Dysphonia severity index (DSI) ($p < 0.001$), median DSI (in the control group) =0.58, median DSI (in the study group) =2.21. Stroboscopic parameters such as the mucosal wave, the amplitude of movement of the vocal folds, and the closure of the glottis were restored in the study group on the 5th day, and in the control group on the 10th day of the postoperative period. There were no statistically significant differences in the VHI-30 and Yanagihara voice scores during the control and interim periods.

CONCLUSIONS

An integrated approach to the treatment of patients with benign laryngeal pathology, in particular with polyps of the vocal folds, including phonosurgery followed by the use of the ALMAG+ device, made it possible to restore the vibratory function of the vocal apparatus in a short period of time, as well as prevent the recurrence of the disease.

OP-1012

Psychological Factors And Voice Outcomes: Individual And Group Mechanisms

Stephanie Misono[1], **Patricia A Frazier**[1], **Erich Kummerfeld**[1], **Kelvin O. Lim**[1]

[1]*University of Minnesota, USA*

BACKGROUND & AIM

The interaction of psychological factors and voice outcomes can be complex and heterogeneous. Recent advances in analytic methodology allow causal examination of how these factors impact each other, raising the possibility of valuable mechanistic insights.

MATERIAL & METHODS

Measures of key voice and psychological factors, including the Voice Handicap Index-10, perceived present control, distress, and affect were collected multiple times per day from adults (n=40) with primary muscle tension dysphonia. Causal analyses were performed using the Greedy Fast Causal Inference algorithm.

RESULTS

At the group level, anxiety was causal for subsequent voice handicap scores. At the individual level, approximately half of participants had a psychological factor causal for voice handicap, but there was heterogeneity in terms of which factors were causal. These included perceived control, negative affect, anxiety, and stress.

CONCLUSIONS

Examination of causality can identify heterogeneity at the individual level which is not apparent at the group level, and is applicable to the complex intersection of psychological factors and voice outcomes. This approach contributes to a foundation for mechanistically individualizing treatment of voice disorders.

Analyzing The Vocal Cycle: Methodological Insights From Electroglottography And Biomechanical Analysis Of Voice

Isabel Cardoso[1,2], **Walter Tenesaca**[3], **Ángel Rodríguez-Paramás**[3], **Roberto Fernández-Baíllo**[3], **Sandra Corvo-Macarro**[4]

[1]Vithas Arturo Soria University Hospital; [2]Universidad Europea; [3]University of Alcalá de Henares; [4]University of Salamanca

BACKGROUND & AIM

To evaluate the ability of biomechanical analysis of voice in sustained non-nasalised vowels to estimate the duration of the phases of the vocal cycle in comparison to the measurement provided by electroglottography.

MATERIAL & METHODS

444 recordings of low, normal, and high pitches of 148 subjects were evaluated, and the measurements of the duration of the vocal cycle phases obtained by electroglottography were compared to the T wave measurements provided by the biomechanical analysis tool Voice Clinical Systems® .

RESULTS

Simultaneous comparative analysis of the electroglottography and T wave has provided equivalent reference points that represent the principal events of the vocal cycle. When comparing the duration of the phases of the cycle based on the pitch of the vocal emission, it was observed that biomechanical analysis can identify a significant reduction in the duration of the closed phase in high pitch compared to the other ($p<0.005$).

CONCLUSIONS

Biomechanical analysis has proved to be an effective tool to measure the phases of the vocal cycle, demonstrating a strong correlation between the T wave and the electroglottography curve. It is also able to detect variations in the duration of the phases of the cycle in relation to changes in the pitch.

KEYWORDS

Electroglottography; biomechanical analysis of voice; vocal cycle phases measurement; mucosal wave.

Surgical Considerations And Speech Outcomes In Infants Who Undergo Cochlear Implantation

Eman A. Hajr, MD[2], **Tahani Alotaibi**[1]

[1]King Abdulaziz University Hospital; [2]College of Medicine, Imam Mohammad Ibn Saud Islamic University

BACKGROUND & AIM

To evaluate the feasibility and outcomes of cochlear implantation (CI) in infancy.

MATERIAL & METHODS

All infants who underwent CI from January 2011 to October 2018 at a tertiary referral center in the Kingdom of Saudi Arabia were retrospectively reviewed. Demographic data, factors associated with early detection, and any surgical difficulties or postoperative complications were extracted from the medical records. The outcome of CI was determined by a speech pathologist.

RESULTS

Fifteen patients underwent CI during the study period (9 bilateral and performed simultaneously, 6 unilateral). The round window was difficult to identify in 5 cases. Incomplete electrode insertion because of cochlear ossification secondary to meningitis was documented in one patient. No major postoperative complications were encountered. The average auditory performance score was 7 and the speech intelligibility rating was 5.

CONCLUSIONS

This study represents the largest national cohort of pediatric patients undergoing CI in infancy. In this series, the surgery was safe and the speech outcome was good. With implementation of the neonatal screening program in the Kingdom of Saudi Arabia, the number of infants undergoing CI is likely to increase in the near future, paving the way for more research in infant CI.

KEYWORDS

To evaluate the feasibility and outcomes of cochlear implantation (CI) in infancy.

OP-1015

Voice Analysis After Endotracheal Intubation

Ahmet KILIÇ[1], **Ömer Faruk ÇINAR**[1], **İsrafil ORHAN**[1], **Muhammed Gazi YILDIZ**[1]

[1]Department of Otorhinolaryngology-Head and Neck Surgery, Faculty of Medicine, Kahramanmaraş Sütçü İmam University, Kahramanmaraş, Türkiye

BACKGROUND & AIM

The aim of this study is to determine the duration of voice disorders associated with endotracheal intibation and the funtional recovery time of patients. Additionally, it aims to estimate the period required for patients to regain their baseline vocal tone and speaking abilities.

MATERIAL & METHODS

In our study, patients undergoing non-laryngeal surgeries under general anesthesia with endotracheal intubation were included. Exclusion criteria were prior voice-altering surgeries, neurological diseases, recent general anesthesia (within 3 months), difficult intubation, advanced septal deviation, allergic rhinitis, nasal polyps, asthma, pregnancy, existing vocal cord pathologies, laryngopharyngeal reflux, recent upper respiratory infections, smoking, and postoperative vomiting. Participants completed the Voice Handicap Index-10 (VHI-10), Grade, Roughness, Breathiness, Asthenia, Strain (GRBAS) scale, Reflux Symptom Index (RSI), and Voice-Related Quality of Life (V-RQOL) questionnaires. Voice recordings were performed in an anechoic room using a Samson CO3U condenser microphone and Adobe Audition. The microphone was positioned 4 cm from the mouth at a 45-degree angle. Participants sustained the /a/ vowel and read a standard text. Acoustic analyses were conducted using Praat software (v.12.1).

RESULTS

In our study, 66 patients (62.1% female, 37.9% male) with a mean age of 38.5 ± 14.2 years were included. Mean intubation duration was 101.4 minutes with 1.25 mean attempts. At T1 (24h post-extubation), statistically significant deteriorations were observed in Acoustic Voice Quality Index (AVQI) (1.91 to 2.78, p=0.000), jitter (0.41 to 0.52, p=0.014), Maximum Phonation Time (MPT) (17.27s to 16.00s, p=0.000), GRBAS (0.41 to 1.05, p=0.000), and VHI-10 scores. No significant changes were found in shimmer (p=0.081), HNR (p=0.932), F0 (p=0.448), or RSI scores (p=0.167). By T2 (5th day), all affected parameters showed a significant recovery trend toward baseline (T0) values.

CONCLUSIONS

In this study, it was found that endotracheal intubation negatively impacts voice quality, vibratory stability, aerodynamic capacity, and voice-related quality of life at 24 hours post-extubation, with recovery beginning by the 5th day. These findings are independent of reflux and purely mechanical-traumatic in origin. Predicting this transient dysphonia is clinically essential—especially for professional voice users—to ensure effective patient counseling, postoperative voice rest planning, and the physician's medicolegal security.

KEYWORDS

Is Acoustic Analysis A Reliable Non-Invasive Method In The Pediatric Population?

Gabriela Guerra[1], **Ramon Hernandez Villoria**[1,3], **Pedro Malave**[1]

[1]Hospital Universitario Dr. Luis Razetti de Barcelona; [2]Complejo Hospitalario Universitario Dr. Luis Razetti; [3]Hospital Clinicas Caracas

BACKGROUND & AIM

Objective: To determine the clinical reliability and applicability of instrumental acoustic analysis as a swallowing assessment method in children.

MATERIAL & METHODS

Methods: An integrative review was conducted, analyzing studies applying digitalized cervical auscultation or sound analysis in pediatric populations with typical development or with dysphagia.

RESULTS

Results: The evidence indicates a nuanced utility profile. The technique is feasible and well-tolerated as a non-invasive procedure. Distinct parameters have been identified across infants, children, and adolescents, establishing age-specific normative curves. It is particularly reliable for detecting suck-swallow-breathe discoordination patterns in preterm infants and for monitoring post-intervention changes in children with cerebral palsy. However, its diagnostic reliability is lower than in adults due to greater anatomical and physiological variability, alongside difficulties in standardizing bolus volume and food consistency. The signal can be degraded by movement or vocalization artifacts, and its correlation with gold-standard instrumental findings (VFSS) is high for detecting aspiration events but moderate for characterizing specific pathophysiology.

CONCLUSIONS

Conclusion: Acoustic analysis is a feasible and moderately reliable non-invasive method in pediatrics. Its greatest strength lies in serial monitoring and screening within high-risk populations. To achieve optimal diagnostic reliability, it must be interpreted by trained professionals within the patient's global clinical context.

Objective And Subjective Evaluation Of Voice Quality In Electronic And Conventional Cigarette Smokers

Handenur Batur Okuyucu[1], **Şevval Şahin**[2], **Özlem Saatçi**[3]

[1]*Sancaktepe Sehit Prof. Dr. İlhan Varank Training and Research Hospital;* [2]*Sancaktepe Sehit Prof. Dr. İlhan Varank Training and Research Hospital;* [3]*Sancaktepe Sehit Prof. Dr. İlhan Varank Training and Research Hospital*

BACKGROUND & AIM

The aim of this study is to compare chronic changes in voice quality between users of conventional cigarettes, electronic cigarettes (e-cigarettes) and both products concurrently (dual users), using objective acoustic, endoscopic and self-reported measures.

MATERIAL & METHODS

48 participants were assessed in four groups: conventional smokers (n=17), e-cigarette users (n=9), dual users (n=13) and healthy non-smoking controls (n=9). Mean age was 30.0 years (range 20–46); mean exposure among users was 8.7 years (maximum 20). Exclusions were professional voice training, previous laryngeal surgery, malignant or premalignant lesion history, lower airway disease or active upper respiratory infection, neurological disease and pre-existing benign vocal fold lesions; controls additionally had no second-hand smoke exposure and had stopped any past smoking at least five years earlier. Tobacco consumption was stopped at least one hour before testing to exclude acute effects. Acoustic analysis (F0, jitter, shimmer, HNR) was performed in Praat on sustained /a/ recordings, laryngeal findings by 70° rigid videostroboscopy, perceptual quality with CAPE-V and self-reported handicap with the VHI-10. Irritation findings were ascertained from the stroboscopy report. Non-parametric tests were used throughout, acoustic values standardised within sex, and pairwise comparisons Holm-corrected.

RESULTS

Laryngeal irritation findings (hyperaemia, oedema, pachydermia) were the clearest discriminator between groups: present in 71% of conventional smokers, 56% of e-cigarette users and 85% of dual users, versus 11% of controls ($p = 0.004$). Pooled, 28/39 users versus 1/9 controls showed irritation ($p = 0.001$). Among acoustic parameters, sex-standardised shimmer differed across the four groups (Kruskal-Wallis $p = 0.047$, $\varepsilon^2 = 0.115$), being highest in conventional smokers and lowest in controls; HNR followed the same ordering ($p = 0.054$). In raw values, shimmer was 5.27% in conventional smokers versus 3.47% in controls, and jitter 0.61% versus 0.43%. However, no pairwise comparison survived Holm correction. Fundamental frequency did not differ significantly between groups ($p = 0.266$). VHI-10 scores did not differ between groups ($p = 0.238$), and 32 of 48 participants scored zero, indicating a marked floor effect.

CONCLUSIONS

In this sample, visible laryngeal irritation was present in the majority of conventional, e-cigarette and dual users but in almost none of the controls, while self-reported voice handicap did not distinguish the groups — suggesting that endoscopic change precedes symptom awareness. Acoustic parameters were ordered in the expected direction, but with the present sample size no individual group contrast is statistically established. These findings do not support e-cigarettes as a vocally safe alternative; however, an e-cigarette-specific effect cannot yet be isolated, as 7/9 e-cigarette users and 10/13 dual users had prior conventional smoking exposure.

Electronic cigarette, Smoking, Voice quality, Acoustic analysis, Videostroboscopy

OP-1018

Free Hands Speech Use In Patients With Tracheoesophageal Voice Prosthesis After Total Laryngectomy

Moisés Matos[1], **Alina Martín Fernandes**[1], **Filipa Armada Ferreira**[1], **Daniela Ribeiro**[1], **Ana Sousa Menezes**[1], **Luís Dias**[1]

[1]*Braga Hospital, Portugal*

BACKGROUND & AIM

Total laryngectomy (TL) remains the gold standard treatment for locally advanced laryngeal cancer. Tracheoesophageal (TE) speech using a voice prosthesis (VP) is currently the main method of voice rehabilitation. Free hands (FH) speech allows digital occlusion-free communication and is associated with improved quality of life and social reintegration. However, long-term adherence remains reported to around 30% of patients. This study aims to evaluate the use and adherence to FH speech among patients rehabilitated with a VP.

MATERIAL & METHODS

The study design was a retrospective cohort and included patients admitted to TL between 2020 and 2024 with at least 6 months follow-up. Voice and speech quality data were prospectively collected as part of standard clinical follow-up with voice handicap index 10 (VHI-10) questionnaire. Time to functional TE speech, FH adoption rate, duration of use, and causes of discontinuation were analyzed.

RESULTS

Thirty-three patients were included. Functional TE speech was achieved in 75.8% of patients at a mean of 5.8 ± 3.01 months postoperatively. Among these, 48% initiated FH speech at a mean of 9.35 ± 4.36 months after surgery. FH speech dropping-out rate was 83,3%, mostly due to patch displacement (44,4%) which held a mean fixation time of 1,5 ± 0,71 hours, followed by prosthesis-related complications (22,2%), shortness of breath (22,2%) and excessive cough (11,1%). FH speech was being used by 21,7% patients 1 year after TL, increasing to 29,4% 2 years after surgery. Among FH speech daily users, the device was used for 11 ± 1,41 hours. Mean VHI-10 score was 12 ± 4.95, with no significant difference between TE users with or without FH devices.

CONCLUSIONS

FH speech represents a promising but currently underperforming extension of TE rehabilitation. Without improvements in device reliability and patient-centered design, its clinical impact will remain limited despite high rates of functional TE speech acquisition.

Occupational Voice Use On Vocal Fatigue, Voice Handicap, Vocal Tract Discomfort, And Acoustic And Aerodynamic Voice Parameters In Academics

Nurcan Alpüran Kocabıyık[1]

[1]*Istanbul Kent University*

BACKGROUND & AIM

This study aimed to determine the level of vocal fatigue associated with occupational voice use among academics actively engaged in teaching/lecturing and to examine the relationship between vocal fatigue, voice handicap, vocal tract discomfort, and acoustic and aerodynamic voice parameters.

MATERIAL & METHODS

Academics at universities were included. Demographic data, occupational voice-use characteristics, weekly teaching duration, microphone use, smoking history, and clinical factors affecting vocal health were recorded. Morning and evening assessments were conducted in participants to examine changes associated with occupational voice use. Vocal fatigue was evaluated using the Turkish Vocal Fatigue Index and a 0–10 Visual Analog Scale. Voice handicap was assessed with the SHI-10/VHI-10, and vocal tract discomfort with the Vocal Tract Discomfort Scale. Acoustic analyses included fundamental frequency, jitter, shimmer, and noise-to-harmonic ratio, whereas maximum phonation time and the s/z ratio were aerodynamic parameters. Data were analyzed using SPSS. Normality was tested with the Shapiro–Wilk test. Normally distributed data were presented as mean ± standard deviation and compared using paired-samples t-tests; non-normal data were presented as median and minimum–maximum and analyzed using Wilcoxon signed-rank tests. Categorical variables were reported as frequencies and percentages. Statistical significance was set at $p<0.05$.

RESULTS

Vocal fatigue levels were expected to increase with greater weekly teaching/lecturing duration and intensive occupational voice use. Evening measurements were expected to show higher vocal fatigue scores, shorter maximum phonation time, altered s/z ratio, and possible deterioration in acoustic voice parameters compared with morning measurements. Academics with higher vocal fatigue levels were also have higher voice handicap and vocal tract discomfort scores.

CONCLUSIONS

This study is expected to contribute to the identification of vocal fatigue risk associated with occupational voice use among academics and to support the development of preventive vocal health strategies.

Nationwide Survey On The Characteristics And Treatment Of Age-Related Vocal Fold Atrophy In Japan

Tomohiro Hasegawa[1], **Kazuhiro Nakamura**[1], **Koji Matsushima**[1], **Naoki Takemoto**[1], **Ichiro Tateya**[1], **Kaoruko Kuraoka**[1], **Kazuya Kurakami**[1], **Jun Okamura**[1], **Takashi Fukumura**[1], **Shigeru Hirano**[1], **Nobuhiko Oridate**[1], **Yukio Katori**[1], **Yusuke Watanabe**[1]

[1]*Department of Otolaryngology–Head and Neck Surgery, Gifu University Hospital, Gifu University School of Medicine*

BACKGROUND & AIM

As the global population ages, age-related vocal fold atrophy (ARVA) is increasingly recognized. However, no nationwide epidemiological studies have been conducted. We aimed to investigate the clinical characteristics and treatments of ARVA in Japan, the world's most aged society.

MATERIAL & METHODS

This multicenter retrospective study, part of the Tokyo Voice Center Initiative, analyzed medical records of 1365 patients diagnosed with ARVA between 2018 and 2022. The primary survey examined the involvement of speech language pathologist (SLP) and the routine use of stroboscopic examinations at 34 certified institutions. The secondary survey assessed hoarseness severity (via maximum phonation time and voice handicap index-10), age of onset, treatment methods, and treatment outcomes at 14 certified institutions.

RESULTS

All diagnoses and assessments were conducted by departments of otolaryngology—head and neck surgery. Of the 1365 patients (637 females, 728 males; mean age: 64.6 ± 14.7 years), 1097 received treatment and 268 did not. Treatments included voice therapy (n = 1031), injection augmentation (n = 162), and surgery (n = 18), with some receiving multiple therapies. Voice therapy was more effective when provided by voicespecialized SLPs. Invasive treatments yielded greater voice improvement overall. Significant differences in age and sex ratios were found between institutions ($P < 0.01$).

CONCLUSIONS

These findings underscore the need for cross-specialty education, broader awareness of ARVA, and establishment of a national database and severity classification system.

OP-1021

Voice Prosthesis Lifetime Before And After Fluconazole Initiation.

Felat Toprak[1], **Arzubetül Duran**[1], **Barış Bayram Büyük**[1]

[1]*Department of Otorhinolaryngology, University of Health Sciences Ankara Dr. Abdurrahman Yurtaslan Oncology Training and Research Hospital, Ankara, Türkiye*

BACKGROUND & AIM

Biofilm-related deterioration is a major cause of tracheoesophageal voice prothesis failure, and fungal colonization is frequently implicated in early device dysfunction. However, the effect of systemic antifungal treatment on prosthesis lifetime remains uncertain. We aim to evaluate whether initiation of fluconazole was associated with a change in completed voice prosthesis lifetime in patience, undergoing repeated prosthesis replacement. Our hypothesis was that prosthesis lifetime might differ after fluconazole initiation.

MATERIAL & METHODS

This was a retrospective interval-based clinical study. Records of 52 patient with 166 voice prosthesis replacement procedures were reviewed. Prosthesis lifetime was defined as the number of days between two consecutive recorded replacement date. Only completed lifetimes, defined as interval bracketed by two replacements procedures, were included in the primary analysis. Patient with fewer than 2 recorded replacements were excluded from interval-based analysis. Lifetimes were assigned according to fluconazole status at the start of each interval. Descriptive interval-level results were summarized using median values. To reduce between-patient variability, we added additionally performed paired patient-level analysis, including only the patients with completed prosthesis lifetimes in both periods. The paired comparison was performed using the Wilcoxon signed-rank test.

RESULTS

Interval-base analysis was possible 32 of 52 patients. A total of 101 completed prosthesis lifetimes were identified, including 82 in the pre-fluconazole period and 19 in the fluconazole period. At the interval level, median prosthesis lifetime was 356 days before fluconazole and 224 days during the fluconazole period. Because multiple completed intervals could arise from the same patient, these values were treated as descriptive rather than inferential. For the primary within-patient comparisons, 12 patients have completed prosthesis lifetimes in both periods and were included in analysis. No statistically significant difference was found between the periods for patient-level, median lifetime, $Z=-0.292$, $p= 0.695$.

CONCLUSIONS

In this retrospective within-patient analysis, fluconazole initiation was not associated with a significant change in the complete voice prosthesis lifetime. These findings do not support a clear prolongation effect of fluconazole in discord in this cohort.

Voice, Speech, And Swallowing Experience During ORL-HNS Residency In Turkiye: A Function-Oriented Multicenter Survey

Arzubetul Duran, MD, MSc.[1], **Esma Altan, MD**[2], **Oğuzhan Katar, MD**[3], **Tuba Doğan Karataş, MD**[4], **Saliha Kuşoğlu Atalay, MD**[5], **Celil Göçer, Prof.**[5], **Güleser Saylam, Prof.**[5], **İlter Denizoğlu, Assos. Prof.**[6], **Engin Dursun, Prof.**[5], **E. Elif Altuntaş, Prof.**[5], **Haldun Oğuz, Prof.**[5]

[1]Ankara Oncology Training and Research Hospital; [2]Ankara Etlik City Hospital; [3]Hacettepe University; [4]Sivas Cumhuriyet University; [5]Lokman Hekim University; [6]Vocology Center

BACKGROUND & AIM

Voice, speech, and swallowing are core domains of the Phoniatrics, clinically relevant for Otorhinolaryngology – Head and Neck Surgery (ORL-HNS) specialist. The International Classification of Functioning, Disability and Health (ICF) emphasizes functioning, activity, and participation, rather than diagnosis, making it a relevant conceptual framework for clinical assessment. Surveys have shown substantial variability in residency education. In parallel, disability-related competencies are underrepresented in graduate medical education. The objective of this study is to assess whether ORL-HNS residency training in Turkiye provides sufficient experience in voice, speech and swallowing for function-oriented clinical decision making.

MATERIAL & METHODS

This cross-sectional, multicenter, survey included 104 ORL-HNS residents from four institution types in Turkiye. The questionnaire was developed using the Turkish ORL-HNS core curriculum, the UEP/UEMS Phoniatrics Logbook perspective, and function oriented-domains reflected in adult disability assessment. The first section evaluated institutional resources, structured teaching, and resident experience in core diagnostic and therapeutic areas. The second section, limited to senior residents, explored self-perceived competence in function-oriented impairment/disability evaluation across six domains.

RESULTS

Any clinical experience was reported by 87.5% of residents in voice, 83.7% in swallowing, and 73.1% in speech, while active participation was lower, 39.4%, 30.8%, and 23.1%, respectively. Perception of structured teaching was uncommon across all domains, with only 14.4% reporting formal training in voice, 8.7% in speech, and 13.5% in swallowing. Stroboscopy showed the broadest hands-on exposure, whereas perceptual/objective voice assessment, and speech assessment were less represented. In the swallowing domain, 35.6% reported no experience with FEES/VFSS. Among senior residents, only 23.1% reported formal teaching in disability regulations, and self-perceived competence was highest for upper airway defects and lower for voice, language, and chewing/swallowing.

CONCLUSIONS

ORL-NHS residency training in Turkiye appears to provide broader experience in voice and swallowing than in speech. But structured teaching remains limited across all three domains. The findings also suggest that multidisciplinary access and planned teaching are associated with broader resident experience. Disability-related teaching is perceived as limited. An ICF-informed, function-oriented approach may help strengthen curriculum design in voice, speech, and swallowing training.

Automated Classification Of Pediatric Vocal Fold Nodules: A Machine Learning Approach Based On Voice Recordings

Elif Ezgi IŞIK[1], **Merve SAPMAZ ATALAR**[2], **Ethem İLHAN**[3], **Faruk Enes OĞUZ**[4], **Mümüne Merve PARLAK**[5], **Ahmet ALKAN**[6], **Ömer Necati DEVELİOĞLU**[7]

[1]University of Health Sciences, Hamidiye Faculty of Health Sciences, Department of Speech and Language Therapy, Istanbul, Turkey; [2]University of Health Sciences, Hamidiye Faculty of Health Sciences, Department of Speech and Language Therapy, Istanbul, Turkey; [3]University of Health Sciences, İstanbul Gaziosmanpaşa Health Research Center, Department of Surgical Medical Sciences Department of Otorhinolaryngology, Istanbul, Turkey; [4]Mustafa Kemal University, Hassa Vocational School, Electronics and Automation, Biomedical Device Technology Program, Hatay, Turkey; [5]Ankara Yıldırım Beyazıt University, Faculty of Health Sciences, Department of Speech and Language Therapy, Ankara, Turkey; [6]Kahramanmaraş Sütçü İmam University, Faculty of Engineering and Architecture, Department of Electrical and Electronics Engineering, Kahramanmaraş, Turkey; [7]University of Health Sciences, İstanbul Gaziosmanpaşa Health Research Center, Department of Surgical Medical Sciences Department of Otorhinolaryngology, Istanbul, Turkey

BACKGROUND & AIM

Vocal fold nodules (VFN) are among the most frequently encountered pathologies in the pediatric group. The relationship between voice disorders and acoustic voice characteristics has been clinically validated. Acoustic features derived from voice signals are effectively utilized in the classification of voice disorders. Research has focused on the role of the voice signal as a part of this process through the use of machine learning models. However, the majority of studies in the literature focus on the

adult population. This study aims to automatically classify pediatric VFN using machine learning methods based on voice recordings.

MATERIAL & METHODS

Within the scope of the study, sustained /a/ phonation and spontaneous speech recordings were obtained from a total of 71 participants, consisting of 32 children diagnosed with VFN by an otorhinolaryngologist and 39 healthy children. All recordings were acquired using the Audacity software and stored in .wav format. Fundamental frequency (F0), jitter, shimmer, and harmonic-to-noise ratio (HNR) were calculated from the sustained /a/ phonation data. Mel-frequency cepstral coefficients (MFCC) and various spectral and energy-based features were extracted from the spontaneous speech data. The most discriminative acoustic features determined using the Welch t-test were modeled with Support Vector Machine (SVM), K-Nearest Neighbors (KNN), Random Forest (RF), and Naive Bayes algorithms using the 5-fold cross-validation method.

RESULTS

According to the classification results, the RF algorithm stands out with 83.1% accuracy, 71.9% sensitivity, 92.3% specificity, a 79.3% F1 score, and an AUC value of 0.891. Naive Bayes ranked second with an accuracy rate of 78.9%, while SVM and KNN methods had the lowest accuracy rate at 74.6%. Although the KNN method reached the highest specificity value at 97.4%, it lagged behind the other models in overall performance with a low sensitivity of 46.9% and an AUC value of 0.774. While the AUC value obtained with SVM in the preliminary analysis using only /a/ phonation features was 0.795, this value increased to 0.891 for RF when both recording types were combined.

CONCLUSIONS

An accuracy of 83.1% and an AUC value of 0.891 were achieved with the RF classifier using acoustic features extracted from sustained vowel phonation and spontaneous speech recordings. The obtained results indicate that voice-based acoustic analysis can be used as a supportive diagnostic tool in the detection of pediatric VFN. Furthermore, the findings suggest that integrating spontaneous speech recordings into sustained vowel phonation analysis may carry a strong and supportive potential as a clinical tool in pediatric VFN detection.

OP-1024

The JISH Speech, Language, And Hearing School Readiness Screening In Jeddah, Saudi Arabia

Yaser Numan Al Sabi[1]

[1]*Headquarters Cochlear Al-Arabia Regional*

BACKGROUND & AIM

This retrospective study presents the results of an Arabic school readiness screening conducted between the years of 2000 and 2010 at the Jeddah Institute for Speech and Hearing (JISH) in Jeddah, Saudi Arabia. The study was conducted to obtain estimates of prevalence of speech, language, and communication disorders and hearing disorders among Arabic-speaking children in the Kingdom of Saudi Arabia prior to entering school (in order to assist in determining the readiness of these children for school) and to determine the types of speech and language deficits exhibited among Arabic-speaking children.

MATERIAL & METHODS

The records of 1543 children were screened using the JISH Arabic Speech, Language and Hearing Screening Protocol between the years of 2000 and 2010 were reviewed. The following materials were used to conduct each screening:

The JISH Arabic Speech-Language-Hearing-Screening Protocol, screening record (pass-fail forms) and

the Oral-Speech-Mechanism-Screening-Examination-Revised (OSMSE-R). Other materials used during

each screening included: gloves, tongue depressors, penlight, stickers, and an audiometer.

RESULTS

Analysis of results showed statistically significant prevalence rates in all areas for which screening was conducted: hearing (7.1% “0.0000”); language comprehension (1.7% “0.0000); language expression (2.7% “0.0000); voice (5.1% “0.0000); fluency (3.2% “0.0000), and articulation (30.3%).

CONCLUSIONS

The findings of the study assured the need to screen speech, language and hearing skills of children before sending them to schools. This is significantly needed in the Middle East and in the whole Arab region due to the fact that general physical examinations are not enforced in most of the medical insurance policies, therefore, communication deficits will not be detected from early ages.

OP-1025

Development Of A Social Validity Questionnaire For Voice Therapy: A Pilot Study

Tuba Kaya[1], **Saime Seyhun Topbaş**[2], **İsmail İlter Denizoğlu**[4], **İsmail Demir**[3]

[1]*Department of Speech and Language Therapy, Faculty of Health Sciences, İnönü University, Malatya, Türkiye.*; [2]*Department of Speech and Language Therapy, Faculty of Health Sciences, Istanbul Medipol University, Istanbul, Türkiye.*; [3]*Department of Audiology, Faculty of Health Sciences, İnönü University, Malatya, Türkiye.*; [4]*Department of Speech and Language Therapy, Faculty of Health Sciences, Izmir Tinaztepe University, Izmir, Türkiye.*

BACKGROUND & AIM

Evaluating the clinical efficacy of voice therapy often overlooks the patient's perspective regarding the intervention's social relevance. This study aims to present the pilot results of a newly developed Social Validity Questionnaire designed to assess the meaningfulness, applicability, and usefulness of voice therapy practices. The goal was to examine the instrument's preliminary psychometric properties and determine its potential as a standardized tool for measuring perceived social validity in clinical settings.

MATERIAL & METHODS

The study utilized a Social Validity Questionnaire developed based on a comprehensive review of the social validity literature and clinical voice therapy practices. The instrument consists of 12 Likert-type items assessing the dimensions of meaningfulness, applicability, and usefulness. To further support the scale and evaluate alignment, additional questions were included regarding the program's contribution. In addition, three open-ended questions were incorporated to explore the most beneficial aspects of the program, areas for improvement, and perceived changes in voice use. The items were reviewed for content relevance and clarity by an expert panel consisting of two speech and language therapists and one otolaryngologist. A pilot study was conducted with 17 participants who had completed a voice therapy program. Quantitative data were analyzed using descriptive statistics, the Wilcoxon Signed-Rank Test, and Cronbach's alpha to evaluate internal consistency. Qualitative data obtained from the open-ended responses were analyzed through content analysis.

RESULTS

The pilot results demonstrated that social validity scores across all subdimensions were significantly higher than the neutral value of 3 ($p < 0.001$). The Cronbach's alpha coefficient for the total scale was calculated as 0.73, indicating acceptable internal consistency. Examination of the subscales revealed acceptable internal consistency for the meaningfulness ($\alpha = 0.74$) and usefulness ($\alpha = 0.64$) dimensions, whereas the applicability dimension demonstrated low internal consistency ($\alpha = 0.27$). Responses to the open-ended questions yielded themes that supported the content validity of the items.

CONCLUSIONS

The findings suggest that the developed Social Validity Questionnaire may be a useful measurement tool for assessing perceived social validity in voice therapy practices. While the meaningfulness and usefulness dimensions showed reliability, the low consistency in the applicability subscale indicates a need for item refinement. Overall, the pilot supports the tool's utility, though further research with a larger sample size is necessary to confirm its long-term construct validity and clinical reliability.

Stages Of Medical Rehabilitation Of The Patients With Bilateral Paresis And Paralysis Of The Larynx

Ekaterina Osipenko[1]

[1]*Department of Phoniatrics of the National Medical Research Center of Otolaryngology of the Russia*

BACKGROUND & AIM

Bilateral laryngeal paresis and paralysis are severe conditions that substantially reduce quality of life due to impairment of respiratory, phonatory, and protective functions. In many cases, modern medicine makes it possible to restore breathing and voice production; however, treatment success depends on an interdisciplinary approach involving surgeons, phoniatrician, speech therapists, and psychologists. The aim of this study was to develop and evaluate the effectiveness of a comprehensive medical rehabilitation program based on the combination of conservative, instrumental, and educational methods in patients with bilateral laryngeal disorders.

MATERIAL & METHODS

At the Phoniatrics Department of the National Medical Research Center for Otorhinolaryngology, 49 patients with bilateral laryngeal paresis and paralysis of various etiologies were examined. The patients were divided into two groups: a control group of 20 patients who received conventional treatment, and a study group of 29 patients who underwent comprehensive medical rehabilitation. In the study group, a three-stage program was used: stage I included drug therapy, psychological support, and assessment of voice, swallowing, and breathing disorders, aspiration risk, laryngeal structural impairment, and patient activity and participation; stage II included instrumental methods and speech therapy aimed at correcting the respiratory pattern and dysphagia; and stage III focused on consolidating breathing and phonation skills and adherence to vocal hygiene.

RESULTS

The analysis demonstrated a significant advantage of the comprehensive approach. In the control group, recovery was slower: 45% of patients continued to have voice impairment and dyspnea. In the study group, 86% of patients achieved stabilization of breathing and widening of the glottic airway without the need for additional surgical correction. In addition, dysphagia was completely resolved in 82% of patients in the study group, which made it possible to eliminate the risk of aspiration complications and improve functional prognosis.

CONCLUSIONS

The three-stage medical rehabilitation program integrating pharmacological, instrumental, and voice therapy methods is superior to conventional approaches. Interdisciplinary patient management makes it possible to restore respiratory, voice, and swallowing functions more effectively, shorten treatment duration, and improve quality of life. The results confirm the feasibility of early initiation of comprehensive rehabilitative treatment and the sequential use of specialized programs in this patient population.

Surgical Success And Resolution Rates Of Endoscopic Sinus Surgery For Odontogenic Maxillary Sinusitis: A Systematic Review And Meta-Analysis

Anas Bassam Barnawi[1], **Abdulrahman Abdullah Almudawi**[1], **Abdulaziz Abdullah Alsaab**[1], **Abdullah Abdulmohsen Alabdulqader**[2]

[1]*College of Medicine, Imam Mohammad Ibn Saud Islamic University (IMSIU), Riyadh, Saudi Arabia;* [2]*Department of Otorhinolaryngology, College of Medicine, Imam Mohammad Ibn Saud Islamic University (IMSIU), Riyadh, Saudi Arabia*

BACKGROUND & AIM

Odontogenic maxillary sinusitis (OMS) is an increasingly recognized cause of chronic unilateral maxillary sinus disease, often requiring combined dental and sinonasal management. While endoscopic sinus surgery (ESS) has become the preferred surgical approach, reported outcomes vary, and a comprehensive quantitative synthesis of surgical success and safety remains limited. This systematic review and meta-analysis aimed to evaluate the effectiveness, recurrence, revision, and complication rates of ESS in the management of OMS.

MATERIAL & METHODS

A systematic search of PubMed/MEDLINE, Web of Science, and the Cochrane Library (January 2000–January 2025) identified studies reporting outcomes of ESS for OMS. Thirty-five studies encompassing 2,586 adult patients met inclusion criteria. Pooled proportions were calculated using random-effects models. Primary outcome was surgical success (disease resolution). Secondary outcomes included recurrence, revision surgery, and complication rates

RESULTS

The pooled surgical success rate following ESS was 97.1% (95% CI: 95.5–98.1%; I^2 = 46.4%). After adjustment for publication bias, the success rate remained high at 92.9%. The pooled recurrence rate was 3.0% (95% CI: 2.0–5.0%), while revision surgery was required in 3.0% (95% CI: 2.0–4.0%) of cases. ESS demonstrated a favorable safety profile, with a pooled complication rate of 2.0% (95% CI: 1.0–5.0%), predominantly minor and self-limiting. Sensitivity analyses confirmed the robustness of all pooled estimates.

CONCLUSIONS

Endoscopic sinus surgery provides excellent disease resolution with low recurrence, revision, and complication rates in patients with odontogenic maxillary sinusitis. When performed as part of multidisciplinary management that includes definitive dental or oral surgical treatment of the odontogenic source, ESS represents a highly effective and safe surgical strategy, supporting its role as the preferred approach for OMS.

Navigating The Middle Ground: A Comprehensive Analysis Of Otolaryngologists' Practices On Middle Turbinate Resection In Endoscopic Sinus Surgery

Dr. Saad Nabeel Algahtani[1], **Dr. Feras Mohammed Alkholaiwi**[2]

[1]*King Saud Medical City*; [2]*Imam Mohammad Ibn Saud Islamic University*

BACKGROUND & AIM

Controversies persist regarding middle turbinate (MT) resection during endoscopic sinus surgery, with conflicting views on its benefits and risks. This study explores current practices among otolaryngologists, assessing the frequency of MT resection and factors influencing decision-making, shedding light on this contentious aspect of sinus surgery. By assessing current practices and identifying factors influencing MT resection frequency, this work sheds light on the ongoing debate on the merits and drawbacks of this surgical intervention.

MATERIAL & METHODS

A survey was used to explore MT resection practices among actively practicing otolaryngology consultants, employing a purposive sampling strategy to ensure demographic diversity. Statistical analysis of questionnaire responses facilitated a robust exploration of factors influencing MT resection variability, revealing MT resection practices among otolaryngologists and recognizing potential limitations.

RESULTS

The analysis of 65 participants revealed significant findings on MT resection practices: 29.2% of participants believed that MT resection was moderately beneficial in improving visualization. Concerning MT resection, 46.2% typically resected the anterior inferior one third. Likelihood of MT resection was significantly increased in CRS with NP, allergic fungal sinusitis, and cystic fibrosis. Empty nose syndrome was the complication of least concern (50.8%). Tertiary hospital practitioners reported significantly lower frequencies ($P<0.001$) of MT resection.

CONCLUSIONS

Significant variations in MT resection practices among otolaryngologists, with variations in practice based on years of experience, practice setting, type of sinus disease, and slight concern for potential complications.

OP-1029

Clinical Outcomes And Morbidity Of The Endoscopic Prelacrimal Recess Approach In Antrochoanal Polyps: A Real-World Experience

Azin Tabari[1], **Tina Davari Nasab**[1], **Seyed Mousa Sadre Hosseini**[1]

[1]*Tehran university of Medical Sciences*

BACKGROUND & AIM

Antrochoanal polyps (ACP) are benign unilateral lesions originating from the maxillary sinus, most commonly affecting children and young adults. Complete surgical excision is the treatment of choice; however, polyps arising from the anterior or inferior maxillary sinus walls are difficult to access using standard endoscopic techniques. The endoscopic prelacrimal recess approach (PLA) provides improved access to challenging maxillary regions while preserving the inferior turbinate and nasolacrimal duct. This study evaluates postoperative morbidity, recurrence rates, and anatomical risk factors in patients with ACP treated using PLA.

MATERIAL & METHODS

This retrospective case series included 42 patients with primary ACP who underwent endoscopic PLA. Patients younger than 10 years, those with recurrent ACP, uncontrolled systemic disease, or other maxillary sinus pathology were excluded. Demographic data, polyp origin, and postoperative outcomes were collected from medical records. Preoperative paranasal sinus CT scans were reviewed to measure the width of the prelacrimal recess (WPR), classified according to Simmen's classification, and the anterior–posterior nasal dimension (APN). Postoperative endoscopic follow-up was performed at one month and continued for at least six months. Morbidity included cheek numbness and epiphora, classified as temporary or permanent. Statistical analysis was performed using SPSS version 27, with a significance threshold of $P < 0.05$.

RESULTS

The cohort included 23 males and 19 females, with a mean age of 15.2 years. Polyps were right-sided in 73.8% of patients. Among cases with documented origin, 69.2% arose from the anterolateral maxillary wall. The mean WPR was 5.9 mm; 52% of patients were classified as type 2, 32% as type 3, and 16% as type 1. Temporary cheek numbness occurred in 28.5% of patients and resolved within three months, while permanent numbness was observed in 9.5%. One patient developed transient epiphora due to nasolacrimal duct injury. Recurrence occurred in one patient (2.4%). No significant association was found between postoperative numbness and WPR type ($P > 0.05$) or mean APN ($P = 0.85$).

CONCLUSIONS

The endoscopic prelacrimal recess approach is a safe and effective technique for complete resection of antrochoanal polyps, including those arising from anatomically challenging maxillary sinus regions. Despite concerns regarding anatomical limitations, PLA demonstrated low recurrence rates and acceptable, predominantly transient morbidity, with no clear CT-based predictors of complications.

Sinonasal Inverted Papilloma .Radiological Findings And Management In Eight Patients

Matthildi Chroni[1]

[1]*Evaggelismos Hopital Athens Greece*

BACKGROUND & AIM

Sinonasal inverted papillomas (IP) are benign nasal tumours, they represent 0,4-4,7% of all nasal tumours and have an incidence of 0,74-1,5 cases per 100.000 population per year. Although histologically benign, they are locally invasive, with high recurrence rates (15-20%) and possibility of malignant transformation.

Objective To present radiological and intraoperative findings regarding the attachment of 8 cases of inverted papilloma that were treated with endoscopic nasal surgery

MATERIAL & METHODS

Eight patients with inverted papillomas were studied .Preoperative CT scan was examined regarding inverted papilloma attachment.Hyperostosis was evident in 3 out of 8 patients .The attachment was determined intraoperatively and involved the lateral nasal wall in 4 cases, maxillary sinus in 2 cases, nasal septum and frontal sinus in one case.

RESULTS

Preoperative CT scan revealed attachment of inverted papilloma in 3 out of 8 cases preoperatively .There was one patient with IP recurrence .

CONCLUSIONS

Preoperative CT scan may fail to show the attachment of the IP .All patients were operated with endoscopic nasal surgery.

Treatment Of Post Viral Olfactory Dysfunction With Olfactory Training: A Systematic Review And Meta-Analysis

Kalpesh Hathi MD[1], **Hannah Brennan MD**[1], **Colin MacKay MSc**[1], **Christopher J Chin MD, FRCSC**[1]

[1]*Division of Otolaryngology - Head & Neck Surgery, Dalhousie University, Halifax, Nova Scotia, Canada*

BACKGROUND & AIM

Post-viral olfactory dysfunction (PVOD) has increased in prevalence and media attention with the COVID-19 pandemic. Pharmacologic therapy for PVOD is limited, and olfactory training (OT) has shown varying efficacy. This study is the first meta-analysis on OT for PVOD in the post-COVID era.

MATERIAL & METHODS

We performed a systematic review and meta-analysis of published English studies queried through MEDLINE, EMBASE, CINAHL and Web of Science. The search strategy was developed in collaboration with a clinical librarian and targeted articles looking at OT for PVOD. The meta-analysis was performed looking at patients achieving minimal clinically important difference (MCID) olfactory testing when treated with OT compared to control groups.

RESULTS

The search yielded 8263 de-duplicated articles; 60 were included. The majority showed improved olfaction with OT. However, 3 studies did not show any difference between OT and control groups. Improved adherence and longer duration of OT were shown to improve olfactory outcome, whereas longer duration of PVOD worsened outcomes. Modifying OT protocols did not seem to impact olfactory outcomes. The meta-analysis revealed that OT is 2.6 times more likely to result in an MCID compared to control groups (OR=2.61; 95%CI 1.26-5.42). Included studies were most commonly moderate quality based on the Methodological Index for Non-Randomized Studies.

CONCLUSIONS

OT for PVOD is shown to have 2.6 times greater odds of achieving MCID compared to control groups. The systematic review suggests that the protocol of OT may have less of an impact compared to patient-specific factors such as adherence, duration

of training and duration of olfactory dysfunction. We have demonstrated that OT is effective and should be utilized as first-line therapy for patients with PVOD.

Intranasal Platelet-Rich Plasma Injection For Persistent Post–COVID-19 Olfactory Dysfunction: A Prospective Randomized Crossover Pilot Study

Chae-Seo Rhee[2], **Jayoung Oh**[1]

[1]*Soonchunhyang UNIVERSITY;* [2]*Seoul National University*

BACKGROUND & AIM

Persistent olfactory dysfunction following COVID-19 infection has emerged as a major clinical problem, with a substantial proportion of patients experiencing prolonged impairment despite standard management such as olfactory training and corticosteroids. Given the limited therapeutic options, regenerative strategies targeting the olfactory neuroepithelium are of increasing interest. Platelet-rich plasma (PRP), enriched with neurotrophic and growth factors, may facilitate neural recovery and mucosal regeneration in post-viral olfactory dysfunction.

MATERIAL & METHODS

This prospective, single-center, single-blind, randomized crossover pilot study enrolled adults aged ≥19 years with persistent olfactory dysfunction lasting more than 2 months after confirmed COVID-19 infection and refractory to conventional therapy. Participants were randomized to receive intranasal PRP followed by saline or saline followed by PRP. Autologous PRP was prepared from 30 mL of peripheral blood using a two-spin protocol, and 2 mL was endoscopically injected into the olfactory cleft mucosa. The primary endpoint was change in Cross-Cultural Smell Identification Test (CCSIT) score at 6 months. Secondary outcomes included CCSIT at 1 and 3 months, Korean Version of the Sniffin' Sticks test (KVSS), Questionnaire of Olfactory Disorders (QOD), visual analog scale (VAS), and growth factor profiling. Safety was assessed through adverse event monitoring and laboratory parameters.

RESULTS

Thirty patients were enrolled, and 25 completed both treatment phases during the study period; 15 reached the 6-month follow-up. The prespecified 6-month CCSIT comparison did not show a significant between-group difference, likely due to a carryover effect inherent to the crossover design. However, during the initial 3-month treatment period, the PRP-first group demonstrated greater improvement in objective olfactory measures compared with the saline-first group (mean KVSS-TDI: 18.25 to 20.96 vs. 17.20 to 19.20). Among patients younger than 60 years, KVSS-TDI improved from 19.72 to 22.04 after PRP, whereas minimal change was observed after saline (19.60 to 19.25), and this improvement was sustained at 6 months. Growth factor analysis revealed substantial increases in BDNF and SDF-1 following PRP administration, supporting a regenerative mechanism. No serious treatment-related adverse events occurred.

CONCLUSIONS

Intranasal autologous PRP appears safe and may promote sustained olfactory recovery in patients with persistent post–COVID-19 olfactory dysfunction, particularly in younger individuals. These findings support further large-scale, parallel-group trials to confirm efficacy and define optimal patient selection.

When De Lab Meets The Polyp: Performance Of Histopathologic Checklist And Validation Of Eosinophiles/Mm2 In Crswnp Polyp Samples

Camilo Rodriguez-Van Strahlen[1,3], **Albert Castro-Soriano**[1], **Joan Lop-Gros**[2], **Mauricio Lopez-Chacon**[1,3,4], **Raquel Albero-Gonzalez**[2], **Maria Concepció Marin**[3,4], **Mireia López-Ardiaca**[1], **Joaquim Mullol**[1,3,4], **Isam Alobid**[1,3,4]

[1]*Departments of Otorhinolaryngology, Hospital Clinic Barcelona, Universitat de Barcelona;* [2]*Departments of Pathology, Hospital Clinic Barcelona, Universitat de Barcelona;* [3]*IDIBAPS. Barcelona, Catalonia, Spain.;* [4]*ISCiii-CIBERES. Barcelona, Catalonia, Spain.*

BACKGROUND & AIM

Chronic rhinosinusitis with nasal polyps (CRSwNP) is a prevalent disorder affecting quality of life. Nasal eosinophilia is a key T2 biomarker, frequently expressed as cells/HPF. Digital anatomopathology enables quantification as cells/mm², offering reproducibility and standardization. This study evaluated the feasibility of structured histopathology in CRSwNP, focusing on tissue eosinophilia and its clinical associations.

MATERIAL & METHODS

Retrospective observational study including 84 consecutive CRSwNP patients (2022–2025, EPOS2020 criteria). Histological samples were analyzed for inflammatory cells, tissue remodelling markers, and eosinophilia quantified per HPF and mm². Clinical associations with asthma, NSAID-exacerbated respiratory disease (N-ERD), and oral corticosteroid (OCS) use were assessed.

RESULTS

Mean tissue eosinophil counts were 196±192 cells/HPF and 965±964 cells/mm², with near-perfect correlation between methods (r=0.980, p<0.001). Asthmatic patients showed significantly higher eosinophilia than non-asthmatics (238±208 vs. 124±134 cells/HPF; 1,168±1,069 vs. 618±626 cells/mm², p<0.01). Charcot–Leyden crystals, eosinophil aggregates, and degranulation correlated strongly with higher eosinophilia. No significant differences were found for N-ERD or OCS subgroups

CONCLUSIONS

Eosinophils/mm² correlates strongly with HPF counts, providing a standardized, reproducible outcome measure for nasal tissue eosinophilia. The association between asthma and higher nasal eosinophilia reinforces the clinical relevance of asthma as a CRSwNP comorbidity.

Efficacy Of Increased Versus Standard Dosage Of Azelastine/Fluticasone Propionate Nasal Spray (Dymista) In Reducing Symptoms In Patients With Persistent Allergic Rhinitis: A Randomized Controlled Trial

Sasicha Siriprapanukul[2], **Stephen J. Ker**[1], **Supinda Chusakul**[2], **Kornkiat Snidvongs**[2], **Jesada Kanjanaumporn**[2], **Prem Wungcharoen**[2], **Kachorn Seresirikachorn**[2]

[1]*Center of Excellence in Biostatistics, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand.*; [2]*Department of Otolaryngology, King Chulalongkorn Memorial Hospital, Bangkok, Thailand*

BACKGROUND & AIM

Intranasal corticosteroids (INCSs) are the mainstay of treatment for allergic rhinitis (AR). However, many patients remain symptomatic despite monotherapy. The fixed-dose combination of an INCS and an intranasal antihistamine (MP-AzeFlu) has demonstrated superior efficacy in relieving nasal and ocular symptoms compared with INCSs alone. Doubling the INCS dose has been reported to accelerate and enhance symptom improvement. However, evidence on the efficacy of higher-dose MP-AzeFlu regimens is limited. This study evaluated the clinical efficacy and safety of an increased-dose MP-AzeFlu regimen compared with the standard dose in patients with persistent AR.

MATERIAL & METHODS

A prospective, randomized, placebo-controlled trial was conducted in patients with persistent AR. Participants were randomized to receive either standard-dose MP-AzeFlu (1 spray per nostril twice daily) or increased-dose MP-AzeFlu (2 sprays twice daily, with optional escalation up to 2 sprays six times daily for refractory symptoms) for 7 days. The primary outcome was the time to achieve a sustained ≥20-point reduction in the Visual Analog Scale (VAS) score. Secondary endpoints included mean daily VAS, total nasal symptom score (TNSS), itchy eye symptom, and adverse events.

RESULTS

Sixty participants were enrolled and equally randomized (n=30 per group; median age 22–23 years). Both regimens achieved a≥20-point reduction in VAS within 2 days. There were no statistically significant differences between increased- and standard-dose groups in mean VAS at day 7 (26.0 ± 4.32 vs 30.2 ± 4.32; mean difference −4.22 ± 6.15; 95% CI −16.27 to 7.82; p = 0.49), TNSS, or ocular itch score. Adverse events were comparable, with bitter taste being most frequently reported.

CONCLUSIONS

Increasing the dosage of MP-AzeFlu did not provide additional benefit over the standard regimen. The standard recommended dose appears sufficient for optimal control of persistent allergic rhinitis symptoms.

Evaluation Of CSF1R And CD206 Levels In Patients With Nasal Polyps

Hamza AYDIN[1], **Muhammed Gazi YILDIZ**[1], **Israfil ORHAN**[1], **Adem DOGANER**[2], **Muhammed SEYITHANOGLU**[3], **Omer Faruk CINAR**[1]

[1]*Kahramanmaraş Sütçü İmam University Medical Faculty, Department of Ear, Nose and Throat and Head and Neck Surgery;* [2]*Kahramanmaraş Sütçü İmam University Medical Faculty, Department of Biostatistics and Medical Informatics;* [3]*Kahramanmaraş Sütçü İmam University Medical Faculty, Department of Medical Biochemistry*

BACKGROUND & AIM

Chronic rhinosinusitis with nasal polyps (CRSwNP) is an inflammatory disease with unclear pathogenesis. Recent studies demonstrate that macrophage polarization, particularly the M1 to M2 transition, plays a key role in disease pathogenesis. Although histological studies show increased M2 macrophage infiltration in polyp tissue, translating this finding into a non-invasive biomarker remains challenging. The relationship between serum levels of the M2 macrophage specific surface receptors CSF1R and CD206 and disease presence and severity remains largely uninvestigated. This study aimed to evaluate the biomarker potential of CSF1R and CD206 in CRSwNP.

MATERIAL & METHODS

A total of 42 adult patients diagnosed with CRSwNP according to the European Position Paper on Rhinosinusitis and Nasal Polyps (EPOS) 2020 criteria and 42 healthy controls without nasal pathology were included in the study. Individuals meeting the general exclusion criteria specified in EPOS 2020 were excluded. Sociodemographic data of the participants were recorded, and symptom severity was assessed using the Sino-Nasal Outcome Test-22 (SNOT-22). Patients were evaluated using the Total Nasal Polyp Score (TNPS) and Lund-Mackay scoring system. Serum CSF1R and CD206 levels were measured using the ELISA method. Statistical analyses were performed using IBM SPSS Statistics version 22.0, and statistical significance was set at $p < 0.05$.

RESULTS

There were no statistically significant differences between the case and control groups in terms of demographic characteristics (Table 1). The SNOT-22 score was significantly higher in the nasal polyp group compared with the control group ($p<0.001$, Table 2).Serum CSF1R and CD206 levels were significantly higher in the nasal polyp group compared with the control group ($p=0.001$ and $p=0.031$, respectively; Table 2).ROC analysis demonstrated that CSF1R and CD206 had statistically significant diagnostic performance in distinguishing CRSwNP patients from healthy controls (Table 3, Figure 1, Figure 2).

CONCLUSIONS

Our study provides important evidence supporting the role of M2 macrophage activation in the pathogenesis of CRSwNP. The significantly elevated serum levels of CSF1R and CD206 in patients with CRSwNP suggest that these molecules may serve as non-invasive biomarkers of disease activity. Our findings indicate that these serum markers may represent potential biomarker candidates for supporting the diagnosis of CRSwNP or for use as objective tools in patient follow-up. Future prospective studies are needed to clarify their clinical applicability by evaluating their relationship with disease course and treatment response.

Comparison Of The Therapeutic Efficacy Of Crosine And Desloratadine In An Ovalbumin-Induced Allergic Rhinitis Model In Rats

Umut Can Musaoğlu[1], **Seyit Mehmet Ceylan**[1], **Semra Külekçi Öztürk**[1], **Aylin Ege Gül**[2], **Kübra Bozali**[2], **Eray Metin Güler**[2]

[1]*Sbü Fatih Sultan Mehmet Education and Research Hospital;* [2]*Sbü Hamidiye Faculty of Medicine*

BACKGROUND & AIM

Allergic rhinitis is a common disease with no definitive cure. Due to the high cost of treatment and the side effects of the medications used, alternative treatments are being investigated. Our aim is to evaluate the histopathological, biochemical, and clinical effects of crocin in an experimental allergic rhinitis model.

MATERIAL & METHODS

Twenty healthy, 8- to 12-week-old Sprague Dawley rats were randomized into five groups of four animals each. The first group served as the control group, and the other rats were administered ovalbumin and aluminum hydroxide intraperitoneally every other day for 14 days to induce allergic rhinitis. These animals received intranasal ovalbumin daily from day 14 onward. Desloratadine was administered by gavage to the third group, 50 mg/kg intraperitoneally to the fourth group, and 100 mg/kg intraperitoneally to the fifth group. The second group received no treatment. Before sacrifice on the 10th day, intracardiac blood was taken and IL4, IL13, IgE levels were examined. Histopathologically, goblet cell increase, cilia loss, vascular dilatation, lamina propria edema, cell infiltration and eosinophilic tissue increase were examined. Nasal symptom scores on the 1st, 14th, 21st and 28th days were evaluated clinically.

RESULTS

IL4-13 and IgE levels were found to be significantly decreased in the high-dose crocin group compared to the allergy and desloratadine groups ($p<0.05$). On day 28, symptoms of sneezing, nasal itching, and nasal discharge were found to be reduced in the high-dose crocin group compared to the allergy group. Goblet cell increase, cilia loss, and vascular dilatation were shown to be reduced in the high-dose crocin group compared to the allergy and desloratadine groups ($p<0.05$). Lamina propria edema, cell infiltration, and eosinophilic tissue increase were also found to be reduced in the 100 mg/kg crocin group compared to the allergy and desloratadine groups.

CONCLUSIONS

The effect of crocin on allergic rhinitis was investigated clinically, histopathologically, and biochemically. We demonstrated that it may be more effective than desloratadine, which is used in the treatment of allergic rhinitis. Our study is the first to use crocin in allergic rhinitis and is believed to be promising in the treatment of the disease.

Sinonasal Presentation And Diagnostic Evaluation Of Chronic Rhinosinusitis In Eosinophilic Granulomatosis With Polyangiitis: A Scoping Review

Alisha Sharma[1], **Alyssa Li**[1], **Teruko Kishibe**[3], **Dennis Wong**[1], **Kevin Sanders**[1], **Maggie Jiang**[2], **Heedo Lee**[1], **Christine Song**[1], **Kieran Mcintyre**[1], **Christian Pagnoux**[1], **Yvonne Chan**[1], **John Lee**[1], **Daniel J. Lee**[1]

[1]*University of Toronto;* [2]*Allergy Hub, Toronto;* [3]*Unity Health Toronto, Toronto*

BACKGROUND & AIM

Chronic rhinosinusitis (CRS) is a common and morbid manifestation of eosinophilic granulomatosis with polyangiitis (EGPA). This scoping review summarizes treatment strategies and sinonasal outcomes for CRS with nasal polyps (CRSwNP) and without nasal polyps (CRSsNP) in EGPA.

MATERIAL & METHODS

We searched MEDLINE, Embase, CENTRAL, CINAHL, and Web of Science from inception to June 4, 2025, for studies reporting CRS in EGPA. Non-English studies without translation and articles without primary data were excluded. Outcomes included treatment, remission and recurrence, and quality of life measures.

RESULTS

109 studies comprising 1087 patients were included. Median age was 53 years (n=154) and 48% (n=390) were male. CRSwNP was more common than CRSsNP (69% vs 31%). Endoscopic sinus surgery (ESS) was reported in 87% (n=64) and always combined with medical therapy. Systemic regimens in all patients included steroids (91%), immunosuppressants (87%), and biologics (59%), primarily mepolizumab (73%), benralizumab (12%) and dupilumab (23%). CRS remission occurred in 68% of medically treated patients (n=156). In mepolizumab-treated patients (n=113), 89% (n=27) achieved CRS remission, with mean SNOT-22 reductions of 48.3 points (n=10) with medical therapy alone, and 64 points (n=2) with ESS plus medical therapy. In a dupilumab subgroup (n=28), 83% (n=6) achieved remission, with a 25.2-point mean SNOT-22 improvement (n=9), and eosinophilia occurred in 68% (n=34).

CONCLUSIONS

Management of CRS in EGPA is shifting toward biologics, particularly mepolizumab and benralizumab for systemic control and cautionary use of dupilumab for refractory sinonasal disease. Standardized outcome reporting and prospective studies are needed to optimize management.

BACKGROUND & AIM

In the prospective, randomized, head-to-head EVEREST trial, dupilumab demonstrated rapid and sustained improvements over omalizumab in upper and lower airway outcomes in patients with severe chronic rhinosinusitis with nasal polyps (CRSwNP) with coexisting asthma. This post hoc analysis compared CRSwNP and asthma outcomes in the subgroup with non-steroidal anti-inflammatory drug (NSAID)-exacerbated respiratory disease (NSAID-ERD).

MATERIAL & METHODS

EVEREST (NCT04998604) randomized adults with severe CRSwNP and coexisting asthma to dupilumab 300 mg every 2 weeks or omalizumab 75–600 mg every 2 or 4 weeks for 24 weeks on background mometasone furoate nasal spray. NSAID-ERD was defined as a history of symptoms following aspirin and/or non-steroidal anti-inflammatory drug intake. Primary endpoints

were Week 24 change in nasal polyp score (NPS, range 0–8) and University of Pennsylvania Smell Identification Test (UPSIT, range 0–40). Other upper airway outcomes assessed were loss of smell (LoS, range 0–3) and the 22-item Sino-Nasal Outcome Test (SNOT-22, range 0–110). Lower airway outcomes assessed were pre-bronchodilator forced expiratory volume in 1 second (FEV1, L) and 7-item Asthma Control Questionnaire (ACQ-7, range 0–6). For each endpoint, we report the least squares mean difference [95% confidence interval] of dupilumab over omalizumab.

RESULTS

360 patients were randomized (dupilumab, n=181; omalizumab, n=179). At baseline, 153 patients had coexisting NSAID-ERD (dupilumab, n=76, 42%; omalizumab, n=77, 43%). Baseline patient characteristics and Week 24 safety events (any treatment emergent adverse events [TEAEs] and serious TEAEs) were comparable between treatment groups for patients with coexisting NSAID-ERD. Among patients with NSAID-ERD, at Week 24 the NPS least squares mean difference [95% confidence interval] was −1.71 [−2.25, −1.17], and for UPSIT, 8.0 [5.3, 10.6]. Improvements were greater with dupilumab than omalizumab for all upper and lower airway outcomes considered (Table 1).

CONCLUSIONS

Dupilumab showed greater improvement in both upper and lower airway outcomes than omalizumab in patients with severe CRSwNP with coexisting asthma and NSAID-ERD. These data support the efficacy of dupilumab in patients with multiple coexisting type 2 respiratory diseases vs an active biologic comparator.

Reduced Tissue IL-41 Levels In Chronic Rhinosinusitis With Nasal Polyps: Association With Disease Presence And Recurrence

Muhammet Fatih Esen[1], **Özgür Kümüş**[1], **Tolga Ersözlü**[1], **Ahsen Yılmaz**[2], **Savaş Güzel**[2], **Erdoğan Gültekin**[1]

[1]*Tekirdag Namik Kemal University Medical Faculty, Department of Otolaryngology, Tekirdag;* [2]*Tekirdag Namik Kemal University Medical Faculty, Department of Medical Biochemistry, Tekirdag*

BACKGROUND & AIM

Chronic rhinosinusitis with nasal polyps (CRSwNP) is a heterogeneous inflammatory disease characterized by complex immune dysregulation. Interleukin-41 (IL-41), a recently identified cytokine, has been suggested to exert immunoregulatory and anti-inflammatory effects in various inflammatory conditions. This study aimed to evaluate tissue IL-41 levels in CRSwNP patients and investigate their association with disease presence and recurrence.

MATERIAL & METHODS

This retrospective case–control study included 70 patients with CRSwNP who underwent endoscopic sinus surgery and 20 control subjects who underwent nasal surgeries for non-inflammatory conditions. IL-41 levels were measured in tissue samples using enzyme-linked immunosorbent assay (ELISA). Disease severity was assessed using Lund–Mackay and SNOT-22 scores. Subgroup analyses were performed based on revision status, body mass index (BMI), and peripheral eosinophil and neutrophil levels. Receiver operating characteristic (ROC) curve analysis was used to evaluate the discriminative performance of IL-41. Multivariate logistic regression analysis was performed only within the CRSwNP group to assess factors associated with recurrence.

RESULTS

Tissue IL-41 levels were significantly lower in the CRSwNP group compared to controls (median: 91.69 vs. 108.11; p=0.030). Patients with revision surgery had significantly lower IL-41 levels than primary cases (median: 78.27 vs. 95.90; p=0.024). No significant correlation was found between IL-41 levels and SNOT-22, Lund–Mackay scores, or hematological parameters (p>0.05). ROC analysis demonstrated moderate discriminative ability of IL-41 for differentiating CRSwNP from controls (AUC: 0.66, p=0.015) and revision from primary cases (AUC: 0.67, p=0.029). In multivariate analysis performed within the patient group, IL-41 was not identified as an independent predictor of recurrence (p>0.05).

CONCLUSIONS

IL-41 levels are decreased in CRSwNP patients and further reduced in recurrent cases, suggesting a potential role in impaired anti-inflammatory regulation. Although IL-41 was not an independent predictor of recurrence, it may contribute to the inflammatory imbalance in CRSwNP. Further prospective studies with larger cohorts are needed to clarify its clinical significance.

Comparison Of Histopathological Changes And Effects On Mucociliary Clearance Of Transseptal Suture Materials In A Rabbit Model

Serhat Pazır[1], **Çağdaş Elsürer**[1], **M. Fatih Gökmen**[1], **Yasemin Öznurlu**[2], **Ahmet Avcı**[3], **Mete Kaan Bozkurt**[1]

[1]*Selçuk University School of Medicine, Department of Otolaryngology, Head and Neck Surgery, Konya, Türkiye;* [2]*Selçuk University School of Veterinary Science, Department of Histology and Embryology, Konya, Türkiye;* [3]*KTO Karatay University, Faculty of Engineering and Nature Science, Department of Mechatronics Engineering, Konya, Türkiye*

BACKGROUND & AIM

The aim of this study was to compare the histopathological changes induced in the nasal mucoperichondrium and the effects on mucociliary clearance associated with different suture materials used in transseptal nasal suturing. The histopathological effects of polylactic acid (PLA) containing silver nanoparticles, septal staplers composed of polylactic-co-glycolic acid (PLGA), polyglactin 910 (Vicryl), and polydioxanone (PDS) were evaluated to determine the most appropriate suture material for septoplasty and septorhinoplasty procedures. Differences among these materials were objectively assessed using histopathological scoring and functional evaluations following standardized surgical techniques in an experimental rabbit model.

MATERIAL & METHODS

A total of 32 adult New Zealand rabbits were included in this study, which was conducted at the Selçuk University Experimental Medicine Research and Application Center. The animals were randomly allocated into four groups: septal stapler (Group 1), PDS (Group 2), Vicryl (Group 3), PLA produced with silver nanoparticles (Group 4). Silver nanoparticle-embedded PLA sutures were fabricated using the electrospinning technique and rendered biocompatible prior to application. All surgical procedures were conducted under general anesthesia. In all groups, the left nasal mucoperichondrium was elevated, and transseptal suturing was performed using the assigned material. Postoperative management included analgesia and infection prophylaxis. At the fourth postoperative week, mucociliary clearance measurements and macroscopic evaluations were performed prior to sacrifice. Subsequently, septal tissues were excised for histopathological examination.All surgical and laboratory procedures were performed by the same investigators in accordance with standardized protocols. The obtained data were analyzed using appropriate statistical methods.

RESULTS

Significant changes in mucociliary clearance were observed within all groups ($p < 0.05$), with median values increasing post-procedure in all groups. Fibrosis showed no significant intergroup difference ($p = 0.112$). Angiogenesis differed significantly among groups ($p < 0.05$), being lowest in Group 1, comparable in Groups 2 and 3, and highest in Group 4. Mononuclear cell infiltration demonstrated a significant difference ($p < 0.05$), with minimal infiltration in Group 1 and similar findings in the remaining groups. No eosinophils were detected in Group 1, whereas they were observed in Groups 2 through 4, with the difference reaching statistical significance ($p < 0.05$). Foreign body reaction varied significantly ($p < 0.05$), absent in Group 1 and most pronounced in Group 4. Epithelial organization also differed significantly, showing the best preservation in Group 1 and the poorest in Group 4 ($p < 0.05$).

CONCLUSIONS

The findings of this study demonstrate that the choice of suture material significantly influences mucosal healing outcomes. Mucociliary clearance time was prolonged in all groups, and notable differences were observed in histopathological parameters among the materials tested. These results suggest that appropriate suture selection plays a critical role in preserving mucosal integrity and optimizing postoperative healing following transseptal nasal procedures.

THE EFFECTIVENESS OF COMPOSITE MESH, PRP, AND EGF IN THE REPAIR OF NASAL SEPTAL PERFORATION

fatma uçak akın[1], **abdulvahap akyiğit**[1], **tuncay kuloğlu**[2], **orkun eroğlu**[1], **irfan kaygusuz**[1], **seyedeh hasti ghorashıan**[1]

[1]*Fırat University Faculty of Medicine, Department of ENT, Elazig, Türkiye.;* [2]*Department of Histology and Embryology, Faculty of Medicine, Fırat University, Elazig, Türkiye.*

BACKGROUND & AIM

Nasal septal perforation (NSP) is a pathological condition characterized by the connection of both nasal passages due to bilateral loss of mucoperichondrium or mucoperiosteum, resulting in cartilage or bone necrosis and reduced quality of life. Although no fully effective treatment modality has yet been established for NSP, current management options include conservative treatments, septal button application, and surgical interventions. The aim of this study was to evaluate the contribution of epidermal growth factor (EGF), platelet-rich plasma (PRP), and composite mesh applications to the healing process in an experimental NSP model through macroscopic and histopathological assessment.

MATERIAL & METHODS

The study was conducted on 20 New Zealand albino rabbits weighing 3000–3500 g and aged 6–8 months. The animals were divided into four groups: Group 1 (perforation created, no treatment), Group 2 (composite mesh application), Group 3 (composite mesh + PRP injection), and Group 4 (composite mesh + EGF injection). On day 14, the animals were sacrificed under high-dose anesthesia, and the nasal septa were resected. The specimens were fixed in 10% formaldehyde, embedded in paraffin, and sectioned at 4–6 µm thickness. The sections were stained with Hematoxylin–Eosin, Masson's Trichrome, and Elastic fiber stains and examined under a Leica DM500 microscope. Statistical analysis was performed using SPSS version 22.0.

RESULTS

Compared with the control group, all treatment groups (Mesh, Mesh+PRP, and Mesh+EGF) demonstrated a significant reduction in hemorrhage and significant increases in epithelial regeneration, fibroblast density, collagen deposition, and elastic fiber parameters. No statistically significant differences were observed among the treatment groups for these parameters ($p > 0.05$). In terms of angiogenesis, mesh application alone produced results similar to the control group, whereas the addition of PRP or EGF to the mesh structure significantly enhanced the vascular response.

CONCLUSIONS

Although mesh application alone promoted histopathological healing, the addition of PRP or EGF provided superiority in stimulating angiogenesis.

Real-Life Outcomes Of Three Different Biologic Therapies In Patients With Chronic Rhinosinusitis With Nasal Polyps

Ceren Aksoy Koçak[1], **Emel Atayık**[2], **Sefer Furkan Eryılmaz**[1], **Cansın Nur Özay Özcan**[1]

[1]*Department of Otorhinolaryngology – Head and Neck Surgery, Konya City Hospital, Konya, Türkiye;* [2]*Department of Allergy and Immunology, Konya City Hospital, Konya, Türkiye*

BACKGROUND & AIM

Biologic therapies have become an important treatment option for patients with severe chronic rhinosinusitis with nasal polyps (CRSwNP). However, real-life data comparing clinical, radiological, and laboratory outcomes across different biologic agents remain limited. This study aimed to evaluate real-world outcomes of three biologic therapies in a tertiary referral center cohort.

MATERIAL & METHODS

A total of 130 patients with CRSwNP treated with omalizumab (n=76), mepolizumab (n=29), or benralizumab (n=24) were retrospectively analyzed. The mean age was 46.1 years, and 60.8% of patients were female. Pre- and post-treatment assessments included SNOT-22 scores, modified Lund–Mackay scores (Zinreich modification), peripheral eosinophil count and percentage, total IgE levels, eosinophil cationic protein (ECP), and forced expiratory volume in one second (FEV_1). Statistical analysis was performed using the Wilcoxon signed-rank test.

RESULTS

Significant improvement was observed in radiological outcomes, with mean modified Lund–Mackay scores decreasing from 36.9 to 28.8 ($p<0.001$). SNOT-22 scores improved from 69.1 to 49.2. The mean eosinophil count decreased from 647/µL to 281/µL ($p<0.001$), and eosinophil percentage declined from 6.9% to 3.54% ($p<0.001$). Mean FEV_1 increased from 82% to 86% ($p=0.002$). Total IgE levels showed a significant reduction ($p<0.001$), whereas no significant change was observed in ECP levels ($p=0.623$). The mean treatment duration differed among biologics.

CONCLUSIONS

In real-life clinical practice, all three biologic therapies were associated with significant improvements in symptom burden, radiological disease extent, and hematological parameters in patients with CRSwNP. Biologic therapy appears to be an effective treatment option in severe CRSwNP. Further prospective comparative studies are warranted to better define differences among biologic agents.

CSF LEAKS- ANALYSING THE OPTIMAL SURGICAL APPROACHES

Mara-Andra Rebosapca[1], **Răzvan Hainarosie**[2], **Viorel Zainea**[2], **Voiosu Cătălina**[2], **Ruxandra Oana Alius**[2], **Irina Gabriela Ioniță**[2], **Andreea Rusescu**[2], **Oana Raluca Pulpa**[2], **Andreea Teofana Carazanu**[1,2], **Alexandra Ileana Sanda**[1], **Anda Selma Crețu**[1], **Augustina Iurkovski**[1], **Maria Laura Burlacu**[1], **Carina Russu**[1], **Miruna Andreea Mateescu**[1]

[1]Institute of Phonoaudiology and Functional Surgery „Prof. Dr. D. Hociotă" Bucharest, Romania; [2]University of Medicine and Pharmacy „Carol Davila" Bucharest, Romania

BACKGROUND & AIM

A cerebrospinal fluid (CSF) leak is defined as the efflux of the CSF resulting from the disruption of the meningeal layers which creates a direct communication between the subarachnoid space and the external environment. Predominantly, they result from craniofacial trauma (80%), followed by iatrogenic causes (16%). The closing technique can be selected according to the characteristics of the fistula (the dimension and the site).

MATERIAL & METHODS

A 10 year-study was conducted in our clinic, including 35 male and female patients diagnosed with spontaneous, iatrogenic and post-traumatic CSF leaks located in the ethmoid; sphenoid and frontal sinuses. The study aimed to assess the viability of different types of endoscopic surgical techniques used to close the defect based on its location and dimension.

RESULTS

The quantitative statistical analysis revealed that Hadad flap was the most frequently used flap for ethmoidal and sphenoidal CSF leaks, with no associated ethmoidal recurrence. The multilayered technique that included fascia lata, Hadad and middle turbinate flap presented no recurrence in the sphenoidal and frontal site.

CONCLUSIONS

The endoscopic approach is the gold standard for large CSF leaks, while the surgical techniques can vary significantly depending on the location and the dimension of the defect. Autografts, namely the Hadad flap and a multilayer approach are associated with a higher degree of efficiency and lower rates of recurrency in large CSF leaks. Furthermore, usage of autologous biological tissue is both cost-effective and correlated with a lower rate of immune incompatibility.

The Relationship Between IL-4 Receptor A Expression And Ectopic Lymphoid Tissue In Chronic Rhino Sinusitis

Akiho Shibata[1], **Kengo Kanai**[1], **Aiko Oka**[1], **Ryo Takagi**[1], **Marie Yamada**[1], **Isao Suzaki**[2], **Kojiro Hirano**[2], **Gunduz Ihisan**[1], **Tomoaki Shirakawa**[1], **Mitsuhiro Okano**[1]

[1]International University of Health and Welfare Narita Hospital; [2]School of Medicine, Showa Medical University

BACKGROUND & AIM

Refractory cases of chronic sinusitis (CRS) exist not only in eosinophilic sinusitis (ECRS) but also in non-eosinophilic sinusitis (non-ECRS). The highly organized aggregation of lymphoid cells, which is termed ectopic lymphoid tissue (eLT), has been found in NPs and was correlated with poor disease control in patients with CRS with nasal polyps (CRSwNP). In the present study, we investigated the patterns of IL-4Rα positive cells infiltrating the sinonasal mucosa in CRS and their association with clinical findings.

MATERIAL & METHODS

Uncinate process (UP) tissue samples from 15 patients with CRS without NPs (CRSsNP) and NP tissues from 52 patients with CRSwNP (36 ECRS and 16 non- ECRS) were obtained during surgery. Immunostaining was performed using anti-IL-4Rα antibody, anti-CD19 antibody, and anti-CD20 antibody.

RESULTS

Immunohistochemical staining revealed that IL-4Rα was expressed in epithelial cells and infiltrating cells in the lamina propria. Twenty-four out of 28 clusters of IL4Rα positive cells coexpressed CD19 and CD20. The eLT formation was detected in UP tissue from one patient (6.7%) with CRSsNP, NP tissues from 6 patients (37.5%) with non-ECRSwNP, and NP tissues from 21 patients (58.3%) with ECRSwNP, showing a significant increase in patients with ECRSwNP. The number of IL4Rα positive cells in eLT was significantly, positively correlated with serum total IgE and Lund-Mackay computed tomography score in patients with CRSwNP.

CONCLUSIONS

The eLTs containing B cells are associated with eosinophilic inflammation in NPs and that eLT could be one of the targets for anti IL4Rα monoclonal antibody treatment for CRSwNP. B cells in NP tissues express IL4Rα and IL-4Rα signaling may contribute to the pathogenesis of CRSwNP with eLTs and IgE.

Evaluation Of The Effects Of Intranasal LM22A-4 Administration On The Olfactory Epithelium In An Experimental Anosmia Model

Tuğçe Uzar[1], **Ayşe Pelin Yiğider**[1], **Murat Sertan Şahin**[1]

[1]*Bahcesehir University School of Medicine*

BACKGROUND & AIM

Olfactory dysfunction is a clinically relevant condition with limited therapeutic options. Experimental 3-methylindole-induced anosmia provides a reproducible model of olfactory epithelial injury. This study aims to evaluate whether intranasal LM22A-4, a TrkB agonist, alone or combined with dexamethasone, improves olfactory function and supports olfactory epithelial regeneration in a mouse anosmia model.

MATERIAL & METHODS

Forty male C57BL/6J mice, aged 9–10 weeks and weighing 18–20 g, will be randomly divided into five groups: control, anosmia, anosmia + LM22A-4, anosmia + LM22A-4 + dexamethasone, and anosmia + dexamethasone. Anosmia will be induced using intraperitoneal 3-methylindole. Olfactory function will be assessed with the food-finding test on days 1, 7, 14, 21, and 28. At the end of the experiment, olfactory epithelium samples will be evaluated by histopathology, immunohistochemistry for OMP and BDNF, and transmission electron microscopy.

RESULTS

The anosmia group demonstrated prolonged food-finding latency, epithelial thinning, increased inflammatory cell infiltration, vacuolization, and ciliary loss. LM22A-4-treated groups showed shorter latency times, better preservation of epithelial thickness, reduced histopathological injury scores, increased OMP-positive cell counts, and stronger BDNF expression compared with the untreated anosmia group. Ultrastructural analysis demonstrated better preservation of ciliary integrity and intracellular organelle organization in treated groups. Combined LM22A-4 and dexamethasone treatment showed the most prominent overall improvement.

CONCLUSIONS

Intranasal LM22A-4 improved functional and histological recovery in experimental anosmia and appeared to support olfactory epithelial regeneration through neurotrophic mechanisms. Combined administration with dexamethasone may further enhance this effect by reducing inflammatory injury. These findings suggest that LM22A-4 may represent a promising experimental therapeutic option for olfactory dysfunction.

The Different Clinical Presentations Of Allergic Fungal Sinusitis

D abdulrhmn alkhatib[1], **D abdulrhmn alkhatib**[1]

[1]*King fahad specialist hospital Dammam Saudi Arabia;* [2]*Dammam central hospital*

BACKGROUND & AIM

Allergic Fungal sinusitis is very common in saudi Arabia

To study the different clinical presentations of extensive allergic fungal sinusitis in the Eastern region of Saudi Arabia

MATERIAL & METHODS

A retrospective chart review to all allergic fungal sinusitis diagnosed and managed in a tertiary referral hospital at king fahad specialist hospital Dammam in the period from 2010 till 2024

RESULTS

The clinical presentations ranges from unilateral, bilateral ,unilateral proptosis ,bilateral proptosis, unilateral and bilateral mucoceles, mixed with invasive granuloma, blindness and 6th nerve palsy and cavernous sinus thrombosis

CONCLUSIONS

The different clinical presentations of allergic fungal sinusitis ranges from unilateral to the extensive intraorbital intracranial extensions with blindness and cavernous sinus thrombosis

KEYWORDS

Surgical Success In Endoscopic Septal Perforation Repair With Double Layer Fascia Lata: Results Of CCCRC, NOSE, Saccharin Test VAS Score

Özlem yağız Agayarov[1], **Kutluhan cevher**[1]

[1]*İzmir tepecik training and research hospital*

BACKGROUND & AIM

This study aims to evaluate the nasalphysiologic effects and surgical success of endoscopic septal perforation repair using a double-layer fascia lata technique.

MATERIAL & METHODS

The surgical method employed a double-layer fascia lata graft for closure. Patients wereevaluated pre-operatively and post-operatively usingthe Connecticut Chemosensory Clinical ResearchCenter (CCCRC) olfactory test for olfactory function, Nasal Obstruction Symptom Evaluation (NOSE)score for nasal obstruction, saccharin test formucociliary clearance, and Visual Analog Scale(VAS)for subjective well-being donor site pain. Statistical analyses were performed to assess thedifferences in pre- and postoperative outcomes.

RESULTS

The researchers conducted a retrospectiveanalysis involving 26 patients who underwent repairfor NSP from 2022 to 2024. Significantimprovements were observed in all evaluationmetrics post-surgery. The success rate of completeclosure was also high.

CONCLUSIONS

The double-layer fascia lata techniquefor septal perforation repair proved highly effectiveand safe. It significantly improved nasal function andpatient quality of life without causing serious cosmetic and functional problems in the donor area.This approach is a reliable option for the surgicaltreatment of large septal perforations.

The Successful Endoscopic Endonasal Repair Of Large Skull Base Defect Using Polymax RAPID Plate

Ahmed Aytah[1]

[1]*Department of Otolaryngology – Head and Neck Surgery, King Faisal Specialist Hospital & Research Centre, Jeddah, Saudi Arabia*

BACKGROUND & AIM

Iatrogenic cerebrospinal fluid (CSF) rhinorrhea after functional endoscopic sinus surgery (FESS) is uncommon, but large bilateral cribriform plate defects with frontal encephaloceles are exceptionally rare and technically demanding

MATERIAL & METHODS

A 28-year-old man developed persistent bilateral watery rhinorrhea two months after bilateral FESS for nasal polyposis. CT/MRI demonstrated a large (2.4 x 2.7 cm) bilateral cribriform plate defect with herniation of the inferior frontal lobes into the nasal cavity. Endoscopic endonasal repair was performed using multilayer autologous grafting (fat and fascia lata), vascularized mucosal flaps (nasoseptal and middle turbinate), and an endonasally contoured poly(L-lactide-co-glycolide) bioresorbable plate as a buttress

RESULTS

CSF egress ceased intraoperatively and the postoperative course was uncomplicated. Serial endoscopic follow-up demonstrated progressive mucosalization and no recurrent CSF leak. At 12 months, CT confirmed stable reconstruction without recurrent encephalocele or pneumocephalus.

CONCLUSIONS

Frontal encephaloceles following FESS are an exceptionally rare complication, with bilateral involvement scarcely reported. This case underscores the efficacy and safety of a minimally invasive, multilayered endoscopic skull base reconstruction technique reinforced by a PolyMax RAPID bioresorbable plate. Such an approach may serve as a valuable alternative to craniotomy, particularly in high-flow CSF leak scenarios with large anterior cranial fossa defects [2,3].

Decoding The Surgical Mind: Can AI Predict Expert Preferences In Rhinoplasty?

Volkan Odabaşı[1], **Bayram Barış BÜYÜK**[1]

[1]*Department of Otorhinolaryngology and Head and Neck Surgery, Ankara Dr. Abdurrahman Yurtaslan Oncology Training and Research Hospital, Ankara, Turkey*

BACKGROUND & AIM

Background and Objective: Rhinoplasty is uniquely complex due to anatomical diversity, traditionally relying on subjective clinical intuition for technique selection. Integrating Artificial Intelligence (AI) offers a significant opportunity for objective, data-driven standardization. This study evaluates the reliability of an AI-driven model (Claude 4.6 Sonnet) in recommending

specific surgical techniques based on preoperative data, including nasal angles and skin thickness. By comparing AI-generated plans with the intraoperative preferences of experienced surgeons across 40 cases, we aim to determine the level of agreement and assess AI's potential as a clinical decision-support tool in aesthetic and functional nasal surgery.

MATERIAL & METHODS

Materials and Methods: This prospective study included 40 primary rhinoplasty patients. Preoperative data—including nasal angles, skin thickness, demographics, ethnicity, and presenting complaints—were systematically recorded. The Claude 4.6 Sonnet (Anthropic, PBC) model served as the analytical engine, utilizing a Retrieval-Augmented Generation (RAG)-like approach. This integrated the AI's pre-trained knowledge with curated evidence-based literature and expert-led clinical guidelines to ensure grounded recommendations.

For each patient profile, the AI suggested specific surgical techniques (e.g., grafts, sutures, osteotomies). Simultaneously, a panel of [Number] senior surgeons (>100 operations), blinded to AI outputs, performed the surgeries and recorded the actual intraoperative techniques utilized. The agreement level between AI-driven recommendations and the surgeons' choices was statistically analyzed using Cohen's Kappa coefficient (κ).

RESULTS

Across 40 primary rhinoplasty cases, the AI model (Claude 4.6 Sonnet) demonstrated substantial agreement with experienced surgeons across 10 surgical categories (mean κ=0.82, p<.001). The highest reliability was observed in selecting surgical approaches (κ=0.90) and graft sources.

AI showed significant accuracy in planning dorsal/bony pyramid management and tip support mechanisms (e.g., columellar strut vs. septal extension). While Tip-Shape and LLC modifications presented the most complex correlations, strong agreement remained for septal and turbinate interventions. Statistically, AI-proposed techniques matched intraoperative decisions in 87.5% of all parameters, with no significant difference found. These findings highlight the high reliability of AI-driven decision support, particularly in identifying foundational and structural surgical maneuvers in rhinoplasty.

CONCLUSIONS

Conclusion:

Claude 4.6 Sonnet successfully processed complex clinical data, achieving 82% agreement with senior surgeons in rhinoplasty planning. These findings establish AI as a reliable Clinical Decision Support System (CDSS), fostering standardization and providing valuable "expert-like" guidance for surgical education. While intraoperative judgment remains the gold standard for nuanced maneuvers, AI integration signifies a paradigm shift. We conclude that AI-assisted planning is a viable, contemporary tool for enhancing precision and consistency in facial plastic surgery, effectively bridging the gap between objective data and surgical expertise in modern clinical practice.

OP-1050

Preoperative CT Hyperostosis As A Predictor Of Tumor Attachment And Recurrence Origin In Sinonasal Inverted Papilloma: A Single-Center Study

Shola Huseynzada[1], **Elif Özdemir**[1], **Kardo Önder**[1], **Özden Savaş**[1], **Aslı Çakır Çetin**[1,2], **Mustafa Cenk Ecevit**[3], **Enis Alpin Güneri**[1]

[1]*Department of Otorhinolaryngology – Head and Neck Surgery, Dokuz Eylul University Faculty of Medicine, Izmir, Turkey;* [2]*Department of Otorhinolaryngology – Head and Neck Surgery, Akdeniz University Faculty of Medicine, Antalya, Turkey;* [3]*Private Practice, Otorhinolaryngology – Head and Neck Surgery, Izmir, Turkey*

BACKGROUND & AIM

Sinonasal inverted papilloma is characterized by a high recurrence rate, often related to incomplete identification of the tumor attachment site during surgery. Computed tomography (CT)-detected hyperostosis has been proposed as a radiologic marker of tumor origin; however, its reliability and relationship with recurrence remain controversial.This study aimed to investigate the relationship between preoperative CT hyperostosis, intraoperative tumor attachment, and recurrence origin in a single-center cohort of patients with sinonasal inverted papilloma.

MATERIAL & METHODS

This retrospective single-center study included patients with histopathologically confirmed sinonasal inverted papilloma who underwent surgical treatment between 2015 and 2025 . Preoperative CT scans were evaluated for hyperostotic bone changes and correlated with intraoperative tumor attachment sites documented in operative reports. Clinical and follow-up data, including tumor stage, surgical approach, recurrence, sex, age were analyzed. Revision cases presenting after surgery at outside institutions were evaluated separately. Categorical variables were analyzed using Chi-square and Fisher's exact tests.

RESULTS

Recurrence was observed in 6 of 32 patients (18.8%). Concordance between preoperative imaging and intraoperative localization was present in 16 patients (50%), while discordance was noted in 16 patients (50%).Recurrence occurred in 31.3% (5/16) of the discordant group compared to 6.3% (1/16) of the concordant group. This difference did not reach statistical

significance (Pearson χ^2 p=0.070; Fisher exact p=0.172). The calculated odds ratio for recurrence in the discordant group was 6.82.

CONCLUSIONS

Discordance between preoperative imaging and intraoperative tumor localization was associated with a higher observed recurrence rate in sinonasal inverted papilloma. Although this association did not reach statistical significance, the magnitude and direction of the effect suggest a potentially clinically relevant relationship. Careful assessment of preoperative imaging findings, particularly hyperostotic changes on CT, may assist in identifying the true tumor attachment site and improving surgical targeting. Larger prospective studies with standardized follow-up are required to further clarify the impact of imaging–surgical correlation on recurrence outcomes.

Paranasal Sinus Fungus Ball: Clinical And Radiological Outcomes From A 15-Year Single-Centre Experience

Banu Tijen Ceylan,MD,Assistant Professor[1], **Berkan Uygun,MD**[1], **Emirhan Akyol,MD**[2], **Alper Ceylan,MD, Professor**[1]

[1]*Department of Otolaryngology–Head and Neck Surgery, Gazi University Faculty of Medicine, Ankara, Türkiye;* [2]*Department of Otolaryngology–Head and Neck Surgery, Adıyaman Training and Research Hospital, Adıyaman, Türkiye*

BACKGROUND & AIM

Paranasal sinus fungus ball is a non-invasive form of fungal rhinosinusitis characterized by fungal accumulation within the sinus cavity, predominantly affecting immunocompetent individuals. Although the maxillary sinus is the most commonly involved site, sphenoid sinus disease may present with nonspecific symptoms, leading to delayed diagnosis. Characteristic radiological findings and anatomical variations may contribute to disease development and diagnosis. This study aimed to evaluate the clinical, radiological, and surgical characteristics of patients with paranasal sinus fungus ball.

MATERIAL & METHODS

This retrospective single-center study included patients who underwent endoscopic surgical treatment for paranasal sinus fungus ball between January 2010 and December 2025. Fifty patients with sufficient clinical, radiological, and histopathological data were included. Demographic characteristics, presenting symptoms, symptom duration, comorbidities, involved sinus, examination findings, radiological characteristics, histopathological results, postoperative complications, and recurrence data were retrospectively reviewed from electronic medical records. Statistical significance was defined as p<0.05.

RESULTS

The mean patient age was 56.86±13.06 years, and 66.0% were female. Maxillary sinus (50.0%) and sphenoid sinus (48.0%) involvement represented the majority of cases(Table 1). The most common presenting symptoms were nasal obstruction (46.0%), headache (34.0%), and facial pain (30.0%). (Table 2).Complete sinus opacification (89.5%) and calcification (76.3%) were the most frequent CT findings (Table 3). Septal deviation and Haller cells were significantly more common on the affected side in maxillary sinus fungus ball patients (p=0.013 and p<0.001, respectively)(Table 5). Recurrence occurred in 6.0% of patients (Table 7).

CONCLUSIONS

Paranasal sinus fungus ball predominantly affects middle-aged female patients and commonly involves the maxillary and sphenoid sinuses. Characteristic CT findings facilitate diagnosis, while anatomical variations such as septal deviation and Haller cells may contribute to disease development. Endoscopic surgical treatment demonstrates favorable outcomes with low recurrence rates. Recognition of these features may improve early diagnosis and treatment planning.

Olfactory And Gustatory Function Changes In Obese Patients Initiating Tirzepatide: A Prospective Pre-Post Study (Preliminary Results)

Berina Slipcevic[1], **Serdal Celik**[2], **Gunes Feyizoglu**[3], **Zeynep Az Aydin**[2], **Mumtaz Takir**[4], **Ahmet Mutlu**[1], **Mahmut Tayyar Kalcioglu**[1]

[1]*Istanbul Medeniyet University, Faculty of Medicine, Department of Otorhinolaryngology, Istanbul, Türkiye;* [2]*Goztepe Prof. Dr. Suleyman Yalcin City Hospital, ENT Clinic, Istanbul, Türkiye;* [3]*Goztepe Prof. Dr. Suleyman Yalcin City Hospital, Internal Medicine Clinic, Istanbul, Türkiye;* [4]*Goztepe Prof. Dr. Suleyman Yalcin City Hospital, Endocrinology and Metabolism Clinic, Istanbul, Türkiye*

BACKGROUND & AIM

Tirzepatide, a dual GIP/GLP-1 receptor agonist, has become a common choice for treating obesity, and reports from pharmacovigilance databases have pointed to taste and smell disturbances as possible side effects. Yet objective,

psychophysical evidence on this remains limited. We prospectively assessed olfactory and gustatory function using validated psychophysical tools before and after three months of tirzepatide treatment. Here, we report preliminary results from an ongoing recruitment.

MATERIAL & METHODS

Patients starting tirzepatide for obesity under endocrinology follow-up are being tested at baseline, before their first dose, with Sniffin' Sticks (Threshold, Discrimination, and Identification subtests, and the composite TDI score) and Odofin taste strips. Treatment consists of 2.5 mg during the first month and 5 mg during months two and three. Testing is repeated at three months, and baseline and follow-up scores are compared with paired t-tests and Wilcoxon signed-rank tests.

RESULTS

In this preliminary study (n=27), patients lost an average of 13 kg (109.5±15.6 kg to 96.6±14.8 kg). Olfactory threshold scores rose from 8.06±2.68 to 9.54±2.79 ($p=0.0002$, $d=0.82$), improving in 18 of 27 patients. Discrimination scores also increased (10.81±2.24 to 12.07±1.86, $p=0.002$), as did the composite TDI score (32.31±5.16 to 35.54±4.67, $p<0.0001$, $d=1.06$; improved in 23 of 27 patients). Identification scores trended upward without reaching significance (13.41±1.82 to 13.89±1.67, $p=0.068$) (Table 1.). Taste strip scores improved from 11.07±3.19 to 12.37±2.86 ($p=0.007$) (Table 1.). Threshold change did not correlate with weight change ($r=0.143$, $p=0.48$).

CONCLUSIONS

These preliminary findings suggest three months of tirzepatide treatment is followed by measurable gains in olfactory and gustatory sensitivity, most pronounced for odor threshold, which sits somewhat at odds with the dysosmia and dysgeusia reported in pharmacovigilance databases. Since the threshold improvement was unrelated to the degree of weight loss, a direct pharmacological effect on chemosensory pathways seems more likely than a weight-loss-mediated one, in line with animal data showing GLP-1 receptor expression in the olfactory bulb.

OP-1053

Predictors Of Stroke In Invasive Fungal Rhinosinusitis: Case Series And Systematic Review

Dr.Abdulmalik Alkhodair[2], **Dr.Abdulaziz Alqahtani**[1]

[1]*King Fahad Medical City;* [2]*King Saud Medical City*

BACKGROUND & AIM

nvasive fungal rhinosinusitis (IFRS) is a life-threatening infection affecting immunocompromised patients, particularly those with uncontrolled diabetes. Its angioinvasive pathogens, including Aspergillus and Mucorales species, can infiltrate major cerebral vessels, causing thrombosis, aneurysm, or rupture that leads to stroke, with mortality rates exceeding 70% and approaching 100% in some reports. Diagnosis is challenging due to stroke-like presentations and overlapping imaging findings. Predictors may include extensive sinonasal disease, cavernous sinus involvement, vascular invasion, and poor glycemic control. This study aims to identify clinical, radiological, and pathological stroke predictors and evaluate whether early medical and surgical intervention reduces cerebrovascular complications and mortality.

MATERIAL & METHODS

Invasive fungal rhinosinusitis (IFRS) is a severe infection affecting immunocompromised patients, especially those with uncontrolled diabetes. Angioinvasive fungi such as Aspergillus and Mucorales can invade cerebral vessels, particularly the internal carotid artery, causing thrombosis, aneurysm, and ischemic or hemorrhagic stroke, with mortality exceeding 70%. Diagnosis is often delayed because symptoms mimic acute stroke. Predictors include extensive sinonasal disease, cavernous sinus thrombosis, vascular invasion, histopathological angioinvasion, and poor glycemic control. This systematic review, following PRISMA 2020 guidelines, will analyze studies from 1991–2025 to identify stroke predictors and assess whether early intervention reduces stroke incidence and mortality.

RESULTS

Anticipated Results

We hypothesize that the extent of surgical resection in chronic invasive fungal rhinosinusitis (CIFRS) significantly influences clinical outcomes. Specifically:

· Extensive sinonasal resection is expected to result in improved local disease control and overall survival due to more effective clearance of infected and necrotic tissue.

· In cases with orbital involvement, orbit-sparing limited resections may achieve comparable outcomes to more aggressive approaches, without increasing the risk of recurrence or mortality, while preserving ocular function.

We anticipate that a tailored surgical strategy, characterized by aggressive resection of sinonasal disease with selective preservation of critical structures such as the orbit and cranial nerves, will be associated with favorable survival outcomes and preservation of neurological and visual function.

The findings of this study are expected to offer practical, evidence-based recommendations for optimizing surgical management of CIFRS, particularly in resource-constrained or endemic settings where individualized decision-making is critical.

CONCLUSIONS

Invasive fungal rhinosinusitis (IFRS) is a life-threatening condition with a high risk of stroke due to fungal angioinvasion, particularly in immunocompromised patients. Stroke significantly increases mortality despite advances in diagnosis and treatment. This study seeks to identify key clinical, radiological, and pathological predictors of stroke and evaluate the role of early intervention. Improved risk stratification and timely multidisciplinary management may reduce stroke incidence, lower mortality, and enhance outcomes in patients with IFRS.

The Clinical Effectiveness Of Clarithromycin Versus Endoscopic Sinus Surgery For Adults With Chronic Rhinosinusitis With And Without Nasal Polyps (MACRO)

Carl Philpott[1,2], David Beard[3], Elnaz Saeedi[3], Jonathan Cook[3], Stephen Jones[3], Caroline Clarke[4], Lucinda Teoh[4], Mike Thomas[6], Paul Little[6], Jane Vennik[6], Valerie Lund[5], Anne Schilder[5], Fei Long[5], Stephen Durham[7], James Boardman[9], Claire Hopkins[8]

[1]University of East Anglia; [2]James Paget University Hospital; [3]Surgical Intervention Trials Unit, Oxford University; [4]Research Department of Primary Care and Population Health, UCL; [5]Ear Institute, UCL; [6]University of Southampton; [7]Faculty of Medicine, National Heart and Lung Institute, Imperial College London; [8]ENT Department, Guy's and St Thomas' NHS Foundation Trust, London; [9]SmellTaste

BACKGROUND & AIM

A paucity of evidence regarding use of endoscopic sinus surgery and antibiotics in managing chronicrhinosinusitis has contributed to a five-times variation in endoscopic sinus surgery (ESS) rates, as well as variation in theuse of antibiotics. The main aim of the present trial was to compare the clinical effectiveness of ESS or 3 months of clarithromycin treatment alongside intranasal medication (IM) in adults with chronic rhinosinusitis with or without nasal polyps.

MATERIAL & METHODS

In this pragmatic, three-arm, randomised, placebo-controlled phase 4 trial, participants were recruited from 20 secondary/tertiary care sites. Adults with chronic rhinosinusitis remaining symptomatic following appropriate medical therapy (intranasal corticosteroids and saline nasal irrigations (IM), and a short course of antibiotics) were randomly assigned (1:1:1) to receive ESS plus IM, clarithromycin (250 mg twice a day for 2 weeks then 250 mg once a day for 10 weeks) plus IM, or placebo plus IM. Participants were allocated with an automated, web-based secure randomisation system, stratified by the presence of polyps and trial site. Participants and site teams were masked to the clarithromycin and placebo allocations, including for outcome assessment. The primary outcome measure was the 22-item Sino-Nasal Outcome Test (SNOT-22) quality-of-life questionnaire at 6 months after randomisation, with analysis by intention to treat (ITT). Adverse reactions were assessed in the safety population and serious adverse events in the ITT population.

RESULTS

Between Nov 1, 2018, and Oct 13, 2023, 514 participants (181 [35%] female and 333 [65%] male), with chronic rhinosinusitis with nasal polyps (n=410) or chronic rhinosinusitis without nasal polyps (n=104), were recruited and randomly assigned to receive ESS (n=171), clarithromycin (n=172), or placebo (n=171), all with intranasal medication. SNOT-22 scores at 6 months after randomisation were significantly lower in the ESS group than in the clarithromycin group (adjusted mean difference −18·13 [98·33% CI −24·26 to −11·99], p<0·0001) and placebo group (−20·44 [−26·42 to −14·46], p<0·0001). 6-month SNOT-22 scores did not differ significantly between participants randomly assigned to clarithromycin versus placebo (−3·11 [−8·56 to 2·33], p=0·17). Ten serious adverse events occurred in nine participants (two events in two [1%] of 172 participants allocated to clarithromycin, three events in three [2%] of 171 allocated to placebo, and five events in four [2%] of 171 allocated to ESS); none were fatal.

CONCLUSIONS

The MACRO trial shows that endoscopic sinus surgery has clinical effectiveness in patients with chronic rhinosinusitis, providing significantly improved disease-specific quality of life at 6 months. Conversely, the trial findings do not support routine long-term use of low-dose clarithromycin. Endoscopic sinus surgery should be recommended if intranasal medication alone is unable to achieve symptom control.

OP-1055

Vaping And Upper Airway Symptoms In Adult Otolaryngology Outpatients: A Cross- Sectional Study

Melis Ece Arkan[1], Mohamad Abu Zaher[1], Yahya Dakri[1], Neel Satish[1], Josh Michaels[1], Mina Fanous[1], Aaron Trinidade[1]

[1]Mid and South Essex NHS Foundation Trust

BACKGROUND & AIM

Vaping is increasingly encountered in otolaryngology practice, yet clinic-based data describing associated symptom phenotypes remain limited and are often confounded by smoking and pre-existing ENT disease. We hypothesised that vaping would be associated with a higher prevalence of upper airway irritative symptoms, particularly rhinitis/nasal congestion and sore throat, among adult ENT outpatients.

MATERIAL & METHODS

We conducted a cross-sectional questionnaire study of adult otolaryngology outpatients attending clinics within Mid and South Essex NHS Foundation Trust. Data collected included demographics, vaping and smoking history, allergy status, prior ENT disease or surgery, and patient-reported ENT symptoms. Vaping status was defined as current or previous use of e-cigarettes or vaping products (yes/no). The primary outcome was the presence of any ENT symptom. Pre-specified symptom categories included rhinitis/nasal congestion and sore throat. Group comparisons were performed using χ^2 tests. Adjusted prevalence ratios (aPRs) were estimated using robust Poisson regression controlling a priori for age, gender, smoking status, allergy history, and prior ENT disease (complete-case analysis).

RESULTS

A total of 549 respondents were included, with vaping status available for 546 participants. Of these, 98 (18.0%) reported current or previous vaping. Any ENT symptom was common in both groups (vapers 83.7% vs non-vapers 73.9%, p=0.055). In unadjusted analyses, vapers reported a higher prevalence of rhinitis/nasal congestion (28.6% vs 18.3%, p=0.031) and sore throat (17.3% vs 8.5%, p=0.014). However, in adjusted models (n=332), vaping was not independently associated with any ENT symptom (aPR 1.00, 95% CI 0.89–1.13; p=0.95), rhinitis/nasal congestion (aPR 1.12, 95% CI 0.71–1.78; p=0.62), or sore throat (aPR 0.86, 95% CI 0.46–1.63; p=0.65). Allergy (aPR 1.17, 95% CI 1.06–1.29; p=0.001) and prior ENT disease (aPR 1.15, 95% CI 1.04–1.27; p=0.005) were independent predictors of reporting any symptom.

CONCLUSIONS

ENT symptoms are highly prevalent among otolaryngology outpatients. Although vapers reported more nasal congestion and sore throat in crude analyses, these associations were not maintained after adjustment for confounding factors. Allergy and underlying ENT disease appear to be key drivers of symptom burden in this population. These findings highlight the importance of considering comorbidities and environmental exposures when evaluating vaping-related symptoms in clinical practice.

OP-1056

The Effect Of Nasal Skin Thickness On Cosmetic Patient Satisfaction After Rhinoplasty

Ozgur Kemal[1], **Nurlan Majıdov**[1], **Mücahit Baharçiçek**[1], **Gülten Taşkın**[1], **Mehmet Çelebi**[1]

[1]Samsun Ondokuz Mayıs University

BACKGROUND & AIM

Traditionally, rhinoplasty outcomes have been assessed by surgeon evaluations; however, the significance of patient-reported outcome measures (PROMs) has risen in recent years. Nasal skin thickness is considered a significant anatomical element affecting cosmetic outcomes. Thick skin may obscure structural alterations and restrict tip definition, whereas thin skin may enhance the visibility of contour imperfections. The clinical significance of nasal skin thickness concerning patient-perceived happiness remains ambiguous. This study sought to assess the correlation between objectively determined nasal skin

thickness and postoperative esthetic satisfaction following rhinoplasty, utilizing the cosmetic component of the Standardized Cosmesis and Health Nasal Outcomes Survey (cSCHNOS).

MATERIAL & METHODS

This retrospective analysis looked at patients who had primary rhinoplasty between June 2023 and June 2025. At least six months after surgery, examinations were done to make sure that the results were stable. After removing people with congenital nasal problems, past septorhinoplasty, or missing preoperative paranasal CT scans, 160 of the 263 cases that were first examined satisfied the eligibility requirements. Power analysis was used to choose the 42 patients with the thinnest and 42 patients with the thickest mean nasal skin thickness values for the comparison. We used preoperative CT scans to objectively assess the thickness of the nasal skin at three typical anatomical points: the radix, the K-point and the nasal tip. An expert radiologist take the measurements. We did postoperative assessments over the phone, and we figured out how much better things became by looking at the difference between the retrospective preoperative and present postoperative c-SCHNOS scores.

RESULTS

Eighty-four patients completed the postoperative assessment, including 42 with thin nasal skin and 42 with thick nasal skin. The mean nasal skin thickness in the entire cohort was 3.13 ± 0.65 mm. Male patients demonstrated greater average skin thickness compared with female patients. Both thin- and thick-skinned groups showed significant postoperative improvement in cosmetic SCHNOS scores. Median postoperative scores decreased markedly in both groups, indicating substantial improvement in patient-perceived nasal appearance. However, statistical analyses revealed no significant differences between thin- and thick-skinned groups in preoperative scores, postoperative scores, or the magnitude of cosmetic improvement ($p > 0.05$). Item-level analysis of the six cosmetic SCHNOS questions also demonstrated consistent improvement across all domains without significant differences between skin thickness groups. Furthermore, correlation analysis showed no significant association between nasal skin thickness and the degree of postoperative cosmetic improvement. Age and gender were not significantly associated with cosmetic outcome changes.

CONCLUSIONS

The results of this study demonstrate that nasal skin thickness does not markedly affect patient-reported cosmetic satisfaction following rhinoplasty. Patients with both thin and thick skin saw similar improvements in cosmetic outcomes, as shown by cSCHNOS scores. These findings indicate that anatomical features alone may not adequately forecast postoperative patient satisfaction. Instead, things like what the patient expects, how well the surgeon and patient communicate, and how well the patient adapts to the surgery may be more important in deciding how successful the surgery is regarded to be.

OP-1057

Impact Of Uncinate Process Attachment And Concha Bullosa On Frontal Sinusitis: A CT Study

Ahmet Ali Celik[1], **Deniz Hanci**[1]

[1]*Department of Otolaryngology, Prof. Dr. Cemil Tascioglu City Hospital, University of Health Sciences, Istanbul, Turkey*

BACKGROUND & AIM

Frontal sinus drainage depends on frontal recess anatomy and may be influenced by uncinate process (UP) attachment patterns and concha bullosa (CB). It is hypothesized that non–lamina papyracea UP attachment (Type B) increases the risk of frontal sinusitis, whereas CB has a limited or no independent effect.

MATERIAL & METHODS

This retrospective clinical study included 150 patients who underwent endoscopic sinus surgery for unilateral frontal sinusitis. Paranasal sinus computed tomography scans were analyzed. Each nasal cavity was evaluated as a separate side-based unit (total 300 sides). Frontal sinusitis was defined using the Lund–Mackay scoring system and dichotomized as absent (0) or present (1–2). UP attachment was classified as Type A (lamina papyracea) or Type B (skull base or middle turbinate). CB was categorized as absent (0) or present (types 1–3). Primary outcome was the presence of frontal sinusitis. Independent variables included UP type and CB presence. Chi-square test and odds ratios (OR) with 95% confidence intervals (CI) were calculated. Within-patient paired comparisons between diseased and contralateral sides were analyzed using McNemar test. A p value <0.05 was considered statistically significant.

RESULTS

Frontal sinusitis was present in 24.3% of sides. Type B UP attachment was significantly associated with frontal sinusitis ($p < 0.001$), increasing the risk approximately sevenfold (OR = 6.95; 95% CI: 3.5–13.8). In contrast, CB was not significantly associated with frontal sinusitis ($p = 0.91$; OR = 0.90; 95% CI: 0.45–1.78). No significant relationship was found between UP attachment patterns and CB presence ($p > 0.05$). Within-patient paired analysis demonstrated a significantly higher prevalence of Type B attachment on the diseased side compared to the contralateral side ($p < 0.001$).

CONCLUSIONS

Non–lamina papyracea UP attachment is a strong and independent risk factor for frontal sinusitis, whereas CB does not appear to contribute significantly. These findings highlight the dominant role of frontal recess anatomy in the pathophysiology of frontal sinusitis.

OP-1058

Typical Vs Atypical Sinonasal Inverted Papillomas: Impact Of Tumor Localization On Surgical Strategy And Outcomes

Aylin Ateş[1], **Gülpembe Bozkurt**[1]

[1]*University of Health Sciences, Prof. Dr. Cemil Taşcıoğlu City Hospital , Department of Otorhinolaryngology–Head and Neck Surgery, Istanbul, Turkiye*

BACKGROUND & AIM

Sinonasal inverted papilloma (SNIP) is a benign but locally aggressive tumor with a propensity for recurrence and malignant transformation. While most arise from the lateral nasal wall atypical localizations are increasingly recognized. Atypical SNIPs are defined as lesions originating from frontal or sphenoid sinuses, or involving uncommon locations like the nasal septum or inferior turbinate.This study aimed to compare clinical characteristics, surgical management, and outcomes between typical and atypical SNIPs.

MATERIAL & METHODS

A retrospective analysis was performed on 74 patients who underwent surgery for SNIP between January 2017 and September 2025 at a tertiary referral center. Tumors were classified as typical or atypical based on localization. Clinical variables included tumor site, association with nasal polyposis, surgical approach (endonasal, external or combined), histopathological discordance, recurrence, and malignant transformation. Recurrence free interval (RFI) .

RESULTS

Fifty-seven patients (77%) had typical localization, and 17 (23%) had atypical localization (frontal sinus, n=3; sphenoid sinus, n=5; inferior turbinate, n=4; nasal septum, n=2; lamina papyracea, n=2; fovea ethmoidalis, n=1). Mean age was 57 years. Recurrence occurred in 8/57 (14.0%) of typical cases and 2/17 (11.8%) of atypical cases (p=1.0). Malignant transformation or dysplasia was observed in 12.3% of typical cases and in none of the atypical cases (p=0.192). Rates of nasal polyposis (10.5% vs. 11.8%, p=0.1) and preoperative–postoperative histopathological discordance (12.3% vs. 29.4%, p=0.131) were comparable; notably, all discordant atypical cases originated from the sphenoid sinus. Kaplan–Meier analysis showed no difference in recurrence-free interval between groups (log-rank p=0.525). Surgical approach differed significantly (p=0.048), with combined approaches more frequently used in atypical cases.

CONCLUSIONS

Atypical SNIPs more often require combined surgical approaches, reflecting greater technical complexity. However, tumor localization was not associated with increased recurrence, malignant transformation or worse recurrence-free interval. Despite differences in surgical strategy, clinical outcomes were comparable. Larger studies are needed to further clarify the impact of tumor localization.

The State Of AI In Rhinology: Gaps In Clinical Development, Risk Of Bias And Reporting

Tanish Patel[2], **Rashi Ramchandani**[3], **Carlos Khalil**[1], **Elena Prigoda-Springall**[1], **Errol Colak**[1], **Yvonne Chan**[1], **Hui-Ming Lin**[4], **John Lee**[1], **Zahra Shakeri**[1], **Daniel J. Lee**[1]

[1]*University of Toronto;* [2]*University of Saskatchewan;* [3]*University of Ottawa;* [4]*Unity Health Toronto*

BACKGROUND & AIM

Artificial intelligence (AI) and machine learning (ML) models are emerging for diagnostic and prognostic applications in rhinology. However, a gap exists in systematically evaluating their clinical relevance, methodological rigor, and reporting quality. This systematic review addresses these crucial aspects within the current landscape of AI/ML models in rhinology.

MATERIAL & METHODS

A systematic review was performed across MEDLINE, EMBASE, Cochrane CENTRAL, and Web of Science. Data were extracted on study characteristics, clinical development stage, risk of bias (assessed using PROBAST: Prediction model Risk of Bias Assessment Tool), and completeness of reporting (assessed with TRIPOD-AI: Transparent Reporting of a multivariable prediction model for Individual Prognosis Or Diagnosis).

RESULTS

Of 4,272 studies screened, 67 studies were included, primarily conducted in hospital/academic settings. All studies were exclusively in the pre-clinical evaluation phase (development and in silico testing); none had progressed to formal clinical evaluation or monitoring stages. Methodologically, 35 out of 67 studies exhibited a high or unclear risk of bias. Reporting quality was also poor, with a median adherence to the TRIPOD-AI checklist of only 48.1%. Critical items were systematically unreported across nearly all studies, including model calibration, assessments of fairness, patient and public involvement, and the public availability of the final model for independent validation.

CONCLUSIONS

The lack of development beyond the pre-clinical stage, high risk of bias and reporting deficiencies critically undermine the trustworthiness and clinical applicability of current AI/ML models in rhinology. Adopting and adhering to better standards is needed to improve the quality of these models for potential clinical application.

OP-1060

Management Of Radicular Cysts Extending Into The Maxillary Sinus: A Multidisciplinary Case Series

Turan Canmurat İzgi[1], **Eda İzgi**[2], **Muhammet Yasin Pektaş**[2], **Fikret Zeybek**[2]

[1]*Kütahya Health Sciences University, Faculty of Medicine, Department of Otorhinolaryngology;* [2]*Kütahya Health Sciences University, Faculty of Dentistry, Department of Oral and Maxillofacial Surgery*

BACKGROUND & AIM

Radicular cyst are inflamatory odontogenic cysts and represent the most common cystic lesions of the jaws. They typically arise at the apex of a non-vital tooth following pulpal necrosis. Most of them are asymptomatic and remain small in size; however, in rare cases, they may enlarge significantly and extend into adjacent anatomic structures. In this study, we aimed to present our surgical experience in the management of radicular cysts with sinonasal extension using combined of endodontic, transoral, and endoscopic transnasal approaches, and to emphasize the importance of a multidisciplinary strategy in such cases.

MATERIAL & METHODS

A total of 7 patients who underwent multidisciplinary surgery for extensive odontogenic radicular cysts involving the maxillary sinus between April 2025 and April 2026 were retrospectively reviewed. The surgiries were performed through a collaborative approach between the Otorhinolaryngology and Oral & Maxillofacial Surgery departments. Demographic characteristics, clinical findings, surgical techniques, histopathological outcomes, and postoperative follow-up data were analyzed.

RESULTS

The study included 7 patients with a mean age of 46 years. Four patients were male and 3 were female. In all cases, the radicular cysts originated from the periapical region of the tooth and expanded into the maxillary sinus. A sulcular incision was preferred in 5 patients (71.4%), while a sublabial incision was performed in 2 patients (28.6%). Piezosurgery was used to remove the bone covering the cyst. Following apical resection of the involved teeth, retrograde root-end filling was performed using Mineral Trioxide Aggregate. In six cases (85.7%), transnasal endoscopic maxillary antrostomy was performed because of the communication between the cyst cavity and the sinus. One patient (14.3%) had previously undergone endoscopic sinus surgery. In 2 cases with extensive bone defects, a buccal fat pad flap was utilized to support the mucosa and prevent defective healing. During the follow-up period (2–12 months), no clinical or radiological recurrence was observed.

CONCLUSIONS

Extensive odontogenic cysts involving the maxillary sinus may require a combined surgical approach. Successful endodontic treatment, intraoral enucleation, endoscopic sinus control, and vascularized soft tissue support constitute an effective and safe treatment approach that enables preservation of the teeth and adjacent sinonasal structures. Although several case reports on radicular cysts have been reported in the literature, comprehensive case series focusing particularly on large radicular cysts extending into the maxillary sinus appear to be limited. This study presents a relatively large case series demonstrating a multidisciplinary approach in the management of extensive radicular cysts associated with the maxillary sinus.

Free Mucosal Grafting As A Rapid Technique To Achieve Re-Epitheliazation

Nicholas J. Campion[1,2], **Ana Miguel Couto**[1,8], **Ruoxin Hua**[1,3], **Justin Qiao**[1,3], **Hardip Gendeh**[1], **Rhea Darbari Kaul**[1,3], **Raquel Alvarado**[1], **Christine Choy**[1], **Peta-Lee Sacks**[1,2,3], **Raewyn G. Campbell**[1,2,5], **Larry Kalish**[1,6,7], **Richard J. Harvey**[1,2,3]

[1]Rhinology and Skull Base Research Group, St Vincent´s Centre for Applied Medical Research, University of New South Wales, Sydney, Australia; [2]Faculty of Medicine and Health Sciences, Macquarie University, Sydney, Australia; [3]School of Clinical Medicine, St Vincent´s Healthcare Clinical Campus, Faculty of Medicine and Health, University of New South Wales, Sydney, Australia; [4]Department of Otorhinolaryngology-Head and Neck Surgery, Singapore General Hospital, Singapore; [5]Department of Otolaryngology, Head and Neck Surgery, Royal Prince Alfred Hospital, Sydney, Australia; [6]Department of Otolaryngology, Head and Neck Surgery, Concord General Hospital, University of Sydney, Sydney, Australia; [7]Faculty of Medicine, University of Sydney, Sydney, Australia; [8]Hospital Garcia de Orta, Lisbon, Portugal

BACKGROUND & AIM

Mucosal grafting has become more established in rhinologic procedures such as frontal sinus surgery, in skull base surgery to cover naso-septal flap donor sites and as part of septal perforation repair. While it might be well accepted that free mucosal grafts take to bone and vascularized recipient beds, the use of mucosal grafting on the contralateral side during septal perforation repair with vascularized flaps is not well recognized but is an important adjunct to ensure healthy re-epithelization of the contralateral septum.

MATERIAL & METHODS

A retrospective case series of consecutive adult patients undergoing endoscopic nasal septal perforation (NSP) repair with application of a contralateral free mucosal graft was performed. The free grafts were simply placed on the defect, opposite to the flap and on collagen matrix, and covered with silastic sheeting. The primary outcome was the integration of the free graft and judged as complete, partial or failed. Secondary outcomes included the overall anatomical closure, Miglani endoscopic score and nasal symptoms assessed via the Sino-Nasal Outcome Test-22 (SNOT-22) Nasal Subdomain score.

RESULTS

Ninety patients (age 44.3±15.5 years; 56.7% female; 10.0% with a history of recreational drug use) were included. Most repairs utilized an anterior ethmoidal artery flap (95.6%). Free graft integration was complete in 85.6% of all cases (6.7% partial). Anatomical closure was achieved in 90.0% and free graft integration was complete in 92.6% of those patients. Endoscopic assessment improved significantly (Miglani 3.4±1.8 vs. 0.7±0.9; $p<0.001$) and nasal subdomain scores also improved (10.2±7.0 vs. 6.4±5.7; $p<0.001$).

CONCLUSIONS

Contralateral free mucosal grafts heal reliably in endoscopic NSP repair, with complete healing in over 92% of patients with successful closure. The technique is simple to perform and assists in achieving re-epithelization and avoids prolonged secondary healing.

Extent Of Sinus Surgery Is Associated With Disease Control In Biologic Treated Type-2 Dominant CRS

Nicholas J. Campion[1,2], **Peta-Lee Sacks**[1,2,3], **Lu Hui Png**[1,4], **Ruoxin Hua**[1,3], **Rhea Darbari Kaul**[1,2], **Raquel Alvarado**[1], **Christine Choy**[1], **Raymond Sacks**[1,2,6,7], **Peter Earls**[3], **Raewyn G. Campbell**[1,2,5], **Larry Kalish**[1,6,7], **Richard J. Harvey**[1,2,3]

[1]Rhinology and Skull Base Research Group, St Vincent's Centre for Applied Medical Research, University of New South Wales, Sydney, Australia.; [2]Faculty of Medicine and Health Sciences, Macquarie University, Sydney, Australia.; [3]School of Clinical Medicine, St Vincent's Healthcare Clinical Campus, Faculty of Medicine and Health, University of New South Wales, Sydney, Australia.; [4]Department of Otorhinolaryngology-Head and Neck Surgery, Singapore General Hospital, Singapore.; [5]Department of Otolaryngology, Head and Neck Surgery, Royal Prince Alfred Hospital, Sydney, Australia.; [6]Department of Otolaryngology, Head and Neck Surgery, Concord General Hospital, University of Sydney, Sydney, Australia.; [7]Faculty of Medicine, University of Sydney, Sydney, Australia.

BACKGROUND & AIM

A greater benefit of biologics is observed after surgery in type-2 chronic rhinosinusitis with nasal polyps (CRSwNP). However, the extent of surgery remains undefined in many studies. This study evaluated the extent of surgery on disease control in patients receiving biologics for refractory type 2 dominant CRSwNP.

MATERIAL & METHODS

A cross-sectional study was performed on patients with CRSwNP treated with biologics for ≥6 months at a tertiary center. All patients had undergone prior sinus surgery which included a complete sphenoethmoidectomy and then extension via Draf I, IIa, IIb, IIc, or III. Disease control was defined as having a SNOT-22 ≤30, endoscopic modified Lund–Mackay ≤4, and absence of rescue therapy within 6 months. Comparisons were made across surgical and biologic groups, and logistic regression was used to identify factors associated with disease control.

RESULTS

159 patients were assessed (age 50.9±12.8yrs, 45.3% female). Disease control was achieved in 49.1%. Disease control was greater with extended surgery (Draf III 60.8%[49.7-70.8%] vs Draf IIc 68.3%[53.0-80.4%] vs Draf IIa 8.7%[2.4-26.8%] vs Draf I 0%[0.0-19.4%], p<0.001). Control was similar across biologic type (anti-IL-4αR 63.3%[45.5-78.1%] vs anti-IL-5/5R 45.7%[37.3-54.3%], p=0.105). On regression, extended surgery (Draf III + IIc) was associated with disease control (Draf III/IIc vs Draf IIa/I: OR 110.2 [12.7-14682.5]) but not biologic type (anti-IL-4αR vs anti-IL-5/5R OR 2.15 [0.7-7.2]). However, class switching had already occurred in 15.1% of patients initially treated with anti-IL-5/5R.

CONCLUSIONS

Disease control was greatest in CRSwNP patients who had both extended sinus surgery and had their biologic treatment optimized.

OP-1063

Effectiveness Of A Vit-GNN-Based Deep Learning Model For The Classification Of Nasal Pathologies On Paranasal CT Images

Enes SIRMA[1], **Ömer TÜRK**[2]

[1]*Gazi Yaşargil Training and Research Hospital, Diyarbakır,Türkiye;* [2]*Mardin Artuklu University Faculty Of Engineering And Architecture Computer Engineering,Mardin,Türkiye*

BACKGROUND & AIM

To evaluate the effectiveness of a ViT-GNN-based hybrid deep learning model in classifying chronic sinusitis, septal deviation, concha bullosa, antrochoanal polyp, and inverted papilloma on paranasal CT images.

MATERIAL & METHODS

This retrospective study included 250 patients who underwent paranasal CT examinations. Patients were categorized into five groups: chronic sinusitis, septal deviation, concha bullosa, antrochoanal polyp, and inverted papilloma (n=50 each). All pathology groups were confirmed based on postoperative histopathological diagnoses.Five representative coronal CT slices demonstrating the pathology most clearly were selected from each patient, yielding 1,250 images. The dataset was split on a patient basis into 70% training (175 patients, 875 images) and 30% testing (75 patients, 375 images).Images were resized during preprocessing to ensure standardization. A hybrid deep learning model combining Vision Transformer (ViT) and Graph Neural Network (GNN) components was used. The ViT extracted global image features, while the GNN modeled relationships between these features. Model performance was evaluated using accuracy, sensitivity, specificity, precision, F1-score, ROC-AUC, t-SNE visualization, and confusion matrix analysis.

RESULTS

The ViT-GNN-based hybrid deep learning model demonstrated high performance in classifying five different nasal/paranasal pathology groups. The overall accuracy on the test set was 93.6%. The macro-average sensitivity was 92.9%, specificity 98.2%, precision 93.1%, and F1-score 92.7%. The mean AUC value was 0.97.Class-wise evaluation showed the highest sensitivity in the septal deviation group (96.5%), followed by concha bullosa (95.2%) and chronic sinusitis (93.4%). Sensitivity was 91.4% for antrochoanal polyp and 88.9% for inverted papilloma.ROC-AUC analysis demonstrated high discriminative performance across all classes.

CONCLUSIONS

The ViT-GNN-based hybrid deep learning model demonstrated high performance in classifying nasal and paranasal pathologies on coronal CT images. This approach represents a promising decision support tool in radiological evaluation. However, further multicenter studies with external validation are required before clinical application.

OUTCOMES OF ENDOSCOPIC RESECTION OF INVERTED PAPILLOMA: RECURRENCE AND RISK FACTORS: A SYSTEMATIC REVIEW

Bayan Khalid Sabb Gul[1], **Mohammed Hassan Shaheen**[1], **Roaa Ahmed Felemban**[1], **Ruba Al-Harbi**[1,2], **Ghaidaa Sameer Hazzazi**[1]

[1]*Heraa General Hospital, Makkah, Saudi Arabia;* [2]*Al-noor specialist hospital,Makkah,Saudi Arabia*

BACKGROUND & AIM

he present systematic review consolidated the existing research concerning the outcomes of endoscopic removal of inverted papilloma (IP), with an emphasis on recurrence and related risk factors.

MATERIAL & METHODS

The review adhered to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) criteria. A comprehensive search of PubMed, Scopus, Web of Science, and Google Scholar was conducted for studies published from January 2016 to December 2025 that detail recurrence outcomes after endoscopic surgical therapy of IP. Two researchers impartially assessed the titles, abstracts, and whole texts of potentially eligible publications. Conflicts were resolved through interpersonal dialogue. The quality assessment was conducted by two investigators utilising the Methodological Index for Non-Randomised Studies (MINORS) tool for evaluating the reviewed studies.

RESULTS

The preliminary database search revealed 180 records. Following the elimination of duplicate records, 119 studies were screened for title and abstract evaluation. After a comprehensive evaluation of 24 articles, 10 studies satisfied the inclusion criteria. The Krouse classification method was the most frequently utilised for tumour staging. The follow-up duration ranged between 33 months and 66.2 months. In all studies reviewed, recurrence rates after endoscopic resection varied from 9.2% to 42.03%. The mean time to recurrence ranged between 11.4 months and 26.07 months. Increased recurrence is associated with tumour attachment to the frontal or maxillary sinus walls. Among the 10 studies included, three studies were regarded as comparative studies and the mean MINORS score was 20±2.64. Among the non-comparative investigations (n = 7), the mean MINORS score was 12.43±1.4.

CONCLUSIONS

Endoscopic excision should be regarded as the primary treatment for the majority of IPs. It is critical to completely remove the tumour and its underlying bone. Frontal sinus and multifocal conditions necessitate careful surgical planning. A minimum five-year long-term follow-up is advised.

IMPACT OF NASAL OBSTRUCTION AND NASAL SURGERY ON DAYTIME SLEEPINESS AND SNORING

João Rainha Fernandes[1], **Daniela Serras**[1], **João Barbosa**[1], **Constança Oom**[1], **Bárbara Roque**[1], **Alberto Santos**[1], **Carlos Macor**[1]

[1]*Unidade Local de Saúde Loures-Odivelas, Otorhinolaryngology and Head and Neck Surgery Department*

BACKGROUND & AIM

Nasal obstruction increases upper airway resistance, promoting turbulent airflow and nighttime discomfort, which may contribute to snoring and daytime sleepiness. Nasal surgery may improve these symptoms. This study aims to evaluate the relationship between nasal obstruction, snoring and daytime somnolence as well as the impact of nasal surgery on these symptoms.

MATERIAL & METHODS

A prospective interventional study was conducted including patients who underwent septoplasty with or without turbinate surgery between july 2025 and february 2026. All patients were evaluated preoperatively and at 3 to 6 months postoperatively. Nasal obstruction was assessed using the Visual Analog Scale for nasal obstruction (VAS-NO) and the Nasal Obstruction Symptom Evaluation (NOSE) scale. Daytime sleepiness was measured using the Epworth Sleepiness Scale (ESS) and snoring was evaluated using the Visual Analog Scale for snoring (VAS-S). Spearman's correlation was used to assess the relationship between preoperative nasal obstruction scores and sleep related symptoms. Pre and postoperative scores were compared using the Wilcoxon signed rank test with statistical significance set at $p<0,05$.

RESULTS

36 patients were included. Preoperatively, a positive correlation was observed between NOSE and VAS-S (rho=0,792; $p<0,01$), as well as VAS-NO and VAS-S (rho=0,542; $p<0,01$). A significant correlation was also found between NOSE and ESS (rho=0,360; $p=0,025$), although no significant correlation was observed between VAS-NO and ESS (rho=0,308; $p=0,060$). Nasal obstruction improved significantly after surgery, with VAS-NO scores decreasing from 6,94±1,94 to 2,69±2,51 ($Z=4,887$, $p<0,001$) and NOSE from 59,44±22,42 to 21,25±20,51 ($Z=5,068$, $p<0,001$). Similarly, VAS-S decreased from 6,03±3,04 to 3,75±2,85 ($Z=3,829$, $p<0,001$) and ESS from 8,94±5,69 to 6,61±4,14 ($Z=2,189$, $p=0,029$).

CONCLUSIONS

Nasal obstruction is positively associated with snoring severity and daytime sleepiness. Nasal surgery leads to an improvement in nasal patency, snoring, and daytime somnolence, supporting its complementary role in the management of sleep related symptoms.

Chronic Granulomatous Invasive Fungal Sinusitis: Do We Need Extensive Surgery?

Mohamed Eesa[1], **Hala Kenawi**[2], **Ehsan Hendawy**[1], **Khaled Gaber**[2], **Fahd Alghamdi**[2], **Mohammed Alghamdi**[2]

[1]Otorhinolaryngology-Head & Neck Surgery at Zagazig University, Egypt.; [2]department of Otorhinoaryngology-Head & Neck Surgery at Saudi German hospital, Jeddah, KSA.

BACKGROUND & AIM

Chronic granulomatous invasive fungal sinusitis (CGIFS) has been observed to occur in immunocompetent hosts and often present with nonspecific symptoms such as nasal obstruction, mucopurulent nasal discharge, epistaxis, headache, and facial pain, necessitating a high degree of clinical suspicion for timely diagnosis. Delayed diagnosis and management of CGIFS are associated with poor outcomes, including high morbidity and mortality rates, further underscoring the need for early detection and appropriate intervention.

MATERIAL & METHODS

The study was performed at tertiary care referral centre. Clinical records from five patients treated for histopathologically confirmed CGIFS from 2022 to 2025 were reviewed. We also presented a review of the relevant literature investigating this rare disease.

RESULTS

Five cases of histopathologically confirmed CGIFS diagnosed in our institution were included with different treatment plans and varying outcomes.

CONCLUSIONS

CGIFS is a serious and possibly fatal disease. Early diagnosis is an important factor in disease management. Our limited experience shows that extensive surgery may carry a major morbidity and unavoidable complications to the patient. Hence, treatment strategy should consist of conservative approach for significant intra-cranial and intra-orbital invasions together with long term antifungal therapy.

OP-1068

Efficacy Of Mepolizumab In Patients With Nasal Polyposis: Real-World Data

Ceren Aksoy Koçak[1], **Emel Atayık**[2], **Mariye Doğru**[3]

[1]Department of Otorhinolaryngology – Head and Neck Surgery, Konya City Hospital, Konya, Türkiye; [2]Department of Allergy and Immunology, Konya City Hospital, Konya, Türkiye; [3]Department of Internal Medicine, Konya City Hospital, Konya, Türkiye

BACKGROUND & AIM

The most common endotype of nasal polyposis is chronic local eosinophilic inflammation, in which interleukin (IL)-5 and type 2 inflammation play a central role in the pathophysiology. The aim of this study was to evaluate the real-world effectiveness of mepolizumab in patients with nasal polyposis, with or without accompanying chronic rhinosinusitis (CRS ± NP).

MATERIAL & METHODS

This single-center, observational, retrospective study included patients receiving mepolizumab therapy for asthma. Among 99 patients treated with mepolizumab, those with CRS ± NP were selected for analysis. Demographic characteristics, serum eosinophil counts, eosinophilic cationic protein (ECP), total IgE levels, Sinonasal Outcome Test-22 (SNOT-22), Asthma Control Test (ACT) scores, and systemic corticosteroid use were recorded at baseline and at months 1, 4, and 12 of treatment. CRS + NP severity was assessed using the Lund–Mackay (LM) score and the Nasal Polyp Score (NPS) at baseline and at month 12. Patients were classified as responders or non-responders based on clinical, radiological, and laboratory outcomes. Of 57 patients with nasal polyposis, 49 with complete data were included in the final analysis. All patients had comorbid asthma, and 27 patients (55.1%) had aspirin-exacerbated respiratory disease (AERD).

RESULTS

Of the patients, 63.3% were female, with a mean age of 46.2 ± 12.9 years. Significant improvements were observed at month 12 compared with baseline in systemic corticosteroid use, SNOT-22 scores, NPS, LM scores, ACT scores, and blood eosinophil counts and percentages ($p < 0.001$ for all parameters). According to predefined criteria, 29 patients (59.2%) were classified as

responders. Regression analysis revealed that aspirin sensitivity, baseline systemic corticosteroid dose, SNOT-22, NPS, and LM scores were significant factors associated with treatment response (p = 0.024, 0.005, 0.001, 0.002, and 0.049, respectively).

CONCLUSIONS

This real-world study supports the effectiveness of mepolizumab as a treatment strategy in patients with nasal polyposis, with or without accompanying chronic rhinosinusitis, and comorbid asthma. Biologic therapy was associated with significant reductions in polyp size and improvement in clinical symptoms. These findings suggest that type 2 inflammation-targeted therapies represent a valuable treatment option in CRS ± NP. Aspirin sensitivity, frequent systemic corticosteroid use, and disease severity may influence the effectiveness of mepolizumab in nasal polyposis.

OP-1069

Structured Histopathological Comparison Of Allergic Fungal Rhinosinusitis And Eosinophilic Chronic Rhinosinusitis With Nasal Polyps In Saudi Arabia

Dr. Ali G. Alrashidi[1], **Dr. Ahmed Alroqi**[1], **Prof. Saad Alsaleh**[1]

[1]*Department of Otolaryngology-Head and Neck Surgery, College of Medicine, King Saud University, Riyadh, Saudi Arabia.*

BACKGROUND & AIM

Allergic Fungal Rhinosinusitis (AFRS) and Eosinophilic Chronic Rhinosinusitis with Nasal Polyps (eCRSwNP) overlap clinically. Whether they represent distinct entities or points on the same spectrum is debated. We hypothesized that AFRS, compared with eCRSwNP, would show higher total serum Immunoglobulin E (IgE), higher unilateral disease rates on Computed Tomography (CT), and a distinct Structured Histopathological (SHP) profile.

MATERIAL & METHODS

We retrospectively reviewed 415 adults who underwent Functional Endoscopic Sinus Surgery (FESS) at a Saudi tertiary referral center (2017–2024). AFRS was defined by Bent and Kuhn criteria (n=50), and eCRSwNP by EPOS 2020 criteria plus more than 10 tissue eosinophils per high-power field (n=365). We compared 13-variable SHP (Rush protocol), clinical, radiographic, and laboratory features using Mann-Whitney U, chi-square tests, and age-adjusted logistic regression.

RESULTS

AFRS patients were significantly younger (median 27 vs 38 years; $p < 0.001$) and had higher total serum IgE (869 vs 191 IU/mL; $p < 0.001$). Unilateral disease on CT was nearly three times more common in AFRS (58.0% vs 19.6%; OR 5.66, 95% CI 3.05-10.51). SHP analysis showed AFRS had significantly less neutrophilic infiltration (OR 0.34, $p < 0.001$), less sub-epithelial edema (OR 0.02, $p < 0.001$), less hyperplastic or papillary change (OR 0.33, $p = 0.012$), and less squamous metaplasia (OR 0.34, $p = 0.028$). These differences remained significant after age adjustment.

CONCLUSIONS

AFRS and eCRSwNP differ across clinical, radiographic, laboratory, and SHP domains in this Saudi cohort, supporting AFRS as a distinct phenotype. Unilateral presentation and high IgE are strong discriminators. The distinct SHP signature suggests divergent inflammatory pathways, which may impact surgical planning and the selection of biologic therapies.

OP-1070

Osteoblastic Activity And Early Bone Remodeling Following Piezoelectric Versus Conventional Rhinoplasty: A Prospective Serological Study

Enes Yiğit[4], **Özgür Yiğit**[2], **Özgül Vupa Çilengiroğlu**[3], **Efe Can**[1]

[1]*Antalya City Hospital;* [2]*Başakşehir Çam And Sakura City Hospıtal;* [3]*Dokuz Eylül University;* [4]*Private Clinic*

BACKGROUND & AIM

Piezoelectric osteotomy is recognized for its precision and reduced soft tissue trauma. While its clinical advantages in reducing postoperative morbidity are established, the biological mechanism regarding nasal bone remodeling remains poorly characterized. This study aimed to quantify the impact of piezoelectric versus conventional techniques on early bone remodeling using serum biomarkers.

MATERIAL & METHODS

Sixty female patients (18–50 years) were prospectively enrolled and divided into three groups (n=20 each): piezoelectric osteotomy, conventional osteotomy, and a control group (septoplasty without bone intervention). All procedures were performed by a single surgeon. Serum total alkaline phosphatase (ALP) and osteocalcin (OC) levels were measured preoperatively, immediately postoperatively, and at 2 weeks and 2 months postoperatively.

RESULTS

No significant between-group differences were found in ALP levels at any time point (p>0.05). At 2 months postoperatively, osteocalcin (OC), a marker of mature osteoblastic activity, was significantly higher in the piezoelectric group compared with both conventional and control groups (p=0.044). Within-group analyses showed significant postoperative increases in biomarkers over time in both osteotomy groups.

CONCLUSIONS

Piezoelectric osteotomy was associated with significantly higher osteoblastic activity 2 months postoperatively compared with conventional techniques. These findings suggest that the clinical advantages reported for ultrasonic surgery may partly reflect a more favorable biological remodeling environment, supporting a potential mechanistic explanation for postoperative tissue recovery in rhinoplasty.

OP-1071

Organoleptic Examination Of Halitosis

Murat Aydin[1]

[1]*DDS, PhD. Dental Professional, Doctor of Philosophy in Microbiology. Private Clinical Practice.*

BACKGROUND & AIM

Organoleptic examination refers to the act of a clinician directly smelling the patient's breath to diagnose halitosis. Typically, the clinician leans in and instructs the patient to exhale towards their face, after which the clinician inhales and attempts to assess the odor

MATERIAL & METHODS

Various modifications have been proposed in the literature to reduce patient discomfort or to standardize the distance between the patient and the examiner, such as the use of tubes or barriers. Training programs and centers have also been established under the premise that an examiner trained in olfactory assessment could offer more accurate diagnoses. However, this assumption lacks robust scientific validation

Results: Despite its frequent mention in the literature, the organoleptic method is inherently flawed. It is inconsistent, rudimentary, highly subjective, potentially harmful for sniffer, and ultimately unreliable. Its major drawbacks include

Non-linear perception: According to psychophysical laws, odor perception does not increase linearly with gas concentration (Weber-Fechner law)

Discomfort and aversion: Patients often find the process repulsive, while clinicians may feel degraded while performing it.

Infection risk: Inhalation of exhaled breath poses a clear risk of respiratory pathogen transmission to the examiner.

RESULTS

Toxicity concern: Halitosis-related gases—such as sulfur compounds, nitrogenous volatiles, organics, and methane—are not biologically inert. Chronic exposure, even at low concentrations, has been linked to metabolic alterations in animal and human studies.

Lack of standardization: There is no consensus on scales (some use 0–6, others 0–10), fasting periods, or even inhalation protocols (nasal vs. oral). Gas mixing in the oro-nasal cavity further complicates breath-source differentiation.

Misdiagnosis of psychogenic halitosis: A weak odor can lead to a false diagnosis of psychological halitosis, even though such cases can coexist with measurable biological halitosis.

Misattribution of odor source: Odor character is often used to infer systemic origin (e.g., nitrogenous odors attributed to renal issues), yet olfactory interpretation varies greatly between individuals.

CONCLUSIONS

irreproducibility: Organoleptic scores are highly variable between repeated trials and across different examiners.

,Unreliable training standards: Training with butanol is irrelevant, as this compound is rarely present in real halitosis cases. Olfactory acuity naturally declines with age and fluctuates with sex, hormonal status, and even time of day. Moreover, the examiner may have undetected halitosis or a shifting odor threshold, both of which compromise accuracy.

Conclusions: Given the profound limitations listed above, organoleptic examination should be restricted in clinical halitosis practice. Its role may be limited to initial screening, but not relied upon for definitive diagnosis or follow-up.

OP-1072

Nasal Floor Augmentation After Total Inferior Turbinectomy – A Case Series

Dr. Peter Ochung'o[1]

[1]Hope Ear Nose and Throat Centre, Nairobi, Kenya

BACKGROUND & AIM

Paradoxical nasal breathing sometimes witnessed as a result of total inferior turbinectomy can be temporarily relieved by nasal moisturisers and nasal irrigation.

However, surgery may be required for re establishing nasal resistance and physiological airflow. These procedures may be accompanied by procedural difficulties.

MATERIAL & METHODS

In this prospective study, the nasal floor of five patients diagnosed with symptoms of empty nose syndrome were augmented with pieces of auricular cartilage. Subjective symptoms were examined .

RESULTS

The nasal floor was successfully augmented in all five patients. At three months after surgery, the total questionnaire score reduced, and the nasal resistance increased.

CONCLUSIONS

The findings of this study suggest that nasal floor augmentation for paradoxical nasal breathing and Empty Nose Syndrome [ENS] is effective in increasing resistance and reducing the nasal symptoms usually casually related to ENS.

PREOPERATIVE SINUS MICROBIOME SIGNATURES PREDICT SURGICAL OUTCOMES IN CHRONIC RHINOSINUSITIS

Bárbara Rodrigues[1], **Gonçalo Quadros**[1], **Márcia Mourão**[1], **Joana Silva**[1], **André Gonçalves**[1], **Inês Pereira**[1], **António Alves**[1]

[1]*Department of Otorhinolaryngology, Unidade Local de Saúde de Viseu Dão-Lafões, Viseu, Portugal.*

BACKGROUND & AIM

Variability in clinical outcomes after functional endoscopic sinus surgery (FESS) in patients with chronic rhinosinusitis (CRS) remains a significant challenge. Emerging evidence suggests that the baseline sinus microbiome may serve as a critical biomarker to predict surgical success and disease recurrence. In this context, we aimed to systematically evaluate the association between preoperative sinus microbiome composition and postoperative clinical outcomes in CRS patients undergoing FESS.

MATERIAL & METHODS

A systematic review was conducted across PubMed, Embase, and Cochrane Library (2015–2025) following PRISMA guidelines. Inclusion was restricted to studies utilizing Next-Generation Sequencing (NGS), including bacterial taxonomic profiling (16S rRNA and pyrosequencing) and host genomic analysis (Whole-Exome Sequencing - WES). Search descriptors included: 'Microbiota', 'Microbiome', 'Chronic Rhinosinusitis', and 'Endoscopic Sinus Surgery', combined with specific terms for genomic analysis (16S rRNA, NGS). Outcomes assessed included symptom improvement, endoscopic scores, and disease recurrence.

RESULTS

Seven studies comprising 281 CRS patients met inclusion criteria. Higher preoperative bacterial alpha diversity was consistently associated with greater symptom improvement and lower recurrence rates. Increased relative abundance of Corynebacterium spp. and other Actinobacteria correlated with favorable surgical outcomes. Conversely, reduced diversity and dominance of Staphylococcus aureus, Pseudomonas aeruginosa, or Enterobacteriaceae were associated with poorer postoperative improvement and higher recurrence. Integrative models combining microbiome and inflammatory data enhanced the ability to identify patients likely to experience favorable surgical outcomes.

CONCLUSIONS

Preoperative sinus microbiome composition is consistently associated with surgical outcomes in CRS, highlighting its potential to inform clinical decision-making and support personalized therapeutic strategies. Future multicenter and longitudinal studies are warranted to validate these findings and to further assess the clinical utility of microbiome-based predictive models in routine practice.

Cerebrospinal Fluid Leakage Following Rhinoplasty, Septoplasty, And Septorhinoplasty: A Case Series

Nader Akbari Dilmaghani[1], **Niloufar Shabani**[3], **Parisa Hashami**[4], **Amir Tabrizi**[2]

[1]Department of Otolaryngology, Head and Neck Surgery, Loghman hakim Educational Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [2]Hearing Disorder Research Institute, Loghman hakim Educational Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [3]Faculty of medicine, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [4]Department of Radiology, Loghman hakim Educational Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Iran

BACKGROUND & AIM

Cerebrospinal fluid (CSF) leakage is a rare but potentially life-threatening complication of nasal surgeries such as rhinoplasty and septoplasty. It often results from improper handling of the ethmoid bone's perpendicular plate. If undiagnosed, it may lead to meningitis, pneumocephalus, intracranial abscess, or death.

MATERIAL & METHODS

We present a retrospective case series of seven patients who developed iatrogenic CSF leaks following rhinoplasty, septoplasty, or septorhinoplasty. The mean patient age was 31.8 years, with an average follow-up of 11 months. Clinical presentations included rhinorrhea (5 patients), generalized headache with fever (1 patient), and combined headache and rhinorrhea (1 patient). Computed tomography (CT) scans of the paranasal sinuses (CT PNS) and CT cisternography were utilized to localize the CSF leak.

RESULTS

Cribriform plate defects were identified in six patients. Three developed meningitis (cases 1, 4, and 6), and pneumocephalus occurred in two (cases 2 and 7). Management strategies included conservative therapy, intravenous antibiotics, and endoscopic CSF leak repair. Except for Case 6, five patients responded well to surgical treatment, and one patient was successfully managed with medical therapy alone, with no complications observed during the follow-up period.

CONCLUSIONS

Rhinoplasty, septoplasty, and septorhinoplasty are technically challenging procedures that require surgeons to employ appropriate techniques, thoroughly understand anatomical details, and carefully handle the perpendicular plate to prevent skull base damage and complications. Early recognition of symptoms such as unilateral rhinorrhea, fever, or severe headache is critical to prevent serious complications.

OP-1075

Microbiological Contamination Of Nasal Topical Preparations Used After Septoplasty: A Comparative Analysis

Numan Kokten[1], Zafer Habip[2], Berina Slipcevic[3], Mustafa Hatipoglu[4], Zeynep Az Aydin[3], Batin Berkay Oznacar[3], Serdal Celik[3], Mahmut Tayyar Kalcioglu[3]

[1]Göztepe Prof. Dr. Süleyman Yalçın City Hospital, ENT Clinic, Istanbul, Türkiye; [2]Istanbul Medeniyet University, Faculty of Medicine, Department of Medical Microbiology, Istanbul, Türkiye; [3]Istanbul Medeniyet University, Faculty of Medicine, Department of Otorhinolaryngology, Istanbul, Türkiye; [4]Göztepe Prof. Dr. Süleyman Yalçın City Hospital, Medical Microbiology Clinic, Istanbul, Türkiye

BACKGROUND & AIM

The aim of this study was to determine microbiological contamination rates of nasal topical preparations (sprays, drops, and ointments) used by patients after septoplasty at the nozzle/tube tip and drug content level. The study also aimed to compare contamination levels in different formulations.

MATERIAL & METHODS

This prospective cross-sectional study included 110 patients (spray: n = 38; drop: n = 34; ointment: n = 38) who underwent septoplasty at the ENT clinic. Patients returned their preparations after at least two weeks of postoperative use. Two separate samples were obtained from each preparation: a swab of the nozzle/tube tip and the drug content. These specimens were inoculated onto blood agar, chocolate agar, and Sabouraud Dextrose Agar. Isolate identification was performed using the VITEK MS (MALDI-TOF MS) system.

RESULTS

Nozzle contamination was detected in 62.7% (n = 69) of the 110 preparations, and content contamination in 40.9% (n = 45). Nozzle contamination was significantly higher in the spray group (89.5%) than in the drop (44.1%) and ointment (52.6%) groups ($p < 0.001$). The most frequently isolated microorganisms were coagulase-negative staphylococci (particularly Staphylococcus epidermidis) and Staphylococcus aureus. Gram-negative bacteria (e.g. Klebsiella spp. and Pseudomonas aeruginosa) and yeast species (e.g. Candida parapsilosis and Candida haemulonii) were detected less frequently.

CONCLUSIONS

Spray formulations had the highest rate of nozzle contamination, while the level of contamination of the drug content was similar across all groups. These findings emphasize the importance of educating patients on the hygienic use of topical preparations during the postoperative period.

PREOPERATIVE NASAL ANALYSIS IN RHINOPLASTY: DEVELOPMENT AND EVALUATION OF AN ARTIFICIAL INTELLIGENCE-ASSISTED CLASSIFICATION SYSTEM

Ramazan Çelik[1], **Cabir Vural**[2], **Ozan Özdemir**[1], **Özgür Yiğit**[3]

[1]*Istanbul Training and Research Hospital, Department of Otolaryngology-Head and Neck Surgery;* [2]*Marmara University Faculty Of Engineering, Electrical And Electronics Engineering, Department Of Telecommunication;* [3]*Çam and Sakura City Hospital, Department of Otolaryngology-Head and Neck Surgery*

BACKGROUND & AIM

The aim of this study was to develop deep learning-based artificial intelligence models capable of automatically classifying nasal morphology from standardized photographs, intended for use in preoperative evaluation of rhinoplasty candidates, and to assess their clinical applicability. Within the scope of this research, specialized classification models were developed for a total of 11 distinct anatomical parameters: brow-tip aesthetic line, nasal dorsum width, tip morphology, dorsal deviation, alar rim position, columella position, nasal projection, radix height, retrognathia status, tip rotation (evaluated separately for males and females), and dorsum profile.

MATERIAL & METHODS

This retrospective descriptive study utilized preoperative standardized photographs of 890 patients who underwent primary or revision rhinoplasty between January 2016 and December 2025. A total of 2,670 photographs captured in frontal, lateral, and superior views were analyzed. All photographs were evaluated and labeled by two independent otolaryngology specialists experienced in rhinoplasty. For image classification, the ResNet-18 (Residual Network-18) architecture, pre-trained on ImageNet, was employed. Through a transfer learning approach, the final layers of the model were retrained for nasal anatomy-specific features. The dataset was split into 70% training, 15% validation, and 15% test sets. Class imbalance was managed using weighted random sampling and weighted loss functions. Model performance was evaluated using accuracy, precision, recall, F1-score, ROC-AUC, Cohen's Kappa, and MCC metrics. The anatomical focus validity of the models was confirmed using the Grad-CAM technique.

RESULTS

All 12 developed models demonstrated accuracy rates ranging from 87% to 100%. The highest performance was achieved in the nasal projection (100%), retrognathia (100%), female tip rotation (100%), and male tip rotation (98.4%) models. The dorsum width model achieved 95.16% accuracy, the brow-tip aesthetic line model reached 94.94%, the superior axis deviation model attained 94.35%, the alar rim model scored 93.33%, the columella model reached 92.86%, the dorsum profile model achieved 92.5%, the radix model obtained 90.48%, and the tip morphology model reached 87.67% accuracy. Across all models, Cohen's Kappa values ranged from 0.795 to 1.00, indicating "substantial" to "almost perfect" agreement with expert decisions. ROC AUC values were found to be in the range of 0.945 to 1.00. Grad-CAM analyses confirmed that the models focused on anatomically meaningful regions such as the dorsum, tip, alar rim, and radix.

CONCLUSIONS

The deep learning-based artificial intelligence models developed in this study can classify nasal morphology with high accuracy in preoperative rhinoplasty evaluation. The system offers surgeons a decision support mechanism by analyzing photographs through a holistic approach without requiring manual marking or millimetric measurements. It holds particular potential as a training tool for inexperienced surgeons and as a "virtual assistant" that enhances standardization in clinical practice. In the future, the clinical integration of the system can be strengthened through multicenter validation studies and correlation analyses with postoperative outcomes.

OP-1077

Biological Therapy For Extensive Allergic Fungal Rhinosinusitis: A Tertiary Hospital Experience

Hussain AlJubarn[1], **Ali Almomen**[2]

[1]*Al Jabr Eye and ENT hospital, Al-ahsa, Saudi Arabia;* [2]*King Fahad Specialist Hospital, Dammam, Saudi Arabia*

BACKGROUND & AIM

Allergic fungal rhinosinusitis (AFRS) is a subtype of chronic rhinusinusitis which is charactarized as a localized inflammatory hypersensitivity reaction in the nasal cavity and sinuses leading to severe inflammation and accumulation of thick mucin rich with eosinophils and fungi hyphae. The high rates of surgical revisions and recurrences of AFRS have prompted the recent hypothesis and ongoing experimentation of an advancement in medical treatment by using biologics. However, the studies in

this aspect are very limited; hence, this study aimed to compare two biological agents with the standard therapy of this condition.

MATERIAL & METHODS

This is a prospective study that involved three groups (Dupilumab, Mepolizumab, and control groups). The patients were followed and assessed in their first presentation and after 12 months of their therapy. Multiple clinical (SNOT-22 and VAS), endoscopic (nasal polyp score), and radiological (Lund-Mackay score) variables were evaluated. SPSS was utilized to analyze the data and compare the groups.

RESULTS

A total of 36 patients participated in the study: nine received Dupilumab, nine received Mepolizumab, and 18 served as controls. The SNOT-22 scores significantly decreased in all groups following treatment, with greater improvements observed in the Dupilumab (70.13 ± 2.8) and Mepolizumab (53.78 ± 11.37) groups compared to controls (35.56 ± 7.25). Similarly, reductions in nasal polyp scores were significantly higher in both biologic groups versus the control group. Regarding olfactory function, the Dupilumab group showed a significant improvement compared with controls, while Mepolizumab showed a non-significant difference. The most common side effect of biological therapy was injection site reaction (seven patients), followed by hair loss, arthralgia, and myalgia (four patients). Only two patients in the control group experienced disease recurrence. Overall, both Dupilumab and Mepolizumab demonstrated superior clinical outcomes compared to standard treatment, with generally mild and manageable adverse effects.

CONCLUSIONS

The use of Dupilumab and Mepolizumab was effective and safe in treating patients with extensive AFRS in comparison to the standard therapy. This modality of treatment has been shown to reduce the rates of surgical revisions and recurrences of AFRS.

OP-1078

Targeted Approach To Residual Septal Deviation: Effective And Safe Reseptoplasty Technique.

Zhanna Mokoyan[1], **Yury Rusetsky**[2], **Valery Svistushkin**[1], **Anastasiya Bershina**[2]

[1]*Sechenov University*; [2]*Central State Medical University*

BACKGROUND & AIM

Revision septoplasty is a challenging procedure due to the postoperative fibrosis and lack of the underlying bony-cartilaginous framework, psychological difficulties and fears of the patient due to an unsuccessful experience. The aim of the study is to introduce the novel minimally invasive approach for management of posterior residual septal perforations.

MATERIAL & METHODS

A prospective case series was conducted at the ENT Department, Sechenov University, from September 2024 to September 2025. Fifteen patients (n=15) undergoing revision surgery for symptomatic residual septal deviation were included. The surgical technique involved a targeted endoscopic approach to address the specific location and type of the residual deformity, minimizing mucosal disruption. Pre- and postoperative evaluations included anterior active rhinomanometry and the Sino-Nasal Outcome Test-22 (SNOT-22) questionnaire. The median postoperative follow-up period was 6 months.

RESULTS

All 15 patients completed the 6-month follow-up. Analysis of pre- and postoperative data demonstrated a significant improvement in nasal airway patency and disease-specific quality of life. Anterior active rhinomanometry showed enhanced nasal airflow, and total SNOT-22 scores exhibited a marked decrease, indicating positive symptomatic relief and functional improvement following the targeted procedure.

CONCLUSIONS

This preliminary study suggests that a targeted endoscopic approach for residual septal deviation is a safe and effective strategy, yielding significant functional improvements and high patient satisfaction in the short term. Further studies with larger cohorts and longer follow-up are warranted to validate these findings.

Residual septal deviation; revision septoplasty; endoscopic septoplasty; nasal obstruction; SNOT-22; rhinomanometry

OP-1079

Role Of Mirna-155 In Chronic Rhinosinusitis

Müzeyyen Doğan[1], **Asst. Prof. Fatma Tuba Akdeniz**[2], **Prof.Dr. Seda Güleç Yılmaz**[3], **Assoc.Prof. Nihal Seden Boyoğlu**[1], **Prof.Dr.Turgay İşpir**[4]

[1]*Istanbul Yeditepe University Faculty of Medicine, Ear Nose and Throat Department*; [2]*İstanbul Okan University Faculty of Engineering and Natural Sciences*; [3]*Istanbul Yeditepe University Faculty of Medicine Department of Medical Biology*; [4]*Istanbul Yeditepe University Department of Molecular Medicine*

BACKGROUND & AIM

The pathogenesis of chronic rhinosinusitis (CRS) shows strong connections with microRNA-155 (miR-155) through its inflammatory pathways. Research has concentrated on determining miR-155 expression levels in patients who receive montelukast treatment as a leukotriene receptor antagonist for asthma and allergic conditions.The immune system depends on miR-155 for its regulation through its effects on T cells and macrophages. The elevated levels of miR-155 promote Th2-mediated inflammation through increased eosinophilic activity and elevated IL-4 and IL-13 pro-inflammatory cytokines.

MATERIAL & METHODS

This study examined 30 patients diagnosed with CRS who did not respond to medical treatment and therefore underwent surgery. Blood samples were taken from the patients before the operation to measure IL-1β and miR-155 levels. They were asked to answer the Sino-Nasal Outcome Test (SNOT-22) to evaluate sinonasal symptoms. After the operation, these patients were given a standard treatment and nasal irrigation with montelukast and saline for one month. One month later, IL-1β and miR-155 levels were measured in serum samples taken from the patients.

RESULTS

When the SNOT-22, miRNA155 and IL-1β values obtained after the operation were compared with the values before the operation, it was seen that they decreased and this difference was found to be statistically significant (p=0.0001, p=0.0030, p=0.0001; respectively). The disease severity and inflammatory status of patients could be monitored through elevated serum miR-155 levels.

CONCLUSIONS

Managing chronic sinusitis remains challenging due to disease heterogeneity, persistent inflammation, limitations in current therapies, and the presence of comorbid conditions. Overcoming these challenges requires a personalized treatment approach,improved diagnostic tools, patient education to enhance adherence, and the incorporation of novel therapies as they become more accessible.The disease severity and inflammatory status of patients could be monitored through elevated serum miR-155 levels. The significance of miR-155 in chronic rhinosinusitis makes it both a therapeutic target and a biomarker for disease management.

OP-1080

Risk Factors For Malignant Transformation And Recurrence In Sinonasal Inverted Papilloma: A 20-Year Retrospective Analysis

Sinan Dheyauldeen[1]

[1]*Department of Otorhinolaryngology, Head and Neck Surgery. Oslo University Hospital –Rikshospitalet, Oslo, Norway;* [2]*The Medical Faculty, University of Oslo, Oslo, Norway*

BACKGROUND & AIM

Sinonasal inverted papilloma (SNIP) is a benign but locally aggressive neoplasm with a recognized potential for malignant transformation (MT). Despite its benign classification, the high rate of recurrence and the risk of developing squamous cell carcinoma necessitate a deeper understanding of its clinical behavior.

The primary objective of this study was to identify specific clinical risk factors, such as gender and smoking, and anatomical localizations associated with increased rates of recurrence and malignancy. Furthermore, the study aimed to assess and compare the sensitivity of the Krus, Cannady, and Han classification systems in predicting these adverse outcomes to improve clinical decision-making

MATERIAL & METHODS

A retrospective analysis was conducted on 137 patients treated at Oslo University Hospital from 2000 to 2020. Variables analyzed included patient demographics, smoking status, and primary tumor localization. The predictive value of the Krus, Cannady, and Han staging systems was statistically evaluated against observed recurrence and MT rates.

RESULTS

Malignant transformation was observed in 11% (n=15) of the cohort, with a mean time to transformation of 40.3 months. Female patients demonstrated a significantly higher risk of MT (22% vs. 7%, p = 0.015). Smoking was identified as a major risk factor, present in 53% of all malignant cases. High rates of MT were noted in the orbit (100%), nasal vestibule (25%), and maxillary sinus (10%). The Cannady (Groups B & C) and Han (Group II) systems showed superior sensitivity for predicting MT compared to the Krus system. While findings regarding the maxillary sinus (N=58) and ethmoid (N=26) are robust, results for the orbit (n=3) and nasal septum (N= 6) should be interpreted with caution due to the limited number of cases representing these specific localizations

CONCLUSIONS

Female gender, smoking, and specific tumor localizations are significant indicators of malignant potential in SNIP. Utilizing the Cannady and Han classification systems allows for better identification of high-risk patients, facilitating more intensive post-operative surveillance.

Does Septal Deviation Affect Uncinate Process Morphometry? A CT-Based Right–Left Comparative Study

Halit Rüzgar[1], **Bahar Atasoy Badur**[2], **Okan Sapan**[1], **Burak Kaan İnan**[1], **Cemil Kurumoğlu**[2], **İbrahim Salih Geçer**[1], **Zahide Mine Yazıcı**[1]

[1]Department of Otorhinolaryngology, Bakırköy Dr. Sadi Konuk Training and Research Hospital, İstanbul, Türkiye; [2]Department of Radiology, Bakırköy Dr. Sadi Konuk Training and Research Hospital, İstanbul, Türkiye

BACKGROUND & AIM

Nasal septal deviation (NSD) may alter the anatomy of the lateral nasal wall and osteomeatal complex through chronic asymmetric airflow changes. However, data regarding its effect on uncinate process morphometry are limited. This study aimed to compare uncinate process morphometry between the deviation side and the contralateral side in patients with NSD using computed tomography (CT).

MATERIAL & METHODS

This retrospective CT-based morphometric study included 170 adult patients with NSD. Uncinate process width, uncinate process–lamina papyracea distance, and infundibulum width were measured bilaterally. Measurements were subsequently reclassified as the deviation side and contralateral side according to the direction of septal deviation. Paired comparisons and correlation analyses with septal deviation angle were performed.

RESULTS

Among the 170 patients, 79 (46.5%) had right-sided and 91 (53.5%) had left-sided NSD. The mean septal deviation angle was 11.63±4.37°. Uncinate process width was significantly lower on the deviation side compared with the contralateral side (1.86±0.78 mm vs. 2.12±0.94 mm; $p<0.001$). Similarly, the uncinate process–lamina papyracea distance was significantly reduced on the deviation side (4.60±1.85 mm vs. 5.34±1.88 mm; $p<0.001$). No significant difference was observed in infundibulum width between the two sides ($p=0.128$). A significant negative correlation was found between septal deviation angle and the asymmetry index of the uncinate process–lamina papyracea distance (rho=-0.260; $p=0.001$), indicating that greater deviation severity was associated with more pronounced asymmetry.

CONCLUSIONS

NSD is associated with asymmetric morphometric changes in the uncinate process and adjacent osteomeatal complex anatomy. Reduced uncinate process width and uncinate process–lamina papyracea distance on the deviation side may be relevant during endoscopic sinus surgery and septoplasty planning. These findings suggest that the anatomical effects of NSD extend beyond the nasal septum itself.

Achieving 96% Success Without Intubation: A 21-Year Institutional Review Of Stentless Endoscopic Dacryocystorhinostomy

Dr REN HUI LO[1], **Dr. Harvinder Singh S/O Dalip Singh**[1], **Dr. Pathma Letchumanan**[1]

[1]ORL-HNS DEPARTMENT, HOSPITAL RAJA PERMAISURI BAINUN IPOH, PERAK, MALAYSIA

BACKGROUND & AIM

Dacryocystorhinostomy (DCR) is traditionally performed via either an external or endoscopic approach, with or without stenting. While surgical techniques vary globally, our center in Malaysia has been performing stentless endoscopic approach for the management of nasolacrimal duct obstruction and chronic dacryocystitis. This presentation reviews our 21-year surgical experience, detailing our standardized operative technique and evaluating long-term clinical outcomes and success rates.

MATERIAL & METHODS

We present this retrospective study evaluating all 238 endoscopic stentless DCR procedures performed over two decades (2005–2025). The series includes 112 right-sided, 102 left-sided, and 24 bilateral cases. Our analysis focuses on clinical indications, success rates, and the primary drivers of surgical failure. By examining 20 years of longitudinal data, we provide evidence-based insights into the efficacy of the endoscopic stentless approach.

RESULTS

The primary surgical success rate was 96.21% (n=229), demonstrating clinical outcomes comparable to established benchmarks for both external (open) dacryocystorhinostomy and endoscopic techniques utilizing nasolacrimal stenting. Postoperative failure was limited mainly due to recurrent infections; nine patients (3.78%) required a primary revision procedure, while two patients (0.84%) necessitated a secondary revision to achieve functional patency.

CONCLUSIONS

Our two-decade experience suggests that the stentless endoscopic approach is a highly effective, minimally invasive alternative that yields success rates on par with traditional stented or open methods, while reducing stent-related morbidity.

Histopathological Effects Of Different Nasal Packing Materials On The Mucosa: An Experimental Study

Sema Güleç[1], **Mithat Arıcıgil**[1], **Naile Yaldız Kökbudak**[2], **Fakih Cihat Eravcı**[1], **Hamdi Arbağ**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, Faculty of Medicine, Necmettin Erbakan University, Konya, Türkiye;* [2]*Department of Pathology, Faculty of Medicine, Necmettin Erbakan University, Konya, Türkiye*

BACKGROUND & AIM

To investigate whether commonly used nasal packing materials differ in their ability to induce a rhinitis-like inflammatory response and associated mucosal alterations in a rabbit model.

MATERIAL & METHODS

This prospective experimental study included 32 New Zealand rabbits randomly allocated into four groups (control, silicone, Merocel, and gauze packing; n=8 each). Packing materials were placed in the right nasal cavity for 72 hours. Biopsy specimens were obtained from the inferior turbinate and septum, including both mucosal and cartilaginous tissues. Eosinophil and total inflammatory cell counts were assessed quantitatively, and mucosal and cartilaginous alterations were graded according to severity. Histopathological evaluation was performed by a blinded pathologist. Data were analyzed using non-parametric statistical tests, with $p<0.05$ considered significant.

RESULTS

Eosinophil counts differed significantly among groups in both turbinate and septal specimens ($p\leq0.001$), with significantly higher eosinophilic infiltration in the Merocel group compared to the control and silicone groups. Epithelial loss and ciliary damage were significantly increased in all packing groups compared to the control group ($p<0.001$). Subepithelial fibrosis was more pronounced in the Merocel and gauze groups ($p\leq0.002$). No significant differences were observed in cartilage degeneration or cartilage thickness ($p>0.05$).

CONCLUSIONS

Nasal packing materials demonstrate significant differences in early inflammatory response and mucosal injury. Merocel and gauze packing were associated with more pronounced eosinophilic infiltration and epithelial damage, whereas silicone packing showed a comparatively limited inflammatory response. These findings suggest that packing selection should account for the risk of rhinitis-like mucosal changes.

Peak Nasal Inspiratory Flow In Asymptomatic Spanish Adults: An Observational Prospective Study - Preliminary Data Presentation

Sebastián Muñoz Suárez[1,2], **Alda Cardesin Revilla**[2], **Yolanda Escamilla Carpintero**[1,2], **Miquel Quer Agusti**[1,3], **Xavier Leon**[1,3]

[1]*Universidad Autonoma de Barcelona;* [2]*Corporació Sanitària Parc Taulí de Sabadell;* [3]*Hospital de la Santa Creu i Sant Pau de Barcelona*

BACKGROUND & AIM

The prevalence of nasal obstruction in Spain is around 30 to 40%, which makes it impossible for our healthcare system to have all patients evaluated by the two main specialties dedicated to nasal obstruction: Allergology and Otorhinolaryngology. Therefore, seeking to leverage inexpensive and simple tools is a necessity in a healthcare environment characterized by increasing costs. This study aims to provide reference values for a fast, easy-to-use, in-office tool for clinical testing in the Spanish population. We report initial findings from the first 31 participants. As recruitment is still active, these data should be interpreted as preliminary trends.

MATERIAL & METHODS

This is an observational, descriptive and prospective study with a cross-sectional data collection design, without follow-up, conducted at a single national clinical center. We report initial findings from the first 31 of 96 planned participants. The study population consists of healthy Spanish adult volunteers with no history of nasal obstruction.

Inclusion Criteria: Subjects aged 18 to 80 years who provide signed informed consent and present a nasal obstruction visual analogue scale (NO-VAS) score ≤ 2.

Exclusion Criteria: Individuals under 18 or over 80 years old. Current pregnancy. Active smoking. History of asthma. Previous nasal surgery. Use of medications: hormonal contraceptives, topical or systemic corticosteroids, nasal decongestants, beta-blockers, Psychotropics: Chlorpromazine, Thioridazine, Amitriptyline, Gabapentin, Alprazolam, Reserpine.

After enrollment, age, gender, height, and weight were recorded, and Patient-Reported Outcome Measures were administered. Three Peak Nasal Inspiratory Flow measurements were performed following international recommendations, and the highest value was used for statistical analysis.

RESULTS

In this preliminary cut (N=31, 33.3% of target), subjective assessment scales demonstrated strict clinical uniformity. The NOSE questionnaire, Visual Analog Scale (VAS), and SNOT-22 all recorded a mode of 0, confirming a highly asymptomatic cohort. The observed ranges were correspondingly narrow, with NOSE ranging from 0 to 5, VAS from 0 to 2, and SNOT-22 from 0 to 29. Anthropometrically, males (n=11; age 37.7±8.0 years) averaged 91.6±23.0 kg in weight and 177.5±8.0 cm in height, registering a mean Body Mass Index (BMI) of 28.9±6.2 kg/m². Females (n=20; age 40.9±13.9 years) averaged 61.1±13.4 kg in weight and 162.2±4.7 cm in height, presenting a mean BMI of 23.2±4.9 kg/m². Maximum bilateral Peak Nasal Inspiratory Flow (PNIF) demonstrated medians by gender: 190.0 L/min (IQR: 157.5–217.5) in males and 147.5 L/min (IQR: 115.0–165.0) in females.

CONCLUSIONS

Given the preliminary nature of these findings, they should be interpreted as suggesting potential trends rather than definitive conclusions. This highly interpretable tool appears to offer practical utility across multiple healthcare tiers. In rhinologic assessment, its clinical value might be optimized when integrated with disease-specific Patient-Reported Outcome Measures (PROMs). In both primary and specialist settings, Peak Nasal Inspiratory Flow (PNIF) could potentially support diagnostic evaluations, referral decisions and tailored therapeutic approaches. Overall, PNIF seems to represent a cost-effective, accessible modality that may prove valuable for routine outpatient monitoring and comparative treatment assessments.

Evaluating Post-Operative Analgesia And Safety Of NSAID-Containing Versus Opioid-Only Regimens After Sinonasal Surgery: A Randomized Controlled Trial

Grace Cheung[1], **Patrick Macinnis**[2], **Connor Brenna**[1], **Molly Zirkle**[1], **Yvonne Chan**[1], **John Lee**[1], **Daniel J. Lee**[1]

[1]*University of Toronto;* [2]*Unity Health Toronto*

BACKGROUND & AIM

Prescription opioids are widely used for post-operative pain after sinonasal surgery but carry risks such as respiratory depression, nausea, vomiting, and persistent use. NSAIDs effectively reduce pain and opioid needs, yet their use has been limited by concerns regarding bleeding and impaired mucosal healing.

MATERIAL & METHODS

This ongoing randomized controlled non-inferiority trial is enrolling 66 adult patients undergoing endoscopic sinus surgery, septoplasty, or septorhinoplasty. Participants are randomized to receive either: (1) acetaminophen with celecoxib, and oxycodone available only as a rescue analgesic (NSAID arm); or (2) acetaminophen and oxycodone alone (opioid-only arm). The primary outcomes are pain severity and pain interference scores on POD7, evaluated using the Brief Pain Inventory. Secondary outcomes include several complimentary pain scales applied from POD1 – POD30, adverse events attributable to NSAIDs or opioids, rescue opioid use, and quality of recovery (QoR-15).

RESULTS

Interim analysis of 55 participants demonstrated no significant differences between NSAIDs and opioid-only groups with respect to POD7 pain severity (mean 1.639 vs. 1.731, p=0.9880) or pain interference scores (mean 2.175 vs. 1.231, p=0.6769), respectively. Timepoint analysis from POD1 – POD7 using repeated-measures ANOVA showed no between-group differences in post-operative pain trajectories. Adverse events were comparable between study groups, with a nonsignificant trend toward fewer events in the NSAID group based on Fisher exact testing.

CONCLUSIONS

Trial recruitment is ongoing, but preliminary data are consistent with non-inferiority of the NSAID regimen. Final analyses will inform whether NSAIDs can be safely integrated into standard discharge protocols following sinonasal surgery, to reduce opioid exposure.

Biologics Are An Underutilised Therapeutic Option For Patients With Uncontrolled Crswnp In The US: A Real-World Study

Peter Howarth[1], **Luz-Adriana Jimenez**[2], **Justin Kwiatek**[3], **Arijita Deb**[4], **Laura Walrave**[5], **Sean D MacKnight**[6], **Guillaume Germain**[6], **Kaixin Zhang**[7], **Kioumars Tavakoli Tafti**[6], **François Laliberté**[6]

BACKGROUND & AIM

Chronic rhinosinusitis with nasal polyps (CRSwNP) is an inflammatory condition affecting the sinuses and nasal mucosa leading to symptoms such as nasal obstruction and impaired sense of smell. Despite the availability of effective biologic therapies, which target the underlying type 2 inflammation driving symptoms and disease progression, recent studies suggest initiation of biologics for patients with CRSwNP is suboptimal. This study aims to assess the cumulative incidence of biologic therapy initiation among biologic-eligible adult patients with inadequately controlled CRSwNP despite receiving intranasal corticosteroids (INCS).

MATERIAL & METHODS

This retrospective study used US claims data among patients with CRSwNP from the Komodo Research Database Plus (2016–2024). The index date was defined as the date when patients became eligible for biologic treatment (dupilumab, omalizumab or mepolizumab). The study population comprised adults with ≥3 INCS dispensings within a 12-month period, evidence of uncontrolled symptoms (i.e. index date) after the third INCS dispensing, ≥12 months of continuous insurance enrolment pre-index and ≥1 diagnosis of nasal polyps and chronic rhinosinusitis before or on the index date. Excluded patients had ≥1 dispensing/administration of any biologic pre-index or ≥1 diagnosis of a condition for which biologics are indicated (other than CRSwNP) within ±30 days of index. Demographics and clinical characteristics were described on the index date or during the 12 months pre-index (baseline period). Cumulative incidence of biologic initiation was assessed during follow-up (from index to insurance disenrollment, end of data or death).

RESULTS

A total of 13,140 biologic-eligible patients with CRSwNP were identified. The mean patient age was 51.8 years, 38.6% were female and 75.3% were seen by an otolaryngologist on the index date. During baseline, 20.8% of patients had comorbid asthma and 13.6% underwent functional endoscopic sinus surgery. In the first year post index, 7.0% of biologic-eligible patients initiated biologic therapy, rising to 10.4% and 13.5% by the end of the second and third years, respectively.

CONCLUSIONS

Among biologic-eligible patients with CRSwNP in the US, biologics remain an underutilised treatment option, with the majority of patients never being escalated to biologics despite evidence of uncontrolled symptoms with INCS treatment.

OP-1087

Diode Laser Turbinoplasty, A Hustle-Free Technique For Inferior Turbinate Reduction.

Ahmed Elbaramawy[1]

[1]Alexandria University

BACKGROUND & AIM

Inferior turbinate hypertrophy is a common cause of chronic nasal obstruction and may require surgical intervention when conservative treatment fails. Various surgical techniques have been described, aiming to reduce turbinate size while preserving nasal function. This study aimed to compare the efficacy and safety of diode laser turbinoplasty with partial inferior turbinectomy in the management of hypertrophied inferior turbinates.

MATERIAL & METHODS

This prospective comparative clinical study included 30 patients suffering from symptomatic inferior turbinate hypertrophy refractory to medical treatment. Patients were randomly divided into two equal groups of 15 patients each. Group I underwent diode laser turbinoplasty, while Group II was treated with partial inferior turbinectomy. Patients were evaluated preoperatively and postoperatively using subjective assessment of nasal obstruction and clinical examination. Operative time, intraoperative bleeding, postoperative pain, crusting, and complications were recorded and compared between the two groups.

RESULTS

Both surgical techniques resulted in significant improvement in nasal obstruction. However, diode laser turbinoplasty demonstrated several advantages over partial inferior turbinectomy, including reduced intraoperative bleeding, shorter operative time, and minimal postoperative discomfort. Postoperative complications such as crusting and synechiae were less

frequent in the diode laser group. No major complications were reported in either group. Overall patient satisfaction was higher in the diode laser turbinoplasty group.

CONCLUSIONS

Diode laser turbinoplasty is a safe, effective, and minimally invasive surgical technique for the treatment of inferior turbinate hypertrophy, offering comparable or superior outcomes to partial inferior turbinectomy with fewer complications and improved patient comfort.

Integrated Multidisciplinary Biologic Therapy In Asthma And Chronic Rhinosinusitis With Nasal Polyps

Prabhsimran Kaur[1], **Prof- Nirmal Kumar**[1], **Imran Aziz**[1], **Stacey Grady**[1], **Kim Gaskell**[1]

[1]*WWI- Wrightington, Wigan and Leigh NHS Foundation Trust*

BACKGROUND & AIM

Asthma and Chronic rhinosinusitis with nasal polyps are closely related airway diseases driven by shared type 2 inflammatory pathways, characterised by overlapping cellular and cytokine profiles. These conditions frequently coexist and are associated with significant morbidity, impaired quality of life, and increased healthcare utilisation. Biologic therapies targeting key mediators of type 2 inflammation have emerged as effective treatment options in refractory disease, demonstrating improvements in symptom control, reductions in exacerbation frequency, and decreased reliance on systemic corticosteroids and antibiotics.

MATERIAL & METHODS

We report outcomes from a dedicated multidisciplinary “one-stop” clinic integrating respiratory and otolaryngology services. Within this model, patients with coexisting asthma and CRSwNP are jointly assessed and managed through a coordinated care pathway, with biologic therapy delivered in accordance with established severity-based guidelines and supported by longitudinal follow-up.

This retrospective cohort study included 41 adult patients with coexisting asthma and CRSwNP managed within a multidisciplinary respiratory ENT clinic. Patients were identified from clinic records and received biologic therapy based on disease severity and established eligibility criteria. Baseline data included demographics, asthma severity, and CRSwNP status. Outcome measures comprised asthma-related hospital admissions, exacerbation frequency, systemic corticosteroid and antibiotic use, and patient-reported nasal symptoms. Pre- and post-treatment outcomes were analysed descriptively.

RESULTS

Biologic therapy (including omalizumab, mepolizumab, dupilumab, benralizumab, and tezepelumab) was associated with a reduction in exacerbation frequency of up to 60%, with reductions of up to 70% observed with mepolizumab. Hospital admissions decreased by up to 90%, and corticosteroid use was reduced by 55–66%, with 30–40% of patients achieving complete cessation of exacerbations. A reduction in clinic presentations for CRSwNP was also observed, with no revision surgeries required in this cohort. Sustained clinical benefit was demonstrated on long-term follow-up of up to seven years, and switching between biologic agents was associated with improved outcomes in selected patients.

CONCLUSIONS

Biologic therapy confers sustained, real-world clinical benefit in severe asthma and CRSwNP, supporting the role of an integrated multidisciplinary, phenotype-driven management approach.

OP-1089

Clinical, Radiological, And Pathological Evaluation Of Unilateral Sinonasal Masses: A Retrospective Analysis Of Predictors For Inverted Papilloma And Malignancy

Onur Büyükkoç[2], **Merih Yalçıner**[1]

[1]*Kocaeli City Hospital, Kocaeli/Türkiye;* [2]*Bilkent City Hospital, Ankara/Türkiye*

BACKGROUND & AIM

Unilateral sinonasal masses present a diagnostic challenge because nonspecific symptoms mimic chronic rhinosinusitis, and delayed identification of inverted papilloma (IP) or malignancy may compromise outcomes. We evaluated clinical, anatomical, and preoperative diagnostic predictors of IP and malignancy in surgical patients with unilateral sinonasal masses.

MATERIAL & METHODS

Retrospective cohort of 143 patients operated at a tertiary center. Final excisional pathology was classified as benign, inverted papilloma (IP), or malignant; three pairwise comparisons were performed (malignant vs. benign, IP vs. benign, IP vs. malignant). Age was compared by Mann–Whitney U test and categorical variables by Chi-square or Fisher's exact test. Diagnostic performance of preoperative biopsy, magnetic resonance imaging (MR), and computed tomography (CT) was calculated within the subset of patients in whom each modality was performed, using sensitivity, specificity, predictive values, and Cohen's kappa.

RESULTS

Final pathology: 113 benign (79.0%), 25 IP (17.5%), and 5 malignant (3.5%). Age increased progressively (benign 44.9±15.6, IP 52.9±10.1, malignant 54.6±15.5 years; Kruskal–Wallis p=0.021). Mean involved sinonasal subsites were higher in IP (3.00) than benign (2.12; p=0.013). IP was associated with sphenoid (p=0.007), posterior ethmoid (p=0.017), and frontal sinus involvement (p=0.026). For malignancy detection: CT (n=143) 40.0% sensitivity/100% specificity; MR (n=70) 80.0%/94.3%; preoperative biopsy (n=90) 100%/100%. For IP detection: CT 20.0%/86.7%; MR 50.0%/96.2%; biopsy 86.7%/85.7%. Three-category agreement of biopsy with final pathology was substantial (κ=0.681); MR–CT agreement was poor (κ=0.12).

CONCLUSIONS

Diagnostic performance differs sharply by target pathology. For malignancy, preoperative biopsy and MR perform reliably. For IP, however, no single preoperative modality is sufficient: CT misses approximately four of five, MR misses half, and even preoperative biopsy misses approximately one in seven. Because IP carries a risk of malignant transformation, this residual diagnostic gap is clinically relevant - a benign biopsy in a patient with IP-suspicious features still leaves a meaningful possibility of an undiagnosed malignancy. Clinical features identified in this study have the potential to aid the decision to proceed to complete surgical excision in suspected IP, regardless of biopsy or imaging findings.

Computed Tomography Evaluation Of Nasal And Maxillofacial Anatomy In Nasal Obstruction Surgery

Devrim Bektaş[1], **Yonca Çoluk**[1], **Muhammed İrfan Şenocak**[1], **Alptekin Tosun**[2]

[1]*Department of Otorhinolaryngology, Giresun University Faculty of Medicine, Giresun, Türkiye;* [2]*Department of Radiology, Trabzon University Faculty of Medicine, Trabzon, Türkiye*

BACKGROUND & AIM

Anatomical variations of the nasal cavity and maxillofacial structures may contribute to chronic nasal obstruction and influence surgical indications. This study aimed to compare radiological anatomical parameters among patients undergoing septoplasty, inferior turbinate radiofrequency ablation, and healthy controls, and to evaluate whether these differences may contribute to chronic nasal obstruction and indications for surgery.

MATERIAL & METHODS

This retrospective study included 240 patients evaluated between September 2023 and February 2024. Group 1 consisted of 80 patients who underwent septoplasty, Group 2 included 80 patients who underwent inferior turbinate radiofrequency ablation, and Group 3 consisted of 80 age-matched controls who underwent computed tomography (CT) imaging for non-rhinologic indications and had no history of nasal surgery or sinonasal pathology. CT measurements were performed by a single radiologist. Nasal floor dimensions, maxillary angles, palatal morphology, apertura piriformis dimensions, internal nasal valve (INV) angles, and inferior turbinate areas were analyzed. Statistical analyses were performed using SPSS version 25.0, and $p<0.05$ was considered statistically significant.

RESULTS

Demographic characteristics were comparable among the groups, with no significant differences in age or sex distribution. Compared with controls, the septoplasty group demonstrated significantly narrower anterior and middle maxillary angles ($p=0.001$ and $p<0.001$), reduced palatal width and arch height ($p<0.001$), and narrower apertura piriformis width ($p=0.006$). Bilateral INV angles were significantly wider in the septoplasty group ($p<0.001$). Patients undergoing inferior turbinate

radiofrequency ablation also exhibited significantly narrower anterior and middle maxillary angles (p<0.001 and p=0.008), reduced anterior nasal floor dimensions (p=0.007), and greater inferior turbinate areas compared with controls (p=0.006). Direct comparison between surgical groups revealed greater palatal arch height and wider total INV area in the septoplasty group (p<0.05).

CONCLUSIONS

Patients requiring septoplasty or inferior turbinate surgery demonstrate distinct radiological anatomical differences compared with healthy controls. Patients with narrower maxillary angles, higher palatal arches, and narrower pyriform aperture dimensions may have a greater need for nasal obstruction surgeries such as septoplasty and inferior turbinate radiofrequency ablation compared with the general population. Preoperative radiological evaluation may improve patient selection and surgical planning.

The Great Escape: When Cerebrospinal Fluid Finds A Clival Exit

Nadine El Hadi[1]

[1]*Lebanese American University Medical Center - Rizk Hospital (LAUMC-RH)*

BACKGROUND & AIM

Spontaneous cerebrospinal fluid (CSF) fistulas are uncommon, and those localized to the clivus are exceedingly rare. Since 1980, only 26 such cases have been documented in the literature. We present two new cases of spontaneous clival CSF fistulas, detailing their clinical presentation, radiographic findings, and successful endoscopic management, alongside a comprehensive literature review.

MATERIAL & METHODS

Case #1: A 67-year-old female presented with a one-year history of spontaneous right-sided clear rhinorrhea, headaches, and a persistent salty taste. Imaging identified a 6mm clival defect associated with a small meningocele. She underwent a successful endoscopic transsphenoidal repair using a meticulous multilayer technique involving temporalis fascia and abdominal fat.

· Case #2: A 60-year-old male with a history of recurrent meningitis presented with left-sided rhinorrhea. CT metrizamide confirmed a clival defect with active CSF seepage. The defect was repaired endoscopically using a composite fat plug, temporalis fascia onlay, and a secondary fat layer.

· Outcome: Both patients remain asymptomatic with no recurrence at long-term follow-up.

RESULTS

The pathophysiology of spontaneous CSF fistulas hinges on a triad: a bony defect, a dural tear, and a pressure gradient. Clival defects specifically may arise from sphenoid sinus hyperpneumatization, persistent embryological remnants, or reduced bone density (e.g., postmenopausal osteoporosis). Furthermore, Idiopathic Intracranial Hypertension (IIH) is a significant contributor; clinicians should look for radiographic hallmarks such as an empty sella or arachnoid pits.

The Endoscopic Endonasal Transsphenoidal (EET) approach has become the gold standard for management. Successful closure requires multilayer reconstruction—often utilizing free grafts or vascularized pedicled flaps. Crucially, addressing underlying intracranial pressure (ICP) is vital to prevent postoperative failure and recurrence.

CONCLUSIONS

: Spontaneous clival CSF leaks are rare but potentially life-threatening conditions that demand a high index of clinical suspicion. Given the anatomical complexity of the clivus, successful management requires advanced surgical expertise and a multidisciplinary approach to both the repair and the management of underlying intracranial hypertension.

OP-1092

Beyond Trials: Real-Life Biologic Outcomes In Severe Crswnp From An ENT-Led Cohort

Jessica Santillan Coello[1], **Virginia Vasallo Garcia**[1], **Alvaro Sánchez Barrueco**[1], **Gonzalo Díaz Tapia**[1], **Luz Lopez Florez**[1], **Ignacio Alcala Rueda**[1], **José Miguel Villacampa Aubá**[1]

[1]*Fundacion Jimenez Diaz University Hospital, Madrid, Spain*

BACKGROUND & AIM

Biologic therapies have transformed the management of severe chronic rhinosinusitis with nasal polyps (CRSwNP). However, real-life data are essential to evaluate effectiveness, disease control and safety outside clinical trials. Since July 2024, biologics have been prescribed from the ENT Department at our centre for selected patients with severe CRSwNP. This study aimed to assess 6- and 12-month outcomes and to explore potential differences between biologic treatments in our cohort.

MATERIAL & METHODS

We conducted a retrospective observational single-centre study of patients with severe CRSwNP treated with biologics. Demographic data, comorbidities, biologic prescribed, baseline disease burden and follow-up outcomes were collected. Outcomes included nasal obstruction, smell impairment and global severity assessed by visual analogue scale (VAS), Sinonasal Outcome Test-22 (SNOT-22), University of Pennsylvania Smell Identification Test (UPSIT), Asthma Control Test (ACT), total nasal polyp score (NPS), blood eosinophil count, adverse events, systemic corticosteroid use, surgery, biologic switch and disease control according to EUFOREA 2023 criteria. Paired comparisons used the Wilcoxon signed-rank test. Exploratory comparisons between dupilumab and mepolizumab used the Mann–Whitney U test and Fisher's exact test.

RESULTS

Thirty-four patients were included, with equal sex distribution. Dupilumab was prescribed in 16 patients, mepolizumab in 15 and tezepelumab in 3. Asthma was present in 30 patients (88.2%) and aspirin-exacerbated respiratory disease in 18 (52.9%). At 6 months, significant improvements were observed in all analysed outcomes: VAS obstruction improved by 4.03 points, VAS smell by 3.18, VAS global severity by 4.24, SNOT-22 by 37.25, UPSIT by 6.67, ACT by 4.22, total NPS by 1.91 and blood eosinophils by 299 cells/µL; all p values ranged from 0.008 to <0.001. Good or excellent EUFOREA control was achieved in 24 patients (72.7%). At 12 months, significant improvement persisted in VAS scores, SNOT-22, UPSIT, total NPS and blood eosinophils, although paired data were available for fewer patients. Exploratory analysis suggested greater sinonasal improvement with dupilumab and greater eosinophil reduction with mepolizumab.

CONCLUSIONS

In this real-life cohort, biologics provided significant clinical, endoscopic and quality-of-life improvement in severe CRSwNP. Comparative findings should be considered exploratory and do not establish treatment superiority.

Role Of Inferior Turbinoplasty In Endoscopic Sinus Surgery

Suliman Ali[1], **Avenie Mavadia**[1], **Alf Cuddeford**[1], **Zahra Mubaarak**[1], **Yadsan Devabalan**[1], **Chuanyu Gao**[1], **Remo Accorona**[2], **Haissan Iftikhar**[1]

[1]*Department of Otolaryngology, Northampton General Hospital NHS Trust, Northampton, United Kingdom;* [2]*Department of Otolaryngology, Azienda Socio Sanitaria Territoriale (ASST) Grande Ospedale Metropolitano Niguarda, Milan, Italy*

BACKGROUND & AIM

Functional endoscopic sinus surgery (FESS) is the gold standard surgical treatment for chronic rhinosinusitis (CRS). Inferior turbinate hypertrophy commonly coexists in CRS and contributes significantly to nasal obstruction, leading many surgeons to perform concurrent inferior turbinoplasty to improve airflow and postoperative outcomes. However, the additional benefit of turbinoplasty remains controversial, with concerns regarding complications and unclear impact on quality of life and olfactory function. Given the lack of consensus and heterogeneity in existing studies, this systematic review aimed to evaluate the clinical outcomes of FESS performed with versus without inferior turbinoplasty.

MATERIAL & METHODS

A systematic review was conducted in accordance with Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. A comprehensive literature search of MEDLINE, Embase, and Cochrane databases was performed to identify studies comparing FESS with and without inferior turbinoplasty. Studies were screened independently by two reviewers using predefined inclusion and exclusion criteria. Eligible studies included those reporting clinical outcomes such as quality of life (QoL), olfactory function, and readmission rates.

Data extraction was performed using a standardised form, and study quality was assessed using validated risk of bias tools. The primary outcomes assessed were postoperative QoL, olfactory outcomes, and surgical safety. Five studies comprising 4,619 patients met the inclusion criteria, including randomised controlled trials and cohort studies, allowing evaluation of both adult and paediatric populations undergoing FESS with or without concurrent turbinoplasty.

RESULTS

Five studies involving 4,619 patients were included in the analysis. All studies demonstrated significant postoperative improvement in QoL following FESS, regardless of whether inferior turbinoplasty was performed. However, only one study demonstrated a statistically significant additional QoL benefit with concurrent turbinoplasty, while the remaining studies found no clinically meaningful difference between groups.

Olfactory outcomes assessed in one study showed no significant improvement with the addition of turbinoplasty. Subgroup analysis suggested patients with chronic rhinosinusitis with nasal polyps may derive greater benefit from concurrent turbinoplasty, particularly in improving nasal obstruction symptoms. Importantly, turbinoplasty was not associated with increased complication rates or higher paediatric readmission risk, supporting its safety profile.

These findings highlight that while turbinoplasty is safe, its routine addition does not consistently provide superior clinical outcomes compared to FESS alone.

CONCLUSIONS

Concurrent inferior turbinoplasty during FESS appears safe and may provide additional benefit in select patient subgroups, particularly those with nasal polyps or significant turbinate hypertrophy. However, routine addition does not consistently improve quality of life or olfactory outcomes. These findings support a selective, individualised approach to performing turbinoplasty rather than routine use. Further high-quality randomised controlled trials are required to better define patient selection criteria and clarify the role of turbinoplasty in optimising outcomes following endoscopic sinus surgery.

OP-1094

COMPARATIVE INFLAMMATORY ANALYSIS OF ANTROCHOANAL POLYPS AND CHRONIC RHINOSINUSITIS WITH NASAL POLYPS

YÜCE İSLAMOĞLU[1], **MEHMET EMİN AK**[1], **TİLBE NUR TOPTAŞ**[1]

[1]*ANKARA BİLKENT CITY HOSPITAL*

BACKGROUND & AIM

Chronic rhinosinusitis with nasal polyps (CRSwNP) is a chronic inflammatory sinonasal disorder associated with persistent eosinophilic and neutrophilic mucosal activation. In contrast, antrochoanal polyp (ACP) is generally considered a solitary benign lesion; however, whether ACP shares a similar systemic inflammatory background remains unclear. Hematologic inflammatory biomarkers derived from routine complete blood count, particularly systemic immune-inflammation index (SII) and eosinophil/neutrophil (E/N) ratio, may provide low-cost information regarding inflammatory burden and eosinophilic predominance. We hypothesized that these markers could differentiate ACP from CRSwNP and contribute to understanding their inflammatory etiopathogenesis

MATERIAL & METHODS

In this retrospective case-control study, 50 ACP patients, 50 CRSwNP patients, and 50 septoplasty patients without inflammatory sinonasal disease were included as controls. Preoperative neutrophil, lymphocyte, platelet, and eosinophil counts were recorded. SII was calculated as platelet x neutrophil/lymphocyte, and E/N ratio as eosinophil/neutrophil. Intergroup comparisons were performed using one-way ANOVA or Kruskal-Wallis test with post hoc analyses. Receiver operating characteristic analysis was used to evaluate the diagnostic performance of both parameters.

RESULTS

In this study, when eosinophil/neutrophil ratios were compared, the ratio was found to be significantly higher in patients with chronic rhinosinusitis with nasal polyps than in patients with antrochoanal polyps ($p < 0.001$). The eosinophil/neutrophil ratio in patients with chronic rhinosinusitis with nasal polyps was 1.8-fold higher than in patients with antrochoanal polyps and 2.2-fold higher than in healthy septoplasty controls. Regarding the systemic inflammatory index, a significant increase was observed in both patients with antrochoanal polyps and those with chronic rhinosinusitis with nasal polyps ($p = 0.003$).

CONCLUSIONS

The results demonstrate that both antrochoanal polyps and chronic rhinosinusitis with nasal polyps increase the inflammatory response. However, antrochoanal polyps appear to develop with a relatively lower inflammatory burden. These findings suggest that inflammation in antrochoanal polyps may be associated mainly with local mucosal factors, whereas systemic inflammatory processes may play a greater role in chronic rhinosinusitis with nasal polyps. Accordingly, local therapeutic approaches may be prioritized in antrochoanal polyps, while treatment strategies targeting systemic inflammation should be considered more prominently in chronic rhinosinusitis with nasal polyps.

OP-1095

EVALUATION OF ORBITAL AND CENTRAL COMPLICATIONS IN PATIENTS WITH SINUSITIS: A RETROSPECTIVE ANALYSIS

Elif Köse[1], **Behram Kılıç**[1], **Aslı Şahin Yılmaz**[1]

[1]*University of Health Sciences, Kartal Dr. Lütfi Kırdar City Hospital*

BACKGROUND & AIM

Sinusitis-related orbital and central nervous system (CNS) complications are rare but potentially life-threatening conditions requiring rapid diagnosis and multidisciplinary management. To describe the clinical profile, complication patterns, inflammatory markers, intensive care unit (ICU) requirements, and surgical outcomes in patients with sinusitis complications, and to compare orbital versus central involvement and pediatric versus adult populations.

MATERIAL & METHODS

A single-center retrospective analysis of 41 consecutive patients admitted with sinusitis complications confirmed by CT or MRI imaging. Continuous variables were compared using the Mann–Whitney U test; categorical variables were compared using Fisher's exact test. To evaluate frontal sinus involvement as a predictor of central complications, Firth's penalized logistic regression was applied given the small number of outcome events (n = 5). Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were calculated with exact 95% confidence intervals using the Clopper–Pearson method.

RESULTS

Mean age was 25.2 years; 61% were male. Orbital complications occurred in 39 patients (95.1%) and central complications in 5 (12.2%), with 3 patients having concurrent involvement. The mean Lund-Mackay score was 12.2 ± 4.9. C-reactive protein (CRP) was the only parameter to differ significantly between orbital and central groups (89.6 vs. 234.0 mg/L; p = 0.004). Three patients (60.0%) in the central complication group required ICU admission, whereas no patient in the orbital group required ICU care (p = 0.001). Frontal sinus involvement was identified as a clinically relevant predictor of central extension, present in 80% of patients with central complications versus 33% of those without (OR 8.0, p = 0.066). A negative predictive value of 96% suggests that absence of frontal disease may serve as a useful reassurance marker in clinical practice. All patients recovered (mortality 0%).

CONCLUSIONS

Markedly elevated CRP should prompt urgent neuroimaging to exclude intracranial extension. ICU admission was exclusive to the central complication group, underscoring the need for early neurosurgical consultation and multidisciplinary coordination in these patients. A negative predictive value of 96% suggests that absence of frontal disease may serve as a useful reassurance marker in clinical practice. These hypothesis-generating findings highlight the need for multicenter collaboration to validate frontal sinus involvement as a predictor of central complications in rhinosinusitis.

Association Between Mode Of Delivery And Nasal Septal Deviation Morphology In Children And Adolescents: A Retrospective Analysis Based On Mladina Classification And Caudal Septal Deviation Grading

Erkan Tezcan, MD, Otorhinolaryngology Specialist[1], **Melisa İlayda Kalkan, MD, Otorhinolaryngology Resident**[1], **Latif Emre Özdemir, MD, Otorhinolaryngology Resident**[1]

[1]*Department of Otorhinolaryngology Head and Neck Surgery, Antalya City Hospital*

BACKGROUND & AIM

Nasal septal deviation is a multifactorial condition influenced by developmental, hereditary, traumatic, intrauterine, and perinatal factors. Mechanical forces during vaginal delivery may affect the anterior cartilaginous septum and caudal septal segment; however, their relationship with later septal morphology remains unclear. This study aimed to evaluate the association between delivery mode and septal deviation morphology in children and adolescents with clinically diagnosed nasal septal deviation, and to investigate whether the post-2015 increase in cesarean delivery rates was accompanied by changes in Mladina deviation patterns or caudal septal deviation severity.

MATERIAL & METHODS

This retrospective observational study included children and adolescents born between 2005 and 2026 who were evaluated at the Department of Otorhinolaryngology, Antalya City Hospital, between 2024 and 2026 and diagnosed with nasal septal deviation. Delivery mode was classified as vaginal delivery or cesarean section. Data on sex, birth-year cohort, Mladina septal deviation type, caudal septal deviation grade, and nasal trauma history were recorded. Patients with known nasal trauma were excluded from the primary trauma-free analysis. Mladina types 1–2 were grouped as anterior/trauma-associated patterns, types 3–4 as intermediate, types 5–6 as developmental/horizontal, and type 7 as combined deformity. Caudal septal deviation was graded using the İşlek–Ciğer classification. Categorical variables were compared using appropriate tests, and adjusted binary logistic regression was performed.

RESULTS

The primary trauma-free cohort included 387 patients: 182 in the vaginal delivery group and 205 in the cesarean section group. Female sex was observed in 43.4% of the vaginal delivery group and 52.2% of the cesarean section group. Mladina classification data were available for 411 patients, and caudal septal deviation grading for 119 patients. Delivery mode distribution differed significantly across birth-year cohorts (p=0.0136), indicating a temporal change in obstetric practice; however, no significant temporal trend was observed in Mladina type distribution or caudal septal deviation severity. Vaginal delivery was associated with lower odds of anterior/trauma-associated Mladina type 1–2 deviations compared with cesarean section (OR=0.575, 95% CI: 0.335–0.986, p=0.0445), remaining significant after adjustment for sex and birth cohort (adjusted OR=0.566, p=0.0414). CSD severity was not associated with delivery mode.

CONCLUSIONS

In children and adolescents with nasal septal deviation, delivery mode showed a weak but statistically significant association with anterior/trauma-associated Mladina type 1–2 patterns. Contrary to the initial mechanical stress hypothesis, vaginal delivery was associated with lower, rather than higher, odds of these deviations. Although delivery mode distribution changed significantly across birth-year cohorts, this temporal shift was not accompanied by measurable changes in Mladina patterns or caudal septal deviation severity. These findings support the multifactorial nature of septal morphology and suggest that delivery mode alone cannot explain septal deviation patterns.

Objective And Subjective Evaluation Of Olfactory Function In Patients With Glaucoma: A Cross-Sectional Case–Control Study Using Sniffin's Sticks And Assessment Of Self-Reported Olfactory Functioning (ASOF)

AHMET BAKİ[1], BERKAY GÜZEL[1], ADALET AŞKİN[1], FERİDE FIRAT[1], BİLGENUR AİŞEOĞLU[1], ELİF ERTAN BAYDEMİR[2], ÖZGÜR YİĞİT[1], MERVE KELEBEK[2]

[1]Başakşehir Çam and Sakura City Hospital, Department of Otorhinolaryngology, Istanbul, Türkiye; [2]Başakşehir Çam and Sakura City Hospital, Department of Ophthalmology, Istanbul, Türkiye

BACKGROUND & AIM

The aim of this study was to evaluate objective olfactory functions measured by the Sniffin' Sticks test, as well as Olfaction-Related Quality of Life (ORQ) and Subjective Rating of Olfactory Performance (SRP) scores reported by patients based on their own perception, in patients with glaucoma, and to investigate the relationship between these parameters.

MATERIAL & METHODS

This study included patients diagnosed with glaucoma and healthy control individuals matched for age and sex. Olfactory function was evaluated using the Sniffin' Sticks test. Subjective olfactory assessment was performed using the Assessment of Self-Reported Olfactory Functioning (ASOF) questionnaire, whose Turkish validity and reliability have been established. In the Sniffin' Sticks test, the total score normally consists of Threshold, Identification, and Discrimination components; however, only the Threshold and Identification components were included in the analysis. Statistical comparisons between groups and correlation analyses were performed.

RESULTS

A total of 50 patients with glaucoma and 50 age- and sex-matched healthy controls were included in the study. The mean total olfactory score (Threshold + Identification) was significantly lower in the glaucoma group (13.6 ± 2.3) compared to the control group (17.4 ± 1.7) ($p = 0.001$). Mean SRP scores were significantly higher in the glaucoma group (4.5 ± 0.7) than in controls (4.1 ± 0.7) ($p = 0.007$). Mean ORQ scores were 4.2 ± 1.2 in the glaucoma group and 4.9 ± 2.5 in the control group, with no statistically significant difference between groups ($p = 0.286$). Within the glaucoma group, correlation analysis demonstrated no significant association between SRP or ORQ scores and Sniffin' Sticks threshold, identification, or total scores (all $p > 0.05$).

CONCLUSIONS

Objective olfactory performance was reduced in patients with glaucoma, whereas subjective olfactory performance was not reduced and olfaction-related quality of life remained preserved. These findings suggest a dissociation between objective olfactory testing and patient perception in glaucoma.

OP-1098

Comparison Of HALP Score And Prognostic Nutritional Index In Patients With Antrochoanal Polyp

BENGİ ARSLAN[1], MEHMET EMİN AK[1], TİLBE NUR TOPTAŞ[1]

[1]ANKARA BİLKENT CITY HOSPITAL

BACKGROUND & AIM

Antrochoanal polyp (ACP) is a benign unilateral sinonasal lesion originating from the maxillary sinus; however, the contribution of systemic inflammatory and immunonutritional mechanisms to its pathogenesis remains unclear. The Hemoglobin, Albumin, Lymphocyte, and Platelet (HALP) score and Prognostic Nutritional Index (PNI) are novel biomarkers reflecting systemic inflammatory and immune status. We hypothesized that patients with ACP may exhibit altered HALP and PNI values compared to non-inflammatory septoplasty controls.

MATERIAL & METHODS

This retrospective case-control study included patients who underwent surgery for ACP and septal deviation between January 2020 and January 2026 at a tertiary referral center. Forty-seven patients with histopathologically confirmed ACP and fifty

septoplasty patients without sinonasal inflammatory disease were enrolled. Preoperative hemoglobin, albumin, lymphocyte, and platelet values were retrieved from hospital records. HALP score was calculated as hemoglobin × albumin × lymphocyte / platelet, and PNI as 10 × albumin + 0.005 × total lymphocyte count. Demographic data and laboratory indices were compared between groups. Statistical analyses were performed using independent samples t-test and Mann–Whitney U test according to data distribution. A p value <0.05 was considered statistically significant.

RESULTS

Mean HALP score was significantly lower in the ACP group than in the septoplasty group (5.34 ± 2.03 vs. 6.78 ± 1.84, p=0.00013). In contrast, mean PNI values were similar between the groups (463.84 ± 30.90 vs. 465.21 ± 24.26, p=0.809). The marked reduction in HALP score suggests an altered systemic inflammatory-immune balance in ACP patients, whereas the absence of significant difference in PNI indicates preserved overall nutritional status.

CONCLUSIONS

In patients who underwent ACP, HALP scores were found to be significantly lower compared to the control group that underwent septoplasty, while PNI values showed no significant difference. These findings suggest that ACP may be associated with mild systemic inflammatory changes rather than a pronounced immuno-nutritional disorder. It appears that HALP is a more sensitive biomarker than PNI in reflecting this relationship and may contribute to our understanding of the inflammatory background of ACP. Although ACP appears to be a localized disease, it affects subclinical systemic inflammation and immunity in the long term.

Modified Draf Iic Vs Draf III: A Retrospective Cohort Study Comparing Outcome In CRS Patients

Azin Tabari[1], **Mina Motasaddizarandy**[1], **Juan Carlos Hernaiz-Leonardo**[1], **Amin Javer**[1]

[1]*University of British Columbia, St' Paul Sinus Center*

BACKGROUND & AIM

Chronic rhinosinusitis (CRS) is a common inflammatory condition affecting approximately 11% of the global population, with substantial impacts on quality of life. Endoscopic frontal sinus surgery is often indicated for patients with recalcitrant CRS. While the Draf III procedure is a well-established approach for managing severe or bilateral disease, it carries a high complication and revision burden due to its extensive nature. In response, a less invasive technique, the modified Draf IIc, has been proposed. This approach consists of bilateral Draf IIb procedures with anterior superior nasal septum resection and preservation of the interfrontal sinus septum and frontal beak.

MATERIAL & METHODS

This retrospective cohort study included adult patients (≥18 years) with CRS who underwent revision frontal sinus surgery at a tertiary sinus center. Patients underwent either a modified Draf IIc or Draf III procedure, all performed by a single senior surgeon to ensure procedural consistency. Demographic, clinical and radiologic data were collected. To evaluate surgical outcomes at one year postoperatively, SNOT-22 scores, Sinonasal New Endoscopic Staging (SiNES) and the need for a revision surgery (minor in the office or major in the operating room) were assessed. Only patients with a minimum postoperative follow-up of three months were included in the analysis.

RESULTS

The initial analysis demonstrated that in the 36 patients that were analyzed (18 per group), both groups had similar sex distribution (10 M, 8 F), and comparable rates of biologics use (39%). The modified Draf IIc group was younger (mean age 58.4 vs. 63.9 years) and had higher rates of asthma (78% vs. 50%) with lower rates of chronic rhinosinusitis with nasal polyps (CRSwNP) (72% vs. 78%). At 1-year follow-up, the modified Draf IIc group had a lower revision rate compared to the Draf III group (5.6% vs 11.1%). Additionally, the mean SNOT-22 score was lower in the modified Draf IIc group (33.55 vs. 39.93).

CONCLUSIONS

These findings suggest that modified Draf IIc provides comparable or better outcomes than Draf III, despite being less invasive.

Practice Patterns Of Biologics Prescriptions And Surgery In Chronic Rhinosinusitis With Nasal Polyps

Dr. Saad Algahtani[1], **Dr. Firas K Almarri**[2], **Dr. Ghassan Alokby**[3], **Dr. Muteb Alanazi**[3], **Dr. Saad Alsaleh**[2]

[1]*King Saud Medical City;* [2]*King Saud University Hospital;* [3]*King Faisal Specialist Hospital*

BACKGROUND & AIM

Chronic rhinosinusitis with nasal polyps (CRSwNP) remains challenging to manage effectively, with high symptom recurrence rates and significant impacts on quality of life, prompting a need to evaluate the real-world use of biologics and optimize treatment strategies.

Our objective is to assess the real-world application and perspectives of American Rhinologic Society (ARS) members on biologic treatments and surgical interventions for CRSwNP, focusing on clinical practice patterns, adoption of biologics, and their impact on surgical practices.

MATERIAL & METHODS

A standardized questionnaire evaluated clinical practice patterns of biologics prescriptions and surgery in treating CRSwNP between July 2022 and August 2023. Data collected from 162 ARS members were analyzed.

RESULTS

Of 162 participants, a substantial majority (95.06%, n = 154) reported prescribing biologics in their practice. Notably, 45.45% (n = 70) found biologics easily accessible, although accessibility challenges remained for some. The impact of biologics on surgical practices was significant, with 36.36% (n = 56) observing a marked reduction in revision sinus surgeries. Among the participants, 47.16% (n = 71) agreed that aspirin-exacerbated respiratory disease (AERD) was the highest phenotype that tended to increase the possibility of biological treatment by more than 20%. Adopting Patient-Reported Outcome Measures (PROMs) was prevalent, with 57.79% (n = 89) utilizing them in patient management.

CONCLUSIONS

The study highlights the evolving landscape in managing CRSwNP, with a marked trend toward integrating biological treatments into clinical practice. It underscores the necessity for continued research, updates to clinical guidelines, and enhanced practitioner education to optimize treatment outcomes for CRSwNP patients.

Investigation Of The Time-Dependent Dissolution Of Corticosteroids In Nasal Irrigation

Sarah Bahoo[1], **Dr Soo Hee Jeong**[2], **Dr Raymond Kim**[1], **Dr Kristi Biswas**[1], **Professor Malcolm Tingle**[2], **Professor Richard Douglas**[1]

[1]Department of Surgery, Faculty of Medical and Health Sciences, University of Auckland; [2]Department of Pharmacology & Clinical Pharmacology, Faculty of Medical and Health Sciences, University of Auckland

BACKGROUND & AIM

Chronic rhinosinusitis (CRS) is commonly treated with topical intranasal corticosteroid preparations. Large-volume saline irrigations containing corticosteroids are increasingly used to improve sinonasal drug distribution. However, this practice remains off-label, and the dissolution kinetics of corticosteroids in saline irrigation have been little studied. This study aimed to quantify the dissolution characteristics of commonly used intranasal corticosteroid formulations in large-volume saline irrigation systems under clinically relevant preparation conditions.

MATERIAL & METHODS

Budesonide, fluticasone propionate and mometasone furoate were prepared in 240 mL NeilMed Sinus Rinse bottles using a range of formulations including commercial nasal sprays, budesonide nebuliser ampoules, pure powder and compounded capsule formulations (with mannitol, xylitol and poloxamer 407 added as solubilising excipients in the capsule). Rinse bottles were shaken for 30 seconds to simulate patient preparation. Aliquots were sampled from the top and bottom of the bottle at 0, 2, 10, and 30 minutes, and immediately quenched in organic solvent to arrest further dissolution of the drug. Drug concentrations and distribution uniformity were quantified using validated HPLC-UV assays.

RESULTS

Across all corticosteroids, concentration recovery and within-bottle distribution were formulation-dependent. Commercial spray and ampoule preparations achieved concentrations approximating theoretical dosing but demonstrated suspension behaviour, with progressive bottom-layer concentrations exceeding top-layer concentrations over time, particularly for less soluble agents (fluticasone propionate and mometasone furoate). Budesonide spray demonstrated persistent bottom>top differences (all $p<0.05$). Fluticasone and mometasone sprays demonstrated progressive settling, with significant top-bottom differences at 10 and 30 minutes. Pure powder preparations demonstrated variable and inconsistent recovery, reflecting limited dissolution in saline. In contrast, compounded capsule formulations for budesonide and fluticasone propionate consistently achieved only ~70% of the expected concentration across all time points, with no time-dependent improvement, suggesting incomplete drug recovery rather than delayed dissolution.

CONCLUSIONS

This study presents the first systematic evaluation of formulation-dependent corticosteroid performance in large-volume saline irrigation systems. Intranasal sprays and budesonide ampoules most closely approximated theoretical dosing, delivering consistent and clinically reliable concentrations when adequately mixed and used promptly. Intranasal sprays represent the most affordable and accessible option in many settings and demonstrated reliable dissolution, supporting their recommendation in clinical practice. Compounded capsule formulations demonstrated consistently reduced drug recovery, indicating incomplete delivery and potential underdosing. These findings highlight the importance of formulation selection in optimising corticosteroid irrigation for CRS management.

High-Volume Budesonide Irrigation After Systemic Steroids In Non-Operated Crswnp: A Randomized Controlled Trial

Marco Aurélio Fornazieri[1], **Natália Medeiros Dias Lopes**[1], **Ellen Cristine Duarte Garcia**[1], **Lisandra Cardoso Bueno**[1], **João Paulo Bispo Gonçalves**[1], **Thiago Freire Pinto Bezerra**[3], **Fábio de Rezende Pinna**[4], **Richard Louis Voegels**[4]

[1]*Londrina State University;* [2]*Pontifical Catholic University of Paraná;* [3]*Federal University of Pernambuco;* [4]*University of São Paulo*

BACKGROUND & AIM

High-volume corticosteroid nasal irrigation has demonstrated benefits in postoperative chronic rhinosinusitis with nasal polyps (CRSwNP), but evidence in non-operated patients is limited. We hypothesized that adding high-volume budesonide irrigation to standard therapy after systemic corticosteroids would improve clinical outcomes and reduce disease severity in non-operated CRSwNP.

MATERIAL & METHODS

This was a double-blind, randomized, placebo-controlled trial conducted in adults with CRSwNP. Thirty-four patients were enrolled in tertiary care centers and randomized to receive high-volume saline irrigation with budesonide (2 mg/day) or placebo for 8 weeks. All participants received baseline intramuscular betamethasone and intranasal budesonide spray. The primary outcome was change in nasal polyp score (NPS). Secondary outcomes included olfactory function assessed by the University of Pennsylvania Smell Identification Test (UPSIT), symptom severity using the Sino-Nasal Outcome Test-22 (SNOT-22) and visual analogue scale (VAS), nasal airflow measured by peak nasal inspiratory flow (PNIF), and need for surgery. Data were analyzed using mixed-effects models for repeated measures.

RESULTS

Thirty patients completed the study (placebo n=16; budesonide n=14). Both groups showed improvement in NPS, with no significant difference between treatments (p=0.22). Olfactory function improved significantly in the placebo group compared to the budesonide group (mean difference 7.9 points; p=0.003). SNOT-22, VAS, and PNIF improved modestly in both groups without significant between-group differences. Most patients remained candidates for surgery, with no difference between groups (p=0.20). No adverse events were observed.

CONCLUSIONS

In non-operated CRSwNP patients receiving systemic and topical corticosteroids, high-volume budesonide irrigation did not provide additional clinical benefit over saline irrigation. These findings suggest limited incremental value of corticosteroid irrigation in this setting.

[1]*King Abdulaziz Medical City, Riyadh, Saudi Arabia;* [2]*King Khalid University Hospital, Riyadh, Saudi Arabia;* [3]*Alhada Armed Forces Hospital, Alhada, Taif City, Saudi Arabia;* [4]*University of Jeddah, Jeddah City, Saudi Arabia;* [5]*Jazan University, Japan, Saudi Arabia;* [6]*King Saud bin Abdulaziz University for Health Sciences, Jeddah City, Saudi Arabia;* [7]*Qassim University, Qassim, Saudi Arabia;* [8]*Umm Al-Qura University, Mecca, Saudi Arabia;* [9]*Jaber Alahmad Hospital, Kuwait;* [10]*Tabuk University, Tabuk, Saudi Arabia;* [11]*King Saud Bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia*

BACKGROUND & AIM

The use of calcium hydroxyapatite (CaHA) for dorsal augmentation and structural support in nonsurgical rhinoplasty (NSR) is growing. CaHA is not enzymatically reversible like hyaluronic acid (HA), which raises safety concerns in the highly vascularized

nasal area. The purpose of this systematic review was to objectively assess existing clinical evidence on the effectiveness, patient satisfaction, complication rates, and methodological quality of trials evaluating CaHA in NSR.

MATERIAL & METHODS

A systematic review was performed following PRISMA guidelines and registered with PROSPERO. A comprehensive search was conducted on PubMed and Google Scholar for studies assessing nonsurgical rhinoplasty using calcium hydroxyapatite (CaHA) in adult patients. Eligible designs included randomized trials, cohort studies, and case series recording clinical outcomes or complications. Comparative studies were utilized for quantitative synthesis when applicable, whilst single-arm studies were integrated into qualitative analysis.

Two independent reviewer pairs conducted study screening and data extraction. Risk of bias was evaluated using the Methodological Index for Non-Randomized Studies (MINORS) and Modified Methodological Score (MMS) tools. Given the small number of studies and methodological heterogeneity, the data were predominantly synthesized narratively, and pooled complication estimates were interpreted with caution.

RESULTS

Out of 243 available records, three studies involving 93 patients fulfilled the inclusion criteria. Two were retrospective comparative studies, and one was a single-arm case series. Sample sizes were limited, and the follow-up periods ranged from 2 weeks to 14 months. Patient satisfaction was reported to range from 84% to 89%, with aesthetic longevity between 6 and 30 months where specified.

The majority of reported adverse effects were mild and transient, including edema, pain, hematoma, and filler displacement. Uncommon events such as infection and vascular compromise have been documented, although the reporting of injection technique, anatomical plane, and safety protocols has been inconsistent.

Limited quantitative comparison between CaHA and HA showed no statistically significant difference in overall complication rates; however, substantial methodological heterogeneity and small sample sizes limited interpretability. Overall, the evidence's certainty was low.

CONCLUSIONS

The existing literature on calcium hydroxyapatite in nonsurgical rhinoplasty is limited and methodologically weak. Despite existing research indicating positive short-term aesthetic outcomes and mostly mild complications, the evidence base remains limited, heterogeneous, and primarily retrospective. The clinical use of CaHA is increasing, yet it outpaces the strength of the available data. There is a notable lack of standardized outcome measures, consistent documentation of injection techniques, and comprehensive vascular safety reporting. High-quality prospective studies are urgently needed to better assess long-term efficacy and safety, thereby enhancing evidence-based guidelines.

Differentiating Neutrophils And Non-Neutrophils Crswnp In Chinese Children Using An Improved P2Pnet Cell Recognition System

Yang Han[1], **Chao Jia**[1], **Pengpeng Wang**[1], **Wentong Ge**[1], **Wenjing Liu**[1]

[1]*Beijing Children's Hospital, Capital Medical University*

BACKGROUND & AIM

Chronic rhinosinusitis with nasal polyps in children (CRSwNP) is highly heterogeneous, and standardized criteria for endotype classification are currently lacking. This study aimed to establish a pathology-based endotyping framework for pediatric CRSwNP using an improved P2PNet cell recognition system and to explore inflammation-driven mechanisms beyond conventional clinical phenotypes.

MATERIAL & METHODS

An improved P2PNet cell recognition system was developed and validated for automated quantification of inflammatory cells in histopathological sections of pediatric nasal mucosa and nasal polyps. Objective abnormal thresholds for eosinophils and neutrophils were determined. Pediatric CRSwNP patients were classified into neutrophilic and non-neutrophilic subtypes based on the neutrophil threshold. Clinical characteristics were compared, and proteomic analyses were performed to investigate underlying inflammatory mechanisms.

RESULTS

The improved P2PNet cell recognition system achieved a mean F1 score of 0.8916 for inflammatory cell detection, with strong consistency between system-derived quantification and ELISA validation. A neutrophil proportion >23.74% defined neutrophilic CRSwNP, whereas eosinophilic CRSwNP was characterized by an eosinophil proportion >15.03%. Hierarchical clustering analysis demonstrated that the Neu cluster exhibited superior diagnostic efficacy. Despite similar clinical features, neutrophilic CRSwNP exhibited endotype–phenotype dissociation, with upregulation of ITGAM, MPO, MMP9, FCGR3B, and

CYBB. Proteomic analysis revealed enrichment of neutrophil extracellular traps, IL-17 signaling, complement/coagulation cascades, phagosome function, and Staphylococcus aureus infection pathways.

CONCLUSIONS

This study developed and validated an improved P2PNet-based cell recognition system and identifies neutrophilic inflammation as a clinically occult but biologically distinct disease subtype. These findings highlight the limitations of phenotype-based assessment and support the relevance of neutrophil-driven mechanisms for precision diagnosis and individualized management in pediatric CRSwNP.

Evaluation Of Biofilm Layer With Nasal Swab And May-Grunwald Giemsa Staining In Patients Undergoing Adenoidectomy

Hatice sema başak[1], **Yunus Dursun**[1], **Aylin eryılmaz**[1]

[1]*Adnan Menderes University, Faculty of Medicine, Department of Otorhinolaryngology*

BACKGROUND & AIM

The aim of this study is to evaluate the presence of biofilms using May-Grunwald Giemsa (MGG) staining in pediatric patients indicated for adenoidectomy and to investigate the relationship between the biofilm layer (if present) and various clinical conditions.

MATERIAL & METHODS

This study was conducted prospectively at the Department of Otorhinolaryngology, Aydın Adnan Menderes University Faculty of Medicine. The patient group consisted of 152 patients aged between 2 and 15 years (males: 59.9%; females: 40.1%). Before the adenoidectomy procedure began, three nasal swab samples were taken from the middle portion of the bilateral inferior turbinates and the adenoid surface. The samples were smeared onto glass slides, air-dried, stained with MGG, and evaluated under 1000× magnification. The relationship between the presence or absence of a biofilm layer and clinical conditions such as the degree of adenoid hypertrophy, purulent discharge, snoring, frequent upper respiratory tract infections (URTI), acute otitis, otitis media with effusion (OME), nasal steroid use, enuresis, and attention deficit was statistically evaluated.

RESULTS

A statistically significant agreement was found between adenoid biofilm and right and/or left inferior turbinate biofilm ($P=0.012$). No significant relationship was found between the presence of purulent discharge and biofilm positivity ($P>0.05$). A significant difference was determined between the degree of adenoid hypertrophy and snoring, with snoring being more frequent in patients with 75–100% adenoid hypertrophy ($P<0.05$). No significant relationship was detected between recurrent ÜSYE, acute otitis, EOM, nasal steroid history, enuresis, and attention deficit and the presence of biofilm ($P>0.05$). Furthermore, no statistically significant difference was observed between adenoid hypertrophy and biofilm positivity.

CONCLUSIONS

The results of our study suggest that the evaluation of nasal swab samples stained with MGG for biofilm detection could be used in outpatient clinic conditions as an easy, applicable, and cost-effective method. Although no relationship was established between adenoid volume and biofilm presence, the coexistence of inferior turbinate and adenoid biofilms supports the concept of a shared microbial ecosystem in the upper respiratory tract mucosa. The fact that biofilms do not directly overlap with clinical findings such as URTI and otitis suggests that biofilms may be an independent factor in the maintenance of chronic inflammation.

OP-1106

Claiming The Storm: Macrolides As Biological Regulators In Chronic Rhinosinusitis

Nadine El Hadi[1]

[1]*Lebanese American University Medical Center - Rizk Hospital (LAUMC-RH)*

BACKGROUND & AIM

Since their initial application in Japan in 1997, long-term, low-dose macrolide therapies have revolutionized the management of Chronic Rhinosinusitis (CRS). While traditionally classified as antibiotics, their clinical efficacy in CRS is driven primarily by potent immunomodulatory and anti-inflammatory properties rather than direct antibacterial action.

MATERIAL & METHODS

This presentation provides a comprehensive literature review tracking the evolution of macrolide therapy. We analyze current evidence to delineate specific CRS phenotypes and endotypes that benefit most from this intervention, offering evidence-based recommendations for clinical practice.

RESULTS

The clinical expression of CRS is highly heterogeneous, shaped by geography, genetics, and environmental factors. While Type 2 (eosinophilic) inflammation predominates in Western populations, non-Type 2 (neutrophilic) inflammation is more prevalent in Asian cohorts. Historically, macrolides were favored for their ability to inhibit neutrophil-induced inflammation, making them the gold standard for non-Type 2 CRS with nasal polyps. However, recent data suggests broader utility: macrolides have demonstrated significant efficacy in persistent, post-surgical CRS across both polyp and non-polyp subgroups. Emerging evidence even indicates a potential for macrolides to modulate eosinophil levels, suggesting a promising role in achieving disease control for Type 2 CRS patients who were previously considered poor candidates for this therapy.

CONCLUSIONS

While macrolides remain a cornerstone for refractory, neutrophilic (non-Type 2) CRS, their therapeutic horizon is expanding. Recent outcomes suggest significant potential in treating eosinophilic (Type 2) CRSwNP and even refractory Aspirin-Exacerbated Respiratory Disease (AERD). As we move toward personalized rhinology, macrolides may offer a versatile, cost-effective tool for difficult-to-treat endotypes.

Eosinophil–Mast Cell Interaction Drives The Cytolytic Inflammatory Pattern In Chronic Rhinosinusitis With Nasal Polyps: A Histopathological Predictive Model

Paula Pérez-Chacón[1,4], **Hugo Lara-Sánchez**[4,1,2], **Juan José Tavarez**[1], **Jorge Freijanes-Otero**[1], **Mario S Almeida-Branco**[1], **Paula Bayo-Juanas**[3], **Pilar Isabel González-Márquez**[3], **Luis Ángel Vallejo-Valdezate**[1,4]

[1]Department of Otorhinolaryngology-Head and Neck Surgery, Rhinology Unit, Río Hortega University Hospital, Valladolid, Spain.; [2]Department of Otorhinolaryngology-Head and Neck Surgery. Segovia General Hospital, Segovia, Spain.; [3]Department of Anatomical Pathology. Rio Hortega University Hospital, Valladolid, Spain.; [4]Faculty of Medicine, University of Valladolid, Valladolid, Spain

BACKGROUND & AIM

Eosinophilic inflammation represents a central mechanism in chronic rhinosinusitis with nasal polyps (CRSwNP). However, the histopathological determinants of the eosinophilic cytolytic pattern and the potential contribution of mast cells remain insufficiently characterized. We aimed to investigate the relationship between inflammatory cell infiltration and eosinophilic cytolysis and to evaluate the diagnostic performance of a combined eosinophil–mast cell model.

MATERIAL & METHODS

A prospective histopathological analysis was conducted in 51 patients undergoing endoscopic sinus surgery for CRSwNP. The eosinophilic cytolytic pattern was dichotomized (0 = non-cytolytic; 1 = cytolytic/mixed). Associations between cytolysis and inflammatory markers were analyzed using non-parametric tests and multivariable logistic regression. Clinical variables including asthma, aspirin-exacerbated respiratory disease (AERD), and previous surgery were also evaluated. Discriminative capacity was assessed through receiver operating characteristic (ROC) analysis.

RESULTS

Eosinophil quantification was significantly higher in cytolytic cases ($p < 0.001$) and showed strong discriminatory performance (AUC 0.896). In multivariable analysis, both eosinophil burden (OR 1.07; 95% CI 1.02–1.13; $p = 0.011$) and mast cell infiltration (OR 1.46; 95% CI 1.03–2.06; $p = 0.035$) independently predicted cytolytic inflammation. The combined model demonstrated excellent discrimination (AUC 0.970; 95% CI 0.924–1.000; $p < 0.001$). Asthma, AERD, and reintervention were not independently associated with cytolysis.

CONCLUSIONS

Eosinophilic cytolysis in CRSwNP is primarily driven by quantitative eosinophilic load and independently modulated by mast cell infiltration. A combined histopathological model achieves near-perfect discrimination, supporting refined inflammatory endotyping and advancing precision-based management strategies.

Bipolar Versus Monopolar Radiofrequency Reduction For Inferior Turbinate Hypertrophy: An Intra-Patient Comparison Of Clinical Efficacy And Complication Rates.

Prof Dr Suat Turgut[1], **Op Dr Dilara Tütüncü Yavuz**[1], **Dr İlayda Simay Rador**[1]

[1]sbü şişli hamidiye etfal eğitim ve araştıma hastanesi

BACKGROUND & AIM

Inferior turbinate hypertrophy is a common cause of nasal obstruction and may significantly reduce quality of life. Radiofrequency (RF) treatment is widely used, but direct comparisons between monopolar and bipolar techniques are limited. This study aimed to compare the clinical outcomes of monopolar and bipolar RF in the treatment of inferior turbinate hypertrophy.

MATERIAL & METHODS

This prospective observational study included adult patients with inferior turbinate hypertrophy who underwent RF treatment between May 2025 and June 2026. Patients were divided into two groups according to the RF technique used: monopolar RF (Group M) and bipolar RF (Group B). Clinical and endoscopic evaluations were performed preoperatively and at 1 week, 2 weeks, 1 month, 3 months, and 6 months postoperatively. Outcomes included NOSE and SNOT scores, postoperative crusting, mucosal healing, and patient satisfaction.

RESULTS

A total of 94 patients were included. Baseline demographic and clinical characteristics were similar between the groups. Both monopolar and bipolar RF significantly improved NOSE and SNOT scores compared with baseline ($p<0.001$). However, the bipolar RF group showed significantly earlier and greater improvement in symptom scores, particularly in the early postoperative period ($p<0.05$). Endoscopic examination demonstrated less crusting and faster mucosal healing in the bipolar group ($p<0.05$). Patient satisfaction was also significantly higher in patients treated with bipolar RF ($p<0.05$). Major complication rates were similar between groups.

CONCLUSIONS

Both monopolar and bipolar RF are safe and effective for inferior turbinate hypertrophy. However, bipolar RF appears to provide superior early postoperative recovery, with faster symptom relief, less crusting, and higher patient satisfaction

Quality Of Life In Patients With Septal Perforation After Surgical Treatment: Long-Term Outcomes Assessment.

Zhanna Mokoyan[1], **Yury Rusetsky**[2], **Valery Svistushkin**[1], **Anna Elumeeva**[2]

[1]*Sechenov University*; [2]*Central State Medical Academy*

BACKGROUND & AIM

Nasal septal perforation (NSP) significantly impacts quality of life (QoL), but no validated Russian-language instrument existed for comprehensive symptom assessment. This study aimed to translate, culturally adapt, and validate the SEPEQoL questionnaire for Russian-speaking populations.

MATERIAL & METHODS

Following ISPOR guidelines, the SEPEQoL was translated into Russian and administered to 30 NSP patients and 30 matched controls. Psychometric properties were evaluated, including internal consistency (Cronbach's α), test-retest reliability (intraclass correlation coefficient [ICC]), and discriminant validity. Surgical outcomes were assessed using validated SEPEQoL in patients undergoing endoscopic septal perforation repair with bilateral mucosal flaps and interposition cartilaginous graft.

RESULTS

The Russian SEPEQoL demonstrated excellent reliability ($\alpha = 0.985$, ICC = 0.98) and strong discriminant validity (21.6 ± 6.4 vs. 4.4 ± 3.9 in controls, $p < 0.01$). Postoperative scores improved dramatically ($\Delta = 15.4$ points, $d = 2.23$, $p < 0.001$), with 100% resolution of whistling ($\delta = 0.95$) and 94% improvement in crusting. Esthetic concerns showed minimal change ($\delta = 0.08$, $p = 0.32$), underscoring the need for adjunct rhinoplasty in select cases. Patient age, gender, and perforation size did not impact outcomes.

CONCLUSIONS

The Russian SEPEQoL is a valid, reliable tool that captures both functional and esthetic outcomes of NSP repair. Its implementation facilitates standardized outcome assessment and highlights persistent challenges in managing external nasal deformities.

BACKGROUND & AIM

Nasal Valve Dysfunction(NVD) contributes to persistent nasal obstruction. However, validated objective assessment is lacking. Rhinomanometry looping and Lateral Wall Insufficiency(LWI) grading have been proposed. This study sought to validate these measures against perceived obstruction and nasal airflow.

MATERIAL & METHODS

A cross-sectional study of preoperative patients with nasal obstruction was performed. NVD was assessed by presence of looping on active anterior rhinomanometry and LWI grading on endoscopy. The LWI grade was defined in both internal(zone 1) and external(zone 2) nasal valve. Collapse was defined as static or dynamic and graded(0-3) on the percentage of valve width to septum (0=normal; 1≤33%; 2=33-66%; 3≥66%). Validation was against a 100point-Visual Analog Scale(VAS), 6-point ordinal score of nasal obstruction, and nasal airway resistance(NAR) in Pa/cm^3/s.

RESULTS

305 patients were assessed (age35.4±14.5years, 44.3% female). Looping was associated with greater symptoms(VAS:73±26 v 54±31, p<0.01) and higher resistance(0.46[0.37–0.71] v 0.35[0.23–0.58]Pa/cm^3/s, p<0.01). The static LWI grade was associated with increasing symptoms(zone 1 VAS:50±32 v 50±33 v 65±27 v 75±24, p<0.01; zone 2 VAS: 53±31 v 69±31 v 72±27 v 82±22, p<0.01) and higher resistance (zone 1: 0.32[0.21–0.47] v 0.34[0.23–0.56] v 0.43[0.26–0.80] v 0.84[0.38–1.98]Pa/cm^3/s, p<0.01; zone 2:0.33[0.22–0.51] v 0.47 [0.32–0.83] v 0.54[0.40–0.92] v 1.52[0.95–12.3]Pa/cm^3/s, p<0.01). Similar associations were seen with dynamic LWI grades.

CONCLUSIONS

Looping and LWI score define greater symptoms and worse nasal airflow. The LWI is easily performed and along with prior intra/inter-test validation, makes it ideal for assessment of severity and impact of interventions for NVD.

CLINICAL AND PATHOGENETIC FEATURES OF CHRONIC TONSILLITIS ASSOCIATED WITH CHRONIC SINUSITIS

Mirzatillayeva M.A.[1], **Bakiyeva Sh.X.**[1]

[1]Tashkent State Medical University

BACKGROUND & AIM

Introduction: Chronic tonsillitis (CT) and chronic sinusitis (CS) are common chronic inflammatory diseases of the upper respiratory tract that frequently coexist and may aggravate each other's clinical course. As a result, chronic tonsillitis associated with chronic sinusitis tends to present with more severe and prolonged symptoms, making this combined pathology an important issue in modern otorhinolaryngology.

The purpose of the study: To evaluate the clinical manifestations and pathogenetic features of chronic tonsillitis associated with chronic sinusitis and to assess their interrelationship.

MATERIAL & METHODS

Material and research methods: A total of 30 patients aged between 18 and 65 years were enrolled in the study. Among them, 18 patients (60%) were female and 12 patients (40%) were male. The participants were divided into two equal groups: 15 patients (50%) were diagnosed with isolated chronic tonsillitis, while the remaining 15 patients (50%) had chronic tonsillitis associated with chronic sinusitis. According to the clinical classification of chronic tonsillitis, 11 patients (36.7%) presented with the toxic-allergic form, whereas 19 patients (63.3%) were diagnosed with the simple form of the disease.

All patients underwent a comprehensive clinical and laboratory examination. Pharyngoscopy was performed to assess the condition of the palatine tonsils and surrounding pharyngeal structures. The collected data were analyzed and expressed in numerical values and percentages.

RESULTS

Results Obtained: The findings of the study demonstrated that patients with chronic tonsillitis associated with chronic sinusitis exhibited a broader and more pronounced clinical symptom profile compared to those with isolated chronic tonsillitis. In the isolated chronic tonsillitis group, sore throat was present in all patients (100%), halitosis was observed in approximately 30% of cases, and general weakness was reported in about 50% of patients. In contrast, patients with combined chronic tonsillitis and chronic sinusitis showed a significant increase in both the frequency and severity of symptoms. Nasal obstruction and postnasal drip were reported in approximately 80% of patients in the combined group, representing a 70% increase compared

to the isolated tonsillitis group. Reflex cough associated with postnasal discharge occurred in approximately 78% of cases, reflecting a 70% increase. Halitosis was detected in around 50% of patients, which is 20% higher than in the isolated group.

CONCLUSIONS

Conclusion: Chronic tonsillitis associated with chronic sinusitis is characterized by a more severe and expanded clinical presentation compared to isolated chronic tonsillitis. In addition to typical tonsillar symptoms, rhino genic manifestations such as nasal obstruction, postnasal drip, facial pressure, and reflex cough are significantly more frequent. The combined pathology is associated with increased inflammatory activity and a higher probability of toxic-allergic forms, reflecting prolonged immune system involvement. These findings substantiate the necessity of comprehensive diagnostic evaluation and simultaneous management of both conditions in order to prevent complications and reduce recurrence rates.

Optimising Biopsy Yield In Sinonasal Lesions

Imon Dasgupta[1], **Safika Zaman**[2], **Pranamita Ray**[1], **Suman Das**[1], **Ranjan Raychowdhury**[1]

[1]*Ramakrishna Mission Seva Pratishthan Vivekananda Institute of Medical Sciences , Kolkata, India;* [2]*Malda Medical College, West Bengal, India*

BACKGROUND & AIM

3% of Head and Neck malignancies are sinonasal. The clinical presentation resembles inflammatory disease. Reactive polypoid change makes it difficult to obtain a representative biopsy. Management depends upon an accurate tissue diagnosis. In 2021 we found a 16% discrepancy between our nasal biopsies and final histopathology. This is similar to the figures in the scientific literature.

MATERIAL & METHODS

We discussed various routes of biopsy in our Joint Head and Neck Clinic: transnasal endoscopic, endoscopic inferior meatal, endoscopic middle meatal and sublabial anterior meatal. The best route was selected based on imaging, and multiple deep biopsies were obtained

RESULTS

In the period from January 2023 to December 2024 , 15 patients underwent biopsy for unilateral sinonasal mass. There was only one discrepancy (6.67%) between a biopsy and the final histopathology. Our agreement rate improved from 83.8% to 93.3%

CONCLUSIONS

In unilateral sinonasal mass biopsy techniques should be tailored to the extent of the disease and imaging to improve diagnostic accuracy, reducing delay in treatment.

Evaluating The Added Diagnostic Value Of MRI In Allergic Fungal Rhinosinusitis: A Retrospective Comparative Study

Dr. Saad Algahtani[1], **Dr. Sultan Alrubayyi**[1], **Dr. Abdulmalik Alkhudair**[1], **Dr. Maha Alshbiny**[1], **Dr. Abdulaziz Jambi**[1], **Dr. Ibrahim Alnofal**[1]

[1]*King Saud Medical City*

BACKGROUND & AIM

Allergic fungal rhinosinusitis (AFRS) is a non-invasive subtype of chronic rhinosinusitis characterized by intense inflammatory response, often associated with bony remodeling that may mimic orbital or intracranial extension on imaging. While computed tomography (CT) is the primary diagnostic modality, magnetic resonance imaging (MRI) is frequently recommended when complications are suspected. However, the clinical utility of routine MRI in AFRS remains uncertain. To evaluate the added diagnostic and surgical value of MRI compared to CT alone in the preoperative assessment of AFRS.

MATERIAL & METHODS

This retrospective cohort study included 21 patients diagnosed with AFRS at a tertiary care center between 2022 and 2024. Patients were divided into two groups: CT-only (n=11) and CT+MRI (n=10), all meeting established criteria for MRI. Preoperative imaging findings were compared with intraoperative findings during functional endoscopic sinus surgery (FESS). Primary outcomes included the detection of orbital or intracranial extension and the impact of MRI on surgical decision-making.

RESULTS

Radiologic findings from both CT and MRI suggested possible orbital or intracranial extension in all patients. However, intraoperative evaluation revealed no true extension in any case, with disease confined to the paranasal sinuses despite the presence of bony dehiscence. MRI did not provide additional diagnostic information beyond CT nor alter surgical management. Notably, patients undergoing MRI had a significantly longer preoperative follow-up period (p = 0.0083), indicating potential delays in care.

CONCLUSIONS

MRI did not demonstrate additional clinical or surgical value over CT in the evaluation of AFRS in this cohort. Routine use of MRI may be unnecessary when high-quality CT findings are available, and its selective use should be guided by clinical suspicion and ambiguous imaging findings to optimize resource utilization and patient care.

Stellate Ganglion Block With Lidocaine For The Treatment Of COVID-19-Induced Parosmia: Double-Blinded, Placebo-Controlled Randomized Clinical Trial. (STELLA)

Andrew Kokavec[1], **Mo Misurati**[2], **Geoff Bellingham**[2], **Lanette Friesen-Waldner**[1], **Leigh Sowerby**[1]

[1]Department of Otolaryngology - Head and Neck Surgery, Schulich School of Medicine and Dentistry, Western University, 1151 Richmond Street, London, ON, N6A 3K7, Canada.; [2]Department of Anesthesia and Perioperative Medicine, Schulich School of Medicine and Dentistry, Western University, 1151 Richmond Street, London, ON, N6A 3K7, Canada.

BACKGROUND & AIM

COVID-19-induced parosmia is estimated to affect 1.2 million people in the United States. Olfactory dysfunction impacts one's quality of life significantly and is an independent predictor of anxiety, depression, and even mortality. Studies prior to the COVID-19 pandemic have supported a beneficial effect of stellate ganglion blocks on olfactory dysfunction. This randomized clinical trial explores the efficacy and safety of ultrasound guided Stellate Ganglion Block (SGB), hypothesized to correct hyper-sympathetic activation associated with Long COVID.

MATERIAL & METHODS

This study was a prospective double-blinded, placebo-controlled, randomized clinical trial. Subjects were volunteers aged 18–70 with a COVID-19 diagnosis >= 6months prior. Of 44 planned participants, an interim analysis was performed on the first 23 randomized individuals (12 SGB; 10 placebo; 1 withdrawal). The primary outcome was improvement in parosmia-related quality of life via the Parosmia Olfactory Dysfunction Outcomes Rating (DisODOR) questionnaire (minimal clinically important difference (MCID) = 15) done pre-intervention and at 1, 3, and 12 months post. Secondary outcomes included other validated questionnaires including CGI-S, UPSIT, and HADS.

RESULTS

Median enrolment ages were similar. Majority of participants were female (83% in SGB and 100% in placebo). Compared to pre-intervention, DisODOR scores at one-month post-intervention decreased by a median of 7.0 (SGB) vs. 6.5 (placebo) [MD 0.5; 95% CI, -15.0 to 14.0]. At three months, scores decreased by 8.0 (SGB) vs. 12.5 (placebo) [MD -4.5; 95% CI, -21.0 to 14.5]. The response rate (reduction >= MCID) was 41.6% vs. 30.0% at one month [difference 11.7%; 95% CI, -26.7% to 48.3%], and 25.0% vs. 40.0% at three months [difference -15.0%; 95% CI, -53.3% to 23.3], for SGB and placebo, respectively. All other secondary outcome measures did not demonstrate a significant difference between groups. No serious adverse events were reported.

CONCLUSIONS

This RCT's interim analysis found that SGB is not superior to placebo in treating COVID-19 parosmia. However, both groups showed significant benefit from baseline, highlighting the need for further research into alternative mechanisms and future patient selection.

Surgery Of Sight-Threatening Graves' Orbitopathy

Tibor Szalóki[1], **Gábor Forgács**[1], **Katalin Korányi**[2], **Bernadett Salomváry**[3], **László Ujváry**[2], **Balázs Geiszelhardt**[2], **Nóra Tóth**[1]

[1]Department of Otorhinolaryngology, Head and Neck Surgery, Semmelweis University, Budapest, Hungary; [2]Department of Ophthalmology, Semmelweis University, Budapest, Hungary; [3]Clinic for Neurosurgery and Neurointervention, Semmelweis University, Budapest, Hungary

BACKGROUND & AIM

The orbit is a multidisciplinary surgical field, however orbital laesions are not very common. We have an orbital-team in our university since 2018 due to this fact.

MATERIAL & METHODS

We would like to present our surgical cases, operated with sight-threatening Graves' orbitopathy (GO) between 2018-2026. The two main indications for surgery were disthyroid optic neuropathy (DON) and corneal breakdown. All DON patients received high-dose methylprednisolon therapy first, in our center according to the European Group on Graves' orbitopathy (EUGOGO) clinical practice guidelines. Patients with corneal breakdown underwent urgent surgery

RESULTS

We have operated 52 balanced orbital decompressions in 31 patients. The early postoperative improvement in visual acuity was significant compared to the preoperative one and stayed stable in most patient during follow-up.

The medial orbital decompressions were done by the transnasal endoscopic way, the lateral wall decompressions via lateral orbitotomy.

CONCLUSIONS

However the orbit is a relatively small anatomical space, we think, multidisciplinarity is the only way to treat it's pathologies.

Systemic Inflammatory Indices And Patient-Reported Outcomes In Antrochoanal Polyps

ZUHAL AYBÜKE GAZELOĞLU[1], **SÜMEYRA DOLUOĞLU**[2], **EMRE APAYDIN**[3], **AHMET SERDAR ÖZDEMİR**[2], **MUHARREM DAĞLI**[2]

[1]*Department of Otorhinolaryngology, Sincan Training and Research Hospital, Ankara, Turkey;* [2]*Ankara Etlik City Hospital, Department of Otorhinolaryngology, Ankara, Turkey;* [3]*Otorhinolaryngology Private Practice, Ankara, Turkey*

BACKGROUND & AIM

Antrochoanal polyp (ACP) is a benign unilateral lesion originating from the maxillary sinus and extending into the choana. Although inflammatory mechanisms are thought to play a role in its pathogenesis, the clinical significance of systemic inflammatory markers remains unclear. This study aimed to compare preoperative Systemic Immune-Inflammation Index (SII) and Systemic Inflammatory Response Index (SIRI) values between pediatric and adult patients with ACP and to evaluate postoperative clinical outcomes using symptom-based questionnaires.

MATERIAL & METHODS

Patients who underwent surgery for ACP between January 2023 and December 2025 were retrospectively analyzed and categorized as pediatric (<18 years) or adult (≥18 years). Preoperative hemogram parameters were recorded and SII (P×N/L) and SIRI (N×M/L) were calculated. Pediatric patients were assessed using VAS and SN-5, while adult patients were evaluated using NOSE scores pre- and postoperatively. Non-parametric tests were used for statistical analysis.

RESULTS

A total of 47 patients were included (8 pediatric, 39 adult). Apart from age, demographic characteristics were similar between groups ($p>0.05$). Preoperative SII ($p=0.59$) and SIRI ($p=0.2$) values did not differ significantly between pediatric and adult patients.

In adult patients, NOSE scores showed a significant postoperative decrease ($p=0.0001$ This improvement remained significant within both low and high SII subgroups ($p=0.0001$ and $p=0.003$, respectively) and SIRI subgroups ($p=0.0001$ and $p=0.002$, respectively). However, percentage improvement in NOSE scores was not associated with SII ($p=0.643$) or SIRI levels ($p=0.275$). In pediatric patients, both VAS ($p=0.012$) and SN-5 ($p=0.017$) scores demonstrated significant postoperative improvement.

CONCLUSIONS

Surgical treatment of ACP resulted in significant symptomatic improvement in both pediatric and adult patients, as demonstrated by validated patient-reported outcome measures. Postoperative reductions in VAS and SN-5 scores in pediatric patients and NOSE scores in adults indicate substantial clinical benefit.

Preoperative SII and SIRI values were not associated with postoperative symptom improvement, which may partly reflect the relatively small sample size, particularly in the pediatric cohort. Nevertheless, patient-reported outcome measures consistently demonstrated meaningful clinical improvement and appear to be reliable indicators of surgical success in ACP.

The Relationship Between Septal Deviation Angle And Mandibular Retrognathia And Hyperdivergent Growth: A Radiological Cross-Sectional Analysis

Zuhal Zeybek Sivas[1], **Efe Can**[1], **Cemil Balaman**[1], **Fatmanur Sahin Akinci**[1]

[1]*Antalya City Hospital, Department of Otorhinolarygology Head and Neck Surgery*

BACKGROUND & AIM

Septal deviation is not merely a local variation causing intranasal airflow impairment but a common anatomical condition associated with craniofacial development. The Takahashi theory proposes that cranial base flexion may predispose to both septal deviation and alterations in mandibular growth, suggesting a shared developmental origin. However, studies examining the quantitative relationship between septal deviation angle (SDA), mandibular sagittal position, and vertical growth patterns are limited. This study tests the hypothesis that increased SDA is associated with mandibular retrognathia and hyperdivergent growth, and aims to evaluate correlations with SNB and SN-GoGn angles while comparing these features across severity groups.

MATERIAL & METHODS

This retrospective cross-sectional radiological study included 221 patients over the age of 18 who presented with complaints of nasal obstruction and underwent paranasal sinus CT. SDA was measured on coronal CT sections utilizing the Lee method relative to the crista galli-spina nasalis anterior reference line. NSD severity was classified according to the criteria of Naaem/Ramirez-Barrios(<9°, 9–14,9°, ≥15°) and Paula (<10°, ≥10°).SNB angle was used to evaluate mandibular sagittal position on lateral scout images and SN-GoGn angle was utilized to assess the vertical growth pattern. Retrognathia was defined as SNB<78°, and hyperdivergence was defined as SN-GoGn ≥32°. Pearson/Spearman correlation, linear regression, ANOVA with Bonferroni correction, Pearson's chi-square test and logistic regression (OR, 95% CI) analyses were performed.

RESULTS

This study included 221 patients:118 males (53.4%) and 103 females (46.6%).The overall mean age was 29.49 ± 6.80 years(range: 18–45).Mean age was 30.15 ± 6.92 years for males (18–44) and 28.73 ± 6.62 years for females(18–45).The mean SDA was 11.21 ± 3.35°,mean SNB 78.90 ± 1.58°,and mean SN-GoGn 32.96 ± 3.68°.A significant negative correlation was observed between SDA and SNB(Pearson r =−0.181,p = 0.007),while a strong positive correlation was found between SDA and SN-GoGn (Spearman r=+0.711, p < 0.001).The prevalence of retrognathia was 34.8%, and hyperdivergent growth was present in 54.3% of patients.According to the Paula classification,retrognathia was significantly more frequent in the severe NSD group compared to the mild group (44.4%vs.8.5%; OR: 8.64; 95% CI: 3.22–23.21; p < 0.001).In the Naeem classification,SNB differed significantly between mild and moderate NSD groups (p = 0.002),but not between moderate and severe groups (p = 1.000),suggesting a threshold effect around 9°.

CONCLUSIONS

Increased SDA shows a significant association with mandibular retrognathia and hyperdivergent growth pattern. These changes are observed significantly more frequently in deviations exceeding approximately 9-10°. The findings suggest that NSD may be a part of broader craniofacial phenotype rather than an isolated nasal pathology. Paranasal sinus CT allows for the assesment of both sinonasal anatomy and mandibular morphology in a single setting. Prospective studies incorporation symptom scores and polysomnography are required to establish causality.

BACKGROUND & AIM

The ANCHOR-1/-2 Phase III trials in patients with chronic rhinosinusitis with nasal polyps (CRSwNP) demonstrated the safety and efficacy of depemokimab, the first ultra-long-acting biologic with enhanced interleukin-5 binding affinity, high potency and an extended half-life, enabling sustained suppression of type 2 (T2) inflammation with twice-yearly dosing. This post hoc

analysis evaluated responses to depemokimab in patients with one prior surgery for CRSwNP and ≥1 T2 inflammation feature (blood eosinophil count [BEC] ≥150 cells/µL, comorbid asthma, N-ERD/AERD).

MATERIAL & METHODS

ANCHOR-1/-2 randomised adults with inadequately controlled CRSwNP to subcutaneous depemokimab 100 mg or placebo, plus standard of care, once every 26 weeks for 52 weeks. This post hoc analysis compared depemokimab responses in two subsets of patients with one prior CRSwNP surgery: those with ≥1 T2 feature (Profile-1) and those with BEC ≥150 cells/µL plus ≥1 additional T2 feature (comorbid asthma, N-ERD/AERD; Profile-2). Patients were assessed using modified EPOS/EUFOREA response criteria at Week 26: reduced nasal polyp size (≥1-point improvement), no use of systemic corticosteroids (SCS) for CRSwNP/no surgery needed, improved quality of life and disease control (Sino-Nasal Outcome Test-22 [SNOT-22]: ≥8.9-point improvement and SNOT-22 <40), improved sense of smell (Verbal Response Scale: ≥0.9-point improvement) and reduced impact of T2 comorbidities (Asthma Control Questionnaire-5: ≥0.5-point improvement). Patients who met more criteria were considered to have a better response.

RESULTS

Of the 528 patients included in ANCHOR-1/-2, 154 met the definition for Profile-1 (depemokimab n=79, placebo n=75) and 98 for Profile-2 (depemokimab n=52, placebo n=46). Proportions of patients meeting 4/5 response criteria (good/excellent response) at Week 26 was greater with depemokimab versus placebo (Profile-1: 30%[n=24] vs 9%[n=7]; Profile-2: 35%[n=18] vs 13%[n=6]); fewer patients receiving depemokimab demonstrated no response (0 criteria) or met only 1 criterion than those receiving placebo (Profile-1: 29%[n=23] vs 45%[n=34]; Profile-2: 27%[n=14] vs 41%[n=19).

CONCLUSIONS

At the first EPOS/EUFOREA recommended 6-month evaluation of treatment response, a higher proportion of patients with CRSwNP with one prior surgery and features indicative of T2 inflammation had a good/excellent response to twice-yearly depemokimab compared with placebo, without requiring SCS or additional sinus surgery, supporting use of depemokimab in this patient population.

Relationship Of The Infraorbital Canal And Vidian Nerve With Surrounding Anatomical Structures

Mehmet Maruf AYDIN[4], **Seda SEZEN GÖKTAŞ**[1], **Dursun Mehmet MEHEL**[3], **Murat NİĞDELİOĞLU**[2], **Kerim KARACA**[2], **Doğukan ÖZDEMİR**[2]

[1]*Department of Otorhinolaryngology, Samsun City Hospital, Samsun, Türkiye;* [2]*Department of Otorhinolaryngology, Samsun University Faculty of Medicine, Samsun, Türkiye;* [3]*Department of Otorhinolaryngology, University of Health Sciences Samsun City Hospital, Samsun, Türkiye;* [4]*Department of Radiology, Samsun City Hospital, Samsun, Türkiye*

BACKGROUND & AIM

The infraorbital canal contains the infraorbital nerve, artery, and vein.Preoperative evaluation of the localization and wall continuity of the infraorbital canal may contribute to reducing the risk of neurovascular injury during maxillofacial surgeries. Anatomical variations of the Vidian canal and infraorbital canal have been evaluated in the literature.[1,2]However,the relationship between these two canals and their connections with surrounding surgical landmarks have not been sufficiently demonstrated.The aim of this study was to evaluate the relationship between the infraorbital canal and surgical landmarks, to investigate the relationship between the infraorbital canal and the Vidian canal, and to reveal a possible anatomical correlation.

MATERIAL & METHODS

Our study was designed as a retrospective cross-sectional study. A total of 850 infraorbital canals from 425 patients were evaluated on coronal and axial sections of paranasal sinus computed tomography scans obtained in the standard position using the same imaging device. Patients with maxillary or sphenoid sinus pathology were excluded from the study. Infraorbital canal type, presence of Haller cells and, if present, the distance between the canal and the Haller cell, the distance between the canal and the maxillary sinus ostium, the angle between the uncinate process and the sagittal plane, and the ipsilateral Vidian canal type were determined and recorded. Statistical analyses were performed using SPSS V.22 software. All data showed nonparametric distribution The Kruskal–Wallis test was used for quantitative variables, and the Chi-square test was used for qualitative variables. A p value of <0.05 was considered statistically significant.

RESULTS

Of the patients, 54.6% were male and 45.4% were female, with a mean age of 32.67 (19–83) years.The distribution of infraorbital canal types was 40.7% for type 1, 35.8% for type 2, and 22.9% for type 3. Haller cells were observed in 32.8% of cases, and their presence significantly differed among canal types (p=0.002), increasing progressively from type 1 to type 3. No significant difference was found regarding the distance between the canal and Haller cells (p=0.225)or the maxillary sinus ostium (p=0.122). A significant relationship was found between the uncinate process angle and infraorbital canal type

(p=0.009),with significantly greater angles in type 1 canals compared to type 3 canals. In addition, a significant relationship was identified between ipsilateral Vidian canal type and infraorbital canal type. Patients with infraorbital canal type 1 showed a significantly higher rate of ipsilateral Vidian canal type 3. Both nerves demonstrated similar intact intracanal patterns.

CONCLUSIONS

Abnormal localization or non-intact wall structure of the infraorbital canal increases the risk of surgical injury. This may result in permanent postoperative paresthesia or hypoesthesia. In addition, due to lower bony resistance at the canal level in infraorbital wall injuries, the canal may frequently be involved in the fracture line. In such cases, intraorbital arterial or venous bleeding may occur in addition to nerve injury caused either by the fracture itself or during reconstruction procedures. Therefore, preoperative evaluation of the localization and structure of the canal and its relationship with surrounding surgical landmarks is important for surgical planning.

Efficacy Of Prophylactic Pre-Operative Desmopressin Administration During FESS For CRS: A Systematic Review And Meta-Analysis

ahmad s alharthi[1]

[1]*Alhada hospital for armed forces*

BACKGROUND & AIM

Intraoperative bleeding is a common complication during functional endoscopic sinus surgery (FESS) which can be progressively severe and subsequently culminate in an unfavourable wet surgical field. Desmopressin is an artificial derivative of vasopressin that plays crucial roles in haemostasis, and is widely employed in various operations to reduce perioperative blood loss and requirement for blood transfusion. So far, no meta-analysis of randomised controlled trials has been carried out to systematically aggregate evidence on the efficacy of prophylactic pre-operative desmopressin during FESS.

MATERIAL & METHODS

Design: Systematic review and meta-analysis of randomised controlled trials (RCTs).

Setting: The Cochrane Central Register of Controlled Trials (CENTRAL), PubMed, Embase, Scopus, and Web of Science databases were screened from inception until 18 March 2022.

Participants: Patients undergoing FESS.

Main outcome measures: Primary efficacy endpoints comprised intraoperative blood loss, visual clarity, and operation time. Secondary endpoints comprised side effects. The efficacy endpoints were summarised as risk ratio (RR) or mean difference (MD) with 95% confidence interval (CI).

RESULTS

Results: Five RCTs comprising 380 patients (desmopressin = 191 patients and placebo = 189 patients) were included. Collectively, the included RCTs had an overall low risk of bias. The pooled results showed that the mean intraoperative blood loss (n =5 RCTs, MD = −37.97ml, 95% CI [−56.97, −18.96], p < .001), 5-point Boezaart scores (n = 2 RCTs,MD = −.97, 95% CI [−1.21, −.74], p < .001), and 10-point Boezaart scores (n =2 RCTs, MD = −3.00, 95% CI [−3.61, −2.40], p < .001) were significantly reduced in favour of the desmopressin group compared with the placebo group. Operation time did not significantly differ between both groups (n =5 RCTs, MD = −3.73min, 95% CI [−14.65, 7.18], p =.50). No patient in both groups developed symptomatic hyponatremia (n =3 RCTs, 194 patients) or thromboembolic events (n = 2 RCTs, 150 patients).

CONCLUSIONS

Conclusions: Among patients undergoing FESS, prophylactic administration of desmopressin does not correlate with significant clinical benefits. Data on safety is limited. Future research may explore the synergistic antihaemorrhagic efficacy and safety of tranexamic acid (TXA) plus desmopressin versus TXA alone among patients undergoing FESS.

The Role Of Nasal Pathologies And Biomarkers In Recurrence After Endoscopic Dacryocystorhinostomy

İREM AĞGÜNLÜ[1], **ZEHRA BETÜL PAKSOY**[2], **FATMA CEMTRE SAZAK KUNDİ**[3], **MELİH ÇAYÖNÜ**[2]

[1]*Department of Otolaryngology, Polatlı Duatepe State Hospital, Ankara, Türkiye;* [2]*Department of Otolaryngology, Ankara Bilkent City Hospital, Ankara, Türkiye;* [3]*Department of Otolaryngology–Head and Neck Surgery, Baylor College of Medicine, Houston, Texas, USA*

BACKGROUND & AIM

Dacryocystitis is the most common pathology of the lacrimal drainage system. Recurrent infections cause epithelial loss, lamina propria fibrosis, vascular injury, and subsequent luminal obstruction. This retrospective study evaluated whether preoperative inflammatory and immune biomarkers, including PNI, SIRI, SII, and PIV, predict recurrence after endoscopic dacryocystorhinostomy performed with a standardized technique in patients with chronic dacryocystitis at a tertiary care center. The study also investigated the impact of nasal pathologies and symptom scores on postoperative recurrence. To our knowledge, this is the first study assessing the prognostic value of PIV and systemic inflammatory indices in endoscopic DCR outcomes.

MATERIAL & METHODS

This retrospective cross-sectional study included patients aged 18–80 years who underwent endoscopic dacryocystorhinostomy for chronic dacryocystitis at the Ankara Bilkent City Hospital between 2019 and 2024 and completed at least 12 months of follow-up. Patients were categorized according to the need for revision surgery. Exclusion criteria were malignancy, irregular follow-up, previous external DCR, and punctal or canalicular obstruction. Demographic data, comorbidities, hospital stay, radiological findings, preoperative laboratory parameters, inflammatory indices, and prognostic nutritional index values were recorded. Preoperative and postoperative symptoms were assessed using a modified Lac-Q questionnaire. All procedures were performed using a standardized endoscopic technique with mucosal flap elevation, lacrimal bone removal, vertical sac incision, rhinostomy creation, and silicone tube placement. Tubes were removed after 3 months. Surgical success at 24 months was defined by epiphora resolution, absence of recurrent dacryocystitis, and patent rhinostomy. Data were analyzed using SPSS 25.0, with $p<0.05$ considered statistically significant.

RESULTS

A total of 69 patients aged between 18 and 80 years who underwent endoscopic dacryocystorhinostomy were included in the study. Of these, 50 patients were female (72.5%) and 19 were male (27.5%). The left eye was affected in 43 cases (62.3%), while the right eye was affected in 26 cases (37.7%). During the 24-month follow-up period, recurrence requiring revision surgery was observed in 12 patients (17.4%), whereas 57 patients (82.6%) remained recurrence-free.

The mean age was 54.33 ± 18.45 years in the revision group and 49.21 ± 14.64 years in the non-revision group, with no statistically significant difference between the groups ($p = 0.358$). Similarly, stent retention duration did not differ significantly between groups ($p = 0.986$). Smoking status, rhinitis, septal deviation, and conchal hypertrophy were not significantly associated with revision surgery.

CONCLUSIONS

A marked improvement was observed in symptom scores after surgery, decreasing from 6.49 ± 2.64 preoperatively to 1.43 ± 1.47 postoperatively. When revision and non-revision groups were compared, routine hematological and biochemical parameters, preoperative symptom scores, and inflammatory indices including PIV, PNI, SIRI, SII, PLR, and NLR showed no significant differences. However, postoperative symptom scores were significantly higher in patients who required revision surgery ($p = 0.047$). Spearman's analysis demonstrated a weak but significant positive correlation between revision status and postoperative symptom score ($r = 0.241$, $p = 0.046$).

BACKGROUND & AIM

Background: Chronic rhinosinusitis with nasal polyps (CRSwNP) is a chronic inflammatory condition affecting the sinuses, resulting in the appearance of nasal polyps and is often associated with comorbidities. Many cases do not respond to corticosteroid treatment or surgery.

Objective: This study aimed to explore the role of tezepelumab in the treatment of CRSwNP.

MATERIAL & METHODS

Pubmed, Embase, Scopus, Web of Science and Cochrane Library were searched. Three randomized controlled trials (RCTs) comparing tezepelumab and placebo in 655 patients with CRSwNP were included. The main outcomes were nasal polyp size (nasal polyp score NPS), nasal congestion or obstruction (nasal congestion score NCS), and quality of life using the Sino-Nasal Outcome Test (SNOT-22).

RESULTS

Three RCTS were included, in which tezepelumab was used to treat CRSwNP. The mean age was 50.9 years, with 56.9% male patients and 75.6% of patients with coexisting asthma. The mean difference (MD) for NPS ranged from -0.9 to -2.0 compared to placebo. Consistent benefits were observed for NCS with MD between -0.8 and -1.0 compared to placebo and SNOT-22 with MD ranging from -10 to -28 points compared to placebo.

CONCLUSIONS

In conclusion, evidence supports the efficacy of tezepelumab for CRSwNP compared to placebo or standard care. In all trials, tezepelumab consistently demonstrated superiority over placebo in reducing NPS and NCS, improvements in SNOT-22, loss of sense of smell and clinically relevant endpoints (reduced need for surgery and corticosteroid use).

COMPARATIVE ANALYSIS OF HEMATOLOGICAL PARAMETERS IN CHRONIC RHINOSINUSITIS WITH NASAL POLYPS

Neslihan Sarı[1], **Hasan Basri Savaş**[2]

[1]Department of Otolaryngology-Head and Neck Surgery, Faculty of Medicine, Mardin Artuklu University, Mardin, Türkiye.; [2]Department of Biochemistry,Faculty of Medicine, Mardin Artuklu University, Mardin, Türkiye.

BACKGROUND & AIM

Chronic rhinosinusitis with nasal polyps (CRSwNP) involves chronic inflammatory lesions of the sinonasal mucosa, with an unclear etiology influenced by both genetic and environmental factors. Over time, these factors interact to drive the disease through various inflammatory mechanisms. Recently, routine hematological parameters have gained attention as markers of systemic inflammation in chronic inflammatory diseases. This study aimed to compare these parameters between patients with CRSwNP and healthy controls to evaluate their association with the disease.

MATERIAL & METHODS

This retrospective, comparative study reviewed patients who underwent functional endoscopic sinus surgery (FESS) for CRSwNP (n=50) at Mardin Training and Research Hospital over a three-year period. The control group consisted of patients who underwent septoplasty or rhinoplasty and had normal paranasal sinus computed tomography (CT) scans (n=50) over a two-year period. Complete blood count parameters—including white blood cell (WBC), neutrophil, lymphocyte, eosinophil, and platelet counts, as well as mean platelet volume (MPV), neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), and eosinophil-to-lymphocyte ratio (ELR)—were analyzed. Statistical analyses were performed to compare the groups, with a p-value <0.05 considered statistically significant.

RESULTS

Among the inflammatory hematological markers, eosinophil and neutrophil counts were statistically significantly higher in the CRSwNP group than in the control group (both $p < 0.05$). Although NLR and PLR values tended to be elevated in patients with CRSwNP, these differences did not reach statistical significance ($p > 0.05$). Eosinophilia was observed in 48% (n = 24/50) of the patients with CRSwNP, while neutrophilia was present in 18% (n = 9/50). In conclusion, these findings suggest a strong association between the systemic inflammatory response and the pathogenesis of CRSwNP.

CONCLUSIONS

Hematological parameters derived from routine blood tests, particularly preoperative eosinophil and neutrophil counts, may serve as useful, inexpensive, and easily accessible biomarkers in patients with CRSwNP. Furthermore, these preoperative inflammatory indices might contribute to predicting disease recurrence and evaluating inflammatory activity. While indices such as NLR and PLR showed an elevated trend in this study, further prospective studies with larger sample sizes are required to fully elucidate their clinical and prognostic utility.

Efficacy And Safety Of Image-Guided Endoscopic Repair For Sphenoid CSF Rhinorrhea: A Tertiary Hospital Experience .

Eman Alanazi[1], **Ali almomen**[1], **Nourah Ali Boukhamssein**[2], **Fatimah Abdulhameed Alwosaibi**[2]

[1]*King fahad specialist Hospital Dammam*; [2]*Maternity and children hospital Dammam .*

BACKGROUND & AIM

Cerebrospinal fluid rhinorrhea (CSFR) occurs due to communication between the sterile subarachnoid space and the nose and paranasal managing CSF rhinorrhea originating from the sphenoid sinuses. The sinuses pose unique difficulties with the vital structures of the carotid artery and optic nerve. We aimed to investigate the clinical applications of image-guided endoscopic surgery (IGES) on the endoscopic repair of different sphenoid CSF rhinorrhea.

MATERIAL & METHODS

This was a retrospective chart review of all sphenoid CSF rhinorrhea cases seen at King Fahad Specialist Hospital (KFSH) in Dammam, Saudi Arabia. Demographics, etiology, presentation, diagnostic tests, methods of endoscopic repair and outcome of surgery were described.

RESULTS

Fifteen cases of sphenoid CSF rhinorrhea were identified and managed by the image guided endoscopic repair approach. Ten (66.7%) were males. The mean age of all patients was 37.4 ± 4.1 years. All cases underwent plain high-resolution CT imaging and intraoperative cisternography. After four to five years of follow-up, none of the patients experienced any recurrences post-surgery. None of the patients had any serious side effects.

CONCLUSIONS

Our study demonstrates that image-guided endoscopic repair is a highly effective and safe modality for managing sphenoid CSF rhinorrhea. Intraoperative navigation significantly enhanced defect localization accuracy and minimized surgical morbidity. The high success rate of CSF leak closure, combined with low postoperative complications, supports this technique as a standard of care, particularly for complex or recurrent cases. A multidisciplinary approach, early diagnosis, and meticulous surgical planning are essential for optimizing outcomes. Future prospective studies with larger sample sizes and long-term follow-up are recommended to further validate these results and refine operative protocols.

OP-1125

The Natural History Of Residual Advanced Juvenile Nasopharyngeal Angiofibroma

Raewyn Campbell[1], **Shivani Kumar**[1]

[1]*Macquarie University*

BACKGROUND & AIM

Juvenile nasopharyngeal angiofibromas (JNAs) are rare, benign but locally aggressive vascular tumours predominantly affecting adolescent males. Advanced-stage disease, characterised by skull base, orbital and/or intracranial extension, presents significant treatment challenges. Following initial therapy, residual or recurrent disease is common in advanced JNAs. The optimal approach to managing such cases, intervention versus surveillance, remains controversial. This systematic review explores the natural history of residual and recurrent JNAs to inform clinical decision-making.

MATERIAL & METHODS

A systematic literature review was conducted according to PRISMA guidelines across PubMed, Embase, Scopus, and Web of Science from inception to 20th February 2025 and was re-run on 21st September 2025. Studies included patients with advanced JNA and documented follow-up of residual or recurrent disease. Descriptive statistics, chi-square analysis and analysis of variance were used to evaluate treatment outcomes across different modalities including surgery, radiotherapy, gamma knife surgery, and medical therapies.

RESULTS

Twenty-two studies encompassing 131 male patients (mean age 16.3 years) were included. Residual or recurrent disease demonstrated complete involution in 41%, stable disease in 29%, and reduction in size in 26% of cases. Only 2% of patients had progressive disease. A statistically significant association was observed between treatment modality and outcome ($p = 0.015$), with radiotherapy, either alone or as part of a multimodal approach, showing the highest rates of spontaneous involution.

CONCLUSIONS

Residual and recurrent JNAs often remain stable or regress without further intervention. Close surveillance with imaging is a safe and effective strategy for asymptomatic patients, minimising the risks of additional treatment in a young patient population with disease near critical anatomical structures.

OP-1126

Diagnostic Accuracy Of Punch Biopsy In Unilateral Nasal Masses: A Retrospective Analysis

Gulcin Ozsoy[1], Tankut Uzun[1]

[1]Izmir Bakircay University

BACKGROUND & AIM

Punch biopsy is widely utilized as an initial diagnostic modality in the evaluation of unilateral nasal masses; however, its diagnostic accuracy remains debated, particularly in histologically heterogeneous and malignant lesions

The aim of this study was to assess the diagnostic accuracy of punch biopsy in unilateral nasal masses and to analyze the impact of histopathological subtype, anatomical location, and biopsy specimen size on diagnostic performance.

MATERIAL & METHODS

Seventy-five patients with unilateral nasal masses who underwent punch biopsy followed by surgical excision were retrospectively analyzed. Demographic data, lesion laterality, histopathological subtype, anatomical origin, and biopsy specimen size were recorded. Diagnostic accuracy, Cohen's kappa coefficient, sensitivity, specificity, predictive values, and subgroup analyses were calculated.

RESULTS

The mean age was 47.8 ± 17.9 years; 64% were male. Right-sided lesions accounted for 54.7% of cases. Overall diagnostic accuracy was 60% (45/75) with weak-to-moderate agreement (κ = 0.331, p = 0.0026). Inflammatory polyps showed high diagnostic accuracy (90.2%), while inverted papillomas demonstrated moderate accuracy (61.5%). Diagnostic performance varied significantly according to anatomical origin (p = 0.0017). The median biopsy specimen size was 9 mm; larger specimens showed higher diagnostic accuracy (64.9% vs 55.3%), although this difference was not statistically significant (p = 0.482). Sensitivity for malignancy detection was 20%, specificity 100%, positive predictive value 100%, and negative predictive value 94.6%. Four of five malignant cases were missed on punch biopsy.

CONCLUSIONS

Punch biopsy demonstrates moderate overall diagnostic accuracy in unilateral nasal masses. Although highly specific for malignancy, it lacks sufficient sensitivity to reliably exclude malignant disease. Diagnostic discordance appears to be related to sampling limitations, tumor heterogeneity, and anatomical constraints affecting representative tissue acquisition.

OP-1127

Relationship Between Adult Chronic Rhinosinusitis And A History Of Pediatric Tonsillectomy And Adenoidectomy

Robert E. Africa[1], Shahrukh Ali[1], Brian J. McKinnon[1], Harold S. Pine[1], Yusif Hajiyev[1], Charles A. Hughes[1], Scott A. Hardison[1]

[1]The University of Texas Medical Branch, Department of Otolaryngology-Head and Neck Surgery

BACKGROUND & AIM

Tonsillectomy and adenoidectomy improve pediatric obstructive sleep apnea (OSA) symptoms and recurrent infections. The procedure's long-term risks are still being investigated, and prior studies suggested potential alteration of life immunity pathways and subsequent impairment on adult health including higher risk of asthma, otitis media, and sinusitis. Given this debate, this study evaluated the epidemiological associations between the development of adult chronic rhinosinusitis (CRS) and treatment with surgery or biologic therapy following pediatric adenotonsillectomy.

MATERIAL & METHODS

This is a multicenter, retrospective cohort study utilizing data from 100 healthcare organizations in the United States. The TriNetX database identified adults (≥18 years) with or without prior childhood tonsillectomy and/or adenoidectomy. Outcomes included CRS without nasal polyposis (CRSsNP), with nasal polyposis (CRSwNP), sinus surgery, and biologic therapy. Subgroup analysis of patients with childhood obstructive sleep apnea (OSA), recurrent/chronic tonsillitis, adenoiditis, or middle ear disease was performed. Time-to-event analysis was conducted with Kaplan–Meier analysis and reporting of hazard ratios (HRs) with 95% CI for each outcome. A $p < 0.05$ was considered statistically significant.

RESULTS

There was no statistically significant difference in the rate of adult CRSsNP, CRSwNP, surgery, and treatment with biologics after pediatric adenotonsillectomy for childhood OSA (HR: 0.94 [0.87–1.02]; 1.07 [0.79–1.44]; 0.87 [0.59–1.28]; 0.85 [0.66–1.09]). Children who had an adenoidectomy alone had a higher rate of CRSsNP as adults (HR: 1.55 [1.30–1.85]). Surgery for tonsillitis and adenoiditis had a higher rate of CRSwNP and surgery (HR: 1.63 [1.21–2.32]; 1.97 [1.36–2.86]). Adenoidectomy for

adenoiditis was associated with CRSsNP (HR: 1.94 [1.73–2.19]). Adults with pediatric middle ear disease who had a childhood adenoidectomy alone had an increased rate of CRSsNP (HR: 1.47 [1.30–1.65]).

CONCLUSIONS

Tonsillectomy with adenoidectomy in the setting of specific childhood infectious diseases was associated with adult CRSwNP and the need for sinus surgery, whereas adenoidectomy was associated with CRSsNP. These findings may suggest that children with recurrent or chronic infections have a predisposition to other infections that persists later in life, and that surgical removal of the tonsils and adenoids for noninfectious reasons alone may not contribute to the development of adult CRS.

OP-1128

Inverted Papilloma: A Single-Center Demographic Study Of 60 Cases

Ömer Erdur[1], **Furkan Gürsul**[1]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, Selçuk University Faculty of Medicine, Konya, Turkey*

BACKGROUND & AIM

Inverted papilloma (IP) is a rare benign sinonasal tumor characterized by local aggressiveness, high recurrence rates, and a 5–15% risk of malignant transformation, most commonly to squamous cell carcinoma. It often presents with nonspecific symptoms and can mimic inflammatory polyps. Accurate identification of the tumor's attachment site and extent using imaging is crucial. Complete surgical excision, particularly via endoscopic approaches, is essential to reduce recurrence.To evaluate attachment sites, spread patterns, surgical approaches, recurrence, malignant transformation, and demographic factors in IP patients.

MATERIAL & METHODS

This study was approved by the Ethics Committee of Selçuk University and designed as a retrospective analysis of patients with histopathologically confirmed inverted papilloma (IP). A total of 60 patients who underwent surgical treatment between 2015 and 2026 were included.

Patient data were retrieved from the hospital information system and medical records. Demographic variables, including age at diagnosis, sex, and admission date, were recorded. Patients with incomplete data or histopathological diagnoses other than IP (e.g., fungal sinusitis, antrochoanal polyp) were excluded.

Statistical analyses were performed using standard software. The normality of continuous variables (age) was assessed with the Shapiro–Wilk test. As data were normally distributed ($p > 0.05$), the Independent Samples t-test was used to compare age between sexes. Categorical variables were expressed as frequency and percentage. A p-value < 0.05 was considered statistically significant.

RESULTS

A total of 60 patients with histopathologically confirmed inverted papilloma (IP) were included. The cohort demonstrated a marked male predominance, with 80% (n=48) males and 20% (n=12) females, corresponding to a 4:1 male-to-female ratio.

The overall mean age at diagnosis was 55.33 ± 12.23 years (range: 28–78). When stratified by sex, the mean age was 54.96 ± 12.94 years for males and 56.83 ± 9.05 years for females.

Independent Samples t-test analysis revealed no statistically significant difference in age at diagnosis between sexes ($p = 0.638$, $p > 0.05$). The median age at diagnosis was 57.0 years in both groups, indicating that IP most frequently presents in the sixth decade of life.

CONCLUSIONS

Inverted papilloma is a locally aggressive sinonasal tumor characterized by high recurrence rates and a potential for malignant transformation. The demographic findings of our study are largely consistent with the existing literature.

OP-1129

Septal Perforation Repair: Comparative Outcomes Of Flap Alone Versus Flap With Interposition Cartilage Graft

Yunus Emre Topan[1]

[1]*Uşak University Faculty of Medicine Training and Research Hospital, ENT department*

BACKGROUND & AIM

The aim of this study was to compare the outcomes of septal perforation repair performed with flap alone versus flap combined with cartilage interposition graft. Specifically, we sought to evaluate differences in perforation closure rates, postoperative symptom scores, and complication profiles between the two surgical approaches, while also considering the influence of perforation characteristics such as size, location, and osteocartilaginous involvement.

MATERIAL & METHODS

This study was designed as a retrospective comparative clinical analysis of patients who underwent surgical repair for septal perforation. A total of 15 patients were included. Patients were divided into two groups according to the surgical technique used: Group 1: Flap alone (n=7), Group 2: Flap + cartilage interposition graft (n=8).

The following parameters were assessed from the dataset: Age, Sex, Perforation size (<10 mm / >10 mm), presence of osteocartilaginous unit involvement, perforation location (anterior/posterior), complete closure, partial closure, postoperative complication, postoperative symptom scores(dryness, crusting, epistaxis, whistling scores)

RESULTS

A total of 15 patients were included in the study. The flap group comprised 7 patients, whereas the flap + cartilage group comprised 8 patients. All patients were followed for a minimum of 3 months postoperatively. Complete closure was achieved in 5/7 patients (71.4%) in the flap group, 7/8 patients (87.5%) in the flap + cartilage group. Partial closure was not observed in the flap group, while it was observed in 1 patient (12.5%) in the flap + cartilage group. No postoperative complications were recorded in either group.

Among symptom scores parameters, dryness score appeared higher in the flap + cartilage group. Although complete closure was numerically higher in the flap + cartilage group, the limited sample size restricts strong statistical interpretation. In addition, the flap + cartilage group included a higher proportion of patients with osteocartilaginous involvement, suggesting that this group may have represented more complex cases.

CONCLUSIONS

Both flap-only repair and flap repair combined with cartilage interposition graft yielded satisfactory results in septal perforation surgery. The flap + cartilage technique demonstrated a numerically higher complete closure rate despite being used in a group with greater osteocartilaginous involvement. These findings suggest that cartilage augmentation may be a useful adjunct in more complex perforations. Nevertheless, larger controlled studies are required to establish its definitive superiority.

Evaluation Of Demographic Characteristics, Functional And Surgical Outcomes Of Patients Underwent Endoscopic Dacryocystorhinostomy Surgery

Muhammet Fatih GÖKMEN[1], **Çağrı Can YURDAER**[1], **Ayşe Bozkurt OFLAZ**[2], **Bengü EKİNCİ KÖKTEKİR**[3]

[1]*Selcuk University, Medical School, ENT Department, Konya, TÜRKİYE;* [2]*Selcuk University, Medical School, Ophtalmology Department, Konya, TÜRKİYE;* [3]*BEK Private Eye Clinic, Konya, TÜRKİYE*

BACKGROUND & AIM

Endoscopic dacryocystorhinostomy (DCR) is a minimally invasive surgical procedure used to treat epiphora, recurrent dacryocystitis, and tear drainage disorders caused by nasolacrimal duct obstruction. It was developed as an alternative to classic external DCR and is preferred, particularly for its cosmetic advantages. It was first described by McDonogh and Meiring in 1989. With advancements in endoscopic techniques and improved image quality, its use has become more widespread since the 2000s.

MATERIAL & METHODS

128 patients who underwent endoscopic DCR were included in the study. All intranasal procedures were performed by a single surgeon. Patient age, gender, surgical site, whether the cases were primary or revision, and complication rates were examined.

RESULTS

Total of the 128 patients, 50 were male (39.1%) and 78 were female (60.9%). The average age was 36.3 years, with the youngest patient being 17 months old and the oldest 89 years old. 45 (35.2%) of the patients were in the pediatric group. 16 cases were bilateral, 54 were right-sided, and 58 were left-sided. All bilateral cases were primary surgeries. Of the right-sided cases, 47 were primary (87%) and 7 were revisions (13%). Of the right-sided revision cases, 5 were female (4 adult, 1 pediatric) and 2 were male (both pediatric). Of the left-sided cases, 47 were primary (81%) and 11 were revisions (19%). Of the left-sided revision cases, 5 were female (3 adult, 2 pediatric) and 6 were male (4 adult, 2 pediatric).

CONCLUSIONS

In patients underwent endoscopic DCR, female gender predominance and a wide age range are noteworthy. The vast majority of cases are primary surgeries, and the need for revision is most frequently associated with the development of synechiae. Rarely, infection and lacrimal sac stones are also among the reasons for revision. It is noteworthy that all bilateral cases are primary. The endoscopic approach appears to be effective in both primary and revision cases, but the development of postoperative synechiae can be a significant cause of failure.

Real-Life Outcomes Of Biological Therapy In Severe Chronic Rhinosinusitis With Nasal Polyps: Preliminary Results From A Prospective Cohort Study

Meltem Akpinar[1], **Beyza Demirci**[1], **Bilge Nur Küçükakça**[1], **Serpil Şahin**[2], **Eylem Tuncay**[3]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, Sancaktepe Şehit Prof. Dr. İlhan Varak Training and Research Hospital, Istanbul, Türkiye;* [2]*Division of Allergy and Immunology, Department of Pulmonary Diseases, Sancaktepe Şehit Prof. Dr. İlhan Varak Training and Research Hospital, Istanbul, Türkiye;* [3]*Department of Pulmonary Diseases, Sancaktepe Şehit Prof. Dr. İlhan Varak Training and Research Hospital, Istanbul, Türkiye*

BACKGROUND & AIM

Chronic Rhinosinusitis with Nasal Polyps (CRSwNP) remains a challenging clinical entity, particularly in patients with comorbid asthma and recurrence despite Functional Endoscopic Sinus Surgery (FESS). While biological agents offer a targeted therapeutic approach, real-world data regarding their efficacy in "difficult-to-treat" populations is essential. This study aims to present updated real-world outcomes of biological therapy in a prospective cohort of patients with severe, recurrent CRSwNP and comorbid asthma.

MATERIAL & METHODS

In this ongoing prospective observational study, 168 patients with CRSwNP were screened. A total of 13 patients with severe CRSwNP initiated biological therapy (Mepolizumab (n=8), Omalizumab (n=3), and Benralizumab (n=2)) based on EPOS 2020 criteria. Comorbid asthma was present in 69% (9/13) of the total cohort. Six patients were excluded from the primary longitudinal analysis due to insufficient follow-up duration at the time of reporting. Consequently, the preliminary longitudinal results of 7 patients (mean age: 42.71±12.89, 57% male) with complete follow-up are presented. Baseline disease severity was high, as evidenced by a mean radiological Lund-Mackay (LM) score of 18.14±4.88(out of 24). Patients were evaluated at baseline (T0), 3 months (T1), and 6 months (T2). Primary clinical outcomes included the SNOT-22 score and the Endoscopic Nasal Polyp Score (NPS). Secondary outcomes included systemic corticosteroid requirement and FEV1 levels to assess asthma control.

RESULTS

The evaluable cohort (n=7) demonstrated significant clinical improvement across all primary endpoints. The mean SNOT-22 score decreased from 78.1±9.6 at baseline (T0) to 53.0±32.1 at 6 months (T2). This 25.1-point reduction represents a clinical impact nearly three times the established Minimal Clinically Important Difference (MCID) of 9 points. Endoscopic findings mirrored symptomatic relief, with the mean Nasal Polyp Score (NPS) regressing from 6.0±1.5 to 3.4±3.0 at T2. Regarding steroid dependency, a 100% reduction in systemic corticosteroid courses was observed at the 6-month mark compared to the preceding 12 months. Regarding surgical indications, 42% (3/7) of the evaluable patients no longer met the criteria for revision FESS after 6 months of therapy of biological agents. Pulmonary function remained stable, with a mean FEV1 of 2.80±0.89 L at T2.

CONCLUSIONS

Our real-world data suggest that biological therapy provides rapid and clinically superior improvement in both subjective and objective measures for patients with severe, recurrent CRSwNP and/or comorbid asthma. The magnitude of SNOT-22 improvement significantly exceeding the MCID, combined with the total elimination of systemic steroid need and a substantial reduction in revision surgery indications, underscores the transformative potential of biologics in this difficult-to-treat population. Further follow-up of the expanded cohort will clarify long-term sustainability.

OP-1132

Evaluation Of Olfactory Function And Olfactory Bulb Volume Before And After Endoscopic Sinus Surgery In Adult Patients With Nasal Polyps

Serhat Bayrak[1], **Zeliha Kapusuz Gencer**[1], **Mehmet Keskin**[1], **Burak Koçak**[1], **Salih Akyel**[1]

[1]*Basaksehir Cam & Sakura City Hospital*

BACKGROUND & AIM

The aim of this study was to evaluate the effects of functional endoscopic sinus surgery (FESS) on olfactory function and olfactory bulb volume in patients with chronic rhinosinusitis with nasal polyposis, to compare preoperative and postoperative changes, and to investigate the relationship between olfactory function and radiological-endoscopic parameters.

MATERIAL & METHODS

This prospective, clinical, observational, and analytical study included 29 patients with chronic rhinosinusitis with nasal polyposis who underwent primary FESS between April 2025 and April 2026. Patients were evaluated preoperatively and at the postoperative thirth month. Olfactory functions were assessed using the Connecticut Chemosensory Clinical Research Center (CCCRC) test. Olfactory bulb volumes were measured on magnetic resonance imaging using manual segmentation with 3D Slicer software. Endoscopic evaluation was performed using the Lund–Kennedy scoring system, while radiological evaluation

was conducted using the Lund–Mackay scoring system. Statistical analyses included paired sample t-tests and appropriate parametric/non-parametric tests. Statistical significance was accepted as $p<0.05$.

RESULTS

The mean age of the patients was 36.62±10.81 years, and 72.4% of the participants were male. Preoperative CCCRC scores were 1.29±1.93 on the left side and 1.53±2.14 on the right side, whereas postoperative scores increased to 3.91±1.91 and 3.72±2.01, respectively. Significant postoperative improvements were observed in CCCRC scores on both sides (left: t=-7.710, p<0.001; right: t=-5.160, p<0.001). Preoperative olfactory bulb volumes were 27.32±11.90 mm^3 on the left and 26.92±13.16 mm^3 on the right, increasing postoperatively to 33.35±10.76 mm^3 and 34.18±13.23 mm^3, respectively. Significant increases in olfactory bulb volumes were observed bilaterally (left: t=-6.912, p<0.001; right: t=-6.977, p<0.001). No significant difference was found between right and left preoperative Lund–Kennedy scores (p=0.631), whereas Lund–Mackay scores were significantly higher on the right side (p=0.046).

CONCLUSIONS

Functional endoscopic sinus surgery not only relieves sinonasal obstruction in patients with chronic rhinosinusitis with nasal polyposis but also provides significant improvement in olfactory function and olfactory bulb volumes. These findings support FESS as an effective treatment option for olfactory dysfunction in patients with chronic rhinosinusitis.

Improvement Of Patient´S Quality Of Live And Prescription Behavior Of Dupilumab, Mepolizumab Und Tezelumab In The Last Year

Isabel-Sophie Stelter[1], **Carlotta Geyer**[1], **Masen Jumah**[1]

[1]*ENT Centre Mangfall-Inn, Rosenheim, Germany*

BACKGROUND & AIM

since November 2025 patients with recurrent nasal polyps are treated with dupilumab 300mg or mepolizumab 100mg or tezelumab 210mg according to the AWMF-guidelines at the ENT-Centre Zentrum Mangfall-Inn in Rosenheim, Oberbayern. One of the most important patient related outcome measurements is the SNOT22 questionnaire. Every patient has to fulfil the questionnaire in unregularly intervals. We present the results of 365 questionnaires of n=102 patients from the last three years.

MATERIAL & METHODS

patients were requested to fulfill the SNOT22 digitally on an Ipad. The total score was automatically calculated by the ENTstatistics software, build by Innoforce, Liechtenstein. Our rhinologic database records previous surgeries, histopathologic findings, concomitant diseases and the beginning and end of the biological therapy

RESULTS

The total score before the biological therapy was 52,94 after 180 days of therapy 23,63 and after 270 days 26,90. Due to the early permission of dupilomab in the treatment of CRSwNP the dupilumab group is with 72 patients the strongest group, whereas mepolizumab with 21 patients and tezelumab with 9 patients are smaller groups. The drop in the SNOT22 score is almost the same in all groups. Adverse events were extremely rare.

CONCLUSIONS

The three Biologicals are highly effective drugs in Samter´s disease and CRS with polyps. However, these drugs are reserved for severe cases of nasal polyps, although not-severe cases with less previous surgeries would benefit from the biological therapy, too. Non-responders or adverse events are very rare. The cost effectiveness of biologicals will be a big issue for our health care system in the next years.

Histopathological Spectrum And Demographic Predictors Of Malignancy In Unilateral Sinonasal Disease

Mustafa Mert Gedik[1], **Ömer Feti Yıldız**[1], **Elvan Onan**[1], **İlda Tanrısever Pehlivan**[1], **Çağlar Eker**[1], **Muhammed Dağkıran**[1], **Özgür Sürmelioğlu**[1], **Süleyman Özdemir**[1]

[1]*Çukurova University Faculty of Medicine, Department of Otorhinolaryngology*

BACKGROUND & AIM

The aim of this study is to evaluate the association between malignancy and demographic characteristics by analyzing the histopathological results of patients who underwent surgery for unilateral sinonasal disease at a tertiary care center.

MATERIAL & METHODS

In this retrospective study, 409 patients who underwent surgery for unilateral sinonasal disease at Cukurova University Faculty of Medicine Balcalı Hospital between January 2014 and January 2026 were included. Demographic characteristics, presenting symptoms and histopathological findings were reviewed. Histopathological diagnoses were classified into three groups: benign, malignant, and inverted papilloma. The relationship between patients age, sex, presenting symptoms, and histopathological outcomes was evaluated.

RESULTS

A total of 409 patients were included; 60% (n=244) were male and 40% (n=165) female, with a mean age of 41.8 years. The most common presenting symptom was nasal obstruction (73%, n=300), followed by headache (10%, n=42). Histopathological evaluation revealed benign lesions in 77% (n=313), malignant tumors in 11% (n=47), and inverted papilloma in 12% (n=49). Nasal polyp was the most frequent benign pathology (51%, n=159), while squamous cell carcinoma was the most common malignant tumor (23%, n=11). Patients with malignant lesions were older (mean 51.4 years) than those with benign lesions (37.9 years), and showed a male predominance (68%), similar to inverted papilloma (81% male). The benign group had a more balanced sex distribution (55% male). Among malignant cases, nasal obstruction was most common (53%), followed by epistaxis (12%).

CONCLUSIONS

In our study, the most frequently encountered histopathology following surgery for unilateral sinonasal disease was nasal polyp, while squamous cell carcinoma was the most common malignant lesion. Male patients exhibited a higher rate of malignancy compared to females. Additionally, patients with malignant histopathology were older than those with benign lesions or inverted papilloma. These findings indicate that advanced age and male sex are important factors associated with malignancy in unilateral sinonasal disease. The predominance of nasal polyps in this patient population underscores the importance of thorough preoperative imaging and targeted biopsy before considering extensive surgical intervention.

OP-1135

Patient And Provider Satisfaction With Telemedicine In Otolaryngology: A Cross-Sectional Study Of First-Visit And Follow-Up Encounters In A Tertiary Care Centre

Abdulaziz Hamed S Almalki[1]

[1]*King Abdulaziz Medical City, Riyadh*

BACKGROUND & AIM

Background

Telemedicine has become increasingly integrated into outpatient practice; however, its suitability in procedure-oriented specialities such as otolaryngology remains under evaluation. Differences between patient satisfaction and provider acceptance, particularly in first-visit versus follow-up settings, require further investigation. This study seeks to assess patient and provider satisfaction with telemedicine in otolaryngology, compare first-visit and follow-up encounters, and identify determinants influencing satisfaction.

MATERIAL & METHODS

Methods

A cross-sectional survey was conducted at a tertiary care center in Saudi Arabia. Adult patients who completed telemedicine consultations and otolaryngology providers participated in structured questionnaires. A composite satisfaction score was constructed from four domains. Non-parametric tests and multivariable linear regression with robust standard errors were used to identify independent predictors of satisfaction.

RESULTS

Results

A total of 250 patients (100 first-visit; 150 follow-up) and 19 providers were included. Overall, patient satisfaction was high, particularly among follow-up encounters. In first-visit consultations, perceived clinical adequacy was lower, and referral for in-person evaluation independently reduced satisfaction. In follow-up visits, communication quality and adequacy of discussion were the strongest predictors of satisfaction. Provider satisfaction was comparatively low, with major concerns related to limited physical examination, procedural constraints, and medico-legal risk.

CONCLUSIONS

Conclusion

Telemedicine in otolaryngology appears most effective for follow-up and triage purposes. While patients report high satisfaction driven by communication quality, provider concerns regarding diagnostic adequacy persist. Structured hybrid care models may optimize safe and sustainable telemedicine integration.

OP-1136

Clinicopathological Characteristics And Recurrence Patterns Of Olfactory Neuroblastoma: A 15-Year Tertiary Center Case Series

Mohsen Naraghi[1,5], **Maryam Lotfi**[2], **Lindelwa Phakamile**[3], **Jazmin Kazravan**[4], **Amirhossein Babaei**[6]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, Otorhinolaryngology Research Center, Tehran University of Medical Sciences, Tehran, Iran;* [2]*Department of Pathology, Tehran University of Medical Sciences, Tehran, Iran;* [3]*Eswatini Antivenom Foundation, Simunye, Eswatini;* [4]*Healthcare Corporation of America, Memorial Hospital of Jacksonville, USA;* [5]*Orphans Worldwide, Jacksonville, USA;* [6]*Rhinology Research Society, Tehran, Iran*

BACKGROUND & AIM
Olfactory neuroblastoma (ONB) is a rare malignant tumor of the sinonasal tract with heterogeneous clinical behavior and recurrence potential. Due to its low incidence, prognostic factors and optimal treatment strategies remain incompletely defined. The objective of this study was to describe the clinicopathological characteristics, treatment approaches, and recurrence patterns of ONB over a 15-year period at a tertiary referral center.

MATERIAL & METHODS
A retrospective case series and literature review were performed. Medical records of nine patients with histologically confirmed ONB treated between 2007 and 2022 were reviewed. Demographic characteristics, presenting symptoms, imaging findings, Hyams histologic grade, treatment modalities, and follow-up outcomes were analyzed.

RESULTS
Patients ranged in age from 18 to 61 years (mean: 43-years), with a male predominance. The most common presenting symptoms were nasal congestion, headache, and nasal mass. All patients underwent endoscopic endonasal surgical resection followed by adjuvant chemoradiotherapy. During a mean follow-up of three years, tumor recurrence occurred in 44.4% of patients. Recurrence was observed across different Hyams grades without a statistically significant association between histologic grade, age, or gender and recurrence.

CONCLUSIONS
ONB demonstrates variable clinical presentation and recurrence patterns, even following multimodal treatment. Histologic grade alone may not reliably predict recurrence in small cohorts.

Olfactory neuroblastoma, esthesioneuroblastoma, recurrence, chemoradiotherapy.

OP-1137

Submucosal Leiomyoma Of The Nasal Cavity

Vladimir Vranjes[1]

[1]*University Clinical Center of the Republic of Srpska, Banja Luka, BiH*

BACKGROUND & AIM
Leiomyomas are rare benign tumors of mesenchymal origin that arise from smooth muscle cells. They most often occur in the uterus, gastrointestinal tract and skin, while their appearance in the head and neck area is extremely rare due to the lack of smooth muscle in these regions, and the nasal cavity is one of the most unusual locations, accounting for less than 1% of all leiomyomas.

To show the specificity of the clinical picture, diagnostic protocol and therapeutic approach in patients with leiomyoma of the nasal cavity.

MATERIAL & METHODS
In this paper, we present the case of a 48-year-old patient who presented with progressive left-sided nasal obstruction, loss of smell, impaired hearing on the same side, which had been going on for a few months before the presentation. Anterior rhinoscopy and endoscopy of the nose revealed a solid, submucous, tumor mass, covered with physiological mucosa, similar to a polyp, which completely obstructs the left nasal cavity. Radiological processing (CT) showed a well-limited soft tissue mass starting from the left lower nasal concha, size 25x20x15mm without signs of infiltration of the surrounding bony structures.

RESULTS
Complete surgical excision of the tumor was performed using an endoscopic approach. Definitive diagnosis was established by pathohistological examination, with immunohistochemical positivity for smooth muscle actin (SMA) and vimetin, while markers of malignancy (S-100 protein) were negative. The postoperative course was uneventful.

CONCLUSIONS

Submucosal leiomyoma of the nasal cavity represents a diagnostic challenge due to its rarity and non-specific clinical picture that can mimic other benign tumors such as polyps or angiofibromas. Complete surgical resection is the method of choice, and the prognosis is excellent with a low rate of recurrence after complete removal of the lesion.

leiomyoma, nasal cavity, benign tumors, immunohistochemistry

OP-1138

PANE: Pneumosinus-Associated Neurogenic Endotype – Prevalence And Radiologic Phenotype In 500 Consecutive Non-Polyp CRS Patients

Martin Nue Møller[1], **Karen Hoffmann**[2], **Marc R Dean**[3,4]

[1]Soernes Privathospital, ENT, Copenhagen, Denmark; [2]Piedmont ENT & Related Allergy, Atlanta, Giorgia, United States; [3]Ear and Sinus Institute, Fort Worth, Dallas, United States; [4]VIMA (Vitruvious Institute for Medical Advancement), Dallas, Texas, United States

BACKGROUND & AIM

Pneumatocele and pneumosinus dilatans are traditionally considered rare radiologic entities characterized by sinus enlargement and bony remodeling. Their prevalence in chronic rhinosinusitis without nasal polyps (CRSsNP) is unknown. We hypothesized that these findings may represent a distinct structural–neurogenic endotype.

MATERIAL & METHODS

In this prospective multicenter cohort study, 500 consecutive adults with persistent (>3 months) sinonasal symptoms were evaluated at three tertiary ENT clinics in the United States and Denmark. All patients underwent nasal endoscopy, validated symptom scoring (SNOT-22, ETDQ-7), and CT imaging. Patients with nasal polyposis were excluded. CT scans were assessed using predefined criteria: (1) sinus hyperpneumatization beyond expected anatomical boundaries and (2) associated bony remodeling or neural dehiscence. Natural ostium diameter was measured.

RESULTS

Forty-five patients (9%; 95% CI, 6.6–11.8%) met radiologic criteria for pneumatocele. The sphenoid sinus was most frequently involved (90%). Neural dehiscence was observed in the vidian nerve (83%), V2 (73%), anterior ethmoidal nerve (47%), infraorbital nerve (43%), and posterior ethmoidal nerve (17%). Ostial narrowing (<2 mm) was present in 92% of PANE cases. Mean sphenoid ostium diameter was significantly smaller in PANE patients compared to non-PANE patients ($p < 0.01$; 3.5 mm in non-PANE cohort). PANE patients demonstrated higher symptom burden, with SNOT-22 scores of 68 (95% CI, 60–78) versus 54 (48–61), and ETDQ-7 scores of 40 (34–44) versus 32 (24–37).

CONCLUSIONS

Pneumatocele-like radiologic changes were identified in 9% of symptomatic CRSsNP patients when systematically assessed. This phenotype is characterized by sinus enlargement, neural dehiscence, ostial narrowing, and increased symptom burden. These findings support the concept of a Pneumosinus-Associated Neurogenic Endotype (PANE) as a distinct structural–clinical phenotype warranting further validation

The Canadian Experience With WAYPOINT - Tezepelumab In Adults With Severe Chronic Rhinosinusitis With Nasal Polyps Phase III Trial

Leigh Sowerby[1], **Michel Bussieres**[8], **Marie-Noelle Corriveau**[8], **Jamie DelCarpio**[2], **Remi Gagnon**[8], **Emilie Milliare**[7], **Jason Ohayon**[5], **Doron Sommer**[5], **Marc Tewfik**[2], **Andrew Thamboo**[4], **Megan Wood**[9], **Jane Ran**[9], **Andrew Foster**[9], **Martin Desrosiers**[3]

[1]Western University; [2]McGill University; [3]Universite de Montreal; [4]University of British Columbia; [5]McMaster University; [6]Universite de Sherbrooke; [7]Universite de Quebec; [8]Universite Laval; [9]AstraZeneca

BACKGROUND & AIM

Tezepelumab has demonstrated efficacy for sinonasal symptoms in patients with severe, uncontrolled asthma and comorbid chronic rhinosinusitis with nasal polyps (CRSwNP). However, its efficacy and safety in adults with severe, uncontrolled CRSwNP independent of asthma remain uncertain. This study reports the Canadian experience from the WAYPOINT clinical trial, including 49 patients.

MATERIAL & METHODS

Adults with physician-diagnosed, symptomatic, severe CRSwNP were randomized to receive standard care plus either tezepelumab (210 mg) or placebo administered subcutaneously every 4 weeks for 52 weeks. The co-primary endpoints were change from baseline in total nasal polyp score (NPS) and mean nasal congestion score at Week 52. Key secondary endpoints included loss-of-smell score, total SNOT-22 score, Lund–Mackay score, and time to first nasal polyp surgery or systemic

glucocorticoid use. UPSIT scores and adverse events were also collected. Effect sizes were calculated using least squares mean differences.

RESULTS

Both co-primary endpoints were significantly reduced in the tezepelumab group, with an NPS reduction of −2.5 compared with −2.1 in the global trial. Secondary endpoints also demonstrated statistically significant improvements favoring tezepelumab, exceeding those observed in the global cohort, including UPSIT (+12.1 vs +9.5), SNOT-22 (−30.4 vs −27.4), and Lund–Mackay score on computed tomography (−6.7 vs −5.7).

CONCLUSIONS

Tezepelumab therapy resulted in significantly greater reductions in nasal polyp size, nasal congestion, and sinonasal symptom burden, along with improvements in objective olfactory function, compared with placebo in adults with severe, uncontrolled CRSwNP. Improvements in the Canadian cohort were greater than those observed in the overall WAYPOINT trial population.

OP-1140

Outcomes Of Functional Endoscopic Sinus Surgery In Chronic Rhino Sinusitis In The Middle East, Systematic Review And Meta-Analysis

Dr. Saad Nabeel Algahtani[1]

[1]*King Saud Medical City*

BACKGROUND & AIM

Chronic rhinosinusitis (CRS) is a prevalent inflammatory condition that significantly impacts quality of life (QOL) and may require surgical intervention when medical therapy fails. Functional endoscopic sinus surgery (FESS) is widely used as a minimally invasive approach for CRS management; however, region-specific evidence from the Middle East remains limited.

Our aim is to systematically review and meta-analyze the available literature assessing the effectiveness of FESS in improving outcomes of CRS patients in the Middle East.

MATERIAL & METHODS

This study was conducted in accordance with PRISMA guidelines and the Cochrane Handbook for Systematic Reviews. Electronic databases, including PubMed, Cochrane Library, and Scopus, were systematically searched. The primary outcome was postoperative quality of life, while secondary outcomes included CRS recurrence rates. A random-effects meta-analysis was performed, and sensitivity analyses were conducted to assess result robustness.

RESULTS

Six studies comprising 335 patients were included. Meta-analysis demonstrated a statistically significant improvement in quality of life following FESS ($p < 0.001$). Only two studies reported recurrence outcomes, with a pooled recurrence rate of 6%. Substantial heterogeneity was observed across studies.

CONCLUSIONS

FESS is associated with significant improvement in quality of life among CRS patients in the Middle East. However, the current evidence base is limited, with only six interventional studies identified in the region. This underscores a critical gap in the literature and highlights the need for more high-quality interventional studies to better evaluate long-term outcomes.

OP-1141

Endoscopic Transnasal Resection Of Juvenile Nasopharyngeal Angiofibroma With Extended Medial Maxillectomy And Pterygopalatine Fossa Exposure – Technical Nuances And Clinical Experience

Agata Gierlotka[1]

[1]*Medical University of Silesia*

BACKGROUND & AIM

Juvenile nasopharyngeal angiofibroma (JNA) is a rare, highly vascular, and locally aggressive tumor that primarily affects adolescent males. Complete surgical excision remains the preferred treatment. This article provides a detailed, stepwise endoscopic technique that emphasizes safe vascular control, radical tumor removal, and minimization of recurrence risk.

Aim: This study aims to present a detailed description of the surgical technique for the removal of JNA, with particular emphasis on anatomical considerations, the stages of the surgical procedure, and factors crucial to the safety and effectiveness of the operation.

MATERIAL & METHODS

This study aims to provide practical guidance applicable to daily clinical practice. The procedure is demonstrated through detailed clinical case presentations.

RESULTS

Preoperative angiography with selective embolization of tumor-feeding branches of the external carotid artery is performed 24 to 48 hours before surgery. Resection is conducted using image-guided navigation. The surgical approach includes middle turbinectomy, uncinectomy, complete ethmoidectomy, wide maxillary antrostomy, and extended medial maxillectomy with drilling of the posterior maxillary wall to expose the pterygopalatine fossa. The sphenopalatine artery is identified and controlled. Tumor attachment is dissected from the pterygopalatine fossa. The sphenoid sinus and Vidian canal are inspected to eliminate potential residual disease.

CONCLUSIONS

Endoscopic resection with wide posterior maxillary wall removal and direct visualization of the tumor attachment in the pterygopalatine fossa provides a safe, anatomically precise, and oncologically sound approach for JNA management. The use of a diamond burr in the endoscopic technique facilitates the precise removal of the bony walls of the pterygopalatine fossa and the skull base.

OP-1142

Photodynamic Therapy As An Adjunct In The Management Of Inverted Papilloma: Preliminary Results

Irina Kirichenko, MD, professor[1], **Valentin Popadyuk, MD, professor**[1], **Natalia Kozlova, assistant**[1]

[1]*RUND university , Moscow, Russian*

BACKGROUND & AIM

Inverted papilloma (IP) is a benign, locally aggressive tumor of the sinonasal tract with a high recurrence rate after surgery. Adjuvant photodynamic therapy (PDT) offers the potential to selectively eliminate residual dysplastic tissue and reduce recurrence. Objective: to improve the treatment results of inverted papilloma

MATERIAL & METHODS

A prospective study included 10 patients (7 men, 3 women; mean age 52.4 years) with histologically confirmed IP (Krause staging T1-T2). All patients underwent functional endoscopic sinus surgery (FESS) followed by PDT. Radachlorin (1.0 mg/kg) was administered intravenously followed by irradiation of the surgical area with a 0.665 μm diode laser (power ≈100–240 V/200 W). Follow-up was performed at 1, 3, 6, and 12 months using nasal endoscopy and MRI.

RESULTS

No major complications were recorded. Four patients developed transient mucosal edema and crusting, resolving spontaneously within 7–10 days. During 12 months of follow-up, no recurrences were observed. Postoperative mucosal healing was favorable, with fewer granulations and less fibrosis compared to standard postoperative cases. Subjective assessment using the VAS scale demonstrated significant improvement in nasal breathing and reduction of discomfort.

CONCLUSIONS

PDT appears to be an effective and well-tolerated adjuvant therapy after surgical removal of IP. It may improve mucosal recovery and reduce recurrence. Further randomized controlled studies with larger cohorts and extended follow-up are required to validate these promising results.

KEYWORDS

OP-1143

Time To Surgery And Patient Outcomes In Sinogenic Intracranial Abscesses: A Retrospective Case Series

Claire Lloyd-Davies[1], **Wanding Yang**[1], **Alfonso Luca Pendolino**[1]

[1]*Imperial College Healthcare NHS Trust*

BACKGROUND & AIM

Acute rhinosinusitis is a common outpatient diagnosis, accounting for approximately 2-10% of all primary care and otolaryngology visits. Although rare, sinogenic brain abscesses are associated with significant morbidity and mortality, with substantial health, economic and social impacts on patients and healthcare systems worldwide. While endoscopic sinus surgery is often advocated there is no guidance on timing. This study examined the relationship between time to surgery and patient outcomes.

MATERIAL & METHODS

A retrospective case series of patients with sinogenic brain abscesses admitted to our tertiary hospital between 01/01/2014-31/12/2025 was performed.

Primary outcomes were morbidity and mortality. Secondary outcomes included length of hospital stay, ITU admission, emergency readmission and radiological resolution. Patient demographics, comorbidities, disease pattern and details of medical and surgical management were also collected.

The Mann-Whitney U test compared time to surgery between binary outcomes, and Spearman's rank correlation assessed associations with ordinal outcomes. $p<0.05$ was considered significant.

RESULTS

Fourteen patients were identified. The mean age was 31.9 years (range 6-62), and 93% were male (13/14). The frontal (11/14), ethmoid (11/14) and maxillary (11/14) sinuses were most frequently involved. Radiological imaging commonly demonstrated mass effect (9/14) and extension to adjacent structures (9/14), including bony erosion and orbital involvement. All patients underwent surgery within 7 days. FESS was the first procedure in 50% (7/14), with three as part of combined neurosurgical and ENT operations. Other procedures included burr holes, craniotomies and craniectomies.

Increased time to surgery was associated with higher rates of long-term complications ($p=0.00$), mortality ($p=0.00$), ITU admission ($p=0.00$), emergency readmission ($p=0.00$) and further operations ($p=0.00$). There were no associations with length of stay, ITU duration, or radiological resolution.

CONCLUSIONS

Increased time to surgery was associated with poorer clinical outcomes. These findings support early surgical management and warrant validation in larger, multi-centre studies.

OP-1144

Relationship Between Nasal Septal Deviation Types And Sphenoid Sinus Anatomical Variations: A Computed Tomography Study

Gülpembe Bozkurt[1], **Veysel Tacit Topalan**[1], **Yavuz Uyar**[1]

[1]*Department of Otorhinolaryngology, University of Health Sciences Prof. Dr. Cemil Taşcıoğlu City Hospital, Istanbul, Turkiye*

BACKGROUND & AIM

Nasal septal deviation (NSD) and sphenoid sinus anatomical variations are frequently encountered findings in clinical practice. However, the relationship between NSD types and sphenoid sinus neurovascular variations has not been thoroughly investigated. This study aimed to evaluate the association between NSD types classified according to the Mladina classification and sphenoid sinus pneumatization patterns and neurovascular variations using computed tomography (CT).

MATERIAL & METHODS

Forty patients (27 male, 13 female; mean age 34.75±11.68 years; range 18–59) who underwent paranasal sinus CT at Prof. Dr. Cemil Taşcıoğlu City Hospital between 2025–2026 were retrospectively evaluated. Nasal septal deviations were classified according to the Mladina classification (Mladina et al., 2008). Sphenoid sinus pneumatization was assessed on sagittal CT images according to the Hamid classification (conchal, presellar, sellar, postsellar). The relationship between the optic nerve and sphenoid sinus was evaluated on coronal and axial images using the DeLano classification (Types 1–4). Additionally, intersphenoid septum (ISS) number and posterior insertion point, internal carotid artery (ICA) protrusion and dehiscence, Onodi cell presence, and anterior clinoid process pneumatization (ACPP) were assessed bilaterally. Pearson Chi-square test was used for statistical analysis; $p<0.05$ was considered statistically significant.

RESULTS

The most common NSD type was Mladina Type 3 (40.0%), followed by Type 5 (20.0%), Type 1 (12.5%), Type 4 (10.0%), Type 6 (10.0%), Type 2 (5.0%), and Type 7 (2.5%). Sellar pneumatization was the most frequent sphenoid sinus type (57.5%). Statistically significant associations were found between Mladina type and Onodi cell presence ($p=0.014$), left optic nerve type ($p<0.001$), and left ICA dehiscence ($p=0.033$). Onodi cells were most frequently observed in Type 5 (37.5%) and Type 7 (100%) deviations. DeLano Type 4 optic nerve configuration was detected in all Type 7 deviation cases. A trend toward significance was observed for right optic nerve type ($p=0.055$), ISS insertion point ($p=0.085$), and right ACPP ($p=0.109$). No significant association was found between Mladina type and pneumatization pattern, ISS number, or ICA protrusion.

CONCLUSIONS

Mladina classification of nasal septal deviation showed significant associations with Onodi cell presence, left optic nerve type, and left ICA dehiscence. These findings suggest that NSD type may serve as a useful predictor of high-risk sphenoid sinus anatomical variations in preoperative planning for endoscopic skull base surgery. Limitations include the retrospective design and limited sample size; larger prospective studies are warranted to confirm these preliminary findings.

Surgical Management Of Sinonasal Mucormycosis - How Much Is Enough

Catalina Voiosu[1], **Irina Gabriela Ionita**[1], **Andreea Rusescu**[1], **Ruxandra Oana Alius**[1], **Viorel Zainea**[1], **Razvan Hainarosie**[1]

[1]*Carol Davila University of Medicine and Pharmacy;* [2]*Prof. Dr. D. Hociota Institute of Phonoaudiology and Functional ENT Surgery*

BACKGROUND & AIM

Sinonasal mucormycosis remains one of the most problematic invasive opportunistic fungal infections that challenges ENT surgeons and connected specialities. The progression of the disease is directly influenced by the patient's general condition and the time of diagnosis. However, taking into account the fact that the profile of the patient who will develop this ubicuitary infection will include multiple comorbidities and poor defence mechanisms, the prognosis is severe in most cases. Surgery is the treatment of choice, but specific antifungal medication and general supportive therapy are mandatory.

MATERIAL & METHODS

A series of cases of patients with confirmed sinonasal mucormycosis were admitted to our tertiary centre, the “Prof. Dr Dorin Hociotă” Institute of Phonoaudiology and Functional Surgery - ENT from Bucharest. The general status of the patients varied from severe, with a comatose patient, to an overall good general condition, the latter including patients who were able to tolerate the fungal infection. The surgical treatment for all these patients included wide resections of necrotic tissue, specific anti-fungal medication and the proper control of subjacent pathologies.

RESULTS

An overall good survival score was achieved, with just one death that occured one month after the surgical intervention. The rest of out patients recovered with good functional results, albeit important resections.

CONCLUSIONS

A multidisciplnary team management is crucial for these patients, where surgery plays a crucial role and requires experience, but apropriate antifungal therapy and the cpntrol of associated comorbidites are also mandatory. The general condition of the patient influences the outcome, but we must also keep in mind the without adequate surgery fatality is the most likely outcome.

Clinical Predictors And Immunological Correlates Of Disease Control After Endoscopic Sinus Surgery In Chronic Rhinosinusitis With Nasal Polyps

Hakan Kara[1,2], **Utkucan Ayeser**[1], **Ayşenur Kökoğlu**[2], **Doğu Vurallı Bakkaloğlu**[3], **Şenol Çomoğlu**[1], **Meryem Nesil Keleş Türel**[1], **Günnur Deniz**[2], **Levent Aydemir**[1]

[1]*Istanbul University, Istanbul Faculty of Medicine, Department of Otorhinolaryngology Head and Neck Surgery;* [2]*Istanbul University, Institute of Graduate Studies in Health Sciences, Aziz Sancar Institute of Experimental Medicine, Department of Immunology;* [3]*Istanbul University, Istanbul Faculty of Medicine, Department of Pathology*

BACKGROUND & AIM

Chronic rhinosinusitis with nasal polyps (CRSwNP) is a heterogeneous inflammatory disease with variable postoperative disease control following endoscopic sinus surgery (ESS). Identifying clinical and immunological predictors of disease control may improve risk stratification. We hypothesized that uncontrolled disease is associated with distinct immune profiles characterized by altered T-cell polarization.

MATERIAL & METHODS

This study included 30 patients with CRSwNP who underwent EES at a tertiary referral center. Clinical variables included age, sex, asthma, atopy, Samter’s triad, smoking exposure, revision status, intranasal corticosteroid adherence, nasal polyp score (NPS) , Lund–Mackay score (LMS), SNOT-22, COSI score, peripheral blood eosinophil count, serum IgE level, and tissue eosinophil count. Immunological variables included peripheral blood and tissue $CD3^+$, $CD4^+$, $CD4^-$, regulatory T cells, and cytokine-producing subsets (IL-5, IL-10, IL-17, IFN-γ), quantified using multiparameter flow cytometry. Plasma and mucus cytokines were measured using multiplex immunoassay. Eight septoplasty patients without inflammatory disease served as healthy controls. The primary outcome was disease control status. Disease control status was assessed 12–24 months postoperatively and classified according to EPOS 2020 criteria. Logistic regression analyses were performed to identify independent clinical predictors and immunological correlates associated with uncontrolled disease.

RESULTS

Mean SNOT-22 score decreased from 45.77 to 30.46, mean LMS decreased from 15.79 to 10.97, and median NPS decreased from 6 to 3 postoperatively ($p<0.001$). Tissue immune profiling showed increased $CD4^+CD25^+$ T cells (Treg) ($p = 0.008$), IL-5–

producing $CD4^+$ T cells (p<0.001), IL-17–producing $CD4^+$ T cells (p = 0.004), and IL-5–producing $CD4^-$ T cells (p = 0.001), with decreased IFN-γ–producing $CD4^-$ T cells (p=0.041). Peripheral blood analyses demonstrated increased Treg (p=0.034), IL-10–producing $CD4^-$ T cells (p=0.028), and IL-10–producing Treg (p=0.038). Nasal mucus IL-5 levels were higher in patients than controls (p=0.002). Logistic regression identified higher Lund–Mackay score (OR 1.32, p = 0.012), lower peripheral $CD3^+$ T-cell proportion (OR 0.24, p=0.031), lower peripheral IFN-γ–producing $CD4^+$ T cells (OR 0.22, p=0.018), and higher tissue IL-17–producing $CD4^+$ T cells (OR 2.77, p=0.032) as significant factors associated with uncontrolled disease.

CONCLUSIONS

Postoperative clinical parameters demonstrated significant improvement compared with preoperative values. Higher preoperative radiologic disease burden, reflected by the LMS, was independently associated with uncontrolled disease. Compared with healthy controls, patients demonstrated altered immune profiles, including increased mucus IL-5 levels and increased tissue IL-5– and IL-17–producing T-cell subsets. Uncontrolled disease was specifically associated with reduced IFN-γ–producing $CD4^+$ T cells and increased IL-17–producing tissue $CD4^+$ T cells. These findings may suggest that uncontrolled disease is associated with mixed inflammatory endotypes, in which type 3 inflammatory signatures coexist with underlying type 2 inflammation.

OP-1147

Evaluation Of Nasal Functions In Transfusion Dependent Beta-Thalassemia Major Patients

Muhammet Yıldız[1], **Erdal Kurtoğlu**[2], **Gül Ergen Yıldız**[3], **Furkan Öztürk**[1], **Nevreste Didem Sonbay Yılmaz**[1], **Erdem Atalay Çetinkaya**[1], **Yeşim Yüksel**[1], **Özer Erdem Gür**[1]

[1]*Department of Otorhinolaryngology, University of Health Sciences, Medical Faculty, Antalya Training and Research Hospital, Antalya, Turkey;* [2]*Department of Hematology, University of Health Sciences, Medical Faculty, Antalya Training and Research Hospital, Antalya, Turkey;* [3]*Department of Allergy and Immunology, University of Health Sciences, Medical Faculty, Antalya Training and Research Hospital, Antalya, Turkey*

BACKGROUND & AIM

Beta-Thalassemia Major (β-TM) is a common inherited congenital disorder of hemoglobin production, which results in hemolytic anemia as well as multi-organ involvement. Management strategies for patients with β-TM consists of regular blood transfusions and iron chelating agents as well as management of secondary complications resulting from iron overload. While regular blood transfusions and iron-chelating agents extend the life expectancy of patients with β-TM, prolonged survival increases the prevalence of disease-related organ damage and complications. This study aimed to evaluate nasal functions in transfusion dependent β-thalassemia major (TDβ-TM) patients and identify risk factors for nasal dysfunction.

MATERIAL & METHODS

This prospective, cross-sectional study included 132 patients with TDβ-TM and 91 controls. All patients underwent detailed physical examination, including nasal endoscopy. Data regarding demographic, clinical, and laboratory characteristics—specifically mean hemoglobin and ferritin levels—were documented for all participants. A quality of life (SNOT) test was used for subjective evaluation of nasal symptoms. The saccharin test, nasal Schirmer test, CCCRC olfactory test, and peak nasal inspiratory airflow (PNIF) were used for objective evaluation of nasal functions.

RESULTS

The patient group had a significantly lower hemoglobin level (p<0.05) and a significantly higher ferritin level (p<0.05) compared to the control group. Mean SNOT test scores were higher in the patient group compared to the controls (p<0.05). Mean Saccharin transit times and Schirmer test scores were higher, while PNIF and CCCRC olfactory test scores were lower in the patient group compared to the controls (p<0.05)). Hyposmia was also found to be significantly more frequent in patients with TDβ-TM than in controls.

CONCLUSIONS

Our study demonstrates that patients with TDβ-TM exhibit significant nasal dysfunction, and clinical parameters such as high serum ferritin levels should be closely monitored as potential risk factors for mucosal damage. Regular otorhinolaryngological evaluations should be integrated into the standard care protocol for TDβ-TM patients to ensure early detection and management of nasal complications associated with chronic iron overload.

OP-1148

Assessment Of Frontal Sinus Pneumatization Patterns And Lateral Extension Of Frontal Sinus Lesions: A Comparative Analysis Of Healthy And Surgical Cohorts

Hazan Başak[1], **Süha Beton**[1], **Cem Meco**[1,2,3]

[1]*Ankara University Faculty of Medicine, Department of Otolaryngology, Head&Neck Surgery;* [2]*Salzburg Paracelsus Medical University Department of Otorhinolaryngology;* [3]*Weill Cornell Medical School Department of Otorhinolaryngology*

BACKGROUND & AIM

Accessing the lateral portion of the frontal sinus and skull base during endonasal endoscopic surgery remains a significant challenge due to anatomical constraints, particularly in cases of well-pneumatized frontal sinuses. The aim of this study is to compare certain preoperative radiological measurements and pneumatization patterns between the healthy adult population and patients who underwent surgery for various frontal sinus lesions, and to explore how different types of frontal sinus pathologies and the lateral extension of frontal sinus lesions may have influenced the surgical approach to address all part of frontal sinus including far lateral preoperatively.

MATERIAL & METHODS

The pneumatization of frontal sinuses on CT was classified into four zones (Z1: medial orbital wall, Z2: midway between medial orbital wall and Z3: midorbital point, Z4: midway between lateral orbital wall and midorbital point and lateral orbital wall) and were measured on 250 CT scan of randomly selected healthy patients. The same measurements were done on 121 patients that underwent surgery between January 2019 and December 2025 in our clinic for various frontal sinus pathologies. Both the pneumatization pattern and the lateral extension of pathology, as well as type of pathology and type of surgery performed were documented. The patients in which the extent of pathology differed from the total sinus length were noted and evaluated separately.

RESULTS

In the healthy cohort (n=250, mean age 44.46±16.07 years), frontal sinus pneumatization was most commonly Zone 1 in 109 patients (43.6%), followed by Zone 2 in 70 (28%), Zone 3 in 42 (16.8%), and Zone 4 in 29 (11.6%).

The surgical cohort included 121 patients (mean age 46.80±14.39 years), with bilateral disease in 88 patients (72.7%), yielding 209 analyzed sides. Pathologies were mainly allergic/inflammatory (76%), sinusitis complications (17.3%) and neoplasms (6.7%). Zone 2 pneumatization was most common (29.7%), followed by Zone 3 (23.9%), Zone 4 (19.6%), and Zone 1 (19.1%); while 15 sides lacked imaging.

Except for 17 patients (14.04%), pathologies extended to the most lateral aspect of the frontal sinus. These exceptions were mostly CRSwNP variants and neoplasms.

Most surgeries performed were revisions (113 cases - 93.3%). Frontal drillout was performed in 47 patients (36.3%), including 31 DRAF III; most commonly in Zone 3 (%54.76) and 4 (%50) lesions.

CONCLUSIONS

The surgical cohort showed slightly greater frontal sinus pneumatization than the healthy cohort. Regardless of pathology type (except osteomas) lesions almost always extended to the most lateral aspect. Thus, adequate visualization and access to far lateral frontal sinus must be achieved in all cases, albeit the correlation between pneumatization pattern and preferred surgical approach being loose. This highlights the importance of selecting the most suitable surgical approach preoperatively. Current literature provides limited data for planning EEA for frontal sinus pathologies, making preoperative assessment crucial to predict surgical extent and ensure complete treatment of all frontal sinus regions, including far lateral.

BACKGROUND & AIM

In the prospective, randomized, EVEREST head-to-head study, dupilumab demonstrated rapid and sustained improvements over omalizumab in upper and lower airway outcomes in patients with severe chronic rhinosinusitis with nasal polyps (CRSwNP) with coexisting asthma. This post hoc analysis compared severe CRSwNP and asthma outcomes in patients enrolled in European countries.

MATERIAL & METHODS

EVEREST (NCT04998604) randomized adults with severe CRSwNP and coexisting asthma to dupilumab 300 mg every 2 weeks or omalizumab 75–600 mg every 2 weeks or every 4 weeks for 24 weeks on background mometasone furoate nasal spray. We considered the following endpoints: Week 24 change in nasal polyp score (NPS, range 0–8, lower is better) and University of

Pennsylvania Smell Identification Test (UPSIT, range 0–40, higher is better). Other upper airway outcomes assessed were loss of smell (LoS, range 0–3, lower is better), nasal congestion (NC, range 0–3, lower is better) and the 22-item Sino-Nasal Outcome Test (SNOT-22, range 0–110, lower is better). Lower airway outcomes assessed were pre-bronchodilator forced expiratory volume in 1 second (FEV1, L, higher is better) and 7-item Asthma Control Questionnaire (ACQ-7, range 0–6, lower is better).

RESULTS

EVEREST randomized a total of 360 patients; 316 were from 14 European countries (dupilumab, n=161; omalizumab, n=155). Patient characteristics were comparable between treatment groups (Table 1). At Week 24 improvements were greater with dupilumab vs omalizumab for all upper and lower airway outcomes investigated (Table 2). For NPS and UPSIT, least squares mean difference comparing dupilumab to omalizumab [95% confidence interval] was −1.67 [−2.05, −1.29] and 8.21 [6.38, 10.05], respectively. Safety profiles of dupilumab and omalizumab were comparable.

CONCLUSIONS

Dupilumab showed nominally greater improvement in both upper and lower airway outcomes than omalizumab in patients from European countries with severe CRSwNP with coexisting asthma. These data support the efficacy of dupilumab in unified airway disease vs an active biologic comparator among European patients and support the known safety profiles of dupilumab and omalizumab.

Modified Trans-Pterygoid Approach To Sphenoid Meningoencephaloceles: Short Steps For Long Gains

Mohamed Eesa[1], **Ehsan Hendawy**[1]

[1]*Otorhinolaryngology-Head & Neck Surgery at Zagazig University, Egypt.*; [2]*department of Otorhinoaryngology-Head & Neck Surgery at Saudi German hospital, Jeddah, KSA.*

BACKGROUND & AIM

Cerebrospinal fluid (CSF) leaks and meningoencephaloceles originating in the lateral recess of the sphenoid sinus can be challenging. The traditional trans-pterygoid approach through the pterygopalatine fossa (PPF) is time consuming and places important structures at risk, which can lead to significant morbidity. We report our experience using a simplified, endoscopic modified transpterygoid approach (MTPA), which spares the PPF contents in the management of lateral sphenoid sinus meningoencephaloceles and CSF leaks.

MATERIAL & METHODS

We report a series of lateral sphenoid recess CSF leaks and meningoencephaloceles evaluating the repair technique and outcome.

RESULTS

Different repair materials were used free septal mucosal graft, gasket seal with middle turbinate free mucosa and bone and vascularized naso-septal flap. There was 100% success rate with no recurrence of CSF leak.

CONCLUSIONS

The MTPA reduces morbidity and greatly simplifies access to the lateral sphenoid sinus for the management of CSF leaks and meningoencephaloceles, without compromising exposure. This technique avoids the need for extensive PPF dissection.

KEYWORDS

An Innovative Triple-Layer Sandwich Graft Technique For Medium-Sized Nasal Septal Perforations

Deniz Hanci MD[1], **Öykü İzel Onaran MD**[2], **Huseyin Altun MD**[3], **Dzhavidan Salimova MD**[1], **Yavuz Uyar MD**[1]

[1]*University of Health Sciences Prof. Dr. Cemil Taşcıoğlu City Hospital , Department of Otorhinolaryngology, Istanbul, Turkey.*; [2]*Department of Otorhinolaryngology, Çerkezköy State Hospital, Çerkezköy/Tekirdağ Turkey.*; [3]*Kocaeli Technology and Health University, Department of Otorhinolaryngology, Kocaeli, Turkey .*

BACKGROUND & AIM

Nasal septal perforation (NSP) is a surgically challenging condition with limited potential for spontaneous healing. Various grafting techniques have been described to achieve reliable closure. This study presents an innovative repair technique using a triple-layer sandwich graft composed of costal cartilage, rectus abdominis muscle fascia, and perichondrium for the management of medium-sized NSPs.

MATERIAL & METHODS

A retrospective analysis was conducted on 22 patients who underwent NSP repair using an open septoplasty approach. All septal perforations were medium-sized, ranging from 1 to 1.5 cm in diameter. Following elevation of bilateral mucoperichondrial flaps, a sandwich graft was prepared with costal cartilage serving as the central structural layer, wrapped with rectus abdominis muscle fascia and perichondrium harvested from the same donor site. The graft was placed between opposing mucoperichondrial flaps to achieve complete defect coverage. Postoperative outcomes were evaluated during follow-up.

RESULTS

The study cohort consisted of 22 patients, including 13 males (59.1%) and 9 females (40.9%), with a mean age of 34.8 ± 6.2 years (range: 22–47). The mean horizontal and vertical diameters of the septal perforations were 12.8 ± 1.6 mm and 13.4 ± 1.9 mm, respectively. The mean follow-up period was 13.6 ± 2.1 months. Complete closure was achieved in 21 of 22 patients (95.5%). One patient (4.5%) experienced partial reperforation during follow-up. No major intraoperative or postoperative complications, including infection, graft resorption, or donor-site morbidity, were observed. All successfully treated patients demonstrated stable septal integrity and satisfactory nasal function at final follow-up.

CONCLUSIONS

The use of a triple-layer sandwich graft consisting of costal cartilage, rectus abdominis muscle fascia, and perichondrium provides a safe, reliable, and effective option for the repair of medium-sized nasal septal perforations. This technique offers strong structural support and favorable healing outcomes, representing a valuable addition to existing surgical methods.

OP-1152

Pott's Puffy Tumor Diagnosis And Management: A Systematic Review

Hannah Brennan MD[1], **Kalpesh Hathi MD**[1], **Christopher J Chin MD, FRCSC**[1]

[1]*Division of Otolaryngology - Head & Neck Surgery, Dalhousie University, Halifax, Nova Scotia, Canada*

BACKGROUND & AIM

Pott's puffy tumor (PPT) is a rare disease process characterized by osteomyelitis of the frontal bone with subperiosteal abscess formation, often arising from the paranasal sinuses. Early diagnosis and aggressive management are fundamental in the management approach and necessary to decrease the risk of intracranial complications and long-term neurological sequelae. However, there is no formal consensus for the management of PPT. This review aims to synthesize and evaluate treatment approaches for PPT to elucidate an evidence-based approach to management of this rare clinical entity.

MATERIAL & METHODS

A systematic review of PubMed, Embase, and CINAHL was completed following PRISMA guidelines. The search strategy was developed in collaboration with a clinical librarian to identify articles examining diagnosis and treatment of PPT. A total of 2170 articles were screened, 286 included in our paper, with a total of 486 patient cases analyzed.

RESULTS

The 486 patients with PPT ranged in age from 4 months to 92 years (average 29.7 years, median 18 (IQR 49.3-12)), with the majority being male (67.3%). The most common etiology was sinusitis (70.0%), followed by trauma (11.5%). The most prevalent presenting symptoms included forehead swelling (68.1%), headache (51.4%) and fever (30.2%). CT and MRI were routinely used in diagnostic and post-treatment assessment. Common isolated pathogens included streptococcus (virdins and group A) and Staphylococcus (aureus and coagulase-negative). Management typically included intravenous antibiotics and surgery. Intracranial involvement was found in 40.9% of cases, with epidural abscess being the most common complication. Intervention varied on the disease extent and included endoscopic sinus surgery (ESS) with external drainage (21.4%), ESS (18.9%), ESS with neurosurgical approach (5.5%), external drainage (21.1%) and external drainage with neurosurgical approach (13.0%). The mortality rate was 1.6%, with a mean follow-up duration of 11 months.

CONCLUSIONS

This is largest systematic review of PPT, including both adult and pediatric patients. We identified the most common etiology, presenting symptoms, imaging modalities routinely employed, isolated pathogens, management approach, complications and outcomes. This review highlights the importance of multidisciplinary approach for management of this rare and clinically significant disease process.

Therapeutic Outcomes Of Biologic Switching In Chronic Rhinosinusitis With Nasal Polyps: A Systematic Review And Meta-Analysis

Hussain Aljubran[1], **Maria R. Alabdulaal**[1], **Latifah A. Aldhaif**[1], **Dalal M. Motabagani**[1], **Ridha M. Alhussain**[1], **Zainab S. AlWusaybie**[1], **Faisal O. Aldhafeeri**[1], **Ali Almomen**[1]

[1]*Aljaber Ophthalmology and Otolaryngology Hospital, Alahsa, Saudi Arabia*

BACKGROUND & AIM

Biological therapy is a newer line of treatment that has been utilized in practice for patients with chronic rhinosinusitis with nasal polyps, showing excellent results. However, some patients with chronic rhinosinusitis with nasal polyposis (CRSwNP) do not respond to this therapy. Hence, this study aims to evaluate the efficacy and safety of biological switching in these patients.

MATERIAL & METHODS

Using the Web of Science, Cochrane, MEDLINE, and Embase databases, we analyzed studies involving biological switching in CRSwNP patients published up to June 2025. The studies were extracted, and data were pooled for meta-analysis.

RESULTS

Of 3,367 studies identified, eight studies (involving 470 patients) were included in the systematic review, four of which were included in the meta-analysis. The results showed that the most common reason for switching was insufficient CRS symptom control (59.7%), followed by undesirable side effects (10.8%). The findings demonstrated dramatic effects of biological switching in terms of the SNOT-22 score, with a mean improvement of 71.4%. In addition, studies that switched patients to dupilumab showed significant improvement after switching in both SNOT-22 and nasal polyp scores ($p = 0.006$ and 0.005, respectively). Overall, the success rate of biological switching ranged from 59.6% to 100%, with an average success rate of 79.2%.

CONCLUSIONS

This review demonstrated the effect of biological switching as an option for patients with refractory CRSwNP or those experiencing biological side effects. These findings highlight a new therapeutic alternative that can serve as a fundamental choice when managing CRSwNP patients.

Deep Learning-Assisted Nasal Endoscopy For The Evaluation Of Chronic Rhinosinusitis With And Without Nasal Polyps

Dipesh Gyawali[1], **Thomas Mundy**[1,2], **Akio Fujiwara**[1], **Quinn O'Malley**[1], **Elena Karras**[1], **Valentina Vargas Marin**[1], **Ashley Conley**[1], **Jonathan Bidwell**[1], **Edward D McCoul**[1,2,3]

[1]*Department of Otorhinolaryngology, Ochsner Health, New Orleans, Louisiana, USA;* [2]*Ochsner Clinical School, University of Queensland, New Orleans, Louisiana, USA;* [3]*Department of Otolaryngology-Head and Neck Surgery, Tulane University School of Medicine, New Orleans, Louisiana, USA*

BACKGROUND & AIM

Nasal endoscopy (NE) is crucial for evaluating sinusitis, but assessment remains subjective. Deep learning can provide clinical decision support by reducing inter-rater variability and automating detection of key features across chronic rhinosinusitis (CRS) phenotypes, including with and without nasal polyposis (CRSwNP, CRSsNP). We developed a deep learning framework to identify mucus and polyps near the middle meatus (MM), providing objective assessment of diagnostic features for CRS in a novel approach to build upon clinical best practices.

MATERIAL & METHODS

6404 NE images from 974 patients were manually annotated for segmentation of middle turbinates, inferior turbinates, mucus, and polyps. A multi-class detection and segmentation model with a rule-based logic for MM localization was developed, implementing a clinical algorithm that applies anatomy IOU and conditional logic for sinusitis diagnosis. The system was validated on 300 images from 117 patients with confirmed CRSwNP or CRSsNP and benchmarked on real-time performance on an NVIDIA RTX 4090 GPU (87.7 fps).

RESULTS

The model achieved performance comparable to trained otolaryngologists with an inter-rater agreement F1-score of 86.0% (86.3% sensitivity, 87.4% precision). Moreover, our model achieved classification specificity of 99.1% for CRSwNP and 96.3% for CRSsNP. The resulting implementation ran faster than real-time performance, indicating suitability for integration into live clinical workflows.

CONCLUSIONS

Our novel deep learning-driven framework enhances decision-making for diagnosing CRS with NE by reducing inter-rater variability and enabling real-time processing. The model's results also validate its capability to perform at a level consistent with contemporary literature. This demonstrates the potential to improve workflow efficiency, patient outcomes, and access to specialist-level care.

Practice Variation In Topical Cocaine Use: Results From A UK-Wide ENT Survey

Sebastian Powell[2], **Roanna Norman**[1], **Shayan Shahidi**[2], **Tim Biggs**[2]

[1]*Torbay and South Devon NHS Foundation Trust;* [2]*Portsmouth Hospitals University NHS Trust*

BACKGROUND & AIM

Topical cocaine has historically been used in nasal surgery for its vasoconstrictive and local anaesthetic properties. Its use remains controversial due to potential systemic side effects and the lack of well-established evidence comparing its safety and efficacy with alternative agents. Additionally, postoperative detectability on urine drug screening may carry medicolegal implications. Given the absence of standardised guidance, this study aimed to assess current practice patterns and attitudes towards topical cocaine in nasal surgery amongst ENT doctors across the United Kingdom.

MATERIAL & METHODS

An online questionnaire evaluating the use of topical cocaine in nasal surgery was distributed to ENT clinicians in the UK across multiple centres, training grades and subspecialties. A total of 89 responses were analysed. The survey identified current use of topical nasal decongestants, preferred cocaine formulations and concentrations, reasons for use and perioperative counselling practices.

RESULTS

Responses were gained from 14 regions across the UK. Most respondents were ENT consultants (50.6%) or registrars (32.6%), with the majority (61.8%) practicing in rhinology. 58.4% of participants reported using a nasal decongestant containing cocaine, most frequently administered as 2 mL of a 5% solution. Phenylephrine was also frequently used, reported by 60.0% of respondents. The primary reason for cocaine use was perceived superior surgical outcomes (67.3%), followed by availability (32.7%). The most common reasons against using cocaine included concerns surrounding side effects, no local availability and perceived equivalent decongestant availability. Patient counselling regarding intra-operative cocaine was inconsistent amongst respondents who used cocaine-containing preparations: only 11.5% routinely inform patients and few consistently communicate the implications for drug testing (15.4%) or driving (9.6%). 12.4% of respondents reported cocaine-related intraoperative or postoperative complications during their careers, most commonly cardiac complications.

CONCLUSIONS

There is significant variability in the use of topical cocaine in nasal surgery across the UK, with inconsistent patient counselling and documentation. These findings highlight the need for clearer guidelines to support patient safety and informed consent. Further comparative research is required to clarify its risk profile and clinical advantage over alternative agents.

OP-1157

Chronic Rhinosinusitis With Nasal Polyps Recurrence After Surgical Treatment : Prevalence And Risk Factors

Triek Ryma[1], **Mohamed Hachemi**[1], **Ouziane Megharebi**[1], **Samira Medkour**[1], **Mokhtar Hasbellaoui**[1]

[1]*ENT department of Mohamed Lamine Debaghine University Hospital*

BACKGROUND & AIM

Chronic rhinosinusitis with nasal polyposis (CRSwNP) is an inflammatory disease of sinonasal mucosa, surgery remains the most effective treatment for patients who are refractory to medical therapy; however postoperative recurrence remains frequent.

Our aim is to assess the prevalence of CRSwNP recurrence after surgical treatment and identify associated risk factors.

MATERIAL & METHODS

A descriptive and analytic retrospective study was conducted in the ENT department of Mohamed Lamine Debaghine University Hospital between 01/2020 and 08/2025. The study included 129 patients who underwent surgery for CRSwNP and had at least six months of postoperative follow-up. Patients lost to follow-up were excluded (n = 11).

Demographics, comorbidities, clinical presentation, CT findings, and surgical approach were the main variables studied. All results were analyzed using IBM SPSS version 31.

RESULTS

Among 129 patients, 62 (46%) experienced recurrence, with a mean time to recurrence of 17 months. Surgical revision was required in 23% of the population. Mean age was comparable between groups (≈46 years), with a sex ratio of 1.7. Smoking was significantly associated with recurrence, as 40% of recurrent patients were smokers compared with 8.6% in non-recurrence group (χ^2 = 10.3, p = 0.001). Although diabetes and hypertension were more frequent among recurrent patients, the association was not statistically significant. In contrast, Widal syndrome showed a significant association with recurrence, being present in 71.2% of recurrent cases versus 52.9% of non-recurrent cases (χ^2 = 4.4, p = 0.03). The mean Lund–Mackay CT score was higher in the recurrence group (21.11) compared with the non-recurrence group (17.75), with a statistically significant difference (p < 0.001). Endoscopic sinus surgery (ESS) was performed in most recurrent patients, whereas polypectomy alone was less frequent.

CONCLUSIONS

Smoking, Widal syndrome, higher CT scores, and limited surgical techniques are key predictors of recurrence, emphasizing the importance of risk stratification and tailored surgical management.

Temporal Dynamics Of The Sinonasal Microbiome In Health And Disease

Joanna Szaleniec[2,1,3], **Sylwia Bozek**[2], **Aldona Olechowska-Jarzab**[3], **Malgorzata Forys**[3], **Marta Biel**[3], **Tomasz Kosciolek**[2]

[1]*Jagiellonian University Medical College, Krakow, Poland;* [2]*Sano Centre for Personalized Computational Medicine, Krakow, Poland;* [3]*University Hospital, Krakow, Poland*

BACKGROUND & AIM

The aim of our study was to characterize the poorly explored temporal dynamics of the sinonasal microbiome, particularly during acute rhinosinusitis (ARS) and exacerbations of chronic rhinosinusitis (AECRS). While current literature provides guidelines for the clinical diagnosis of bacterial versus non-bacterial ARS, there is no evidence for differentiating between bacterial and non-bacterial AECRS, and most episodes are treated with antibiotics. The aim of this study was to define the microbiological patterns of bacterial and non-bacterial ARS and AECRS.

MATERIAL & METHODS

In this longitudinal observational study, samples of the sinonasal microbiome were obtained from 55 subjects (36 patients with CRS and 19 healthy volunteers) at regular intervals at baseline, as well as during episodes of ARS, AECRS, and after antibiotic treatment. A total of 293 samples were collected. Microbiological analyses included bacterial culture and full-length 16S rRNA sequencing. To our knowledge, this is the largest longitudinal study of the sinonasal microbiome to date utilizing third-generation sequencing, which enables species-level identification of bacteria.

RESULTS

Bacterial ARS was characterized by “blooms” (marked dominance) of a single pathogen. Infections with a clinical presentation of viral or post-viral ARS were usually not associated with significant microbiome shifts; however, “blooms” of M. catarrhalis and H. influenzae were sometimes observed. Similar “blooms” were noted in 25% of AECRS cases, while in the remaining 75% no apparent shifts were observed. Interestingly, expansion of pathogens, including S. aureus, was frequently clinically silent.

CONCLUSIONS

Active bacterial infection in the sinuses is characterized by a significant expansion of a single pathogenic species. Some episodes of clinically “viral” or “post-viral” ARS follow the microbiological pattern of bacterial infection but remain self-limiting and do not require antibiotics. Sequencing may provide a valuable tool for differentiating between bacterial and non-bacterial AECRS and reducing the overuse of antibiotics in AECRS.

OP-1159

Effect Of Bupivacaine With Epinephrine/Topical Vasoconstrictor Injection On Intraoperative Bleeding During Endoscopic Sinus Surgery: A Double-Blind, Randomized Controlled Trial

Azin Tabari[1], **Juan Carlos Hernaiz**[1], **Manal Al Noumani**[1], **Leonora Beltran**[1], **Amin Javer**[1]

[1]University of British Columbia, St Paul Sinus Center

BACKGROUND & AIM

Endoscopic sinus surgery (ESS) is widely used for chronic rhinosinusitis (CRS) and other sinonasal conditions. Intraoperative bleeding remains a major challenge, affecting visualization and operative efficiency.

Aim:To evaluate whether submucosal injection of 0.25% bupivacaine with epinephrine reduces intraoperative bleeding, blood loss, and operative time compared to sham injection during ESS.

MATERIAL & METHODS

This interim analysis includes 47 of 80 planned patients randomized to receive either bupivacaine with epinephrine or sham injection during ESS. The primary outcome was intraoperative bleeding using the Boezaart score, assessed separately for septoplasty and sinus surgery. Secondary outcomes included mean arterial pressure (MAP), total blood loss, operative time, and postoperative pain. Owing to limited sample size, results are reported descriptively without formal hypothesis testing.

RESULTS

Among 47 patients (23 Injection, 24 Sham), median Boezaart scores were lower in the Injection group for the septum (1.0 [IQR 0] vs 2.1 [1.1]) and sinus region (1.8 [1.06] vs 2.25 [0.46]). MAP was similar between groups. Mean blood loss was lower in the Injection group (125 ± 51 mL) compared to Sham (365 ± 144 mL). Operative time was comparable (131.7 ± 41.4 vs 139.4 ± 39.8 minutes). Postoperative pain scores were similar across time points. Final analyses will include the full sample and apply conventional hypothesis testing thresholds ($p < 0.05$).

CONCLUSIONS

Submucosal bupivacaine with epinephrine may reduce intraoperative bleeding and blood loss without affecting operative time, MAP, or pain. Final analysis with the full sample will determine statistical significance.

Impact Of Endoscopic Endonasal Skull Base Surgery On Olfactory Function, Nasal Airway Resistance, And Quality Of Life: A Prospective Study

Alparslan Eker[2], **Muammer Melih Şahin**[1], **Emrah Çeltikçi**[1], **Ozan Yavuz Tüfek**[3], **Muhittin Akalın**[4]

[1]Gazi University Faculty of Medicine,Otorhinolaryngology department,Ankara/Türkiye; [2]Gölbaşı Şehit Ahmet Özsoy Hospital, Ankara/Türkiye; [3]Adıyaman Training and Research Hospital, Adıyaman/Türkiye; [4]Gaziantep City Hospital, Gaziantep/Türkiye

BACKGROUND & AIM

In endoscopic transnasal skull base surgery, surgical success is commonly assessed by tumor resection rates and neurological outcomes, while sinonasal functions are often overlooked. The aim of this study was to evaluate postoperative rhinological outcomes in patients undergoing endoscopic transnasal skull base tumor surgery, with particular focus on changes in olfactory function, nasal airway resistance, and sinonasal quality of life. Additionally, the relationship of these parameters with surgical technique and postoperative sinonasal morbidities such as crusting and synechiae was investigated.

MATERIAL & METHODS

In this prospective single-center study, 106 patients who underwent primary endoscopic transnasal skull base tumor surgery for sellar, suprasellar, parasellar, and clival pathologies between February 2024 and June 2025 were included. All patients were evaluated preoperatively and at the 1st and 3rd postoperative months.

The assessment included nasal endoscopic examination, measurement of total inspiratory resistance (TIR) and total expiratory resistance (TER) using active anterior rhinomanometry, and evaluation of olfactory function with the Sniffin' Sticks test. Sinonasal symptoms and quality of life were assessed using the SNOT-22 questionnaire, nasal obstruction using the NOSE scale, and symptom severity using a visual analog scale (VAS). The presence of crusting and synechiae was recorded endoscopically.

According to the surgical extent, patients were classified into an extended surgery group (septal resection >2 cm) and a standard surgery group. Outcomes were also analyzed based on the use of a nasoseptal flap.

RESULTS

The mean age of the patients was 48.4 ± 15.0 years; 58.5% were female and 41.5% were male. The most common pathology was pituitary adenoma (PitNET), accounting for 67.9% of cases. At postoperative month 1, nasal airway resistance and olfactory function showed marked deterioration, accompanied by worsening NOSE, SNOT-22, and VAS scores. This impairment was more pronounced in patients undergoing extended surgery and in those with nasoseptal flap reconstruction.By postoperative month 3, nasal and olfactory functions generally improved and approached preoperative levels; however, in the extended surgery group, odor threshold and total olfactory scores remained lower than baseline values. In patients with nasoseptal flap reconstruction, parameters returned to baseline by the third month.Patients with crusting had worse NOSE scores, whereas those with synechiae demonstrated poorer olfactory function. Crusting and synechiae were more frequent in the extended surgery group, while early crusting in the nasoseptal flap group regressed during follow-up.

CONCLUSIONS

Endoscopic transnasal skull base surgery results in a temporary decline in olfactory function and an increase in nasal airway resistance during the early postoperative period; however, both objective and subjective parameters show significant recovery by the third month. Although an extended surgical field and nasoseptal flap reconstruction increase early nasal morbidity, appropriate surgical technique and effective postoperative nasal care allow olfactory function and nasal airflow to return close to preoperative levels. These findings underscore the importance of mucosa-preserving approaches and strategies aimed at minimizing crusting and synechiae formation during surgical planning.

OP-1161

Title: Surgical Outcomes Of Nasal Septal Hematoma: A 15-Year Single-Center Experience

Kardo Önder[1], **Beste Yıldırım**[1], **Özden Savaş**[1]

[1]*Dokuz Eylul University, School of Medicine, Department of Otolaryngology–Head and Neck Surgery, Izmir, Türkiye*

BACKGROUND & AIM

Nasal septal hematoma (NSH) is a rare but potentially serious otolaryngologic emergency characterised by the accumulation of blood between the septal cartilage and perichondrium. If not diagnosed early, it may lead to septal abscess, cartilage necrosis, and long-term deformity. The primary treatment is timely surgical drainage. This study aimed to analyse the clinical characteristics, etiological factors, management, and surgical outcomes of NSH cases treated over a 15-year period in a tertiary centre.

MATERIAL & METHODS

This retrospective study included 24 patients who underwent surgical drainage for NSH between January 2010 and December 2024. Demographic characteristics, etiology, time to presentation, imaging findings, surgical approach, and complications were recorded. The time to presentation was categorised as early (≤48 hours) or delayed (>48 hours). In adult patients, SNOT-22 nasal domain scores were evaluated pre- and postoperatively. All patients were followed clinically for postoperative complications including septal abscess, deviation, perforation, and cosmetic deformity. Statistical analyses were performed to assess the relationship between delayed presentation and complication development.

RESULTS

Seventeen patients were male (71%) and seven were female (29%), with a mean age of 31.9 years (range: 1–82). Trauma was the most common etiology (14 patients, 58.3%), followed by iatrogenic causes (6 patients, 25%). The median presentation time was 3 days, and 10 patients (41.7%) presented late (>48 hours). CT was performed in 10 cases, all showing findings compatible with septal hematoma. The mean follow-up was 40 months. Complications occurred in 13 patients (54.2%): septal abscess (n=6), deviation (n=4), perforation (n=1), saddle-nose deformity (n=1), olfactory dysfunction (n=2), synechia (n=1), and revision surgery (n=1). No intracranial or orbital complications were observed. Adult SNOT-22 nasal domain scores improved from 16.2 preoperatively to 8.5 postoperatively. Delayed presentation significantly increased the complication rate ($p<0.05$).

CONCLUSIONS

NSH is an uncommon but clinically significant emergency, and early diagnosis with prompt surgical drainage is crucial to prevent severe complications. Delayed presentation markedly increases the risk of septal abscess and structural deformities. Long-term outcomes demonstrate that appropriate surgical management is effective, and timely intervention remains the key factor influencing prognosis.

OP-1162

Air Quality In Jamaica's Main Urban Areas From 2010-2023

Dr Adrienne Williams[1], **Dr Warren Mullings**[2]

[1]*University of the West Indies;* [2]*Kingston Public Hospital*

BACKGROUND & AIM

Objectives: Air quality is measured by monitoring pollutants, including particulate matter (PM2.5 and PM10). This study aims to assess air quality in three urban areas from 2010-2023 to evaluate pollution patterns and potential health risks in Jamaican cities.

MATERIAL & METHODS

Methods: PM 2.5 data collected from 2015-2023, and PM10 data collected from 2010-2023 by NEPA monitoring stations in Spanish Town, Kingston & St. Andrew (KSA), and Montego Bay were analyzed and compared with annual WHO Air Quality Guidelines (AQG) to evaluate particulate matter concentrations across cities, considering industrial activity and weather.

RESULTS

Results: Eight-year average PM2.5 concentrations were highest in Spanish Town (22.3 ± 8.88 µg/m³), followed by Montego Bay (13.5 ± 6.23 µg/m³) then Constant Spring (KSA, 10.34 ± 6.79 µg/m³). Thirteen-year average PM10 concentration, averaged from multiple stations across KSA only, was 41.40 ± 25.16 µg/m³.

CONCLUSIONS

These results indicate that Jamaica's annual air quality levels are high in urban areas (PM2.5: >5 µg/m³ annually per WHO, >9 µg/m³ per US EPA; PM10: >15 µg/m³ annually per WHO, N/A for US EPA). Continued monitoring and validation against Air Quality measurements from international satellites are needed to inform pollution reduction efforts and mitigate public health risks. We acknowledge support from NEPA.

OP-1163

Dysfunction Of The Anterior Superior Alveolar Nerve In Lateral Nasal Wall Surgery - A Prospective Study

Andre de Sousa Machado[1,2], **Miguel Castelo Branco**[2], **Hans Rudolf Briner**[3], **Daniel Simmen**[3]

[1]*Department of Otolaryngology, ULSTMAD, Portugal;* [2]*FCS-UBI, Portugal;* [3]*ORL Zentrum - Hirslanden Klinik, Zürich, Switzerland*

BACKGROUND & AIM

Sensory disturbances involving the anterior superior alveolar nerve (ASAN) are frequently reported after lateral nasal wall surgery, particularly following extended anterior maxillary approaches. Prospective data comparing ASAN sensory dysfunction across lateral nasal wall surgical techniques are scarce.

MATERIAL & METHODS

A prospective cohort of 40 patients undergoing lateral nasal wall surgery was analysed. Procedures included Prelacrimal Window Approach (PLWA), Pyriform Turbinoplasty (PT), combined PT + PLWA, and Endoscopic Modified Medial Maxillectomy (EMMM). Outcomes included postoperative crusting, pain, and subjective sensory symptoms assessed by the Visual Analogue Scale (VAS), as well as objective sensory testing using sharp/blunt stimuli and Semmes–Weinstein monofilaments at 1 week, 1 month, and 3 months postoperatively.

RESULTS

Crusting and pain scores did not differ significantly between surgical techniques. Sensory disturbances were more frequent following extended procedures (PT + PLWA and EMMM), peaking at 1 week postoperatively ($p < 0.05$). Both subjective symptoms and objective sensory thresholds showed progressive improvement, with recovery in over 80% of patients by 3 months. No persistent sensory deficits were observed.

CONCLUSIONS

ASAN-related sensory dysfunction is common after extended lateral nasal wall surgery but is typically transient and reversible. ASAN dysfunction is common after extended anterior maxillary approaches but is transient and reversible, supporting neurapraxia rather than permanent nerve injury.

OP-1164

ADIPOSE TISSUE DERİVED MICROVASCULAR FRAGMENTS ON NASAL SEPTAL PERFORATION REPAIR: EXPERIMENTAL RABBIT MODEL

Mehmet Ece[1], **Bilge Türk**[2], **Suat Turgut**[2]

[1]*Istanbul Haseki Research and Training Hospital;* [2]*Hamidiye Etfal Research and Training Hospital*

BACKGROUND & AIM

Nasal septal perforation is defined as a full-thickness tissue defect involving bilateral mucoperichondrium, septal bone, and/or cartilage. The objective of this study is to investigate the effect of adipose tissue-derived microvascular fragments (Ad-MVF) on surgical success during nasal septal perforation repair with a local flap technique, using macroscopic and histopathological evaluations.

MATERIAL & METHODS

This is a randomized, controlled, single-blind experimental animal study. Fourteen New Zealand white rabbits, each weighing 2–3 kg, were randomly assigned to two groups: the study group (n=7) and the control group (n=7). Under general anesthesia, iatrogenic full-thickness septal perforations measuring 10x10 mm were created in all animals. Septal perforations in all animals were repaired using a local advancement flap technique. Following flap closure, 1 ml of Ad-MVF was injected into the flap interface in the study group, whereas 1 ml of sterile saline (SF) was injected in the control group. After a two-week follow-up period, all animals were sacrificed. Macroscopic evaluations included perforation closure rates, residual defect sizes, and local

infection signs. Histopathological assessments included inflammation, congestion, and fibrovascular tissue formation, with intergroup comparisons performed.

RESULTS

At the end of the two-week observation period, perforation closure was achieved in 4 of 7 animals in the study group, whereas no perforations were closed in the control group. The perforation closure rate was significantly higher in the study group compared to the control group ($p = 0.035$). Analysis of residual perforation sizes revealed that the mean residual defect area in the study group was significantly smaller than in the control group ($p = 0.001$). Macroscopic evidence of purulent discharge suggestive of infection was observed in 1 animal in the study group and 2 animals in the control group, with no statistically significant difference between the groups regarding complication rates. Histopathological scoring of inflammation and congestion (0–3 scale) showed no significant difference between the groups. However, fibrovascular tissue formation at the surgical site was significantly greater in the study group compared to the control group ($p = 0.026$).

CONCLUSIONS

The use of autologous Ad-MVF in the surgical repair of nasal septal perforations was shown to significantly enhance perforation closure rates and reduce residual defect size. While no significant difference was observed in complication rates, histopathological analysis demonstrated a significant increase in fibrovascular tissue formation in the Ad-MVF-treated group. These findings suggest that the application of Ad-MVF during the surgical repair of iatrogenic or habitual septal perforations may improve surgical outcomes and tissue healing. Further large-scale, controlled experimental studies are warranted to confirm these results and support the potential clinical use of Ad-MVF in septal perforation repair.

OP-1165

Risk Factors For Intervention In Patients With Severe Epistaxis : A Multivariate Analysis

Jean-Marie Moukarzel[1], **Nadim Khoueir**[1], **Maria Al Achkar**[1], **Walid Abou Hamad**[1]

[1]*Department of Otolaryngology–Head and Neck Surgery, Hôtel-Dieu de France University Hospital, Saint-Joseph University, Beirut, Lebanon.*

BACKGROUND & AIM

Epistaxis is a common otorhinolaryngological emergency that may require invasive management. This study aims to identify risk factors for the failure of conservative treatment, thereby justifying early recourse to surgical arterial ligation or endovascular embolization.

MATERIAL & METHODS

This retrospective case-control study included 165 patients hospitalized for epistaxis between 2000 and 2024 in Hôtel Dieu de France Hospital. Patients were divided into two groups : a control group treated successfully with nasal packing and an intervention group requiring surgical or endovascular treatment following failure of nasal packing. Univariate and multivariate analyses were performed to identify predictive factors for invasive intervention and to guide therapeutic decision-making

RESULTS

Eighty-eight patients were successfully treated with nasal packing alone, whereas 77 underwent surgical or endovascular intervention. Multivariate logistic regression analysis showed that a history of prior nasal packing or intervention for epistaxis (OR = 4.8), the need for iterative nasal packing during the current episode (OR = 11), and bilateral nasal packing (OR = 6) were independently associated with the need for invasive treatment ($p \leq 0.05$).

Among patients requiring intervention, anticoagulant therapy (OR = 6.8) and bilateral epistaxis (OR = 8) were independently associated with endovascular embolization rather than surgical arterial ligation ($p \leq 0.05$).

CONCLUSIONS

Several clinical factors may help predict failure of conservative management in epistaxis. Patients with a history of prior epistaxis treatment and those requiring iterative and/or bilateral nasal packing may benefit from early escalation to invasive intervention. Furthermore, anticoagulated patients presenting with bilateral epistaxis appear to be better candidates for endovascular embolization than for surgical arterial ligation.

Evaluation Of Pre-Diagnostic Inflammatory And Nutritional Indices In The Development Of Rhinocerebral Mucormycosis

Safiye Giran Örtekin[1], **Ozan Özdemir**[3], **Gülçin Hilal Alay**[2], **Adalet Aşkin**[1], **Feride Fırat**[1], **Cemile Baykan Eryiğit**[1], **Emre Baran**[3], **Özgür Yiğit**[1]

[1]Başakşehir Çam and Sakura City Hospital, Department of Otorhinolaryngology, Istanbul, Türkiye; [2]Başakşehir Çam and Sakura City Hospital, Intensive Care Unit, Istanbul, Türkiye; [3]Istanbul Training and Research Hospital, Department of Otorhinolaryngology, Istanbul, Türkiye

BACKGROUND & AIM

Rhinocerebral mucormycosis (RCM) is an invasive fungal infection characterized by rapid progression and high mortality. Therefore, easily accessible biomarkers capable of identifying high-risk patients in the pre-diagnostic period are needed. This study aimed to evaluate the association between inflammatory and nutritional indices derived from routine laboratory parameters and the development of RCM.

MATERIAL & METHODS

This retrospective, multicenter, individually matched case–control study included 35 patients with RCM and 82 controls between 2013 and 2026. Controls were matched for age, sex, primary etiology and active immunosuppressive therapy.To reduce temporal bias, laboratory values in the case group were obtained from a median of 10 days before diagnosis, while equivalent time points were used in the control group. Neutrophil-to-lymphocyte ratio (NLR), systemic immune-inflammation index (SII), prognostic nutritional index (PNI), and C-reactive protein-to-albumin ratio (CAR) were calculated.

RESULTS

The median CAR value was significantly higher in the RCM group compared with the control group (4.07 vs. 0.36; $p < 0.001$), whereas the median PNI value was significantly lower (31.0 vs. 38.0; $p < 0.001$). In ROC analysis, CAR demonstrated excellent discriminative performance (AUC = 0.91; 95% CI: 0.86–0.96), while PNI showed good performance (AUC = 0.79; 95% CI: 0.69–0.88). The optimal cutoff values were determined as 2.87 for CAR (sensitivity 82.9%, specificity 89.0%) and 34.0 for PNI (sensitivity 77.1%, specificity 76.8%). In multivariable logistic regression analysis, the combined model yielded an AUC of 0.916. CAR remained an independent and dominant predictor (OR = 1.45, 95% CI: 1.11–1.90), whereas PNI did not retain independent significance. In subgroup analyses according to primary etiology, both CAR and PNI maintained discriminative performance in diabetic and hematological subgroups.

CONCLUSIONS

CAR and PNI may serve as supportive indicators for identifying patients at risk of RCM. Rather than functioning as direct diagnostic tools, these indices may contribute to clinical monitoring strategies; however, larger studies are required before routine clinical use.

OP-1167

The Sensory Frontier: Mapping The Evidence For Olfaction As A Window To The Recovering Frontal Lobe

Tiago Soares[1], **Nikita Bhoombla**[1], **Catherine Rennie**[1]

[1]Imperial College Healthcare NHS Trust

BACKGROUND & AIM

Post-traumatic olfactory dysfunction in Traumatic Brain Injury (TBI) is associated with poorer neurocognitive outcomes, yet its evolution in the sub-acute phase (first 30 days post-injury) remains poorly characterised. This scoping review maps the evidence for early olfactory assessment as both a prognostic tool and gateway for intervention. We evaluate whether early olfactory return serves as an isolated deficit or a “lead indicator” for global cognitive recovery, and its potential to guide rehabilitation and patient counselling.

MATERIAL & METHODS

A scoping review was conducted according to PRISMA-ScR guidelines. Systematic searches of MEDLINE, EMBASE, and PsycINFO were performed to identify studies using objective olfactory testing in adult TBI patients during the acute and sub-acute phases. We mapped relationships between olfactory recovery and executive function, radiological correlates of olfactory bulb/tract injury, and the feasibility of standardised bedside assessment.

RESULTS

Preliminary findings confirm that while chronic anosmia predicts poor functional outcomes, the sub-acute trajectory is rarely studied. Existing literature highlights that identifying early olfactory patterns (eg. mechanical shearing vs reversible oedema) is essential for realistic prognostic modelling, as well as for identifying patients who may benefit from early intervention. A key focus is the distinction between sensory restoration and broader cognitive gains in the existing literature, highlighting a significant gap in multi-domain recovery data.

CONCLUSIONS

The olfactory system offers an often-neglected but unique and accessible window into frontal lobe integrity and neuroplasticity. This review establishes the rationale for repositioning olfactory assessment from a peripheral sensory issue to a central prognostic marker. Defining the baseline is essential to determine if early olfactory stimulation (via traditional smell training or novel targeted delivery platforms) can catalyse global neuroplasticity rather than just sensory return. This review

provides a scientific foundation for a planned prospective trial evaluating early olfactory monitoring and stimulation as both a prognostic biomarker and therapeutic conduit for global neuro-recovery.

OP-1168

The Extent Of Surgical Management In Chronic Invasive Fungal Rhinosinusitis: Case Series And Systematic Review

Dr.Abdulmalik Alkhodair[2], **Dr.Abdulaziz Alqahtani**[1]

[1]*King Fahad Medical City;* [2]*King Saud Medical City;* [3]*King Saud Medical City*

BACKGROUND & AIM

Chronic invasive fungal rhinosinusitis (CIFRS) is a rare, serious condition with slow progression and challenging diagnosis, often confused with chronic sinusitis or malignancy, causing delays, especially in endemic regions like Saudi Arabia. Standard treatment involves surgical debridement with systemic antifungal therapy, but there is no consensus on the optimal extent of resection, particularly for orbital or skull base involvement. Outcomes vary widely and often rely on surgeon experience. This study evaluates surgical strategies, comparing conservative versus aggressive resections, and assesses survival, vision preservation, and neurological outcomes to provide evidence that may guide future management guidelines for CIFRS.

MATERIAL & METHODS

This study used a dual-arm design combining a retrospective case series from a tertiary center and a systematic review conducted وفق PRISMA guidelines. The retrospective arm analyzed clinical presentation, disease extent, surgical approach, and outcomes in CIFRS patients. The systematic review searched PubMed, Embase, Scopus, and Cochrane, identifying 14 eligible studies after screening 542 records. Included cases required histopathological confirmation and orbital and/or intracranial extension. Data extracted included demographics, surgical strategy (orbit-sparing vs. exenteration), antifungal therapy, survival, vision, and neurological outcomes. Due to heterogeneity, results were synthesized narratively, with descriptive statistics applied to institutional cases.

RESULTS

Anticipated Results

We hypothesize that the extent of surgical resection in chronic invasive fungal rhinosinusitis (CIFRS) significantly influences clinical outcomes. Specifically:

· Extensive sinonasal resection is expected to result in improved local disease control and overall survival due to more effective clearance of infected and necrotic tissue.

· In cases with orbital involvement, orbit-sparing limited resections may achieve comparable outcomes to more aggressive approaches, without increasing the risk of recurrence or mortality, while preserving ocular function.

We anticipate that a tailored surgical strategy, characterized by aggressive resection of sinonasal disease with selective preservation of critical structures such as the orbit and cranial nerves, will be associated with favorable survival outcomes and preservation of neurological and visual function.

The findings of this study are expected to offer practical, evidence-based recommendations for optimizing surgical management of CIFRS, particularly in resource-constrained or endemic settings where individualized decision-making is critical.

CONCLUSIONS

Chronic invasive fungal rhinosinusitis (CIFRS) is a challenging condition with no clear consensus on optimal surgical management, particularly in cases with orbital or intracranial extension. This study suggests that surgical approaches should be individualized, balancing adequate disease clearance with preservation of vision and neurological function. Orbit-sparing surgery may provide acceptable outcomes in selected patients, while aggressive resection may be necessary in advanced cases. Further multicenter and prospective studies are needed to establish standardized, evidence-based treatment guidelines to improve survival and functional outcomes.

Optimal Degree Of Reverse Trendelenburg Position In Patients Undergoing Endoscopic Sinus Surgery: A Double-Blind Randomized Controlled Trial

Parijja Jantasing[1], **Prok Laosuwan**[2], **Peerada Arreenich**[1], **Niti Adisaipaopan**[1], **Songklot Aeumjaturapat**[3], **Kornkiat Snidvongs**[3], **Supinda Chusakul**[3], **Kachorn Seresirikachorn**[3], **Jesada Kanjanaumporn**[3]

[1]Department of Otolaryngology, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [2]Department of Anesthesiology, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [3]Endoscopic Nasal and Sinus Surgery Excellence Center, King Chulalongkorn Memorial Hospital, Bangkok, Thailand

BACKGROUND & AIM

The reverse Trendelenburg position (RTP) is an established approach to reduce intraoperative blood loss and improve visualization during functional endoscopic sinus surgery (FESS). However, the optimal angle that balances hemostatic control with cerebral perfusion remains uncertain.

MATERIAL & METHODS

A prospective, double-blind, randomized controlled trial was conducted involving 42 patients undergoing Full-House FESS were performed under a standardized anesthetic and medication protocol. Patients were randomized to either a 20° RTP (n=21) or 40° RTP (n=21). Primary outcomes were total intraoperative blood loss and blood loss rate. Secondary outcomes included operative time, hemodynamic parameters, cerebral desaturation events. An additional post-operative surgeon satisfaction was conducted in 40° group.

RESULTS

Baseline demographic and clinical characteristics were comparable between groups. There was no statistically significant difference in total blood loss (391.09 ± 231.29 mL vs. 345.69 ± 228.06 mL; p = 0.526), blood loss per minute or operative time between the 40° RTP and 20° RTP groups, respectively. Intraoperative hemodynamic monitoring revealed higher mean arterial pressure (MAP) and systolic blood pressure in the 40° RTP group ($p < 0.05$). One transient cerebral desaturation event occurred in the 40° RTP group. No other complications were observed in either group. Surgeon satisfaction with 40° RTP was neutral (3/5), citing ergonomic strain and procedural difficulty at the steeper angle.

CONCLUSIONS

Increasing the RTP angle beyond 20° did not improve hemostatic control and was associated with reduced surgeon comfort, possible risk of cerebral desaturation and potential hemodynamic instability. Therefore, the 20° RTP remains the optimal position for FESS.

Ostectomy Technique In Crooked Nose Deformity

Ozgur Kemal[1], **Emre Demirel**[2], **Ali Yavuz Abdullahoglu**[1], **Mehmet Celebi**[1]

[1]Department of Otorhinolaryngology, Faculty of Medicine, Ondokuz Mayis University, Samsun, Turkey; [2]Department of Otorhinolaryngology, Samsun City Hospital, Samsun, Turkey

BACKGROUND & AIM

Crooked nose deformity may be driven by bony pyramid asymmetry, in which one nasal bone is longer than the contralateral side. We hypothesized that preoperative computed tomography (CT)–based quantification of nasal bone length discrepancy, followed by selective piezoelectric ostectomy of the longer side combined with standard osteotomies, would significantly improve objective nasal deviation and patient-reported outcomes.

MATERIAL & METHODS

This prospective clinical case series included 20 consecutive patients with crooked nose deformity undergoing primary open rhinoplasty at a tertiary referral center. On preoperative CT, nasal bone lengths were measured bilaterally at caudal and medial canthal levels, and side-to-side differences were calculated. Surgical correction consisted of piezo-assisted lateral, transverse, and median osteotomies, and ostectomy performed to the longer bony segment to equalize bony parts. Outcomes were assessed preoperatively and at postoperative 3 months using deviation angle and validated questionnaires. Deviation angle was defined as the angle between a line from the midpoint of the nasion to the midpoint of the upper lip and the other line from the midpoint of the nasion to the midpoint of the nasal tip. Patient-reported outcomes included Rhinoplasty Outcomes Evaluation (ROE) and Standardized Cosmesis and Health Nasal Outcomes Survey (SCHNOS). Normality was tested (Shapiro–Wilk), and paired-samples t-tests were used (α=0.05).

RESULTS

Preoperative CT confirmed significant bony asymmetry at both levels (caudal difference 2.82±1.79 mm; canthal difference 1.14±0.86 mm; both $p<0.001$) (Table 1). Mean deviation angle improved from 7.26±1.89° preoperatively to 1.08±0.65° (mean reduction 6.17°, 95% CI 5.35–7.00; $p<0.001$) (Table 2). ROE increased from 5.20±3.52 to 19.55±4.41 ($p<0.001$), and SCHNOS decreased from 36.00±9.50 to 8.60±7.90 at postoperative 3 months ($p<0.001$) (Table 2).

CONCLUSIONS

CT-guided identification of nasal bone length discrepancy and selective piezo-assisted equalization of the longer bony segment, combined with standard osteotomies, produced significant early improvement in nasal alignment and patient-

reported aesthetic/functional outcomes at 3 months. Longer follow-up and comparative studies are warranted to confirm durability and define optimal indications.

The Hidden Loop: Mucous Recirculation Syndrome In Refractory Chronic Rhinosinusitis

Jad Hosri[1], **Nadine El Hadi**[2], **Anne Marie Daou**[1], **Usamah Hadi**[1]

[1]*American University of Beirut Medical Center;* [2]*Lebanese American University Medical Center - Rizk Hospital*

BACKGROUND & AIM

Mucous recirculation syndrome is an underrecognized yet curable cause of persistent chronic rhinosinusitis (CRS), particularly in patients with persistent symptoms following functional endoscopic sinus surgery (FESS).

MATERIAL & METHODS

This study aims to describe the clinical presentation, diagnostic features, and surgical outcomes of mucous recirculation syndrome through a focused case series. A prospective case series of 14 patients presenting with CRS refractory to maximal medical therapy was conducted. All patients underwent detailed nasal endoscopy, which demonstrated active mucous recirculation between two or more sinonasal ostia, including natural maxillary ostia, accessory ostia, and surgically created antrostomies. Computed tomography was reviewed when available to identify anatomical features suggestive of recirculation. Surgical management consisted of endoscopic unification of involved ostia by removal of the intervening mucosal bridge to create a single common drainage pathway.

RESULTS

The most common presenting symptoms were persistent postnasal drainage and nasal obstruction (73%). Using methylene blue staining, endoscopic evaluation identified mucous recirculation most frequently between the natural maxillary ostium and a misplaced middle meatal antrostomy (47%), followed by recirculation involving accessory ostia and inferior meatal antrostomies (33%). All patients underwent targeted endoscopic correction. Postoperatively, elimination of visible mucous recirculation was achieved in all cases, with corresponding clinical improvement and resolution of refractory symptoms. No significant complications were observed.

CONCLUSIONS

Mucous recirculation syndrome is a surgically correctable and frequently overlooked cause of refractory chronic rhinosinusitis. Recognition of characteristic endoscopic findings and targeted surgical correction can result in symptom resolution and prevent unnecessary prolonged medical therapy or repeated revision sinus surgery.

Predictors Of Disease Recurrence In Frontal Sinus Following Endoscopic Sinus Surgery: A Retrospective Analysis

Dr. Omar Almansouri[1], **Dr. Mazin Alsarraj**[3], **Prof. Osama Marghlani**[2]

[1]*king fahad general hospital, jeddah, saudi arabia;* [2]*King Faisal specialist hospital, Jeddah, Saudi Arabia;* [3]*East jeddah hospital, Jeddah, Saudi Arabia*

BACKGROUND & AIM

Background: Endoscopic sinus surgery (ESS) is effective for chronic rhinosinusitis (CRS), but disease recurrence remains a challenge, especially after frontal sinus surgery. Identifying patients at high risk for recurrence is of great importance, but predictive models tailored to the Saudi population are lacking.

Objective: To identify independent predictors of disease recurrence in the frontal sinus following ESS.

MATERIAL & METHODS

Methods: This retrospective cohort study included 293 patients who underwent ESS by a single surgeon at a tertiary care center between 2018 and 2022. Data on demographics, clinical history (including primary vs. revision surgery), pre-existing diagnoses, and procedures performed were extracted. Univariate logistic regression was performed, followed by a multivariate logistic regression model including variables with $p < 0.3$ in the univariate analysis to identify independent predictors of recurrence.

RESULTS

Results: Disease recurrence occurred in 37 patients (12.6%). In the final multivariate model, significant independent predictors of recurrence were: revision surgery (adjusted Odds Ratio [aOR] 5.38, 95% CI 2.26-13.3, $p < 0.001$), a diagnosis of nasal polyps (aOR 3.41, 95% CI 1.23-10.5, p=0.018), and having undergone myringotomy with tube insertion (aOR 73.3, 95% CI 5.13-1,014, p=0.003). Factors significantly associated with decreased odds of recurrence were increasing age (aOR 0.94 per year, 95% CI

0.90-0.97, p < 0.001) and undergoing nasal polypectomy (aOR 0.26, 95% CI 0.08-0.71, p=0.008). The Frontal Ostium Grade (FOG) was not associated with recurrence.

CONCLUSIONS

Conclusion: Revision surgery, nasal polyps, and prior myringotomy were significant independent risk factors for recurrence in the frontal sinus after ESS, while increasing age and nasal polypectomy were protective. These findings can aid in risk stratification and patient counseling. The FOG system did not predict recurrence in this study.

Steroid-Sparing Effects Of Biologics In Chronic Rhinosinusitis With Nasal Polyps: Systematic Review And Meta-Analysis Of Randomized Control Trials

Ali Alsudays[1], **Yasser G Alarimah**[2], **Khaled A Almanea**[3], **Ahmad Alroqi**[1]

[1]*Department of Otolaryngology – Head and Neck Surgery, College of Medicine, King Saud University, Riyadh, Saudi Arabia;* [2]*Department of Otolaryngology, King Saud Medical City, Riyadh, Saudi Arabia;* [3]*Department of Otolaryngology, prince Sultan Military Medical City, Riyadh, Saudi Arabia.*

BACKGROUND & AIM

Chronic rhinosinusitis with nasal polyps (CRSwNP) presents significant treatment challenges, particularly because patients rely on systemic corticosteroids (SCS) for symptom management. This systematic review and meta-analysis compare the Steroid-Sparing Effects of Biologics regarding efficacy and safety with other biologics or standard care in CRSwNP. Key outcomes include reducing SCS Use and drug safety.

MATERIAL & METHODS

We searched PubMed, Embase, Cochrane Library, Scopus, and the Web of Science. We included randomized controlled trials (RCTs) comparing biologics versus placebo/standard care in adults with CRSwNP. The primary outcomes were SCS reduction and safety. Meta-analyses, which use a statistical method called random-effects models, were employed.

RESULTS

This meta-analysis of seven randomized controlled trials (n=3,097) revealed that biologic therapies significantly reduce systemic corticosteroid use in CRSwNP patients (pooled proportion: 20.9%, 95% CI: 8.4%-37.0%), though with substantial heterogeneity (I^2=98.3%). Trial-level predictors included control-arm safety profiles (higher serious adverse effects (SAEs) reduced treatment effects) [OR 0.70]. In contrast, placebo-arm SAEs enhanced them [OR 1.81]) and sample size (larger trials showed diluted responses [OR 0.993 per patient]). These results highlight the role of trial design and baseline patient risk in determining the interest of the results. They further highlight the possibility for individualized strategies in terms of treatment and call for more in-depth studies with patient-level data to refine the steroid-sparing therapeutic strategy, providing an impetus for future work in this area.

CONCLUSIONS

The biologics, specifically dupilumab, represent a paradigm shift in treating CRSwNP , significantly decreasing the burden of SCS—their consistent safety and efficacy support integration into treatment algorithms for severe cases.

Coblation Turbinoplasty: Our Experience In The Newer Wand Technology

Khairullah Anuar[1]

[1]*Universiti Sains Islam Malaysia*

BACKGROUND & AIM

Turbinates reduction surgery is a commonly perform surgeries by ENT Surgeon. The surgery itself has undergone tremendous technological advancement. One of a newer technique which involve mucosal preservation surgery is coblation turbinoplasty. The coblation technology itself has evolved with introduction of a newer wand. The Aris coblator wand werewolf. This article attempts to discuss the use of this technology and sharing our experience. Retrospective review of 32 cases undergone coblation Turbinoplasty with Aris Coblator with or without other procedures in a period of 18 months

MATERIAL & METHODS

All cases adult and children that undergone Coblation Turbinoplasty using Aris Coblator were included in a period of 18 months and we emphasize on intraoperative or post operative morbidity. We monitored the intraoperative and postoperative bleeding and pain, nasal crusting formation and turbinate reduction size endoscopically.

RESULTS

In general the intraoperative bleeding was minimal, post operative pain was better, nasal crusting formation was less and turbinate reduction noticed within short period less than one week

CONCLUSIONS

The coblation turbinoplasty with Aris coblator looks promising and embracing newer technology for better patient care is encouraged

Effectiveness Of Intranasal Insulin For The Treatment Of Olfactory Dysfunction: A Systematic Review

Atheer Ali Al-Talhi[2], Bassam AlRajhi[3], Abdulaziz Hamed S Almalki[1], Mohamed Alqazenli[3], Muhnnad AlGhamdi[3], Fadi Abdu Munhish[4], Ibrahim Sumaily[5]

[1]King Abdulaziz Medical City, Riyadh; [2]Otorhinolaryngology Head & Neck surgery department Dr. Soliman Fakeeh Hospital, Jeddah, Saudi Arabia; [3]College of Medicine, King Saud bin Abdulaziz University for Health Sciences, Jeddah, Saudi Arabia; [4]College of Medicine, Jazan University, Jazan, Saudi Arabia; [5]ENT Department, King Fahd Central Hospital, Jizan, Saud Arabia

BACKGROUND & AIM

Introduction: To assess the effectiveness and safety of Intranasal Insulin (INI) for the treatment of Olfactory Dysfunction (OD) in patients with anosmia and/or hyposmia compared to placebo or no treatment

MATERIAL & METHODS

Methods: We searched four databases: Medline, Scopus, Directory of Open Access Journals (DOAJ), and Springer Nature. The study protocol was registered in the International Prospective Register of Systematic Reviews (PROSPERO) (ID: CRD42023456891). The protocol design was in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA). Participants with hyposmia or anosmia aged ≥ 18 years were included. Patients with an altered sense of smell due to anatomical malformations, trauma, neurodegenerative diseases, surgery, or intranasal lesions were excluded from the study.

RESULTS

Results: Five studies with 131 participants were included. There were 131 participants, of whom 63 were men and 68 were women. The participants' ages ranged from 16 to 56 years. Almost all studies used a dose of 40 IU, except one that used different doses for different participants. Glycemic assessment was performed in three studies, which showed a very slight decrease in glucose, except in one study in which the drop in glucose reached 10.4 mg/dl. All studies agreed that olfactory function improved after INI administration.

CONCLUSIONS

Conclusion: This systematic review concluded that INI can be an effective treatment option for patients with OD. However, further well-designed clinical trials are required to establish robust clinical recommendations.

COMPARISON OF ANKAFERD-CONTAINING PVA–PCL NANOFIBERS IN A RABBIT EPISTAXIS MODEL: SILVER NANOPARTICLE ENCAPSULATION AND SPRAY-COATING METHOD

Yasin KAPLAN[1], Mehmet Akif DÜNDAR[1], Rukiye Özçelik ERDEM[1], Fakih Cihat ERAVCI[1], Ahmet AVCI[2], Hamdi ARBAĞ[1]

[1]Department of Otorhinolaryngology, Faculty of Medicine, Necmettin Erbakan University, Konya, Türkiye; [2]KTO Karatay University, Faculty of Engineering and Natural Sciences, Mechatronics Engineering, Konya, Turkey

BACKGROUND & AIM

This study aimed to develop a novel nasal packing model for faster and more effective control of epistaxis. The hemostatic efficacy of PVA–PCL-based nanofiber mats modified with Ankaferd extract and Ankaferd-mediated silver nanoparticle encapsulation was investigated.

MATERIAL & METHODS

In this study, three different nanofiber mats were fabricated using the electrospinning technique: pure PVA–PCL nanofiber mat (PCV), PVA–PCL nanofiber mat coated with Ankaferd extract by spraying (AE/PCV), and PVA–PCL nanofiber mat containing silver nanoparticles encapsulated by green synthesis using Ankaferd extract (eAgNPs/PCV). The nanofiber structures were evaluated in terms of morphological, physicochemical, and mechanical properties using scanning electron microscopy, FTIR, XRD, tensile testing, water contact angle measurement, blood clotting analysis, and platelet activation analysis. In the in vivo phase, 30 New Zealand rabbits were divided into three groups (n=10). The epistaxis model was established by creating a standardized full-thickness mucosal defect at the same anatomical point in the anterior part of the left nasal septum of each

rabbit. The nasal packs were prepared using sterile eye spears covered with nanofiber mats. Time to hemostasis and blood loss were recorded, and the data were analyzed.

RESULTS

SEM showed regular fiber morphology in all groups, with eAgNPs/PCV displaying the thinnest, most homogeneous, and densely packed fibers. Mean fiber diameters were 497.34, 255.31, and 216.05 nm for PCV, AE/PCV, and eAgNPs/PCV, respectively. FTIR and XRD confirmed successful incorporation of active components while preserving the polymeric structure. Water contact angles decreased from PCV to AE/PCV and eAgNPs/PCV (57.08°, 46.02°, and 41.79°), indicating greater hydrophilicity in eAgNPs/PCV. Tensile strength was highest in eAgNPs/PCV (11.04 MPa), followed by PCV (6.46 MPa) and AE/PCV (2.87 MPa). In vitro, AE/PCV showed lower supernatant absorbance values. In vivo, eAgNPs/PCV achieved the shortest hemostasis time and lowest blood loss. Post-hoc analyses confirmed its significant superiority over PCV and AE/PCV for both parameters ($p<0.001$).

CONCLUSIONS

The PVA–PCL-based nanofiber mat containing silver nanoparticles encapsulated with Ankaferd extract demonstrated the highest hemostatic performance in the experimental epistaxis model by providing the shortest time to hemostasis and the lowest blood loss. These findings suggest that this composite structure may represent a potentially biocompatible and functional next-generation nasal packing candidate capable of providing rapid bleeding control in the treatment of epistaxis. In this respect, the developed material provides a promising basis for translational studies aimed at clinical use.

Prediction Of Clinical Response To Full House Endoscopic Sinus Surgery For Crswnp Based On The Amsterdam Classification Of Completeness Of Endoscopic Sinus Surgery (ACCESS) Score And The Sinus Surgery Completeness Score (SSCS)

Hugo Lara-Sánchez[1,2], **Paula Pérez-Chacón**[1], **Mario Vara-Blanco**[1], **Juan José Tavarez**[1], **Jorge Freijanes-Otero**[1], **Mario S Almeida-Blanco**[1], **María de la O Hernández-Herrero**[3], **Jesús Garzón-Ruiz**[3], **Luis Ángel Vallejo-Valdezate**[1]

[1]Department of Otorhinolaryngology-Head and Neck Surgery, Rhinology Unit, Río Hortega University Hospital, Valladolid, Spain.; *[2]Department of Otorhinolaryngology-Head and Neck Surgery. Segovia General Hospital. Segovia, Spain.*; *[3]Department of Radiology. Head and Neck Unit, Río Hortega University Hospital, Valladolid, Spain.*

BACKGROUND & AIM

Although Full House Endoscopic Sinus Surgery (Full House ESS) has demonstrated efficacy in Chronic Rhinosinusitis with Nasal Polyps (CRSwNP), objective predictors of response in revision cases remain unclear. We aimed to evaluate whether the extent of previous endoscopic sinus surgery, assessed using the Amsterdam Classification of Completeness of Endoscopic Sinus Surgery (ACCESS) score and the Sinus Surgery Completeness Score (SSCS), influences postoperative outcomes in refractory CRSwNP patients.

MATERIAL & METHODS

A consecutive series of previously operated patients undergoing revision Full House ESS for recalcitrant CRSwNP was prospectively evaluated. Baseline CT scans were analyzed to calculate ACCESS and SSCS scores. Clinical assessment included Nasal Polyp Score (NPS), active anterior rhinomanometry, acoustic rhinometry, Peak Nasal Inspiratory Flow (PNIF), 22-item Sinonasal Outcome Test (SNOT-22), and Visual Analog Scales (VAS). Favorable outcome was defined according to EPOS/EUFOREA criteria and achievement of normal functional nasal airflow values.

RESULTS

Overall favorable outcome was achieved in 88.89% (16/18) of patients, with a mean follow-up of 18.75 ± 7.02 months. Baseline ACCESS and SSCS scores were associated with postoperative response, with optimal predictive cut-offs of 13.78 ± 3.77 and 10.22 ± 3.92 points, respectively. Responders demonstrated marked improvement in both objective and subjective measures. PNIF increased from 133.03 L/min (95% CI 110.46–155.61) preoperatively to 202.99 L/min (95% CI 182.12–223.86) at 6 months ($p < 0.001$). Rhinomanometry showed significant and sustained airflow improvement ($p < 0.001$). SNOT-22 decreased from 48.67 to 9.41 and VAS from 7.57 to 0.72 (both $p < 0.001$). PNIF inversely correlated with SNOT-22 at early follow-up ($p \leq 0.032$).

CONCLUSIONS

Radiological completeness of previous surgery, as assessed by ACCESS and SSCS, appears to influence clinical outcomes after revision Full House ESS. CT-based scoring systems may serve as objective tools to support prognostic stratification and surgical planning in refractory CRSwNP.

OP-1178

Biologics Impact The Volume Of Endoscopic Sinus Surgery And Referral Patterns

Daniel J. Lee[1], **Donna Sibley**[2], **Mandolin Bartling**[1], **Yvonne Chan**[1], **John Lee**[1], **Lyn Sibley**[2]

[1]*University of Toronto;* [2]*Ontario Medical Association*

BACKGROUND & AIM

Biologic therapies for chronic rhinosinusitis with nasal polyps (CRSwNP) may reduce the need for revision endoscopic sinus surgery (ESS). This study characterizes changes in ESS volumes and referral patterns in Ontario, Canada, following the introduction of biologics.

MATERIAL & METHODS

A population-based retrospective cohort study was conducted using Ontario administrative data from 2017 to 2024. Segmented linear regression was used to analyze monthly volumes, comparing pre-biologic (2017–2019) and post-biologic (2022–2024) trends while excluding active pandemic years to isolate the biologic signal from systemic recovery.

RESULTS

Among 17,873 patients, annual revision ESS volume declined 22.9% (p=0.04) in the post-biologic period. Time-series modeling revealed a permanent volume reset. While aggregate Complete ESS volume demonstrated a significant positive recovery trend (+0.73 cases/month, p=0.02), the Complete Revision ESS subset showed no significant recovery slope (p=0.80), confirming a "blunted recovery" specific to revision cases. Tertiary rhinologist referrals declined 27.9%, while Otolaryngology-to-Respirology/Allergy referrals increased 42.9% (p=0.01). Socioeconomic analysis indicated the proportion of low-income patients undergoing complete revision ESS increased by 22.2% (p=0.03).

CONCLUSIONS

The introduction of biologics is associated with a sustained reduction in revision ESS volume. The lack of surgical volume recovery for revision cases—despite data showing the system had the capacity to recover volume for extensive procedures—suggests a reduced demand for salvage intervention. Rising cross-specialty referrals confirm a shift toward multidisciplinary care.

OP-1179

Glucose Dysregulation And Chronic Rhinosinusitis: A Scoping Review Of Metabolic And Mechanistic Evidence

Haissan Iftikhar[2]

[1]*NHS Greater Glasgow and Clyde;* [2]*Northamptonshire Healthcare NHS Foundation Trust*

BACKGROUND & AIM

Chronic rhinosinusitis (CRS) affects over 134 million people globally, with rising prevalence paralleling epidemic increases in sugar consumption and diabetes mellitus. Emerging evidence suggests metabolic-inflammatory pathways may link glycaemic dysregulation to CRS pathophysiology, including glucose transporter-mediated epithelial effects and elevated local sinonasal glucose. However, the relationship between glucose dysregulation and CRS outcomes remains poorly characterised, and the role of modifiable dietary sugar intake is unclear. We aimed to systematically map and synthesise evidence examining relationships between glucose dysregulation and CRS across metabolic and mechanistic domains, and identify research priorities.

MATERIAL & METHODS

This scoping review followed PRISMA-ScR guidelines and Joanna Briggs Institute methodology. Five databases (PubMed/MEDLINE, Embase, Emcare, CINAHL, Cochrane) were searched from inception to 13 October 2025, using a structured concept-based strategy combining CRS terms with glucose, sugar, dietary and metabolic terms, supplemented by citation and grey-literature searching. Studies assessing systemic or local glucose dysregulation, glycaemic markers, or dietary sugar in relation to CRS outcomes were eligible. Quality was appraised using the Mixed Methods Appraisal Tool. Findings were synthesised narratively; quantitative pooling was not feasible.

RESULTS

Ten studies (2,879 participants, four countries, 1991-2025) met inclusion. Seven metabolic studies consistently associated hyperglycaemia or diabetes with adverse CRS outcomes, including higher post-operative recurrence at 1-3 years and less SNOT-22 improvement in diabetic patients. Three mechanistic studies demonstrated that sinonasal epithelial cells express functional glucose transporters (GLUT1, GLUT3), with elevated glucose enhancing pro-inflammatory cytokine production, compromising epithelial barrier integrity, and promoting bacterial biofilm formation. Two studies documented elevated glucose in nasal secretions of CRS patients. Critically, no study assessed dietary sugar or sugar-sweetened beverage consumption using validated dietary tools, a fundamental gap. Evidence derived predominantly from single-centre retrospective studies (China 40%, USA 40%), limiting generalisability. Overall quality was moderate.

CONCLUSIONS

This review identifies consistent metabolic and mechanistic evidence linking glucose dysregulation with adverse CRS outcomes, supported by biologically plausible pathways. This suggests glycaemic optimisation should be considered within comprehensive CRS management. However, the complete absence of validated dietary exposure assessment prevents translation to preventive strategies, leaving potentially the most modifiable risk factor unexplored. Priority research includes prospective cohort studies using validated dietary tools and randomised trials of sugar reduction, alongside multi-ethnic replication and dose-response mechanistic work.

OP-1180

Do Hematological Indices Predict Disease Severity In Nasal Polyposis? A Lund-Mackay CT-Based Study

Dr. Sunel Bade Özen[1], **Doç. Dr. Belgin Tutar**[1]

[1]*Prof. Dr. Cemil Taşçıoğlu Şehir Hastanesi*

BACKGROUND & AIM

Nasal polyposis is a chronic inflammatory condition of the sinonasal mucosa driven predominantly by Th2-mediated eosinophilic inflammation. Although the Lund-Mackay CT scoring system remains the reference standard for objectively grading disease severity, imaging is not universally accessible and does not always reflect the systemic inflammatory burden. Hematological indices derived from routine complete blood count — including NLR, PLR, MLR, SII, SIRI, MPV, and peripheral eosinophil parameters — have been proposed as low-cost surrogates of systemic inflammation in oncological and cardiovascular diseases. Whether these indices meaningfully reflect radiological disease severity in nasal polyposis remains unclear.

MATERIAL & METHODS

We conducted a retrospective analysis of 129 patients who underwent functional endoscopic sinus surgery (FESS) for nasal polyposis in 2025 and 2026. Exclusion criteria included active infection at the time of blood sampling, systemic corticosteroid use within the preceding four weeks, age <18 or >70, hematological disease, immunosuppressive therapy, and known malignancy. Preoperative complete blood count values were retrieved, and the following indices were calculated: NLR (neutrophil/lymphocyte), PLR (platelet/lymphocyte), MLR (monocyte/lymphocyte), SII (platelet × neutrophil / lymphocyte), and SIRI (neutrophil × monocyte / lymphocyte). Eosinophil percentage, absolute eosinophil count, and MPV were also recorded. Preoperative CT scans were scored using the Lund-Mackay system, and patients were stratified into three groups: mild (0–7, n=43), moderate (8–18, n=50), and severe (19–24, n=35). Statistical analysis included Spearman rank correlation, Kruskal-Wallis test with Bonferroni-corrected post-hoc comparisons, and ROC curve analysis with bootstrap confidence intervals.

RESULTS

The cohort included 129 patients (median age 40 years, IQR 29–51). Of the eight hematological parameters evaluated, only eosinophil-related measures demonstrated a statistically significant and consistent association with Lund-Mackay severity. Eosinophil percentage correlated positively with CT score ($r=+0.393$, $p<0.001$), with median values rising progressively from 2.6% in mild to 3.8% in moderate and 6.6% in severe disease ($p<0.001$). Absolute eosinophil count followed the same pattern ($r=+0.349$, $p<0.001$). ROC analysis identified eosinophil percentage as the strongest predictor of severe polyposis (AUC=0.751, 95% CI: 0.650–0.842; optimal cutoff 5.6%, sensitivity 66.7%, specificity 79.1%). NLR, PLR, MLR, SII, SIRI, and MPV showed no significant correlation with disease severity in either Spearman or Kruskal-Wallis analyses (all $p>0.05$).

CONCLUSIONS

This study demonstrates that widely used hematological inflammatory indices including NLR, SII, and SIRI do not reflect radiological disease severity in nasal polyposis. They are predominantly neutrophil-driven, and nasal polyposis is a Th2-polarized, eosinophilic disease. Applying inflammation markers validated in oncology&sepsis to a disease with a distinct immunological profile may simply be asking the wrong question of the wrong cells. By contrast, an eosinophil percentage above 5.6% was associated with severe radiological disease. Clinicians should be cautious about over-interpreting routine inflammatory ratios in this context, and future work should focus on disease specific biomarkers of nasal polyposis.

Prospective Evaluation Of The Effects Of Inferior Turbinate Radiofrequency And Inferior Turbinate Lateralization On Nasolacrimal Duct Functions

METİN YILDIRIM[1], **FUNDA TAŞKIN**[1], **TÜRKÜ BAYRAMOĞLU**[1], **FATİH ENES ŞAFAK**[2], **FATMA SAVUR**[2], **ÖZGÜR YİĞİT**[1]

[1]BASAKSEHİR CAM VE SAKURA CITY HOSPITAL DEPARTMENT OF OTOLARYNGOLOGY; [2]BASAKSEHİR CAM VE SAKURA CITY HOSPITAL DEPARTMENT OF OPHTALMOLOGY

BACKGROUND & AIM

Inferior turbinate surgery is commonly performed during septoplasty in patients with septal deviation and turbinate hypertrophy. Due to the close relationship between the inferior turbinate and the nasolacrimal system, surgery may affect lacrimal function and cause postoperative epiphora. However, data on different techniques remain limited. This study prospectively compared radiofrequency and lateralization techniques on nasolacrimal duct function using subjective and objective assessments in septoplasty patients.

MATERIAL & METHODS

This prospective comparative clinical study included 42 patients who underwent septoplasty combined with inferior turbinate surgery for septal deviation and inferior turbinate hypertrophy between December 2025 and March 2026 at Başakşehir Çam and Sakura City Hospital. Patients were divided into two groups according to the surgical technique applied: inferior turbinate radiofrequency (RF) and inferior turbinate lateralization. Patients with previous nasal or lacrimal surgery, known nasolacrimal duct obstruction, dacryocystitis, or systemic connective tissue diseases were excluded from the study.

Nasolacrimal duct functions were evaluated preoperatively and at the first postoperative month using subjective and objective assessment methods, including Munk score, Fluorescein Dye Disappearance Test (FDDT), and fluorescein disappearance time. Demographic characteristics and postoperative epiphora complaints were also recorded. Statistical analyses were performed using SPSS software.

RESULTS

A total of 42 patients undergoing septoplasty with inferior turbinate surgery were analyzed, including 26 treated with radiofrequency (RF) ablation and 16 with lateralization. Groups were comparable at baseline regarding FDDT grade ($p = 0.366$) and clearance time ($p = 0.223$). No patient reported epiphora, and Munk scores remained zero pre- and post-operatively. Within-group analysis showed no significant changes in FDDT grade or clearance time after either procedure. Between-group comparisons also revealed no significant differences postoperatively (FDDT grade $p = 0.054$; clearance time $p = 0.142$). In a subgroup with prolonged preoperative FDDT (>5 min), RF ablation significantly improved clearance time (10.0 to 6.0 min; $p = 0.004$), while lateralization showed no change. Both procedures were safe for lacrimal drainage function.

CONCLUSIONS

Both inferior turbinate radiofrequency ablation and lateralization appear to be safe with respect to nasolacrimal duct function, as neither technique caused significant postoperative deterioration in subjective or objective lacrimal drainage parameters. Although radiofrequency ablation demonstrated a significant improvement in fluorescein clearance time among patients with prolonged preoperative drainage, no significant between-group differences were observed overall. Further prospective studies with larger cohorts, longer follow-up, and controlled designs are needed to evaluate both the long-term safety and potential therapeutic effects of inferior turbinate surgery on nasolacrimal drainage function.

Absence Of Allergic Reaction To Shellfish-Derived Chitosan Nasal Packing In Shellfish Allergic Patients

Leigh Sowerby[1], **Ameen Biadsee**[2], **Rehab Simsim**[3], **Ianette Friesen-Waldner**[1], **Taciano Rocha**[1], **Brian Rotenberg**[1]

[1]*Western University*; [2]*Tel Aviv University*; [3]*Princess Nourah Bint Abdulrahman University*

BACKGROUND & AIM

NOVAPAK® is a chitosan-based nasal packing commonly used following endoscopic sinus surgery. Because chitosan is derived from shellfish exoskeletons, its use is often avoided in patients with shellfish allergy despite the absence of protein allergens such as tropomyosin. Clinical data supporting the safety of intranasal NOVAPAK use in shellfish-allergic patients are limited.

The aim of this study was to evaluate the safety of NOVAPAK nasal packing in adults with confirmed shellfish allergy.

MATERIAL & METHODS

This prospective pilot safety study enrolled adults aged 18–60 years with a documented history of shellfish allergy confirmed by clinical history, prior oral challenge and skin prick testing. Participants underwent a staged provocation protocol in a monitored hospital setting. Initial cutaneous exposure to NOVAPAK was followed, in the absence of reaction, by intranasal application to the inferior turbinate. Vital signs, symptoms, and nasal congestion scores were assessed before and after exposure. Participants were observed for immediate reactions and followed by telephone at 48 hours. Allergic reactions were defined according to World Health Organization anaphylaxis criteria.

RESULTS

Ten participants with confirmed shellfish allergy were enrolled and completed the provocation protocol. No local or systemic allergic reactions were observed during cutaneous testing, intranasal challenge, post-procedure observation, or 48-hour

follow-up. No participants met criteria for anaphylaxis, required pharmacologic intervention, or demonstrated worsening nasal congestion attributable to NOVAPAK exposure.

CONCLUSIONS

In this pilot study, intranasal exposure to NOVAPAK was well tolerated in shellfish-allergic patients, with no observed allergic reactions. These findings support the preliminary safety of chitosan-based nasal packing in this patient population and justify further evaluation in clinical use for shellfish-allergic patients.

Comparative Performance Analysis Of Four Artificial Intelligence Models In The Diagnosis Of Inverted Papilloma: A Retrospective Single Center Study With 60 Patients

Muhammed Kürşad Güçlü[1], **Derya Özer**[1]

[1]*Department of Otorhinolaryngology - Head and Neck Surgery, Çiğli Training and Research Hospital, Bakırçay University, Izmir, Turkey*

BACKGROUND & AIM

Inverted papilloma is a benign yet locally aggressive sinonasal tumor with a malignant transformation risk. Distinguishing these lesions from inflammatory nasal polyps radiologically remains challenging. Furthermore, comprehensive comparative evaluations of modern large language models for sinonasal pathology are currently lacking. Therefore, this study aims to compare the diagnostic performance of four artificial intelligence models (Gemini, ChatGPT/GPT-4, DeepSeek, and Abacus AI) in distinguishing inverted papilloma from nasal polyps using CT imaging.

MATERIAL & METHODS

This retrospective single-center study included 60 patients (30 with inverted papilloma, 30 with inflammatory nasal polyps) who underwent paranasal sinus CT between January 2020 and December 2024. Four artificial intelligence models (Gemini, ChatGPT/GPT-4, DeepSeek, and Abacus AI) independently evaluated the CT images using standardized prompts under blinded conditions to distinguish between the two pathologies. Diagnostic performance was assessed by calculating sensitivity, specificity, accuracy, positive/negative predictive values, and F1 scores, with 95% confidence intervals. Histopathological examination served as the gold standard for all comparisons.

RESULTS

Gemini achieved 91.67% accuracy (95% CI: 81.93-96.39%), 96.67% sensitivity, and 86.67% specificity with only 5 misclassifications. ChatGPT/GPT-4 reached 87.5% accuracy with 100% sensitivity but 75% specificity. DeepSeek showed 87.5% accuracy with 75% sensitivity and 100% specificity. Abacus AI produced 75% accuracy with 100% sensitivity and 50% specificity. Mean accuracy across models was 85.00%.

CONCLUSIONS

AI models, particularly Gemini, demonstrate high diagnostic accuracy in distinguishing inverted papilloma from nasal polyps on CT. Significant performance variations exist among models, reflecting distinct sensitivity-specificity trade-offs. AI serves as a valuable adjunct tool; however, integration with clinical judgment and histopathological confirmation remains essential.

OP-1184

Beyond The Sinuses: FESS And Biologic Therapy Are Associated With Reduced Depression In Chronic Rhinosinusitis

Shahrukh Ali[1], **Robert Africa**[1], **Scott Hardison**[1]

[1]*University of Texas Medical Branch;* [2]*University of Texas MD Anderson Cancer Center*

BACKGROUND & AIM

Chronic rhinosinusitis (CRS) is associated with substantial symptom burden and impaired quality of life, with depression frequently reported among affected patients. However, the impact of surgical and biologic treatment strategies on depression risk in CRS remains incompletely defined. This study aimed to evaluate the association between functional endoscopic sinus surgery (FESS), with or without adjunct biologic therapy, and incident depression in patients with CRS.

MATERIAL & METHODS

A retrospective cohort study was conducted using de-identified electronic health record data from the TriNetX US Collaborative Network. Adult patients (≥18 years) diagnosed with CRS between January 2015 and December 2023 were included. Patients were categorized into three groups: medical management without surgery, FESS alone, and FESS with adjunct biologic therapy. Propensity score matching was performed to balance demographic and clinical characteristics across

cohorts. The primary outcome was incident depression within 24 months following the index date. Hazard ratios (HR) with 95% confidence intervals (CI) were calculated.

RESULTS

After propensity score matching, baseline demographic and clinical characteristics were well balanced across cohorts. At 24 months, patients undergoing FESS alone demonstrated a significantly lower incidence of depression compared with matched non-surgical controls (7.4% vs 10.2%; HR 0.73, 95% CI 0.69–0.77; p < 0.001). Patients treated with FESS plus biologic therapy exhibited an additional reduction in depression incidence compared with those undergoing FESS alone (5.1% vs 7.4%; HR 0.69, 95% CI 0.62–0.77; p < 0.001). Findings remained consistent across sensitivity analyses.

CONCLUSIONS

Functional endoscopic sinus surgery was associated with a reduced 24-month incidence of depression among adults with chronic rhinosinusitis, with further risk reduction observed when biologic therapy was incorporated. These findings suggest that effective CRS management may provide meaningful mental health benefits beyond sinonasal symptom control.

Subjective And Objective Outcomes After Septoplasty: A Multidimensional Analysis Of Functional Improvement And Predictive Factors

Burcu Vural Çamalan[1], **Banu Öksüz Ok**[1], **Sümeyra Doluoğlu**[1]

[1]*Ankara Etlik City Hospital, Ankara, Turkey*

BACKGROUND & AIM

The relationship between patient-reported outcomes and objective measures of nasal patency after septoplasty remains controversial, with evidence suggesting a mismatch between symptom perception and airflow metrics. This study aimed to evaluate postoperative changes in subjective and objective parameters after septoplasty and to identify predictors of functional improvement using radiological and clinical variables.

MATERIAL & METHODS

In this retrospective cohort study, 37 adult patients undergoing septoplasty with or without turbinate surgery were analyzed. Preoperative and 6-month postoperative assessments included SNOT-22 and NOSE scores, anterior and posterior rhinomanometry, and evaluation of nasal asymmetry. Septal deviation angle was measured using computed tomography. Within-subject changes were analyzed using the Wilcoxon signed-rank test. Associations between changes (Δ values) were assessed with Spearman's correlation. Multivariable linear regression was used to identify independent predictors of improvement in SNOT-22 scores.

RESULTS

Preoperative NOSE and SNOT-22 scores were 60 (39.5–78) and 63 (31.5–78.5), respectively. Anterior and posterior rhinomanometry values were 0.237 (0.192–0.423) and 0.423 (0.324–0.543), and nasal asymmetry was 1.7 (1.35–1.9). The median septal deviation angle was 13 (8–16.5). At 6 months, NOSE and SNOT-22 scores decreased to 21 (13–29) and 21 (15.5–33), respectively (both p = 0.0001). Anterior rhinomanometry decreased to 0.213 (0.143–0.240) (p = 0.001), posterior rhinomanometry to 0.218 (0.171–0.306) (p = 0.0001), and asymmetry to 1.20 (1.10–1.25) (p = 0.0001). Changes in NOSE and SNOT-22 scores were strongly correlated (r = 0.86, p = 0.0001). Correlations between subjective and rhinomanometric changes were weak (r = 0.22–0.36) and not consistently significant (p = 0.02–0.17). Septal deviation angle correlated negatively with improvement (r = -0.431, p = 0.008) and was the only independent predictor in regression analysis (B = -2.59, p = 0.002).

CONCLUSIONS

Septoplasty significantly improves both subjective and objective outcomes; however, these domains are only weakly associated. Septal deviation angle may serve as a clinically relevant predictor of postoperative improvement.

Real-World Outcomes Of Dupilumab On Olfactory Function In Chronic Rhinosinusitis With Nasal Polyps Using The Sniffin' Sticks Test

Maryam Khalifa, MD, FEBORL-HNS[1], **Leigh Sowerby, MD, MHM, FRCSC**[1], **Brian Rotenberg, MD, FRCSC**[1], **Babak Pourmomen, MD**[1], **Cristian Dihel, MSc**[1]

[1]*Division of Otolaryngology – Head and Neck Surgery, Western University, London, Ontario, Canada*

BACKGROUND & AIM

Background

Chronic rhinosinusitis with nasal polyps (CRSwNP) is commonly associated with loss of smell and reduced quality of life. Dupilumab has been shown to improve symptoms and olfaction in clinical trials, but most studies have measured smell using identification tests only. The Sniffin' Sticks test allows assessment of olfactory threshold, discrimination, and identification (TDI), providing a more complete evaluation of olfactory function.

Objective

To evaluate changes in olfactory function in patients with CRSwNP treated with dupilumab using the Sniffin' Sticks TDI score.

MATERIAL & METHODS

This prospective study included adult patients with recalcitrant CRSwNP who were started on dupilumab at a tertiary rhinology clinic. Patients were assessed at baseline and during follow-up with Sniffin' Sticks TDI scores (Threshold, Discrimination, and Identification), nasal polyp scores on endoscopy, and SNOT-22 symptom scores (Sino-nasal Outcome Test-22). The number of prior sinus surgeries was also recorded and analyzed in relation to olfactory outcomes. Long-term outcomes were assessed at 36 ± 6 months. Statistical analysis included paired comparisons, repeated-measures ANOVA, and correlation analysis between prior surgical burden and TDI scores.

RESULTS

Fifteen patients were enrolled and thirteen completed long-term follow-up. SNOT-22 scores showed a significant improvement compared with baseline, with a mean reduction of 42 points at 36 months ($p < 0.001$). Mean total TDI scores improved from 24.7 at 6 months to 29.6 at long-term assessment. Threshold scores also showed a gradual upward trend, increasing from a mean of 5.1 to 6.4. Six patients demonstrated an improvement of more than 3 points in threshold scores compared with their 6-month results. Among those considered responders, the average threshold improvement was 5.7 points after 6 months. Notably, three patients who had anosmic threshold scores at 6 months improved into the borderline normosmic range at the 3-year follow-up. Two patients showed some decline in threshold scores over time. Nasal polyp scores also improved over time. No relationship was found between the number of prior sinus surgeries and olfactory outcomes.

CONCLUSIONS

Dupilumab treatment in patients with CRSwNP was associated with sustained improvement in symptoms and quality of life, with gradual recovery of olfactory function in many patients over long-term follow-up.

Comparison Between Steroidal Irrigation And Nasal Spray In The Treatment Of Chronic Rhinosinusitis: A Systematic Review

Dr. Christian Eliud Galindo Salazar[1], **Dr. José J. Leija Martínez**[4], **Dr. Luis Eduardo Valdez García**[3], **Dra. Lizette Montserrat Cabrera López**[2], **Dr. Juan José Reyes Fortanelli**[1], **Dra. María Fernández Olvera**[1]

[1]Department of Otolaryngology and Head and Neck Surgery, Hospital Regional de Alta Especialidad "Dr. Ignacio Morones Prieto"; [2]Medical School, Universidad Autonoma de San Luis Potosi; [3]Department of Neurology and Psychiatry, Instituto Nacional de Clencias Medicas y Nutricion Salvador zubiran; [4]Head, Outpatient Division, Hospital Regional de Alta Especialidad "Dr. Ignacio Morones Prieto"

BACKGROUND & AIM

Chronic rhinosinusitis (CRS) is a chronic inflammatory disease that significantly affects quality of life. Topical corticosteroids are a cornerstone of treatment, commonly administered as intranasal sprays; however, limited sinus penetration may reduce their efficacy, particularly in patients with nasal polyps or a history of previous surgery. High-volume corticosteroid irrigations may improve drug delivery and enhance outcomes. However, their comparative effectiveness versus conventional steroid sprays remains unclear. This systematic review aimed to evaluate the efficacy and safety of corticosteroid nasal irrigations compared with intranasal corticosteroid sprays in patients with CRS, considering symptom control, endoscopic outcomes, radiologic findings, and adverse events.

MATERIAL & METHODS

A systematic review was conducted following PRISMA 2020 guidelines. PubMed, BVS, and Cochrane Library databases were searched for studies published from October 2015 to October 2025. Search terms included chronic rhinosinusitis, nasal irrigation, corticosteroids, and intranasal spray. Randomized controlled trials and observational studies comparing high-volume corticosteroid nasal irrigations versus intranasal corticosteroid sprays in adult CRS patients were included. Eligible populations included patients with or without nasal polyps and with or without previous endoscopic sinus surgery. Outcomes assessed were symptom severity using SNOT-22, endoscopic findings, radiologic outcomes, adverse events, and treatment discontinuation. Data extracted included study design, patient characteristics, interventions, outcomes, and safety measures. Certainty of evidence was assessed using the GRADE approach. Four studies meeting inclusion criteria were included for qualitative synthesis

RESULTS

Four studies involving 368 patients were included, comprising three randomized controlled trials and one observational study. Both corticosteroid irrigations and intranasal sprays significantly improved symptoms, with no consistent differences in SNOT-

22 outcomes between groups. However, corticosteroid irrigations demonstrated greater improvement in objective endoscopic outcomes, including reduction of mucosal inflammation and polyp size, particularly in patients with chronic rhinosinusitis with nasal polyps and those with prior endoscopic sinus surgery. Limited radiologic evidence also favored corticosteroid irrigations. Safety profiles were favorable in both groups, with predominantly mild local adverse effects such as nasal irritation and transient discomfort. No significant systemic adverse effects or hypothalamic-pituitary-adrenal axis suppression were reported. GRADE assessment showed high-quality evidence supporting corticosteroid irrigations for postoperative patients and moderate-quality evidence in non-operated patients, with no significant safety concerns identified across studies.

CONCLUSIONS

Both corticosteroid nasal irrigations and intranasal corticosteroid sprays are effective and safe in CRS management. While symptom improvement appears comparable, corticosteroid irrigations may provide superior objective endoscopic outcomes, especially in patients with nasal polyps and previous sinus surgery. Corticosteroid irrigations may represent a preferred option in selected CRS subgroups. Further randomized trials with standardized protocols and larger populations are needed to better define their role across different CRS phenotypes.

OP-1188

When Autoimmunity Meets The Sinuses: Insights From A Nationwide Study Of Chronic Rhinosinusitis Phenotypes

Anne Marie Daou, MD[1], **Zeina Korban, MD**[1], **Jad Hosri, MD**[1], **Prof. Usama Hadi**[1]

[1]*American University of Beirut Medical Center*

BACKGROUND & AIM

Chronic rhinosinusitis (CRS) is a heterogeneous inflammatory condition of the paranasal sinuses, clinically categorized as CRS with nasal polyps (CRSwNP) and without nasal polyps (CRSsNP). While both forms share overlapping symptoms, they differ in clinical presentation, underlying pathophysiology, and treatment response. Emerging evidence suggests a potential association between autoimmune diseases and CRS, particularly CRSwNP. This is the first large-scale study to examine the relationship between autoimmune diseases and CRS phenotypes using a nationwide electronic health record database.

MATERIAL & METHODS

We conducted a retrospective cohort study using Epic Cosmos, a nationwide database aggregating de-identified electronic health records from over 200 million patients across U.S. health systems. Patients with documented diagnoses of autoimmune diseases were identified using structured queries within Epic Cosmos. The search included the following conditions: Inflammatory Bowel Disease, Rheumatoid Arthritis, Sarcoidosis, Psoriasis, Ankylosing Spondylitis, Systemic Lupus Erythematosus, Sjögren Syndrome, Scleroderma, Other Autoimmune Diseases.The primary outcomes were the diagnosis CRSsNP and CRSwNP. Patients with corresponding diagnostic codes were classified accordingly.

RESULTS

A total of 96,938 patients with autoimmune diseases were identified through Epic Cosmos. Among them, the overall prevalence of chronic sinusitis (including chronic sinusitis with and without nasal polyps) was 5.2%. The calculated risk ratio (RR) for chronic sinusitis in patients with autoimmune disease compared to those without autoimmune conditions was 0.959 (95% Confidence Interval: [0.904 , 1.017]), suggesting no significant increase in overall risk.

The prevalence of chronic sinusitis varied by autoimmune disease subtype. Sjögren syndrome (RR = 1.77, CI: 1.61–1.95) and ankylosing spondylitis (RR = 1.44, CI: 1.29–1.60) were associated with a significantly increased risk of chronic sinusitis compared to the non-autoimmune population and both had the highest prevalence of CRS patients with 9.1% and 7.4% respectively.

All other autoimmune conditions had no statistically significant increase in risk, and in some cases (e.g., psoriasis and IBD), showed a modestly decreased risk.

CONCLUSIONS

In this large, population-level cohort study using Epic Cosmos, the overall prevalence of chronic rhinosinusitis among patients with autoimmune diseases was 5.2%. While the overall risk of chronic sinusitis in patients with autoimmune diseases was not significantly increased, specific conditions, particularly Sjögren syndrome and ankylosing spondylitis, were associated with a markedly higher risk. These findings suggest that while autoimmune disease as a broad category may not confer increased overall risk for chronic sinusitis, specific autoimmune conditions may be more strongly associated with CRS and warrant further investigation.

VIRTUAL REALITY ENHANCED OLFACTORY REHABILITATION THERAPY

Aslı Çakır Çetin[1], **Kıvanç Korkmaz**[1], **Beyazıt Buğra Akbay**[1]

[1]*Dokuz Eylül Üniversite Hastanesi Kulak Burun Boğaz Hastalıkları*

BACKGROUND & AIM

This study investigated the efficacy and safety of olfactory rehabilitation treatment aided by virtual reality technology, compared with conventional 12-week olfactory training with four different odors.

MATERIAL & METHODS

The study was conducted with 26 patients at Dokuz Eylül University Department of Otorhinolaryngology. Participants were randomly assigned to control (n=13) and study (n=13) groups based on inclusion and exclusion criteria. All patients underwent Sniffin' Sticks test before and after treatment. The control group received 12 weeks of olfactory rehabilitation with four odors (rose, lemon, peppermint, clove), while the study group was presented with a virtual reality video containing visual stimuli of the odors simultaneously with the odorants.

RESULTS

Age, gender, etiology, neurocognitive scores, and baseline Sniffin' Sticks total, threshold, discrimination, and identification scores were comparable between the groups, with no meaningful differences observed ($p > 0.05$ for all comparisons).

Following treatment, improvements were observed in Sniffin' Sticks total, threshold, and identification scores in both groups (p values 0.002, 0.003, and 0.002, respectively). No meaningful differences were identified between the groups ($p > 0.05$). No side effects were observed in either group, and treatment compliance was comparable.

CONCLUSIONS

Visual stimulus-assisted virtual reality-based olfactory rehabilitation is as effective and reliable as conventional 12-week olfactory training with four different odors.

Clinicopathological Characteristics, Surgical Management, And Oncologic Outcomes Of Sinonasal Inverted Papilloma: A Single-Center Retrospective Analysis

MÜSLÜM BARAN KARAOĞLU[1], **SEMA ZER TOROS**[1], **ÇİĞDEM TEPE KARACA**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, Haydarpaşa Numune Training and Research Hospital, University of Health Sciences, Istanbul, Türkiye*

BACKGROUND & AIM

Sinonasal inverted papilloma is a benign tumor characterized by locally aggressive behavior, a significant risk of recurrence, and a low but clinically meaningful potential for malignant transformation. This study aimed to evaluate the demographic characteristics, tumor localization, surgical approaches, histopathological findings, and recurrence rates of patients diagnosed with sinonasal inverted papilloma.m

MATERIAL & METHODS

The medical records of 73 patients diagnosed with sinonasal inverted papilloma between 2011 and 2025 at the Department of Otorhinolaryngology–Head and Neck Surgery, University of Health Sciences Haydarpaşa Numune Training and Research Hospital, were retrospectively reviewed. Demographic characteristics, computed tomography findings, tumor stage according to the Krouse classification, surgical methods performed, histopathological results (dysplasia/malignancy), and recurrence status were systematically analyzed.

RESULTS

Of the 73 patients, 63 (86.3%) were male and 10 (13.7%) female, with a mean age of 52.2 ± 13.2 years (range, 21–83). The most common sites were the nasal cavity and maxillary sinus. According to the Krouse system, 9 (12.3%) were stage I, 15 (20.5%) stage II, 46 (63%) stage III, and 3 (5.4%) stage IV. All underwent endoscopic tumor excision; 22 with extensive disease underwent endoscopic medial maxillectomy, 5 Caldwell–Luc, and 1 external frontal sinus surgery. Histopathology showed dysplasia in 10 (13.6%) and squamous cell carcinoma in 3 (4.1%). Among 43 patients followed >6 months, 10 (23%) had radiologic recurrence, with 5 (11.6%) confirmed histopathologically. One recurrence involved the soft palate. Well-differentiated squamous cell carcinoma developed in one patient at 95 months.

CONCLUSIONS

Sinonasal inverted papilloma is more common in middle-aged men and is frequently diagnosed at advanced stages. Endoscopic surgery is an effective and safe treatment modality for most cases; however, medial maxillectomy and other external surgical approaches should be considered in advanced-stage or extensively spreading disease. The tumor carries a low but clinically significant risk of recurrence and malignant transformation. Although rare, recurrence at atypical locations should be

considered, comprehensive head and neck examination should be performed at each follow-up visit, and long-term regular postoperative surveillance should be maintained.

Surgical Outcomes And Evolution Of Vascular Management In Juvenile Nasopharyngeal Angiofibroma: A 17-Year Single-Center Experience

Sinan Dheyauldeen[1]

[1]*Department of Otorhinolaryngology, Head and Neck Surgery. Oslo University Hospital –Rikshospitalet, Oslo, Norway;* [2]*The Medical Faculty, University of Oslo, Oslo, Norway*

BACKGROUND & AIM

Objectives: To evaluate the long-term outcomes of surgical management for Juvenile Nasopharyngeal Angiofibroma (JNA) at a tertiary referral center, focusing on the efficacy of different surgical approaches and the safety of preoperative vascular interventions

MATERIAL & METHODS

Methods: A retrospective review was conducted on 39 male patients (median age 17.8 years) treated for JNA between 2007 and 2024. Tumors were staged using the Radkowski classification (Stage I: 8; Stage II: 26; Stage III: 5). Surgical management included endonasal endoscopic resection (n=12) or an open sublabial approach (n=27). Postoperative surveillance utilized annual MRI until age 22–25 to monitor for late recurrence

RESULTS

Results: Complete resection was achieved in 56% of cases. Of the 17 patients (44%) with residual tumor, 12 remained stable or regressed spontaneously. Five progressive residuals required endoscopic re-intervention, with two requiring adjuvant proton beam radiotherapy for hemorrhage control. At the final follow-up (median 52 months), 90% of patients were disease-free. Notably, surgical morbidity was low with no major intraoperative complications. However, preoperative embolization was associated with a 7% major complication rate, including one TIA and one permanent blindness. This prompted a successful institutional shift to coiling as the primary devascularization method, after which no further vascular complications occurred.

CONCLUSIONS

Conclusion: Multidisciplinary management ensures excellent long-term control of JNA with a 90% cure rate. While endoscopic resection is highly effective for lower-stage disease, advanced cases still benefit from open or multimodal strategies. Given the inherent risks of embolization, coiling represents a safer vascular adjunct. Our findings emphasize that stable residuals can be safely observed, reserving aggressive intervention for progressive disease

OP-1192

Atypical Fungal Mycetoma Coexisting With An Organized Hematoma In The Maxillary Sinus: A Rare Case Report

Siriwimol Nusri[1]

[1]*Bhumibol Adulyadej Hospital, Royal Thai Air Force, Bangkok, Thailand*

BACKGROUND & AIM

Fungal mycetoma is a common condition in the maxillary sinus, predominantly caused by Aspergillus species; other fungal species are rarely identified. Organized hematoma is also a rare sinonasal lesion that frequently mimics a tumor. The concomitant occurrence of a non-Aspergillus fungal mycetoma and an organized hematoma in the maxillary sinus is an exceedingly rare phenomenon.

MATERIAL & METHODS

Case Presentation: A 61-year-old male with multiple comorbidities—including hypertension, coronary artery disease (status post-percutaneous coronary intervention one year prior), a history of old cerebrovascular accident (CVA), and end-stage renal disease (ESRD) on maintenance hemodialysis—presented with intermittent left-sided epistaxis. He was on daily antiplatelet therapy. Nasal endoscopy revealed a polypoid swelling at the left middle meatus, and an initial tissue biopsy showed only a nasal polyp. Preoperative computed tomography (CT) demonstrated total opacification of the left maxillary sinus with internal high-density content and fine punctate calcification, causing obstruction of the ostiomeatal unit (OMU), accompanied by sclerotic thickening of the maxillary sinus wall. Magnetic resonance imaging (MRI) revealed a T1-weighted (T1W) hypointense and T2-weighted (T2W) hyperintense lesion with peripheral enhancement in the middle meatus, causing OMU obstruction.

RESULTS

Management and Outcomes: The patient successfully underwent an endoscopic endonasal approach (endoscopic modified medial maxillectomy) to completely remove the mycetoma and hematoma. Intraoperative findings showed mild polypoid mucosa of the maxillary sinus without necrotic tissue. The histopathological report revealed an abundant accumulation of broad, pauciseptate, ribbon-like hyphae with irregular branching within the tissue, accompanied by neutrophils and necrotic tissue. This was intermixed with hemorrhage, dilated vessels, and fibrin exudation, consistent with an organized hematoma. Postoperatively, the patient achieved a satisfactory outcome, regaining normal sinus function with no recurrence of epistaxis.

CONCLUSIONS

Conclusion: The concomitant finding of a non-Aspergillus fungal mycetoma and an organized hematoma in the maxillary sinus is a very rare condition that clinicians should consider in patients presenting with unilateral nasal masses and epistaxis, especially those with multiple vascular risk factors and ESRD on antiplatelet therapy.

Does Preoperative Blood Eosinophilia Predict Pathology And Revision In Unilateral Endoscopic Sinus Surgery? A 10-Year Single-Center Experience

Dr. İsmet Vurur[1], **Op. Dr. Özgenur Koçak**[1], **Prof. Dr. Zahide Mine Yazıcı**[1], **Dr. Meryem Açelya Çiftçi**[1]

[1]*Dr. Sadi Konuk Training and Research Hospital*

BACKGROUND & AIM

Peripheral blood eosinophil count has been incorporated into prognostic frameworks for bilateral chronic rhinosinusitis with nasal polyps (CRSwNP), where Type 2 inflammation dominates the endotype. Whether the same biomarker behaves comparably in unilateral sinonasal disease — a clinical category in which anatomic, infectious, and neoplastic processes frequently drive surgical indication — has received limited dedicated study, and Turkish surgical data on this question are scarce.

MATERIAL & METHODS

We reviewed 251 consecutive unilateral ESS procedures performed at the Otorhinolaryngology Department, Dr. Sadi Konuk Training and Research Hospital, Istanbul, between February 2016 and May 2026. After de-identification, we extracted age, sex, final pathology, revision status, and preoperative absolute eosinophil count ($\times 10^3/\mu L$) from hospital records. Free-text pathology reports were re-coded into nine standardized categories. Group comparisons used Mann-Whitney U or Kruskal-Wallis tests for continuous data and chi-square/Fisher exact for categorical data; the diagnostic performance of eosinophil count was assessed by ROC analysis with Youden-based cut-offs.

RESULTS

Median age was 37 years (IQR 22–51); the male-to-female ratio was 1.67. CRSwNP/inflammatory polyp (32.7%), polyp-free CRS (18.3%), and antrochoanal polyp (17.5%) were the leading diagnoses; inverted papilloma accounted for 7.2% and malignancy for 2.0%. Pathology distribution was strongly age-dependent ($p<0.001$): neoplastic lesions rose from 4.3% in pediatric to 22.4% in patients ≥60 years. Median preoperative eosinophil count was 160 cells/µL (IQR 100–270), with only 10% exceeding the 450 cells/µL threshold often quoted in bilateral CRSwNP literature. Eosinophil count did not separate neoplastic from non-neoplastic pathology (AUC 0.566, 95% CI 0.449–0.682) nor predict revision (AUC 0.485). Revision rate was 7.2% (16/222), concentrated in inverted papilloma (20.0%) and antrochoanal polyp (11.4%). Older age was associated with revision ($p=0.035$); eosinophil count was not ($p=0.838$).

CONCLUSIONS

In this Turkish cohort, the histopathological mix of unilateral ESS was broadly consistent with international reports, while malignancy was less frequent than some Western series. The most instructive finding is a negative one: preoperative blood eosinophilia neither separated pathology categories nor flagged revision risk. Biomarker frameworks built for bilateral CRSwNP should not be transposed uncritically to unilateral disease, whose endotype landscape appears to be substantially more heterogeneous.

OP-1194

Assesment Of The Impact Of Inflammatory Phenotype And Olfactory Dysfunction On Smell-Related Quality Of Life In Patients With Chronic Rinosinusitis

Tuğçe Kaya Yıldız[1], **Okan Mustafa Yıldız**[1], **Melis Demirağ Evman**[1], **Aslı Şahin Yılmaz**[1]

[1]*Kartal Dr. Lütfi Kırdar City Hospital*

BACKGROUND & AIM

Although an improvement in overall symptoms is generally expected after endoscopic sinus surgery in patients with chronic rhinosinusitis, changes in olfactory function and smell-related quality of life may vary among patients. The aim of this study was to evaluate the impact of inflammatory phenotype and olfactory dysfunction on smell-related quality of life in patients with chronic rhinosinusitis who underwent bilateral functional endoscopic sinus surgery (FESS).

MATERIAL & METHODS

This retrospective, observational, and analytical study included 30 patients who underwent bilateral FESS for bilateral nasal polyposis at the Department of Otorhinolaryngology of Kartal Dr. Lütfi Kırdar City Hospital between September 2024 and July 2025. Preoperative and postoperative 6th-month Visual Analog Scale (VAS), SNOT-22, and Questionnaire of Olfactory Disorders (QOD) scores, phenotypic characteristics, serum eosinophil percentage, total eosinophil count, and Lund-Mackay scores were evaluated. Delta scores were calculated by subtracting postoperative values from preoperative values in order to assess the magnitude of change. Correlation analyses and group comparisons were performed to investigate the effects of inflammatory phenotype on clinical improvement and smell-related quality of life.

RESULTS

The mean preoperative and postoperative total SNOT scores were 39.03±19.99 and 21.17±15.94, respectively, demonstrating a statistically significant postoperative reduction ($p<0.0001$). The mean preoperative and postoperative QOD scores were 36.30±18.00 and 34.30±14.46; however, the change in QOD scores was not statistically significant ($p=0.586$). A moderate positive and statistically significant correlation was found between delta SNOT-22 and delta VAS ($r=0.573$, $p=0.001$). In contrast, no significant correlation was found between delta SNOT-22 and delta QOD ($r=0.260$, $p=0.165$). There were no significant differences in delta scores according to asthma, allergic rhinitis, NSAID allergy, comorbidity, or smoking status. Serum eosinophil percentage showed a moderate positive and statistically significant correlation with delta VAS (rho=0.503, $p=0.0046$). Moreover, a weak-to-moderate positive and statistically significant correlation was found between serum eosinophil percentage and delta QOD (rho=0.362, $p=0.0496$). Total eosinophil count was significantly correlated with delta VAS (rho=0.543, $p=0.0019$), whereas its relationship with delta QOD remained borderline significant (rho=0.359, $p=0.0511$).

CONCLUSIONS

While bilateral FESS provides significant improvement in overall symptom burden in patients with chronic rhinosinusitis, changes in smell-related quality of life appear to be more heterogeneous. Classical clinical phenotypes did not significantly predict changes in QOD scores. In contrast, serum eosinophil percentage was significantly associated with improvement in smell-related quality of life. These findings suggest that postoperative improvement in olfactory quality of life may be more closely related to inflammatory burden than to conventional clinical phenotype labels.

The Role Of Paranasal Sinus Anomalies In Primary Acquired Nasolacrimal Duct Obstruction And Chronic Dacryocystitis

Associate Professor DR. OĞUZHAN DİKİCİ[1], **DR MEHMET EMİN ASLANCI**[2], **DR İSMAİL ALKAN**[1], **Associate Professor DR OSMAN DURGUT**[1], **Associate Professor DR FEVZİ SOLMAZ**[1]

[1]*Bursa City Hospital Department of Otorhinolaryngology*; [2]*Bursa City Hospital Department of Ophthalmology*

BACKGROUND & AIM

The aim of this study is to evaluate the role of nasal and paranasal sinus anomalies in the development of primary acquired nasolacrimal duct obstruction (PANDO) and chronic dacryocystitis. Given the close anatomical relationship of the nasolacrimal duct with the maxillary sinus and nasal cavity, nasal and sinus-derived inflammatory processes may contribute to the pathogenesis of PANDO and dacryocystitis.

MATERIAL & METHODS

In this retrospective study, 30 patients diagnosed with PANDO, 24 patients diagnosed with chronic dacryocystitis, and 30 healthy controls were evaluated. All participants underwent paranasal sinus computed tomography (CT) imaging. Septal deviation, the Mladina classification, agger nasi cells, paradoxical middle turbinate, concha bullosa, accessory maxillary ostium (AMO), and maxillary sinus pathologies were analyzed.

RESULTS

No statistically significant differences were observed between the PANDO and chronic dacryocystitis groups regarding the Mladina classification, presence of septal deviation, localization of the deviation, or side of the deviation. However, when the control group was compared with the PANDO and chronic dacryocystitis groups, statistically significant differences were identified in terms of the presence and side of septal deviation. Nasal polyps were found to be located on the same side as chronic dacryocystitis. In addition, the presence of right-sided paradoxical middle turbinate was significantly higher in the chronic dacryocystitis group compared to the PANDO group. Comparisons between the control group and the PANDO/chronic dacryocystitis groups demonstrated statistically significant differences regarding right paradoxical middle turbinate, left

paradoxical middle turbinate, right concha bullosa, right accessory maxillary ostium (AMO), and left accessory maxillary ostium (AMO).

CONCLUSIONS

This study demonstrates that nasal polyps, paradoxical middle turbinates, and hypoplastic maxillary sinuses are significantly associated with chronic dacryocystitis. In particular, maxillary sinus hypoplasia may contribute to the development of dacryocystitis by altering the course of the nasolacrimal duct through the medial wall of the maxilla and by increasing persistent inflammation within the sinus. Comprehensive evaluation of the nasal cavity and paranasal sinuses in patients with chronic dacryocystitis may improve treatment outcomes.

OP-1196

Long-Term Systemic Antibiotic Therapy For Chronic Rhinosinusitis With And Without Nasal Polyposis: A Systematic Review And Network Meta-Analysis

Omar Almansouri[1], **Mazin Alsarraj**[2]

[1]*king fahad general hospital, jeddah, saudi arabia;* [2]*East Jeddah Hospital*

BACKGROUND & AIM

Chronic rhinosinusitis (CRS) affects 9% of adults and is categorized into phenotypes with or without nasal polyps. Treatment varies by inflammatory endotype, and the utility of systemic antibiotics in management remains unclear. Given conflicting data, this meta-analysis used only randomized clinical trials to evaluate the impact of systemic antibiotics on objective clinical markers and patient-reported outcomes in patients with CRS with or without nasal polyps.

MATERIAL & METHODS

We retrieved relevant articles up to December 2025 from PubMed, Scopus, Web of Science, and Cochrane Library. Data were extracted from eligible studies by two independent reviewers, including baseline information, Sino-Nasal Outcome Test (SNOT) scores, Lund-Mackay Scores (LMS), and Lund-Kennedy Scale (LKS). All analyses were conducted using R v. 4.3.3.

RESULTS

We collected 2,561 records from four databases, after excluding 695 duplicates. Eventually, 17 randomized controlled trials were included. Pooled data analysis revealed no statistically significant differences in patient-reported SNOT scores between systemic antibiotics (amoxicillin-clavulanate, azithromycin, clarithromycin, and doxycycline) and usual care (UC). However, significant improvements were found in objective measures. For LMS, all evaluated antibiotics outperformed UC, with the most substantial reduction seen in azithromycin (MD -7.27), followed by doxycycline (MD -2.13) and clarithromycin (MD -0.74). Regarding LKS, both clarithromycin (MD -0.67) and azithromycin (MD -0.32) significantly reduced scores compared to UC, whereas amoxicillin-clavulanate (MD 0.10) showed no significant benefit. While macrolides, specifically azithromycin and clarithromycin, demonstrated superior efficacy in improving radiographic and endoscopic outcomes, these objective improvements did not translate to significant changes in subjective symptom scores.

CONCLUSIONS

Antibiotics improve objective markers like radiographic and endoscopic findings, but these do not necessarily translate to patient-reported symptom relief.

Correlation of intranasal Schirmer test to nasal symptoms score

Dr. Passavit Opassathavorn[1], **Dr. Navarat Tangbumrungtham, M.D.**[1], **Asst. Prof. Boonsam Roongpuvapaht, M.D.**[1], **Assoc. Prof. Kangsadarn Tanjararak, M.D.**[1], **Dr. Paramee Leaungchairat, M.D.**[1]

[1]*Ramathibodi Hospital, Mahidol University, Bangkok, Thailand*

BACKGROUND & AIM

Chronic rhinitis is a prevalent respiratory condition characterized by nasal congestion, itching, sneezing, and rhinorrhea. Objective quantification of nasal secretion remains challenging. The intranasal Schirmer test, adapted from ophthalmologic tear testing, offers a simple, non-invasive method for measuring nasal mucosal secretion. However, its relationship with patient-reported symptom severity remains unclear.

This research is to evaluate correlations between intranasal Schirmer test measurements and symptom severity scores, assess agreement between septal and inferior turbinate measurements, and compare secretion values according to rhinitis subtype, medication use, and hydration status.

MATERIAL & METHODS

A cross-sectional study was conducted in Thai adults aged 18–65 years with chronic rhinitis, including allergic rhinitis and non-allergic rhinitis. Intranasal Schirmer testing was performed under controlled humidity conditions (40–60%), with Schirmer strips placed at the anterior nasal septum and inferior turbinate for 10 minutes. Symptom severity was assessed using visual analog scale and total nasal symptom score. Statistical analyses included paired comparisons, correlation analysis, subgroup analysis, Lin's concordance correlation coefficient, Bland–Altman analysis, and regression analysis.

RESULTS

Seventy-five participants were analyzed. Septal and inferior turbinate measurements demonstrated excellent agreement (Lin's concordance correlation coefficient = 0.89; mean difference 0.11 mm). Correlations between Schirmer measurements and VAS/TNSS domains were weak and predominantly non-significant. Allergic rhinitis patients demonstrated significantly higher septal secretion values than non-allergic rhinitis patients (p=0.012). Hydration status and medication use were not significantly associated with intranasal Schirmer measurements.

CONCLUSIONS

The intranasal Schirmer test demonstrated high reproducibility and consistency between septal and inferior turbinate measurements, supporting its reliability as an objective measure of nasal secretion. However, weak correlations with symptom severity suggest that intranasal Schirmer testing reflects objective mucosal secretory activity rather than subjective symptom perception in chronic rhinitis.

OP-1198

Primary Nasopharyngeal Chordoma: A Case Report And Literature Review

Selin Özdin Toptaş[1], **Zehra Şahin**[2], **Alperen Vural**[1], **Yetkin Zeki Yılmaz**[1]

[1]*Department of Otorhinolaryngology – Head and Neck Surgery, Istanbul University-Cerrahpaşa, Faculty of Medicine, Istanbul, Türkiye;* [2]*Department of Pathology, Istanbul University-Cerrahpaşa, Faculty of Medicine, Istanbul, Türkiye*

BACKGROUND & AIM

Chordoma is a rare malignant tumor arising from embryonic notochordal remnants, with predilection for the axial skeleton, most commonly the sacrococcygeal region, followed by the cranio-cervical/spheno-occipital region, especially the clivus. Nasopharyngeal chordoma is exceptionally uncommon and may mimic other midline nasopharyngeal lesions, particularly nasopharyngeal carcinoma (NPC), causing diagnostic delay and inappropriate treatment. We report a case initially misdiagnosed as clear cell NPC and treated with chemoradiotherapy externally before referral to our tertiary care center, and systematically review reported primary nasopharyngeal chordoma cases from PubMed, Web of Science, Google Scholar, and additional sources, highlighting key clinicopathological features and major diagnostic pitfalls.

MATERIAL & METHODS

This study was designed as a case report combined with a literature review. Clinical, radiological, histopathological, and immunohistochemical data of a 64 year old woman referred after chemoradiotherapy for presumed clear-cell nasopharyngeal carcinoma were retrospectively reviewed. Revision pathology included hematoxylin–eosin assessment and an immunohistochemical panel, with particular emphasis on brachyury expression. A literature search was performed up to 30 April 2026 using PubMed/MEDLINE, Web of Science, Google Scholar, and reference-list screening, with combinations of "chordoma", "notochordal", "nasopharynx", "clivus", and "skull base". Case reports and case series describing histologically confirmed nasopharyngeal chordoma with extractable patient-level data were included. Duplicate reports, non-nasopharyngeal chordomas, clival chordomas, unconfirmed cases, and studies without usable clinical data were excluded. Demographic, clinical, imaging, pathological, treatment, and outcome variables were extracted independently by two reviewers and summarized descriptively.

RESULTS

Revision pathology of the index case demonstrated classical chordoma, with physaliphorous cells in a myxoid matrix and diffuse nuclear brachyury positivity. INI-1 was retained, while EBER, PAX-8, GATA-3, p40, p63, CK7, CK20, and CAIX were negative, excluding major mimickers including EBV-associated nasopharyngeal carcinoma and metastatic clear-cell carcinoma. The literature review identified 14 studies reporting 24 patients; together with the present case, 25 patients were analyzed. The mean age was 31.6 years, with a range of 5–66 years, and pediatric patients represented 34.8% of cases. A slight female predominance was observed. Nasal obstruction was the most frequent presenting symptom. Imaging commonly showed a midline nasopharyngeal mass, often T2-hyperintense, with variable clival association. Surgery was the main treatment in most evaluable cases, while adjuvant proton-beam radiotherapy was used selectively. Brachyury was positive in all tested cases.

CONCLUSIONS

Nasopharyngeal chordoma is an exceptionally rare midline tumor that may closely mimic benign lesions and NPC, leading to diagnostic delay and inappropriate treatment. This case shows that epithelial and S100 positivity may be misleading, especially

in clear cell or myxoid nasopharyngeal lesions. Therefore, brachyury immunohistochemistry should be routinely included when chordoma is considered. Early clinicopathological correlation, careful imaging assessment for clival or midline tract involvement, and multidisciplinary evaluation are essential. Maximal safe resection, with adjuvant particle-beam radiotherapy when appropriate, remains central to management. Recognition of this entity is crucial to avoid unnecessary chemoradiotherapy and improve patient outcomes.

Gemelli IRCCS, Largo Agostino Gemelli, 8, 00168 Rome Italy;* [3]*Department of Physics, Biological Institutes, Università Cattolica del Sacro Cuore, Largo Francesco Vito 1, 00168, Rome, Italy.*

BACKGROUND & AIM

Olfaction is one of the most evolutionarily ancient senses, strongly linked to emotional regulation and clinical pathologies such as Major Depressive Disorder (MDD). Despite its importance, objective systems for measuring olfactory perception remain limited. The Neuroscent project, financed by the National Recovery and Resilience Plan (PNRR), intends to establish the first objective system for interpreting neural activity during olfactory stimulation. We hypothesize that custom machine learning (ML) algorithms can identify unique "brain signatures" in electroencephalographic (EEG) traces to classify odor perception and intensity in real-time.

MATERIAL & METHODS

This non-randomized, parallel-assignment study (Open Label) involves 1,000 participants (>18 years old) divided into four groups: normosmics (n=550), hyposmics (n=150), tinnitus patients with hyposmia (n=150), and tinnitus patients without hyposmia (n=150). Participants get a thorough ENT and olfactory assessment, utilizing the Sniffin' Sticks test, yielding an encompassing Threshold-Discrimination-Identification (TDI) score (the maximum is 48). During olfactory assessment, 64-electrode EEG recordings are taken to capture unique brain wave patterns. Data analysis applies Random Forest methods and t-SNE dimensionality reduction to identify EEG signals and analyzes the association between olfactory disorders and tinnitus features.

RESULTS

Preliminary examination of Alpha and Theta power (μV^2) and Fourier transform features shows significant clusters between normosmic and hyposmic participants. The Random Forest model is currently being established, with performance measured via accuracy and Fleiss' Kappa against TDI values. Secondary outcomes incorporate Pure Tone Audiometry, Tinnitus Handicap Inventory (THI), and Auditory Brainstem Response (ABR) to connect olfactory brain processes with auditory impairment. Early modeling implies that, EEG characteristics can reliably predict odor categories across all groups.

CONCLUSIONS

The Neuroscent project provides a novel framework for the objective diagnosis of sensory disorders. By integrating high-density EEG with ML, this study aims to validate a high-precision diagnostic tool for hyposmia, even in complex clinical cases involving tinnitus. These "brain signatures" may offer new therapeutic targets and improve diagnostic paths for sensory dysfunction.

Evaluation Of Extended Dupilumab Dosing Intervals In Chronic Rhinosinusitis With Nasal Polyposis: A Real-World Study From Saudi Arabia

Abdullah S. Alghamdi[1], **Faisal A Saati**[1], **Salma Alkhammash**[1], **Adeeb A. Bulkhi**[2], **Sumaiya H Muathen**[1], **Omar A Abu Suliman**[1]

[1]*King Abdullah Medical City, Makkah, Saudi Arabia;* [2]*Umm Al-Qura University, Makkah, Saudi Arabia*

BACKGROUND & AIM

Chronic rhinosinusitis with nasal polyposis (CRSwNP), often associated with asthma, significantly impacts quality of life. Dupilumab 300 mg every two weeks (Q2W) is effective but costly. This Saudi real-world study assessed whether extending dosing to every four weeks (Q4W) maintains effectiveness in patients with CRSwNP with or without asthma.

MATERIAL & METHODS

In this retrospective cohort study, 42 adult patients with CRSwNP who had completed at least one year of stable treatment with Q2W dupilumab were transitioned to Q4W dosing and monitored for at least one additional year. Clinical, biomarker, and imaging outcomes were assessed.

RESULTS

Clinical outcomes between Q2W and Q4W were largely comparable. Median nasal polyp scores remained stable, and symptom scores for nasal congestion, discharge, smell loss, and fatigue showed no significant changes. Sino-Nasal Outcome Test (SNOT)-22 and Lund-Mackay scores trended lower in the Q4W group compared to Q2W group but were not statistically significant. Blood eosinophils were modestly reduced, while asthma control remained stable, with high asthma control test scores. Total IgE levels (IU/mL) were significantly lower in the Q4W group (32.5 [10.1–76.4] vs. 52.7 [19.8–215], p<0.001), suggesting immunologic benefit. Fractional exhaled nitric oxide (FeNO) levels were unchanged. Overall, 92.9% maintained symptom control on Q4W for one year; three reverted to Q2W due to worsening of asthma control symptoms.

CONCLUSIONS

Extending dupilumab dosing from Q2W to Q4W is a viable and effective option for most patients with CRSwNP and asthma after at least one year of stable treatment, offering a potential reduction in treatment burden without compromising clinical outcomes.

Determinants Of Revision Timing After Endoscopic Sinus Surgery: Disease Extent Vs. CT Findings

Refik Berke Dereli[1], **Bürge Dereli**[1], **Beyzanur Güney**[1], **Gülpembe Bozkurt**[1]

[1]*Department of Otorhinolaryngology, Prof. Dr. Cemil Taşcıoğlu City Hospital, Istanbul, Türkiye*

BACKGROUND & AIM

Revision endoscopic sinus surgery (ESS) remains a significant clinical challenge. Although conservative surgical aproaches and anatomical obstructions are frequently implicated, the relative contribution of postoperative radiological findings and their affects of them to timing of revision remains unclear. We hypothesized that the higher amounts of anatomical landmarks that would cause obstruction and their computed tomography findings (CT) would be associated with early revision, whereas lesser CT findings would cause late revision.

MATERIAL & METHODS

This retrospective single-center study included 67 patients who underwent revision ESS in our clinic between the years 2019 to 2025. We separated patients into 2 groups such as early (n=11) and late (n=56) revision groups based on the time passed between revisions. Demographic variables such as age and sex were noted. Preoperative CT scans of Revision ESS's were searched for residual uncinate process, maxillary antrostomy obstruction, lateralized middle turbinate, osteitis, frontal recess obstruction, sphenoid ostium issues, suprabullar cells, and retained agger nasi cells. Extention levels of pathologies were evaluated using Lund-Mackay score. Statistical analyses were performed using appropriate parametric and non-parametric tests to find associations between independent variables and revision timing, with p<0.05 considered significant.

RESULTS

Late revision group were significantly older than early revision group (50.4±12.4 vs. 41.3±14.3 years, p=0.042). Males were significantly associated with delayed revision (89.3%, p=0.013). None of the evaluated CT findings demonstrated a statistically significant association with revision timing (p>0.05 for all comparisons). We found out that LM scores were higher in late revision group compared to early revision group (median 18.0 [interquartile range (IQR): 14.0–21.0] vs. 9.0 [IQR: 6.0–21.0], p=0.013).

CONCLUSIONS

Contrary to our hypothesis, preoperative CT findings did not have a contributing factor to the timing of revision. Instead, overall radiological disease burden, as reflected by LM score, was significantly associated with delayed revision. These findings suggest that global disease severity may play a more critical role than isolated anatomical factors in determining revision timing and should be considered in postoperative evaluation and follow-up strategies.

OP-1202

Does The Use Of The Hammer Graft Reduce The Need For Additional Grafts In Rhinoplasty? A Retrospective Study

Vecide Pinar Altınısık Dogan[1], **Mustafa Cakir**[1], **Erkan Soylu**[1]

[1]*Istanbul Medipol Universty*

BACKGROUND & AIM

Rhinoplasty aims to improve both functional and aesthetic aspects of the nose [1,2]. Structural support of the dorsum and caudal septum is commonly achieved using spreader grafts, septal extension grafts, and columellar struts [3–6]. The hammer graft, described by Soylu et al. in 2023, is a multifunctional graft that combines these three functions in a single structure [7,8].

To retrospectively evaluate whether the use of hammer grafts reduces the total number and types of additional grafts required in primary and revision rhinoplasty.

MATERIAL & METHODS

This retrospective study was approved by the İstanbul Medipol University Non-Interventional Clinical Research Ethics Committee (Decision No: 2025/478; Date: 21.08.2025). A total of 171 open rhinoplasty cases performed between June 2024 and April 2025 were analyzed. Patients aged 16–56 years who underwent primary or revision rhinoplasty were included. Cases with significant comorbidities, congenital nasal deformities, cleft lip and palate, or facial trauma history were excluded. Patients were divided into two groups: Group A (n=100), without hammer graft; Group B (n=71), with hammer graft. The number and types of grafts were compared using the Mann–Whitney U test ($p<0.05$).

RESULTS

The mean number of grafts per patient was significantly lower in Group B (2.60 ± 1.18) compared to Group A (3.68 ± 1.27) ($p=0.001$). Marked reductions were observed in septal extension grafts (25.4% vs 75%), spreader grafts (42.3% vs 57%), columellar strut grafts (15.5% vs 36%), and rim grafts (23.9% vs 98%). The reduction remained significant when primary and revision cases were analyzed separately ($p<0.01$).

CONCLUSIONS

The hammer graft is a multifunctional graft, and its use reduces the need for additional grafts. This feature is of great importance, as it allows the patient's own cartilage to be utilized efficiently while providing sufficient material for effective reconstruction.

OP-1203

"Prevalence And Anatomical Distribution Of Onodi Cells On CT: Systematic Review And Meta-Analysis"

Mohammed Alsayyari[3], **Mohammed Alshenaiber**[2], **Nourah Farhan Alanezi**[2], **Talal Alharbi**[1], **Abdullah Alkhaldi**[1], **Riyadh Alhedaithy**[1]

[1]Department of Otorhinolaryngology-Head&Neck Surgery, MNGHA; [2]College of Medicine, King Saud bin Abdulaziz University for Health Sciences, Riyadh; [3]College of Medicine, King Saud University, Riyadh

BACKGROUND & AIM

The Onodi cell, also known as the sphenoethmoidal air cell, is a clinically important anatomical variation of the posterior ethmoid sinus because of its close relationship to the optic nerve and internal carotid artery. Failure to recognize this variation during preoperative evaluation may increase the risk of major complications during endoscopic sinonasal and skull base surgery. Reported prevalence rates vary considerably across radiological studies, and the anatomical characteristics of Onodi cells on computed tomography (CT) have not been comprehensively synthesized.

MATERIAL & METHODS

A systematic review and meta-analysis of radiological studies evaluating Onodi cells on CT imaging was performed. Only studies that clearly defined the Onodi cell, utilized CT-based imaging, and reported anatomical distribution data were included. Random-effects meta-analyses were conducted to estimate pooled prevalence proportions with corresponding 95% confidence intervals (CIs). Subgroup analyses were performed according to geographic region, population type, study design, imaging modality, and CT slice thickness. Secondary outcomes included bilateral occurrence, sex differences, optic nerve protrusion or dehiscence, and internal carotid artery (ICA) protrusion or dehiscence. Heterogeneity was assessed using the I^2 statistic, and publication bias was evaluated using funnel plot inspection and Egger's test.

RESULTS

Thirty-three studies comprising 9,983 patients were included. The pooled prevalence of Onodi cells was 29.95% (95% CI: 21.73–39.70), with substantial heterogeneity (I^2 = 97.1%). Asian studies demonstrated the highest prevalence (38.7%), whereas African studies reported the lowest prevalence (17.6%). Population type significantly influenced prevalence estimates ($p < 0.001$), with mixed-indication populations demonstrating the highest prevalence. The pooled prevalence of bilateral Onodi cells was 35.84% (95% CI: 25.95–47.11). No significant sex difference was identified between males and females (OR = 1.04, 95% CI: 0.85–1.28, $p = 0.695$). The pooled prevalence of optic nerve protrusion and dehiscence was 21.77% and 12.99%, respectively, while ICA protrusion and dehiscence were observed in 20.38% and 7.42% of cases. Sensitivity analyses confirmed the robustness of pooled estimates, although high heterogeneity persisted across most outcomes.

CONCLUSIONS

Onodi cells are common anatomical variations identified on CT imaging and frequently demonstrate clinically significant relationships with the optic nerve and internal carotid artery. Considerable heterogeneity exists across studies, likely related to differences in imaging methodology, population characteristics, and diagnostic criteria. Accurate preoperative recognition of Onodi cells and their anatomical variations remains essential for improving surgical planning and reducing the risk of complications during endoscopic sinonasal and skull base procedures.

Sphenopalatine Ganglion Block In Septorhinoplasty: A Systematic Review And Meta-Analysis

Ahmed Abu-Zaid[2], **Mohammed Alotaibi**[3], **Manal Aldaihani**[3], **Fatemah Alshamari**[3], **Hessa Mohammed Alfayadh**[4], **Ahmad S Alharthi**[5], **Mohammad H Shaheen**[1]

[1]*Otolaryngology Department, Hera General Hospital, Makkah, Saudi Arabia;* [2]*College of Medicine, Alfaisal University, Riyadh, Saudi Arabia;* [3]*Kuwait Institute for Medical Specializations, Kuwait City, Kuwait;* [4]*College of Medicine, Almaarefa University, Riyadh, Saudi Arabia;* [5]*Department of Otolaryngology & Head and Neck Surgery, Alhada Armed Forces Hospital, Taif, Saudi Arabia*

BACKGROUND & AIM

Postoperative pain is a common and clinically significant complication following septorhinoplasty. Effective pain control is essential for patient comfort and recovery. This study aimed to assess the analgesic efficacy of the sphenopalatine ganglion block (SPGB) in patients undergoing septorhinoplasty.

MATERIAL & METHODS

A systematic literature search was conducted across Web of Science, PubMed, Google Scholar, Scopus, and the Cochrane Central Register of Controlled Trials to identify randomized controlled trials and observational studies evaluating SPGB in septorhinoplasty. The primary outcome was postoperative pain intensity, while secondary outcomes included operative duration and intraoperative blood loss. Dichotomous and continuous data were pooled using relative risks (RRs) and standardized mean differences (SMDs), respectively, with corresponding 95% confidence intervals (CIs).

RESULTS

Five studies involving a total of 279 participants were included. SPGB significantly reduced postoperative pain at multiple time points: 1–2 hours (SMD −1.91, 95% CI −3.81 to −0.01; $p<0.05$), 4–6 hours (SMD −1.07, 95% CI −1.92 to −0.23; $p=0.01$), and 24 hours postoperatively (SMD −0.94, 95% CI −1.52 to −0.37; $p<0.001$). In addition, SPGB was associated with a significant reduction in intraoperative blood loss (SMD −3.11, 95% CI −5.06 to −1.15; $p<0.001$). No significant difference was observed in operative duration between the SPGB and control groups ($p=0.94$)

CONCLUSIONS

SPGB is an effective adjunct for postoperative analgesia in septorhinoplasty, providing significant pain reduction for up to 24 hours after surgery. It also significantly decreases intraoperative blood loss without increasing operative time, supporting its safe and beneficial role in perioperative management.

Drug-Induced Rhinitis, Treatment And Diagnosis

Elena Bolshakova[1]

[1]*Belarusian State Medical University*

BACKGROUND & AIM

Objective — to assess the feasibility of using laser reduction of the inferior turbinates in patients with drug-induced rhinitis during complex therapy due to the impossibility of self-refusal of nasal decongestants without medical assistance.

MATERIAL & METHODS

To confirm the clinical utility of 7-watt pulsed laser radiation, developed on pig head models (N=5), we continued the experiment on live rabbits (N=4). We decided to study the visual and morphological state of the nasal mucosa dynamically (0–1–2–3 months) after submucosal laser destruction of the rabbit nasal mucosa.

In 2021-2025, 100 patients with drug-induced rhinitis who had been abusing topical decongestants for more than one year underwent surgery in the ENT department of the 11th Clinical Hospital in Minsk. Age from 18 to 72 years. In addition to an otolaryngological examination, included endonasal endoscopy, the use of the SNOT-22, and the performance and analysis of CT scans of the paranasal sinuses, rhinomanometry, olfactory (Sniffin' Sticks test). For laser reduction of the inferior nasal

conchae, a laser device with the following settings was used: radiation wavelength - 1560 nm; radiation emission mode - continuous; power - up to 6-7 W.

RESULTS

Morphological changes in the nasal mucosa of rabbits after laser vaporization with a frequency of 1560 nm and 7 W at 0-1-2-3 months. Clinical resalts.When analyzing the results of the questionnaire, it was found that in the late postoperative period, 7 patients out of 100 returned to dependence on nasal decongestants within a year, which amounted to 7.%, 93 patients refused to use vasoconstrictor drops - 93% , which indicates the high effectiveness of this method in the fight against drug dependence.

CONCLUSIONS

The results of a clinical study showed that to eliminate nasal obstruction, it is advisable to use laser reduction of the inferior turbinates with a wavelength of 1560 nm (1.56 µm) and a power of up to 7 W in a pulsed mode. This method is effective in refusing the treatment of drug-induced rhinitis, effective in the form of reduction of the inferior turbinates with the elimination of nasal obstruction, safety (no complications), the possibility of performing the method in a cost-effective way on an outpatient or inpatient basis (with 1 bed-day).

Nasosinusal Mucoceles : A 40-Case Analysis Of Surgical Outcomes And Recurrence Predictors

Walid Bijou[1,2], **Sarah Hafidi**[1], **OUKessou Youssef**[1,2], **Roundi Sami**[1,2], **Reda Allah Abada**[1,2], **Mohamed Roubal**[1,2], **Mohamed Mahtar**[1,2]

[1]Ibn Rochd hospital university; [2]Hassane II university

BACKGROUND & AIM

Nasosinusal mucoceles represent a benign expansile pathology whose orbital and endocranial extension constitutes a major therapeutic challenge. The objective of this study was to analyze the clinical, radiological, and surgical characteristics of a single-center series of complex mucoceles, and to identify prognostic factors for recurrence using an improved data collection form integrating specific variables validated by international literature.

MATERIAL & METHODS

Single-center retrospective study including 40 patients operated for nasosinusal mucocele with orbital and/or cranial extension between 2015 and 2024. Epidemiological, clinical, radiological (CT and MRI), surgical, and follow-up data were collected using a standardized form. Radiological variables analyzed included: primary sinus involved, laterality, precise location of bone erosion (medial orbital wall, frontal anterior table, skull base), type of orbital extension (medial, lateral, superior), endocranial extension, presence of muopyocele, and estimated lesion size. Endoscopic surgical techniques (Draf classification for frontal sinusotomies, marsupialization width, intraoperative ostial patency) and combined approaches were documented. Mean follow-up was 12 to 24 months with endoscopic control of ostial patency and SNOT-22 score evaluation.

RESULTS

The cohort comprised 27 women (67.5%), mean age 51.4 years (range 12–87). Fronto-ethmoidal involvement was predominant (57.5%), followed by isolated frontal (22.5%). Orbital extension was documented in 82.5%, endocranial extension in 15%, and bone erosion in 80%. Leading symptoms included periorbital swelling, exophthalmos (40%), and headaches (30%). Prior endonasal surgery was identified in 30% of cases. Treatment was purely endoscopic in 72.5%. At final follow-up, 85% achieved satisfactory ostial patency on endoscopic control, , mean postoperative SNOT-22 was 16, and overall recurrence rate was 15% .

Prognostic Factors Analysis : Multivariate analysis identified several significant adverse factors. Young age was associated with increased recurrence. Prior functional endonasal surgery doubled recurrence risk. Orbital extension constituted a major prognostic factor: 100% of recurrent cases presented initial orbital extension. Presence of muopyocele was also adverse (25.0% vs 13.9%). Draf IIb type, associated with more complex mucoceles.

CONCLUSIONS

This series confirms the efficacy of endoscopic surgery in managing complex nasosinusal mucoceles with an 85% success rate. Identification of specific prognostic factors (young age, surgical history, orbital extension, muopyocele, technical complexity requiring Draf IIb) enables optimization of surgical strategy and postoperative follow-up. Wide marsupialization with intraoperative confirmation of ostial patency and rigorous endoscopic surveillance are essential to prevent recurrence. These results advocate for the use of mucocele-specific radiological and surgical variables, more relevant than generic chronic sinusitis scores, in prognostic evaluation and future clinical research.

Real World Data: Improvement Of Patient´S Quality Of Live With Dupilumab, Mepolizumab Und Tezelumab In Crswnp In The Last Year.

Klaus Stelter[1], **Camelia Daniela Bumbas**[2], **Carlotta Geyer**[1], **Isabel-Sophie Stelter**[1]

[1]*ENT Centre Mangfall-Inn, Rosenheim, Germany;* [2]*RoMed Clinic for head and neck surgery, Bad Aibling, Germany*

BACKGROUND & AIM

Since November 2025 patients with recurrent nasal polyps are treated with dupilumab 300mg or mepolizumab 100mg or tezelumab 210mg according to the AWMF-guidelines at the ENT-Centre Zentrum Mangfall-Inn in Rosenheim, Oberbayern. One of the most important patient related outcome measurements is the SNOT22 questionnaire. Every patient has to fulfil the questionnaire in unregularly intervals. We present the results of 365 questionnaires of n=102 patients from the last three years.

MATERIAL & METHODS

Patients were requested to fulfill the SNOT22 digitally on an Ipad. The total score was automatically calculated by the ENTstatistics software, build by Innoforce, Liechtenstein. Our rhinologic database records previous surgeries, histopathologic findings, concomitant diseases and the beginning and end of the biological therapy.

RESULTS

The total score before the biological therapy was 52,94 after 180 days of therapy 23,63 and after 270 days 26,90. Due to the early permission of dupilomab in the treatment of CRSwNP the dupilumab group is with 72 patients the strongest group, whereas mepolizumab with 21 patients and tezelumab with 9 patients are smaller groups. The drop in the SNOT22 score is almost the same in all groups. Adverse events were extremely rare.

CONCLUSIONS

The three Biologicals are highly effective drugs in Samter´s disease and CRS with polyps. However, these drugs are reserved for severe cases of nasal polyps, although not-severe cases with less previous surgeries would benefit from the biological therapy, too. Non-responders or adverse events are very rare. The cost effectiveness of biologicals will be a big issue for our health care system in the next years.

The Role Of Prophylaxis Antibiotics In The Prevention Of Meningitis In Endonasal Anterior Skull Base Surgery: A Systematic Review And Meta-Analysis

Azfar Javed[1], **Muhammad U. Farooq**[3], **Abdullah Alburaiki**[3], **Hamad Khan**[4], **Haissan Iftikhar**[2], **Harpreet Chohan**[4]

[1]*Royal Stoke University Hospital, U.K.;* [2]*Department of Otolaryngology, University Hospital Northampton, UK.;* [3]*University Hospital Birmingham NHS Trust, U.K.;* [4]*Walsall Manor Healthcare Trust, U.K.*

BACKGROUND & AIM

Anterior skull base surgery is commonly used for the treatment of a variety of skull base lesions. One serious postoperative complication of this procedure is meningitis. Prophylactic antibiotics are widely used but with considerable variability in duration and regimes due to lack of guidelines. This systematic review was carried out to determine the benet of prophylactic antibiotics in preventing meningitis in patients undergoing endonasal anterior skull base surgery.

MATERIAL & METHODS

The review was undertaken according to PRISMA guidelines. Online searches including PubMed, MEDLINE, EMBASE, Cochrane, and gray literature were performed up to May 2, 2024. Articles reporting on patients undergoing endoscopic anterior skull base surgery, the use or not of prophylactic antibiotics, and follow-up outcomes were included for selection. Data extracted included demographics, pathology, prophylactic antibiotic duration/type, nasal pack use, CSF leaks, meningitis rates, sinusitis rates, and other complications.

RESULTS

A total of 32 studies were included in this systematic review, totaling 26,477 patients published between 1981 and 2023. The overall rate of developing meningitis with any duration of use of antibiotics was 2%. Patients receiving intraoperative antibiotics alone had a higher rate of subsequent meningitis (3%) compared with patients receiving a postoperative course of 24 hours or a longer course (1%). Patients who had an intraoperative or postoperative CSF leak had a higher rate of meningitis (10%) than those without (0%).

CONCLUSIONS

This review indicates that postoperative antibiotic course may be more effective in preventing meningitis. Patients who develop a CSF leak have a higher risk of developing meningitis.

Anterior Skull Base Pseudomeningoceles: A Scoping Review Of Skull Base Pseudomeningoceles

Haifa Alsheikh[1], **Kholoud Alamari**[2], **Zahra Alshurafa**[1], **Yara Akkielah**[1], **Abdullah S. AlDughaither**[3], **Naif Alotaibi**[1,2]

[1]*College of Medicine, Alfaisal University, Riyadh, Saudi Arabia;* [2]*Department of Otolaryngology, Head & Neck Surgery and Communication Sciences, King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia;* [3]*College of Medicine, King Saud University, Riyadh, Saudi Arabia*

BACKGROUND & AIM

The main sites, clinical symptoms, and causal elements linked with pseudomeningoceles at the cranial base are sought by this thorough study. Apart from organizing present data to support therapeutic decision-making, it aims to evaluate diagnostic techniques and the appropriate course of action.

MATERIAL & METHODS

Using the terms "skull base" AND/OR "pseudomeningocele," a thorough search was done in the MEDLINE, PubMed, and Cochrane databases. Articles offering explicit data on the localization and management of pseudomeningocele published in English, French, or Spanish were taken into consideration. Review papers, case studies, and case reports were taken under consideration; reviews, conference abstracts, and papers lacking enough or inaccessible data were turned away. Data gathered covered demographics, location, cause, presentation, diagnosis tools, management strategies, and results.

RESULTS

Twenty 29-person trials were examined. The primary location of pseudomeningocele development was the sphenoid bone (31%), followed by the posterior cerebral fossa (44.8%). At 42.9%, the main etiology was iatrogenic; traumatic reasons came second at 34.5%. Mostly post-surgical, these factors were blamed. MRI was the main imaging modality in 79.3% of cases; CT was used in 62.1% of those cases. Though for most individuals, surgical intervention proved to be the definitive cure, initial conservative treatment was tried. There was limited follow-up data; most patients showed neither morbidity nor mortality. Mostly, preventing problems depends on fast diagnosis and suitable intervention.

CONCLUSIONS

Skull base pseudomeningoceles are rare events that are sometimes missed due to their uncertain appearance and diagnostic difficulties. This study emphasizes how important quick imaging and improved clinical awareness are to guide management decisions. Although traditional methods are usually used, in complicated or unresolved cases, surgical intervention is usually justified. These findings highlight the need for raising awareness and thorough documentation in order to enhance the results for the impacted individuals.

OP-1210

Clinical Approach To Paranasal Sinus Osteomas: Towards Better Surgical Decision-Making

Salih Ozan Korkmaz[1], **Oğuzhan Cumalı**[1], **Şahin Öğreden**[1], **Fatma Demirkol**[1], **Özgür Yiğit**[1]

[1]*İstanbul Başakşehir Çam-Sakura Hospital*

BACKGROUND & AIM

INTRODUCTİON

Paranasal sinus osteomas are benign, slow-growing lesions most commonly arising from the frontal and ethmoid sinuses. Although frequently asymptomatic and incidentally detected, larger lesions or those in critical locations may require surgical intervention. The decision-making process depends on multiple factors, particularly lesion size and anatomical localization.

OBJECTİVE

To evaluate our clinical approach to paranasal sinus osteomas by analyzing:

- Indications for surgery
- Choice of surgical technique
- The relationship between lesion size, location, and management strategy

MATERIAL & METHODS

A retrospective review was conducted on 22 patients diagnosed with paranasal sinus osteomas. The following parameters were analyzed:

- Age and gender
- Lesion location
- Maximum lesion size
- Management strategy (surgical vs. follow-up)

• Type of surgical approach

RESULTS

A total of 22 patients were included (13 males, 9 females), with a mean age of approximately 45 years.

LOCALİZATİON

• Frontal sinus: 50%

• Ethmoid sinus: 36%

• Maxillary sinus: 9%

• Combined (fronto-ethmoidal): 5%

MANAGEMENT

• Surgical treatment: 50% (n=11)

• Conservative follow-up: 50% (n=11)

SURGİCAL APPROACHES

• Endoscopic: 27%

• External: 18%

• Combined: 55%

CONCLUSIONS

Management of paranasal sinus osteomas should be tailored to each patient. Lesion size and localization are the most critical factors influencing surgical decision-making. Endoscopic approaches are safe and effective for appropriately selected cases, whereas combined techniques remain essential for larger and more complex lesions.

BACKGROUND & AIM

This study aimed to objectively and subjectively evaluate the effect of nasal septal deviation (NSD) types, classified according to the Baumann system, on Eustachian tube function.

MATERIAL & METHODS

A total of 107 NSD patients (78 males, 29 females; mean age: 35.39 ± 9.55 years) were included. NSD was categorized into six types based on the Baumann classification. All patients completed the NOSE (Nasal Obstruction Symptom Evaluation) scale and ETDQ-7 (Eustachian Tube Dysfunction Questionnaire). Eustachian tube function was evaluated using the ETF-1(Eustachian Tube Function-1) test, and correlations with NSD types were evaluated.

RESULTS

Advanced deviation types (Types 5–6) were associated with higher NOSE and ETDQ-7 scores and significantly reduced tympanometric pressure responses during both Toynbee and Valsalva maneuvers. Type 6 exhibited the highest ETDQ-7 scores and the lowest Pmax–Pmin values.

CONCLUSIONS

Eustachian tube dysfunction was more pronounced in advanced NSD types. Septoplasty indications should therefore consider not only nasal obstruction but also the potential impact of septal deviation on Eustachian tube dysfunction.

septal deviation, Eustachian tube, ETDQ-7, tympanometry

OP-1212

Side-Based Volumetric Analysis of Paranasal Sinuses and Mastoid Cells in Pediatric Unilateral Antrochoanal Polyps:A Retrospective Study

Mahmut DEMİRTAŞ[1], **Aybike CAN**[1]

[1]Department of Otorhinolaryngology, Aydın Adnan Menderes University Training and Research Hospital

BACKGROUND & AIM

Pediatric antrochoanal polyps (ACPs) are among the most common nasal polyps in childhood. They are benign, typically unilateral lesions originating from the maxillary sinus mucosa. This study aimed to quantitatively evaluate the association between unilateral ACPs and the development of the paranasal sinuses and mastoid air cell system in patients under 18 years of age. We also investigated whether side-specific volumetric differences were associated with accompanying anatomical factors, including septal deviation, concha bullosa, and adenoid hypertrophy. Finally, the potential relationship between these anatomical and volumetric characteristics and postoperative recurrence was explored.

MATERIAL & METHODS

This retrospective cohort study included patients aged <18 years with histopathologically confirmed antrochoanal polyps (ACPs) who underwent endoscopic sinus surgery at our clinic between 2015 and 2026. Bilateral volumes of the maxillary, sphenoid, and frontal sinuses and mastoid air cells were manually segmented on preoperative thin-section CT scans (≤1.25 mm) using a PACS workstation and classified as ipsilateral or contralateral to the ACP. Septal deviation, concha bullosa, middle-ear pathology, mastoid pneumatization, and adenoid hypertrophy (graded 1–4) were also evaluated. An exploratory cumulative ipsilateral anatomical burden score (0–4) incorporating ACP, septal deviation, concha bullosa, and adenoid hypertrophy was calculated. Paired and unpaired non-parametric tests were used as appropriate. Firth penalized logistic regression assessed recurrence after adjustment for age and sex, while linear mixed-effects models with patient-level random intercepts were used for bilateral mastoid analyses.

RESULTS

Among 27 patients (mean age, 13.3±3.5 years; 63.0% male), recurrence occurred in 5 (18.5%) during a median 82-month follow-up, all within 41 months. Recurrent patients were younger (median, 10.0 vs. 14.5 years; p=0.041) and had lower ipsilateral maxillary sinus volumes (8.60 vs. 15.70; p=0.011) and greater negative ipsilateral–contralateral maxillary volume differences (−1.90 vs. +0.65; p=0.039). Ipsilateral maxillary volume correlated with age (Spearman ρ=0.57; p=0.002); its association with recurrence was attenuated after age- and sex-adjustment (Firth OR=0.83; p=0.162). No significant ipsilateral–contralateral differences were observed in maxillary, sphenoid, frontal, or mastoid volumes, and sphenoid, frontal, and mastoid volumes were not associated with recurrence. Septal deviation showed no contralateral predominance (p=0.791). Increasing anatomical burden showed a nonsignificant trend toward lower mastoid volume (age-adjusted β=−0.97; p=0.116). Mastoid volume and pneumatization were unrelated to recurrence.

CONCLUSIONS

Younger age was associated with recurrence in pediatric ACP, whereas smaller ipsilateral maxillary sinus volume was not independently associated with recurrence after adjustment for age and sex. Developmental anatomy and potentially more conservative surgical approaches in younger children may contribute to recurrence risk. ACP laterality and associated sinonasal anatomical factors showed no significant relationship with septal displacement or mastoid development. Larger prospective studies incorporating detailed surgical variables are needed to clarify these developmental and recurrence-related interactions.

OP-1213

Endoscopic Resection Of Juvenile Nasopharyngeal Angiofibroma Without Preoperative Embolization: Outcomes Of Intraoperative Internal Maxillary Artery Ligation Through A Modified Denker Approach In Uzbekistan

Azizbek Uzokov[1,3], **Ravshanbek Umarov**[2], **Lutfiniso Tulaganova**[3]

[1]*Tashkent Medical Academy;* [2]*Tashkent Institute of Postgraduate Medical Education;* [3]*Central Asian University*

BACKGROUND & AIM

Juvenile nasopharyngeal angiofibroma (JNA) is a rare, highly vascular tumor that primarily affects adolescent males. Preoperative embolization is commonly used to reduce intraoperative blood loss but increases treatment costs and carries a risk of complications, including stroke, visual impairment, and cranial nerve injury. Although endoscopic techniques have advanced considerably, evidence regarding the management of JNA without preoperative embolization remains limited, particularly in Central Asia. This study reports the experience of a tertiary referral center in Uzbekistan using intraoperative internal maxillary artery ligation through a modified Denker approach to achieve vascular control during endoscopic resection of JNA.

MATERIAL & METHODS

A retrospective review was conducted of 52 consecutive male patients with histologically confirmed JNA who were treated at a tertiary referral center in Uzbekistan between January 2023 and December 2025. The center receives referrals from across Uzbekistan and neighboring Central Asian countries. All patients underwent contrast-enhanced CT angiography for preoperative assessment and were staged according to the Radkowski classification. Endoscopic tumor resection was performed without preoperative embolization in all cases. Early vascular control was achieved through ligation of the IMAX via

a modified Denker approach. Surgical outcomes, complications, and recurrence rates were analyzed. A comprehensive surgical video was recorded to demonstrate the operative technique and key steps of vascular control.

RESULTS

The majority of tumors were intermediate- to advanced-stage lesions. Radkowski stages IIA, IIC, and IIIA accounted for 39 patients (75%), while stage IIIB disease was present in 9 patients (17%). Intraoperative IMAX ligation was successfully performed in all cases, providing effective vascular control and facilitating endoscopic tumor resection without embolization. Complete tumor removal was achieved in the majority of patients, including advanced-stage lesions. No major vascular, neurological, or orbital complications were encountered. During follow-up, recurrence was observed in 5 patients (9.6%). Recurrences occurred predominantly in tumors with extension toward the cavernous sinus, particularly Radkowski stage IIIB lesions, where complete resection was limited by proximity to critical neurovascular structures.

CONCLUSIONS

To our knowledge, this represents one of the largest reported single-center experiences with endoscopic JNA surgery from Central Asia and demonstrates that preoperative embolization may not be mandatory for successful management in experienced hands. Early ligation of the internal maxillary artery through a modified Denker approach provides reliable vascular control, enabling safe resection of intermediate- and advanced-stage tumors while avoiding the additional costs and potential complications associated with embolization. The accompanying surgical video further illustrates a reproducible technique that may be particularly valuable for surgeons practicing in resource-limited settings.

OP-1214

Development And Validation Of An LDW Grading System For Surgical Management Of Radiation-Induced Nasopharyngeal Skull Base Necrosis

Zhaohui Shi[1], **Tianfeng Zhao**[2], **Tian Yuan**[1], **Huiyi Deng**[1], **Weifeng Kong**[1], **Xifu Wu**[1], **Xiaoping Lai**[1], **Gehua Zhang**[1], **Qintai Yang**[1]

[1]*Third Affiliated Hospital of Sun Yat-sen University;* [2]*General Hospital of Southern Theatre Command*

BACKGROUND & AIM

Surgery is a cornerstone in the management of radiation-induced nasopharyngeal skull base necrosis. The key surgical principles are thorough debridement, reliable reconstruction, and prevention of major complications. Successful reconstruction is central to favorable outcomes, whereas reconstructive failure remains a major cause of mortality. However, a reconstruction-oriented grading system to guide surgical decision-making in nasopharyngeal skull base necrosis is still lacking. This study aimed to develop and validate a grading system for radiation-induced nasopharyngeal skull base tissue necrosis, guide salvage surgery and reconstructive strategy based on necrosis severity, and evaluate postoperative outcomes.

MATERIAL & METHODS

Patients diagnosed with radiation-induced nasopharyngeal skull base tissue necrosis who underwent surgical treatment at the Third Affiliated Hospital of Sun Yat-sen University between September 2023 and September 2025 were prospectively enrolled. Patients with recurrent nasopharyngeal carcinoma were excluded. A novel LDW grading system was established based on three dimensions of necrotic extent: length, depth, and width. Necrosis was graded according to the LDW system, and the reconstructive method was selected accordingly. Postoperative follow-up was continued until March 2026. Survival analysis was performed across different necrosis grades, and Cox regression was used to identify prognostic risk factors and validate the clinical utility of the grading system.

RESULTS

A total of 101 patients were screened. Seventeen were excluded, including 16 with recurrent nasopharyngeal malignancy and 1 with maxillary osteonecrosis. The final cohort consisted of 84 patients, with a mean age of 53.80 years (range, 28-73 years). Of these, 61 were male and 23 female. The median follow-up period was 12.07 months (range, 5.32-28.9 months). The average time after radiotherapy for necrosis development was 60.02 months (range, 2-276 months). During follow-up, 6 patients died: 4 from internal carotid artery rupture and 2 from pneumonia. The surgical success rate for radiation-induced nasopharyngeal skull base necrosis was 93.1%. Based on the LDW grading system, reconstructive strategies included: 17 patients received pedicled intranasal mucosal flaps (20%), 42 received temporalis muscle flaps (49.4%), 19 received free anterolateral thigh myocutaneous flaps (22.4%), and 5 received radial forearm free flaps (5.9%). One patient didn‘t undergo reconstruction (1.2%). Postoperative effectiveness exceeded that of published grading systems.

CONCLUSIONS

Radiation-induced nasopharyngeal skull base necrosis presents a high mortality rate and significant treatment challenges. This study proposes a novel grading system to guide the selection of reconstructive methods and demonstrates its effectiveness in clinical practice. The LDW grading system aids in the clinical decision-making process, helping to identify appropriate surgical candidates for different types of flap reconstruction and supporting standardization of treatment approaches across centers.

A Convnext Based Model With Coordinate Attention And Multi-Pooling For Sinonasal Pathology Classification From CT Images

DOÇ.DR.ORKUN EROĞLU[1], **PROF.DR.ABDULVAHAP AKYİĞİT**[1], **DR.MİSLİNA AKKURT**[1], **DOÇ.DR.MUHAMMED YILDIRM**[2], **OP.DR.ÖMER KORKMAZYÜREK**[3], **PROF.DR.İRFAN KAYGUSUZ**[1]

[1]*FIRAT ÜNİVERSİTESİ KULAK BURUN BOĞAZ VE BAŞ BOYUN CERRAHİSİ ANABİLİM DALI;* [2]*FIRAT ÜNİVERSİTESİ YAPAY ZEKA VE VERİ MÜHENDİSLİĞİ;* [3]*MARDİN DERİK DEVLET HASTANESİ*

BACKGROUND & AIM

Background: Sinonasal pathologies are diagnostically challenging because benign and malignant lesions often present with similar nonspecific symptoms and complex radiologic findings. Artificial intelligence (AI) integrated with computed tomography and radiyomik analysis shows high potential in differentiating between benign and malignant pathologies in sinonasal tumors. The aim of this study is to investigate the effectiveness of integrating artificial intelligence and emerging multimodal imaging models with clinical practice in the early diagnosis and treatment of malignant sinonasal tumors.

MATERIAL & METHODS

Methods: This retrospective study includes 200 patients who underwent functional endoscopic sinus surgery for sinonasal pathology over a 15-year period at a single tertiary center. ConvNeXt-Tiny is a hybrid model developed for the classification of sinonasal pathologies based on deep learning. Model performance was evaluated using accuracy, precision, recall, and F1-score metrics, and the results were analyzed in detail using confusion matrices. Pretrained CNN architectures including ResNet50, DenseNet121, EfficientNet-B0, and RegNetY-032 were compared to determine the optimal backbone architecture. The dataset consisted of benign, malignant, and normal sinonasal CT images collected retrospectively.

RESULTS

Results: Among the pre-trained CNN architectures evaluated, ConvNeXt-Tiny demonstrated the best overall performance. ConvNeXt-Tiny, a hybrid model developed by integrating Coordinate Attention and Multi-Pooling, achieved 96.81% test accuracy, 96.80% sensitivity, recall, and F1 score. This hybrid model correctly classified 607 out of 627 test images. 199 out of 209 images in the benign group were correctly classified, while 203 out of 213 images in the malignant group were correctly identified. All 205 normal CT images were correctly classified. Compared to other architectures, the proposed model demonstrated superior discrimination ability for benign, malignant, and normal sinonasal pathologies, outperforming RegNetY-032 (95.53%), EfficientNet-B0 (95.06%), DenseNet121 (94.58%), and ResNet50 (88.84%).

CONCLUSIONS

Conclusion: The study findings demonstrates the superiority of entegrated hybrid model in terms of backbone selection and the combined use of attention and multi-pooling strategies. The entegrated AI-assisted CT classification hybrid model demonstrated high diagnostic performance in sinonasal pathology classification. This model is highly beneficial for radiologists and surgeons in non-invasive differentiation between benign and malignant sinonasal pathologies.

OP-1216

The Role And Efficacy Of Magnesium Sulfate Administration During Functional Endoscopic Sinus Surgery On Surgical Field Clearance And Surgery Outcomes: A Systematic Review And Meta-Analysis

Osama Marglani[3], **Muhannad Abdulaziz AlGhamdi**[1], **Abdullah Alkhaldi**[1,2]

[1]*King Abdulaziz Medical City - National Guard Health Affairs, Riyadh, Saudi Arabia;* [2]*King Abdullah International Medical Research Center (KAIMRC);* [3]*King Faisal Specialist Hospital and Research Center, Jeddah, Saudi Arabia*

BACKGROUND & AIM

Functional Endoscopic Sinus Surgery (FESS) is a minimally invasive procedure to treat various sinus condition. Magnesium sulfate ($MgSO_4$) has been investigated as an adjunct to anesthesia, but its efficacy compared to other agents remains uncertain; therefore, this research aimed to explore its effectiveness in improving key surgical outcomes.

MATERIAL & METHODS

Data were collected from multiple sources including Pubmed, Medline, OpenAIRE, and Cochrane. Studies focused on sinus management other than FESS were excluded.

RESULTS

This review included a total of 13 well-designed randomized control trials with a total number of 1075 patients. Our network-analysis indicated that $MgSO_4$ was effective in reducing surgery duration, with a SUCRA ranking of 62.7, followed by dexmedetomidine and BB. Dexmedetomidine ranked highest for reducing anesthesia time (SUCRA 88.62), while BB showed

the longest time to first rescue analgesia (SUCRA 97.88). $MgSO_4$ demonstrated a significant advantage in post-operative recovery time, with a mean difference of -0.77 (95% CI: -1.12, -0.42). Meta-analysis of MAP stability post-induction also favored dexmedetomidine.

CONCLUSIONS

Our meta-analysis suggests that $MgSO_4$ could be a valuable anesthetic adjunct in FESS, primarily for enhancing post-operative recovery and reducing surgery duration. However, studies are needed to standardize protocols and further explore $MgSO_4$'s efficacy across varied clinical settings.

THE EFFECTIVENESS OF THE PROPEL DEVICE IN DACRYSTORHINOSTOMY

Khasanov U.S.[1], **Rakhimov J.M.**[1]

[1]*Republican specialized scientific and practical medical center of otorhinolaryngology and head and neck diseases*

BACKGROUND & AIM

Dacryocystorhinostomy (DCR) is an effective surgical method performed in obstructive conditions of the lacrimal canal. One of the most common complications after the operation is scarring of the rhinolacrimal ducts and, as a result, recurrent lacrimal canal obstruction. Modern biodegradable implants, including the PROPEL device, are of great importance in solving this problem.

The aim of the study was to evaluate the clinical effectiveness of the PROPEL device in preventing recurrence of the disease after dacryocystorhinostomy.

MATERIAL & METHODS

During 2024–2025, 30 patients underwent endoscopic dacryocystorhinostomy. They were divided into two groups: Group 1 (Comparison group, n=15) underwent standard DCR surgery, while Group 2 (Main group, n=15) underwent PROPEL placement along with DCR. All patients were followed for 6 months. The effectiveness of the operation was assessed based on the results of a comprehensive examination, including changes in clinical symptoms, endoscopic examination of the nasal cavity, and wound healing.

RESULTS

During the 6-month follow-up, the postoperative status of both groups was analyzed. In the main group, the stoma remained open in 28 (93.3%) patients, and complete obstruction was observed in only 2 patients. In the comparison group, the stoma remained open in 22 (73.3%) patients, and re-obstruction was noted in 8 (26.7%). In the statistical analysis, the results of the χ^2 test showed a significant difference in maintaining stoma patency in the PROPEL group ($p<0.05$). When analyzing nasal function, respiratory function was fully restored in patients who used the PROPEL device after the procedure. The PROPEL device acted as a temporary structure without blocking the airflow and was absorbed naturally within 30-45 days. PROPEL reduced inflammation by releasing a local steroid (mometasone furoate) and led to rapid healing of the mucosa.

CONCLUSIONS

The use of PROPEL in dacryocystorhinostomy has been shown to be highly effective in maintaining stoma patency in the postoperative period, restoring nasal breathing function, ensuring rapid and complete healing of the mucosa, reducing the risk of granulation formation, and increasing patient satisfaction. This method is a highly effective innovative approach to the treatment of lacrimal outflow disorders.

Neural Dissimilarity: A Promising New Fmri-Based Measure Of Smell? Changes In The Olfactory System Following Treatment For Severe Crswnp With Monoclonal Antibodies

Mads Bolding Rasmussen, MD[1], **Christian Korsgaard Pedersen, MD**[1], **Thomas Hummel, MD, Professor**[3], **Jens Volkmar Schwarzbach, Prof. Dr. rer. nat.**[2], **Christian von Buchwald, MD, DMSc, Professor**[1]

[1]*Department of Otorhinolaryngology, Head & Neck Surgery and Audiology, Copenhagen University Hospital, Copenhagen, Denmark;* [2]*Department of Psychiatry and Psychotherapy, University of Regensburg, Regensburg, Germany;* [3]*Department of Otorhinolaryngology, Technische Universität Dresden, Dresden, Germany*

BACKGROUND & AIM

This study investigates rehabilitation of olfactory dysfunction (OD) in patients with chronic rhinosinusitis with nasal polyps (CRSwNP) treated with biologics.

OD is the symptom with greatest negative effect on health-related quality of life in patients with CRSwNP and remains difficult to treat. Recently, monoclonal antibody therapy have shown substantial patient-reported improvements in smell and quality

of life. However, predicting and monitoring recovery remains challenging. Clinicians largely depend on subjective reports and psychophysical tests with limited objectivity.

We aim to develop an accurat and consistent, brain-based biomarker of olfactory function using functional MRI, behavioral testing and Representation Similarity Analysis before and after biologics.

MATERIAL & METHODS

A longitudinal, observational study recruiting approximately 20 patients with OD due to CRSwNP before or shortly after they receive the first injection with monoclonal antibodies. Patients will undergo nasal endoscopy and a validated olfactory test (Threshold, Identification and Discrimination test (TDI). fMRI will be obtained along while three different odorants presented to the participants. Odorant presentation will be synchronized with inhalation. A group of age-adjusted, normosmic controls will undergo the same examinations. Testing will be repeated in both groups after 24 weeks.

Representation Similarity Analyses will be conducted to compare functional changes in the brain before and after treatment with biologics.

RESULTS

We expect olfactory function to increase in the majority of participants after 24 weeks of treatment with monoclonal antibodies. We expect to be able to show increases in behavioral and neural representational dissimilarity matrices between the two scan sessions in the participants as the smell score improves. Furthermore, we plan to use measurement from the baseline and follow-up to predict outcome.

CONCLUSIONS

The objective of this study is to establish an imaging biomarker for the alterations in the central olfactory system to enable MRI-based assessment and monitoring, and to serve as a potential predictor of treatment efficacy and recovery of olfaction.

Moreover, as OD is a common early manifestation in various neurodegenerative conditions such as Parkinson's disease, Alzheimer's disease, Lewy body dementia and multiple sclerosis, this project has potential beyond CRSwNP.

OP-1219

Efficacy Of The Latera Implant In Nasal Valve Collapse: A Prospective Study Using The Functional Rhinoplasty Outcome Inventory-17

Kaled Elgogqry[1], **Jiakying Tan**[1], **Mohammed Basamh**[1], **Mohamed Salem**[1], **Abdelrahman Ezzat Ibrahim**[1]

[1]*United Lincolnshire Teaching Hospitals NHS Trust*

BACKGROUND & AIM

Background: Nasal valve collapse (NVC) is a common cause of nasal obstruction that significantly impairs quality of life (QoL). The absorbable Latera implant provides structural support to the lateral nasal wall, but prospective data on its impact using validated, procedurespecific QoL measures are limited.

Aim: To evaluate the efficacy and safety of the Latera implant in patients with NVC using the Functional Rhinoplasty Outcome Inventory-17 (FROI-17), a comprehensive functional rhinoplasty-specific QoL instrument.

MATERIAL & METHODS

A prospective cohort study was conducted between 2022 and 2025. Twenty-two adults with isolated NVC refractory to medical therapy underwent Latera implant placement. The primary outcome was the change in FROI-17 scores from baseline to 6 months postprocedure. Secondary endpoints included complicat

RESULTS

A significant improvement in FROI-17 scores was observed in 90.9% of patients (20/22), with a mean score increase of +43.2 points ($p<0.01$). One patient reported no change, and one worsened due to an unrelated septal issue requiring revision. No major complications, such as infection or implant extrusion, were recorded.

CONCLUSIONS

The absorbable Latera implant is a safe and effective intervention for NVC, demonstrating a high success rate in significantly improving procedure-specific quality of life as measured by the FROI-17. These findings support its role as a valuable minimally invasive option, though further comparative studies with long-term follow-up are warranted

OP-1220

Reversibility Of Mucociliary Function After Radiofrequency Treatment Of Inferior Turbinate

Meltem akpınar[1], **Nur Begüm Koç**[1]

[1]Department of Otorhinolaryngology, Sancaktepe Şehit Prof. Dr. İlhan Varank Training and Research Hospital, Istanbul, Turkey

BACKGROUND & AIM

Radiofrequency ablation is a widely used treatment for inferior turbinate hypertrophy. However, its short-term effects on mucociliary function remain unclear. This study aims to evaluate early changes and the reversibility of mucociliary clearance following radiofrequency treatment using the saccharin test.

MATERIAL & METHODS

This is an ongoing prospective clinical study planned to include 50 patients with inferior turbinate hypertrophy undergoing radiofrequency ablation. Mucociliary clearance was assessed using the saccharin transit test preoperatively, at postoperative week 1, and week 3.A ~1 mm saccharin particle was placed on the anterior portion of the inferior turbinate, approximately 1 cm posterior to its anterior end. Patients were instructed not to speak, sneeze, cough, or sniff. Time to perception of a sweet taste was recorded.Patients aged ≥18 years with no prior nasal surgery were included. Those with previous turbinate procedures, active infection, chronic rhinosinusitis, or smoking were excluded.

RESULTS

Preliminary analysis of the first 5 patients (mean age: 34.2 years) showed a mean saccharin transit time of 12.4 ± 2.1 minutes preoperatively, increasing to 18.6 ± 3.2 minutes at postoperative week 1, and decreasing to 13.1 ± 2.4 minutes at week 3. A transient prolongation in mucociliary clearance time was observed in the early postoperative period, followed by recovery toward baseline values.

CONCLUSIONS

Radiofrequency ablation of the inferior turbinate appears to cause a temporary impairment in mucociliary function in the early postoperative period, with recovery observed by the third postoperative week. These findings suggest that mucociliary dysfunction is reversible. Further data will help to confirm these results.

Inferior turbinate, radiofrequency ablation, mucociliary clearance, saccharin test, rhinology

OP-1221

An Overview Of Switching Biological Therapies For Chronic Rhinosinusitis With Nasal Polyposis (Crswnp)

Talal Alharbi[1], **Ahmad Alroqi**[2], **Nawaf Alsubaie**[2]

[1]King Abdulaziz Medical City, Riyadh, Saudi Arabia; [2]King Saud University, Riyadh , Saudi Arabia

BACKGROUND & AIM

Chronic rhinosinusitis with nasal polyposis (CRSwNP) is a type 2 inflammatory disease, which can lead to significant impact on quality of life due to symptoms of local and systemic inflammation and has a high recurrence rate despite optimal medical or surgical treatment. Recalcitrant CRSwNP can be treated with biological therapies with specific immunological targets, such asIgE (Omalizumab), IL4α receptors (Dupilumab), or IL-5(Mepolizumab), which have been approved for this use. The purpose of this narrative review was to review the currently available literature on biological therapies for CRSwNP and their switching in cases of inadequate disease control.

MATERIAL & METHODS

Keywords such as 'biologic'; 'anti-IgE'; 'anti-IL5'; 'anti-IL4'; 'sinusitis'; 'chronic rhinosinusitis'; 'nasal polyps'; 'switch'; and 'recurrence' were combined using the 'AND' or 'OR' Boolean operators to search databases including Google Scholar, Medline, and EMBASE; free-text search was also utilized for this purpose.

RESULTS

While there is sufficient evidence to support the use of biological therapies for recurrent and refractory CRSwNP despite the use of nasal corticosteroids as an add-on or adjunctive therapy, there is paucity of evidence regarding switching from one biologic to another. Evidence on biologic switching for recurrent CRSwNP supported the use of Dupilumab while switching from anti-IgE or anti-IL5 biologics, due to better symptom control and improved quality of life outcomes.

CONCLUSIONS

Biological treatments for CRSwNP have good real-life efficacy in managing nasal symptoms and improving quality of life.Multidisciplinary consensus from immunologists or allergists, otorhinolaryngologists, and pulmonologists is essential for aiding decision-making regarding switching biologics.

OP-1222

Nasal Mucociliary Clearance And Quality Of Life In Pregnancy

Pelin YILDIZ[1], **Tuğrul YILDIZ**[1], **İbrahim KARACA**[1]

[1]Izmir Bakırçay University Çiğli Research and Training Hospital

BACKGROUND & AIM

Pregnancy induces hormonal and systemic changes affecting the upper respiratory tract. Although pregnancy rhinitis impacts 20–30% of pregnant women, alterations in nasal mucociliary clearance (MCC) and their relationship with clinical symptoms and hematological markers remain unclear. While hormonal shifts may reduce mucociliary transport speed, the clinical impact measured by SNOT-22 and correlations with inflammatory markers like the neutrophil-to-lymphocyte ratio (NLR) are not fully elucidated. This study evaluates MCC time and sinonasal quality of life differences between pregnant and non-pregnant women, investigating correlations between clearance time, gestational age, and hematological profiles.

MATERIAL & METHODS

This prospective cross-sectional study was conducted at Izmir Bakircay University Cigli Training and Research Hospital, following approval from the Izmir Bakircay University Ethics Committee. A total of 62 women (31 pregnant, 31 non-pregnant controls) were enrolled. All participants in the pregnant group were in their third trimester of pregnancy. Nasal mucociliary clearance was evaluated using the saccharin transit test. Subjective sinonasal symptoms were assessed via the SNOT-22 questionnaire. Hemogram parameters (Hb, Hct, eosinophil count, and neutrophil-to-lymphocyte ratio), age, gestational age and BMI were recorded. Data were analyzed using independent t-tests, Mann-Whitney U tests, and Pearson correlation analysis.

RESULTS

The study included 62 participants (31 pregnant, 31 controls). Hematological parameters, including Hb, Hct, and eosinophil counts, were significantly lower in the pregnant group, while the neutrophil-to-lymphocyte ratio (NLR) was significantly higher ($p < 0.001$). Regarding mucociliary clearance, the saccharin transit time (STT) was shorter in the pregnant group (8.45 ± 5.53 min) than in controls (13.23 ± 12.82 min), though this was not statistically significant ($p = 0.103$). However, a significant positive correlation was found between STT and gestational age ($r = 0.387$, $p = 0.031$), suggesting clearance slows as pregnancy progresses. Interestingly, SNOT-22 scores were significantly lower in the pregnant group (17.00 ± 9.68 vs. 28.45 ± 15.11, $p < 0.001$). SNOT-22 scores correlated positively with Hb ($r = 0.288$, $p = 0.023$) and Hct levels ($r = 0.365$, $p = 0.004$). No significant correlation was observed between STT and SNOT-22 scores.

CONCLUSIONS

In conclusion, although nasal mucociliary clearance (MCC) time shows no significant difference between pregnant and non-pregnant women, it correlates positively with gestational age ($r = 0.387$, $p = 0.031$). This suggests that mucociliary transport slows as pregnancy progresses, likely due to hormonal changes and mucosal edema. Interestingly, pregnant women reported significantly lower SNOT-22 scores, indicating better perceived sinonasal quality of life. Correlations between SNOT-22 and hematological parameters suggest that systemic adaptations influence subjective symptoms. Further longitudinal studies with larger cohorts are needed to elucidate these mechanisms across all trimesters.

OP-1223

Association Of Antrochoanal Polyp Extension With Neutrophil-To-Lymphocyte Ratio And Eosinophil Percentage

Kübra Altunel Demir[1], **Tuğçe Gültepe Zorlu**[1], **Ayşe Enise Göker**[1]

[1]*Istanbul Prof. Dr. Cemil Taşçıoğlu City Hospital*

BACKGROUND & AIM

Antrochoanal polyps are benign inflammatory lesions originating from the maxillary sinus. Although inflammatory mechanisms may contribute to their development, the relationship between polyp extension and systemic inflammatory markers remains unclear. This study aimed to investigate the association between antrochoanal polyp extension length and inflammatory parameters including neutrophil-to-lymphocyte ratio and eosinophil percentage.

MATERIAL & METHODS

This retrospective study included 48 patients diagnosed with Antrochoanal Polyp who underwent endoscopic sinus surgery between 2011 and 2026. Demographic characteristics including age and sex were recorded for all patients. Preoperative hematologic parameters, including eosinophil, neutrophil, and lymphocyte percentages, were obtained from complete blood count analyses performed prior to surgery. Neutrophil-to-lymphocyte ratio (NLR) values were calculated using neutrophil and lymphocyte percentages.

Radiologic evaluation was performed using paranasal sinus computed tomography scans. Polyp extension length was measured in the sagittal plane as the maximal distance between the point where the polyp exited the maxillary sinus and its extension into the choana. The association between polyp extension length and inflammatory parameters was analyzed using Spearman correlation analysis.

RESULTS

A total of 48 patients were included in the study, comprising 25 males and 23 females, with a mean age of 30.25 years (range: 9–65 years). Correlation analysis demonstrated no statistically significant association between antrochoanal polyp extension

length and NLR, eosinophil percentage, neutrophil percentage, or lymphocyte percentage. Although elevated NLR values were observed in some patients with larger polyps, no significant correlation was identified between radiologic polyp extension and systemic inflammatory markers overall.

CONCLUSIONS

The extent of Antrochoanal Polyp extension was not significantly associated with systemic inflammatory markers, including neutrophil-to-lymphocyte ratio and eosinophil percentage. These findings suggest that systemic inflammatory parameters may have limited value in reflecting radiologic polyp extension, and that local inflammatory or anatomical factors may play a more prominent role in the growth pattern of antrochoanal polyps.

OP-1224

Missed Dehiscence Of Lamina Papyracea: Orbital Herniation Mimicking Sinusitis And Potential Complications.

Dr. Ali G. Alrashidi[1], **Prof. Saud Alromaih**[1]

[1]*Department of Otolaryngology-Head and Neck Surgery, College of Medicine, King Saud University, Riyadh, Saudi Arabia.*

BACKGROUND & AIM

•FESS has become the gold standard for treating chronic rhinosinusitis and it is regarded as a relatively safe and effective technique.

• Orbital complications of FESS have been reported for many years owing to the close anatomical relationship between the paranasal sinuses and the orbit.

•Accidental injury of the lamina papyracea during FESS, has been described in up to 5% of cases.

•Preventing complications begins with preoperative planning and careful review of CT scans.

•To identify cases where LPD (Dehiscence) was present but not reported by radiologists.

•To Emphasize the critical need for surgeons to perform an independent, thorough pre-operative review of CT images.

MATERIAL & METHODS

•A multicentric national survey across Saudi Arabia (Riyadh, Jeddah, Makkah).

•Data gathered from fellowship-trained Rhinologists and Skull Base surgeons

•January 2021 – December 2023.

•Required high-resolution CT scans (<0.6 mm thickness) with axial and coronal views.

•Identifying LPD cases missed in initial radiology documentation.

RESULTS

•16 patients (11 Male / 5 Female).

•Median Age: 37 years (Range: 19–53).

•Distribution:

•Right side: 8 patients (Most prevalent).

•Left side: 5 patients.

•Bilateral: 3 patients.

•12 out of 16 patients had no history of trauma or prior sinus surgery. LPD is often a silent anatomical variant.

CONCLUSIONS

•Injury to the LP is a well-known avoidable complication of FESS. Rarely, radiologists might miss a dehiscent lamina papyracea; thus, surgeons should not rely completely on radiologists during the interpretation of a CT scan.

•It is crucial for surgeons to perform a careful and attentive review of CT scan images pre-operatively.

OP-1225

The Role Of Narrow Band Imaging (NBI) In Diagnosing Nasal Manifestations Of Vasculitis And Arthritis: A 2-Year Retrospective Study

Mohammed Salem[1], **Abdulselam Daif**[1], **Abdelrahman Ibrahim**[1]

[1]*United Lincolnshire teaching Hospitals Trust NHS*

BACKGROUND & AIM

Nasal involvement in vasculitis and arthritis presents diagnostic challenges. Narrow Band Imaging (NBI) enhances mucosal vascular pattern visualization, but its diagnostic value in this context is underexplored.

MATERIAL & METHODS

Methods:

- Design: Retrospective analysis (2022–2024) of 15 patients with suspected vasculitis/arthritis-related nasal pathology.
- Investigations:
- NBI endoscopy (all patients). - Biopsy (all patients; 3 positive). - Blood tests (9 positive for vasculitis/arthritis markers).
- Outcome: Correlation between NBI findings, histopathology, and serology.

RESULTS

- NBI Findings: All 15 patients showed abnormal vascular patterns (e.g., twisted capillaries, microerosions).
- Biopsy vs. NBI: Only 3/15 biopsies confirmed vasculitis, but NBI detected mucosal changes in all cases.
- Serology: 9/15 had positive blood tests; NBI abnormalities were more pronounced in these patients.

CONCLUSIONS

Conclusion: NBI is a sensitive tool for detecting mucosal changes in vasculitis/arthritis, even when biopsies are negative. It may serve as a non-invasive adjunct to biopsy and serology, aiding early diagnosis.

KEYWORDS

Keywords: Nasal vasculitis, narrow band imaging, biopsy, arthritis, diagnostic accuracy.

OP-1226

Investigation On The Factors Associated With The Persistence Of Anosmia And Ageusia In COVID-19 Patients

Dr. Saad Nabeel Algahtani[1]

[1]*King Saud Medical City*

BACKGROUND & AIM

The Coronavirus Disease 2019 (COVID-19) outbreak caused by the severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) resulted in a worldwide pandemic of a highly infectious disease. The difficulty of dealing with COVID-19 is the broad spectrum of clinical manifestations that involves various pathophysiological mechanisms, severities, duration, and complications.

This study aims to help emphasize the factors related to the persistence and duration of anosmia (loss of smell) and ageusia (loss of taste) as part of post-acute COVID-19 syndrome in COVID-19 patients via a retrospective cross-sectional design.

MATERIAL & METHODS

Eight hundred and eighty-one participants were recruited between March and April 2021. Those participants were 18 years or older, recovered from the COVID-19 infection, and completed 14 days after the onset of the acute phase of the disease. Among the 881 recruited participants, 808 have submitted eligible responses and were included in data analyses.

RESULTS

The most common persistent symptoms in post-acute COVID-19 syndrome were anosmia (33.8%) and ageusia (26.4%). The data also showed a significant association between female sex and the incidence and the persistence of anosmia and ageusia. In multivariable analysis, anosmia during the acute phase was associated with BMI, asthma and shortness of breath, while anosmia during the post-acute phase was associated with sex. Ageusia during the acute phase was associated with sex, myalgia and arthralgia, while ageusia in the post-acute phase was associated with sex.

CONCLUSIONS

The most prevalent symptoms during the acute and subacute phase of COVID-19 infection were anosmia and ageusia. A significant association was found between female sex with both the incidence and the persistence of anosmia and ageusia. Hopefully, these findings will enrich our understanding of the nature of those two symptoms and encourage further studies to enhance the knowledge toward post-acute COVID-19 syndrome.

Prevalence And Demographic Characteristics Of Tornwaldt And Mucous Retention Cysts In The Nasopharynx

Fatih Recai KABLAN[1], **Ali Rıza YAĞMUR**[1], **Ali Can SUNGUR**[1], **Zehra ÖZCAN**[1], **Şeydanur YILĞAN**[1], **Mehmet Ali GÖÇER**[1], **Esra BEKTAŞ ÇİFTÇİ**[1], **Ensar ÖLEKLİ**[1], **Kayıhan AKIN**[2], **Engin DURSUN**[1], **Celil GÖÇER**[1], **Hatice Seyra ERBEK**[1]

[1]*Department of Otorhinolaryngology, Lokman Hekim University Hospital, Ankara, Türkiye;* [2]*Department of Radiology, Lokman Hekim University Hospital, Ankara, Türkiye*

BACKGROUND & AIM

Nasopharyngeal cysts are uncommon lesions that are usually detected incidentally during nasopharyngoscopy or imaging studies. Tornwaldt cysts (TC) and mucous retention cysts (MRC) are the most common cystic lesions in this region. This study aimed to determine the prevalence and demographic characteristics of these lesions in a large patient population.

MATERIAL & METHODS

Following ethics committee approval, magnetic resonance imaging (MRI) examinations including the head and neck region performed between January 1, 2024, and June 30, 2025, at hospitals affiliated with Lokman Hekim University Faculty of Medicine were retrospectively reviewed. A total of 5,360 patients were evaluated for the presence of TC and/or MRC, lesion size measured on axial sections, and age and sex distribution. Patients who underwent surgery for TC during the same period were also analyzed.

RESULTS

At least one lesion was detected in 14.81% (n=794) of cases. MRCs constituted the majority of lesions (9.63%), whereas TCs were observed in 5.75% of patients. Both lesions coexisted in 0.56% of cases.

The overall lesion prevalence was significantly higher in males than in females (16.74% vs. 13.43%, p=0.003). MRC prevalence was 10.80% in males and 8.78% in females, while TC prevalence was 6.52% and 5.19%, respectively. TC size was significantly larger in males (5.49 mm vs. 4.43 mm), whereas MRC size did not differ significantly between sexes.

MRC prevalence was higher in younger age groups and declined progressively with age. The MRC rate, which reached its highest level in the 20–39-year age group (12.29–12.50%), decreased to 3.85% in patients aged ≥80 years. In contrast, TC prevalence remained relatively stable across all age groups.

Five patients underwent surgery for TC during the study period. Indications included serous otitis media, nasal obstruction, and halitosis.

CONCLUSIONS

The prevalence rates of TC and MRC were consistent with those reported in the literature. Both lesions are generally incidental findings with limited clinical significance. However, the higher prevalence of MRC in males and younger patients may warrant greater clinical awareness in these populations.

Predictive Biomarkers Of Recurrence In Chronic Rhinosinusitis With Nasal Polyps

Maria-Delia Florean[1,3], **Anda Gata**[3], **Livia Budisan**[4], **Oana Zanoaga**[4], **Stefan Vesa**[3], **Veronica Trombitas**[2,3], **Silviu Albu**[2,3]

[1]Emergency Clinical Hospital Alba Iulia; [2]CF Clinical Hospital Cluj-Napoca, Department of Otolaryngology, Cluj-Napoca, Romania; [3]Iuliu Haţieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania; [4]Research Center for Functional Genomics, Biomedicine and Translational Medicine, Cluj-Napoca, Romania

BACKGROUND & AIM

More than 50% of patients with chronic rhinosinusitis with nasal polyps (CRSwNP) experience recurrence within 3 years after functional endoscopic sinus surgery. Biomarkers can provide means to monitor treatment response, assess efficacy of novel biologic therapies, and evaluate disease severity. Some biomarkers extensively studied in CRS are associated with a Th2 inflammatory endotype that predicts poor prognosis. The aim of this study was to investigate periostin, procalcitonin, eotaxin-3 and SPARC expression in recurrent CRSwNP.

MATERIAL & METHODS

This prospective study enrolled 69 patients with CRSwNP who underwent surgical treatment. Preoperative blood samples were collected and periostin, procalcitonin, eotaxin-3 and SPARC expression patterns were assessed using immunohistochemistry and enzyme-linked immunosorbent assay (ELISA). Postoperative endoscopic findings, POSE score, symptom scores (SNOT-22) at 1, 3, 4 and 5 years, osteitis score on computed tomography (CT), and miR-125 and miR-203 values were analyzed and compared with serum biomarkers.

RESULTS

Serum periostin and SPARC levels were significantly higher in CRSwNP patients. A strong correlation was found between periostin, procalcitonin, eotaxin-3, SPARC and high nasal endoscopy score conclusive for recurrence of CRSwNP ($p < 0.05$). Only eotaxin-3 showed a weak correlation with SNOT-22 ($p < 0.05$), but this result was influenced by depression scores. A weak correlation between eotaxin-3 and osteitis score was also observed. Higher miR-125 levels were corelated with high biomarkers levels as well ($p < 0.05$).

CONCLUSIONS

Periostin, eotaxin-3, procalcitonin and SPARC may serve as predictive factors for postoperative recurrence. They could be potential biomarkers for assessing disease severity and prognosis. Further research on biomarkers is needed to advance precision therapy in chronic rhinosinusitis.

Periostin, eotaxin-3, procalcitonin, SPARC, Chronic rhinosinusitis with nasal polyps

OP-1229

Objective Comparison Of Spreader Grafts, Otospreader Flaps, And Combination Techniques In Rhinoplasty: A Side-Specific PNIF Analysis Of 160 Sides

Aykut ÖZDOĞAN[1], **Zülküf KÜÇÜKTAĞ**[1], **Gökçe SAYGI UYSAL**[1]

[1]*Ankara Etlik City Hospital*

BACKGROUND & AIM

The aim of this study is to objectively evaluate the functional efficacy of different internal nasal valve interventions, including spreader grafts, otospreader flaps, and their combinations, using Peak Nasal Inspiratory Flow (PNIF) measurements in patients undergoing rhinoplasty.

MATERIAL & METHODS

A total of 160 sides from 80 patients were analyzed prospectively. The surgical interventions were categorized into four groups based on the technique applied to each side: Spreader Graft (SG), Otospreader Flap (OF), Spreader + Otospreader (SGF), Dorsal Preservation (DP). PNIF measurements were performed preoperatively and at the 6th month postoperatively. Statistical analysis was conducted using the Wilcoxon signed-rank test for intra-group comparisons and the Kruskal-Wallis H test for inter-group comparisons.

RESULTS

The distribution of the 160 sides was as follows: 107 SG, 35 OF, 12 SGF, and 6 DP.

· In the SG group, PNIF scores significantly increased from 64.25 ± 23.0 to 82.62 ± 21.91 (p=0.001).

· In the OF group, PNIF scores significantly increased from 58.29 ±18.39 to 75.57 ± 16.75 (p=0.001). · Although improvements were observed in the SGF group (60.83 ±42.52 to 77.92 ± 30.11; p=0.105) and the DP group (79.17 ± 24.17 to 99.17 ± 17.15; p=0.072), they did not reach statistical significance. · There was no statistically significant difference between the groups regarding the mean change in PNIF scores (p=0.855).

CONCLUSIONS

Both spreader grafts and otospreader flaps are highly effective in improving nasal inspiratory flow. Since no single technique showed statistical superiority over the others in terms of PNIF improvement, the choice of technique should be tailored to the specific anatomical needs of each side of the nose to optimize functional outcomes.

OP-1230

Symptom And Quality Of Life Improvement After Endoscopic Sinus Surgery In Patients With Different Phenotypes Of Chronic Rhinosinusitis

Liang-Chun Shih[1]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, China Medical University Hospital*

BACKGROUND & AIM

Chronic rhinosinusitis (CRS) affects approximately 3–6.4% of the population in Taiwan. While medical therapy remains the first-line treatment, endoscopic sinus surgery (ESS) is an important option for patients with refractory disease or with complications. CRS includes multiple phenotypes with potentially different responses to surgery. This study investigates symptom and quality-of-life improvement after ESS across various CRS phenotypes using the Sinonasal Outcome Test-22 (SNOT-22).

MATERIAL & METHODS

This retrospective study reviewed patients who underwent ESS at our institution between 2015 and 2020. Patients were classified into five phenotypes: (1) CRSwNP-eCRS, (2) CRSwNP-non-eCRS, (3) Isolated sinusitis, (4) Central compartment atopic disease (CCAD), and (5) Allergic fungal rhinosinusitis (AFRS). SNOT-22 scores were collected preoperatively and at 2 weeks, 1 month, and 3 months postoperatively to evaluate symptom changes.

RESULTS

A total of 523 patients (mean age 47.2 years) were included: 198 CRSwNP-eCRS (37.86%), 134 CRSwNP-non-eCRS (25.62%), 88 isolated sinusitis (16.83%), 75 CCAD (14.34%), and 28 AFRS (5.35%).Baseline SNOT-22 scores were similar across groups (30.48–35.98).Postoperative improvement (Δ SNOT-22) showed varying degrees of symptom reduction among phenotypes:At 2 weeks: CRSwNP-eCRS (−15.14), CRSwNP-non-eCRS (−8.75), isolated sinusitis (−7.54), CCAD (−8.23), AFRS (−10.24).At 1 month: CRSwNP-eCRS (−15.03), CRSwNP-non-eCRS (−6.25), isolated sinusitis (−9.64), CCAD (−4.86), AFRS (−8.55).At 3 months: CRSwNP-eCRS (−19.57), CRSwNP-non-eCRS (−6.86), isolated sinusitis (−6.74), CCAD (−3.22), AFRS (−5.50).Several groups showed statistically significant improvements at specific postoperative time points.

CONCLUSIONS

FESS resulted in significant symptom and quality-of-life improvement as measured by SNOT-22. The CRSwNP-eCRS, isolated sinusitis, and AFRS phenotypes demonstrated the most substantial postoperative improvement. These findings highlight the importance of CRS phenotype classification for predicting surgical outcomes and guiding individualized treatment strategies.

Transphenoidal Pituitary Endoscopic Approach: The Rationale To Go Transeptal Rather Than Transnasal

charbel rameh[1], **omar aawar**[1]

[1]*mount lebanon hospital Balamand University medical center*

BACKGROUND & AIM

Historically, Neurosurgeons used to go translabial to do pituitary surgeries. This is too invasive and carries painful consequences for the patients. With the advent of advanced endoscopic sinus surgeries, and with teamwork between neurosurgeons and otolaryngologists, we are turning minimally invasive. Two approaches are commonly used, the transnasal and the transeptal. After doing a big number of these surgeries, We believe the transeptal approach to be much less invasive than the transnasal approach for our patients

MATERIAL & METHODS

Experience from live hands-on surgeries carried out with the neurosurgery team

RESULTS

the transeptal approach offers lots of advantages when compared to the transnasal approach: more reliable anatomical landmarks, no nasal septal mucosal breach and thus preserving the intergrity of the sphenoid sinus in case of CSF leak, less or virtually no nasal blood oozing post operatively, and no need to pack the nose postoperatively, in addition to the added benefit of better nasal breathing after fixing the septal deviation.

CONCLUSIONS

Transeptal pituitary endoscopic approach should be the gold standard main approach to the pituitary gland surgeries

OP-1232

Free Mucosal Graft For Endoscopic Septal Perforation Repair Using The Pocket Technique: A Comparative Study

Dr.Abdulaziz Alqahtani[1]

[1]*King Fahad Medical City*

BACKGROUND & AIM

Septal perforation repair remains a challenging procedure. Many surgical techniques and reconstruction options have been utilized with variable degrees of complexity and outcomes. We aimed to describe and evaluate the outcome of a single layer free mucosal graft using the Pocket technique.

MATERIAL & METHODS

Patients undergoing endoscopic repair of septal perforation between 2022 and 2025 were identified by a retrospective review of medical records. Demographic and clinical data were collected and compared between patients having surgery with a free mucosal graft using the Pocket Technique and those with the AEA-based pedicled flap using the tunnel technique. Statistical analyses were preformed to determine if any differences in the patient demographics, perforation characteristics, complications, and repair outcomes at the 3-months follow up.

RESULTS

A total of 23 patients were identified; 7 of 23 (30%) patients underwent free mucosal graft repair using the Pocket Technique, and 16 patients underwent AEA-based pedicled flap repair using the tunnel technique. The AEA flap was used for significantly larger defects compared to the free mucosal graft group (1.24±0.53 cm vs. 0.68±0.38 cm; p=0.022). Successful perforation repair was achieved in 86% (6/7) of the free mucosal graft group and 94% (15/16) of the AEA flap group (p=0.53).

CONCLUSIONS

The free mucosal graft using the Pocket Technique is a reliable alternative for the repair of small (≤1 cm) septal perforations. The Pocket Technique provides an effective support and secures the graft, preventing mobilization during the early healing phase. The vascularized AEA flap remains the preferred option for larger defects That require axial blood supply.

OP-1233

Periostitis Of The Maxilla With Oroantral Fistula As The Initial Manifestation Of Denosumab-Associated Osteonecrosis Of The Jaw

Viktoria Matis[1], **Herwig Swoboda**[1]

[1]*Barmherzige Brüder Hospital Eisenstadt, Department of Otorhinolaryngology*

BACKGROUND & AIM

Denosumab is a RANKL inhibitor used for the prevention of skeletal-related events in solid tumors, such as prostate cancer. A known complication is medication-related osteonecrosis of the jaw (MRONJ). We report a case in which the CT image of an apparent maxillary sinusitis led to the diagnosis of denosumab-induced irregular-type periostitis of the maxilla.

MATERIAL & METHODS

A male patient with osseous metastatic prostate cancer and a history of ongoing denosumab treatment for the last 6 years presented with a foul-smelling, secreting oroantral fistula in the edentulous region 17 and 18, purulent rhinorrhea from the middle nasal meatus, jaw lock, and right-sided facial pain after FESS (functional endoscopic sinus surgery) in October 2025. In addition, a tubotympanic transudate was clinically evident. An interdisciplinary case discussion was carried out with urology, microbiology, and oncology. The literature was systematically reviewed.

RESULTS

CT scans showed no typical sinusitis but a periosteal reaction of the right maxilla with involvement of the pterygoid process as a sign of MRONJ stage 3. The diagnosis was established clinically and radiologically according to the AAOMS criteria (2022). Denosumab therapy was discontinued; conservative therapy with systemic antibiotics (amoxicillin/clavulanate + metronidazole) and antiseptic rinses was initiated. The literature documents a cumulative MRONJ incidence of more than 13 % after three years of high-dose denosumab as well as a close association between periosteal reaction and a prognostically unfavorable course. Debridement surgery is considered after improvement of infection.

CONCLUSIONS

In patients on long-term denosumab therapy, patients should be screened for MRONJ when maxillary sinusitis is the presenting feature. Early interdisciplinary cooperation is crucial to prevent sequestration and progression to advanced stages with maxillary sinus involvement and spread to adjacent structures.

KEYWORDS

MRONJ, denosumab, oroantral fistula, sinusitis

OP-1234

Sinonasal Malignancies In Sudan: Incidence And Clinicopathological Insights

Ayat Abdallah[1], **SHARFI AHMED**[1]

[1]*FACULTY OF MEDICINE, OMDURMAN I UNIVERSITY, SUDAN*

BACKGROUND & AIM

Sinonasal malignancies are uncommon neoplasms with several histopathological subtypes. These malignancies have a poor prognosis, and because of the nonspecific nature of the symptoms, most patients are diagnosed late when the disease is already at an advanced stage.

This study aims to determine the incidence and clinicopathological correlations of sinonasal malignancies among Sudanese patients.

MATERIAL & METHODS

This is a descriptive prospective hospital-based study. All Ear, nose, and throat hospitals in Khartoum state,

Sudan, were included. Data were collected using a structured interviewer questionnaire and analyzed using the statistical package for social sciences (SPSS) from 01/09/2020 to 30/09/2023.

RESULTS

In Khartoum state, the study encompassed all patients diagnosed with sinonasal malignancies who willingly participated. Out of the consenting participants, 44 were enrolled, with males constituting 61.4% of the cohort and females representing 38.6%. Noteworthy is the observation that 38.6% of the patients fell within the age range of 50–60 years old.

The estimated incidence of sinonasal malignancies is 0.6 per 1000 individuals. Unilateral nasal obstruction emerged as the most frequent presentation (72.7%), followed by epistaxis in 56.8%. In terms of risk factors, 18.2% were identified as smokers, and 6.8% were woodworkers; however, a notable proportion (63.6%) did not exhibit any of the known risk factors.

CONCLUSIONS

Sinonasal malignant tumors have non-specific symptoms in the nose and paranasal sinus, including nose obstruction and epistaxis. Furthermore, the greatest frequency of sinonasal malignant tumors occurs in elder males

Evaluation Of Serum Cell Division Cycle 42 (CDC42) Levels In Patients With Nasal Polyps

Burakhan YILDIRIM[1], **İsrafil ORHAN**[1], **Adem DOGANER**[2], **Muhammed SEYITHANOGLU**[3], **Muhammed Gazi YILDIZ**[1], **Omer Faruk CINAR**[1]

[1]Kahramanmaraş Sütçü İmam University Medical Faculty, Department of Ear, Nose and Throat and Head and Neck Surgery; [2]Kahramanmaraş Sütçü İmam University Medical Faculty, Department of Biostatistics and Medical Informatics; [3]Kahramanmaraş Sütçü İmam University Medical Faculty, Department of Medical Biochemistry

BACKGROUND & AIM

Chronic rhinosinusitis with nasal polyps (CRSwNP) is an inflammatory disease with incompletely understood pathogenesis. Type 2 inflammation plays a central role in both asthma and CRSwNP and is primarily regulated by Th2 lymphocytes, which mediate humoral immunity and allergic responses. Cell Division Cycle 42 (CDC42) is a small guanosine triphosphate–binding and hydrolyzing enzyme (GTPase) involved in cytoskeletal organization, cell polarity, and inflammatory cell migration, and it promotes Th2 differentiation while inhibiting Th1 and Th17 pathways. Serum CDC42 levels correlate positively with Th2 lymphocytes in asthmatic children. This study aimed to evaluate the biomarker potential of CDC42 in CRSwNP.

MATERIAL & METHODS

This prospective study included 42 adults with CRSwNP diagnosed according to the European Position Paper on Rhinosinusitis and Nasal Polyps (EPOS) 2020 criteria, 42 healthy controls without nasal pathology, and 42 adults with CRSsNP. Individuals meeting EPOS 2020 exclusion criteria were excluded. Sociodemographic data were recorded, and symptom severity was assessed using the Sino-Nasal Outcome Test-22 (SNOT-22). Patients were evaluated using the Lund-Kennedy and Lund-Mackay scoring systems. Serum CDC42 levels were measured by ELISA. Statistical analyses were conducted using IBM SPSS version 31.0, with $p < 0.05$ considered statistically significant.

RESULTS

No statistically significant differences were observed between the case and control groups in terms of age and sex (Table 1). SNOT-22, Lund-Kennedy, and Lund-Mackay scores were significantly higher in the CRSwNP group compared with the control group ($p < 0.001$, Table 2).Serum CDC42 levels were significantly higher in the CRSwNP group compared with the control group and the CRSsNP group ($p = 0.001$, Table 2). ROC analysis demonstrated that CDC42 levels had significant diagnostic performance in distinguishing CRSwNP patients from healthy controls ($p < 0.001$, Table 3, Figure 1).

CONCLUSIONS

Our study provides important evidence supporting the role of type 2 inflammation in the pathogenesis of CRSwNP. The significantly elevated serum CDC42 levels in patients with CRSwNP suggest that this molecule may serve as a non-invasive biomarker of disease activity. Our findings indicate that CDC42 may represent a potential biomarker candidate to support the diagnosis of CRSwNP or to be used as an objective tool in patient follow-up. Future studies should clarify its clinical applicability by evaluating its relationship with disease course and treatment response.

Comparison Of Piezoelectric And High-Speed Drills For Frontal Beak Osteotomy In Endoscopic Sinus Surgery

Marta Kwiatkowska[1], **Łukasz Skrzypiec**[1], **Kornel Szczygielski**[1], **Dariusz Jurkiewicz**[1]

[1]Department of Otolaryngology and Oncological Laryngology with Clinical Department of Cranio-Maxillo-Facial Surgery, Military Institute of Medicine - National Research Institute, 128 Szaserów Street, 04-141 Warsaw, Poland

BACKGROUND & AIM

Frontal beak reduction is a critical and challenging step in endoscopic sinus surgery (ESS) for chronic rhinosinusitis (CRS). Traditional high-speed drills can risk thermal injury and soft tissue trauma, whereas piezoelectric surgery uses ultrasonic vibrations for selective bone cutting and may improve surgical precision. This study compared piezoelectric devices with conventional drills for frontal beak reduction.

MATERIAL & METHODS

A double-blind exploratory study with randomization was conducted during the years 2019-2022. Adult CRS patients (n=43) with prominent nasofrontal beak undergoing ESS were randomized to piezoelectric knife (n=22) or high-speed drill (n=21). Exclusion criteria included prior sinus surgery, septoplasty, neoplasms, or systemic contraindications. Outcomes included Lund–Kennedy, Lund–Mackay, Sino-Nasal Outcomes Test (SNOT-22), visual analogue scale (VAS) scores, and frontal sinus ostium dilatation, measured preoperatively and at 1, 4, and 24 weeks postoperatively.

RESULTS

Both groups showed significant postoperative improvements in Lund–Mackay and SNOT-22 scores ($p<0.05$). At 1 week, the piezo group had significantly lower Lund–Kennedy scores ($p=0.022$), suggesting better mucosal healing. Correlations in the piezo group were observed between ostium dilatation and improved Lund–Mackay ($R=-0.527$; $p=0.008$) and SNOT-22 ($R=-0.405$; $p=0.049$) at 24 weeks. No significant differences were found in ostium width gain, VAS scores or complications. With piezo devices, median time of surgery was increased.

CONCLUSIONS

Piezoelectric instrumentation represents a feasible and safe adjunct to traditional high-speed drills for frontal beak reduction, particularly in complex anterior skull base anatomy. In this study, piezoelectric instruments demonstrated some early postoperative advantages—such as reduced discomfort and favorable short-term mucosal healing—while long-term clinical, endoscopic, and radiological outcomes were comparable between both techniques. Presented findings support the role of piezoelectric devices as a complementary option that may enhance surgical control and perioperative patient experience in selected cases. Larger, prospective randomized studies are required to more definitively establish the clinical value and optimal indications for piezoelectric instrumentation in endoscopic frontal sinus surgery.

SINGLE-LAYER VERSUS DOUBLE-LAYER NASAL SEPTAL PERFORATION CLOSURE COMBINED WITH RHINOPLASTY: A COMPARATIVE STUDY

Sergey Gorbunov[1,2], **Yury Rusetsky**[1], **Igor Reshetov**[3], **Sergey Mastin**[1]

[1]Department of Otorhinolaryngology, Central State Medical Academy, Moscow, Russia; [2]Department of Head and Neck Surgery, Ilyinskaya Hospital, Moscow Region, Russia; [3]Department of Oncology, Radiotherapy and Reconstructive Surgery, Sechenov University, Moscow, Russia

BACKGROUND & AIM

Nasal septal perforation (NSP) is associated with symptoms that may significantly impair quality of life. Surgical closure remains technically challenging, particularly in large defects and in patients requiring simultaneous correction of external nasal deformity. Vascularized flap techniques are considered the standard approach due to their reliable blood supply and favorable healing outcomes. However, the optimal number of reconstructive layers remains controversial, especially when combined with rhinoplasty. The aim of this study was to compare the effectiveness of single-layer and double-layer NSP closure using vascularized flaps performed concomitantly with rhinoplasty and to evaluate patient satisfaction with surgical outcomes.

MATERIAL & METHODS

A retrospective comparative analysis included 100 patients presenting with combined NSP and external nasal deformity. Patients were allocated into two groups: Group 1 (n=50) underwent single-layer NSP closure with a vascularized flap; Group 2 (n=50) underwent double-layer closure using vascularized flaps. All patients simultaneously underwent rhinoplasty. Outcomes were assessed by nasal endoscopy with measurement of perforation size and by patient-reported outcome measures using the SNOT-25 and ROE questionnaires preoperatively and at 14 days, 1 month, 6 months, and 12 months postoperatively. Statistical analysis compared anatomical closure rates and quality-of-life outcomes between groups.

RESULTS

Complete anatomical closure was achieved in 80% of patients in Group 1 and 94% in Group 2 ($p=0.034$). For perforations <20 mm, intergroup differences were not statistically significant (84.6% in Group 1 vs. 92% in Group 2, $p>0.05$). However, for defects ≥20 mm, the double-layer technique demonstrated significantly higher efficacy (75% in Group 1 vs. 96% in Group 2, $p<0.05$). Both groups showed significant postoperative improvement in SNOT-25 and ROE scores ($p<0.001$), with no significant differences between groups.

CONCLUSIONS

When combined with rhinoplasty, double-layer vascularized flap closure is preferable for NSP ≥20 mm, whereas both techniques are equally effective for smaller defects. Patient satisfaction with aesthetic outcomes did not correlate with the closure technique. These findings support the feasibility and effectiveness of simultaneous NSP repair and rhinoplasty.

OP-1238

Spontaneous Cerebrospinal Fluid Rhinorrhea: Clinical And Radiologic Correlates With Intracranial Hypertension And Transverse Venous Sinus Stenosis

Omar A. Elbanhawy[1], **Mohamad O. El-Banhawy**[2], **Enas Taha**[2]

[1]Menoufia University; [2]Delta University for Science and Technology; [3]Menoufia University; [4]Delta University for Science and Technology

BACKGROUND & AIM

Objective: To analyze the clinical presentation, radiologic features including transverse venous sinus stenosis (TVSS), and intracranial pressure (ICP) parameters in adult patients with spontaneous cerebrospinal fluid (CSF) rhinorrhea.

MATERIAL & METHODS

Methods: A prospective observational study was conducted involving 30 adult Egyptian patients presenting with spontaneous CSF rhinorrhea. Clinical data, imaging findings (HRCT, CT cisternography, MRI, MRV), and intraoperative ICP measurements were analyzed.

RESULTS

Results: The majority of patients were 28 obese females (93.3%), with 26 (86.7 %) being of reproductive age. Common symptoms included headache (100%) and pulsatile tinnitus pulsatile tinnitus, 24 (80) % meningitis: 2 cases (6.6%)

. HRCT and CT cisternography revealed unilateral cribriform plate defect 25 patients (83.3%), bilateral in 2 (6.6%) and defect in the roof of the ethmoid in 3 (10%). Beside the site of the leaks MRI showed features of elevated ICP including empty sella (either complete or partial) in 28 (93.3%) and optic nerve sheath enlargement 4 (13.3) and optic nerve sheath dilation in 25 (8.3)%. MRV revealed bilateral TVSS in 25 (83.3%) of patients. All patients had elevated opening pressures (>25 cm H_2O), but no correlation was found between pressure and degree of TVSS.

CONCLUSIONS

Conclusion: Spontaneous CSF rhinorrhea is strongly associated with features of elevated ICP and venous sinus stenosis. Recognition of these patterns is essential for diagnosis, surgical planning, and long-term management. To our knowledge, this is the first prospective Egyptian cohort linking spontaneous CSF rhinorrhea with bilateral TVSS

The Second Haemostatic Hit: A Scoping Review Of Serotonin Reuptake Inhibitors And Bleeding Risk In HHT

Tiago Soares[1], **Melanie Dias**[1], **Catherine Rennie**[1]

[1]*Imperial College Healthcare NHS Trust*

BACKGROUND & AIM

Hereditary Haemorrhagic Telangiectasia (HHT) is characterised by structural vascular fragility, resulting in chronic, life-altering epistaxis. Management typically focuses on surgical and anti-angiogenic interventions, however common modifiable pharmacological triggers may remain overlooked. Serotonin Reuptake Inhibitors (SRIs), including SSRIs and SNRIs, inhibit the serotonin transporter, depleting intra-platelet serotonin - a critical co-factor for aggregation. We hypothesise that SRIs act as a "second haemostatic hit", imposing a functional platelet defect upon structural vascular vulnerability. This scoping review aims to map the literature on SRI-induced epistaxis exacerbation and identify safety gaps.

MATERIAL & METHODS

A systematic scoping review was conducted according to PRISMA-ScR guidelines. Searches were performed in MEDLINE, Embase, and the Cochrane Library (inception to April 2026). Inclusion criteria focused on HHT clinical outcomes and pharmacological studies addressing serotonin-mediated bleeding.

RESULTS

Preliminary mapping reveals a stark evidence desert. No prospective studies currently quantify SRI risk in HHT. Pharmacological synthesis confirms, however, that serotonin transporter inhibition by SRIs significantly impairs the primary haemostatic plug, essential for managing high-flow telangiectasia. Anecdotal signals froma high-volume HHT centre suggest a correlation between SRI use and potential increased epsitaxis severity scores.

CONCLUSIONS

SRIs represent a theoretically potent but clinically overlooked risk factor in HHT. This review highlights a major unrecognised safety gap and advocates for baseline monitoring when initiating such antidepressants in HHT patients. Further prospective multi-centre sudies are required

Technical, Clinical, And Safety Effects Of Brief Standardized Education On Smartphone IMU-Measured Intranasal Corticosteroid Spray Technique: A Prospective Observational Cohort Study

Muhammed Mirza Doğan[1], **Ejder Ciğer**[1], **Baturalp Çetin**[1], **Emre Çelik**[1], **Artun Kırmızıtaş**[1]

[1]*Department of Otorhinolaryngology, İzmir Katip Çelebi University Atatürk Training and Research Hospital, İzmir, Türkiye*

BACKGROUND & AIM

The efficacy and local tolerability of intranasal corticosteroid (INCS) sprays depend on directing the nozzle away from the septum and toward the lateral nasal wall. This study aimed to objectively quantify natural-use technique with a smartphone-based inertial measurement unit (IMU), determine whether brief standardized education improves technique, and explore whether technical change is associated with short-term clinical outcomes and adverse effects.

MATERIAL & METHODS

This manuscript reports the first locked analysis of an ongoing prospective cohort and includes 29 adults starting INCS therapy. At baseline, a 10-second IMU recording was obtained for each nostril during natural use; a brief standardized education session was then delivered and the recording was repeated at the same visit. Head position was standardized in neutral gaze with the chin kept parallel to the ground. Right and left technical change were analyzed separately using nostril-specific lateral-positive recoded signed Z. The primary clinical endpoint was change in TNSS at day 14–28. Adverse effects were captured as epistaxis, dryness, burning/irritation, and oral taste/throat symptoms.

RESULTS

: Median TNSS improved from 8 to 3 (median change -4; p<0.001). Median change in right recoded Z was +6.28° (p=0.010), in left recoded Z +10.12° (p=0.011), and in mean recoded Z +9.00° (p<0.001); all three key technical endpoints remained significant after Holm correction. The number of patients within the 15–45° lateral corridor increased from 1 to 7 on the right and from 0 to 9 on the left. Epistaxis occurred in 6 patients (20.7%), dryness in 4 (13.8%), oral taste/throat symptoms in 3 (10.3%), and burning/irritation in 1 (3.4%). In this cohort, technical lateralization metrics were not independent predictors of TNSS change or epistaxis.

CONCLUSIONS

Brief standardized education produced a measurable bilateral lateral shift in nozzle orientation on smartphone IMU and was accompanied by clinically meaningful improvement. This framework offers a practical way to quantify patient technique in routine care.

OP-1241

Comparison Of AI Models For Detecting Concha Bullosa On Paranasal Sinus CT Images

Ahmet Kısa[1], **Atakan Utku Şen**[1], **Furkan Çetin**[1], **Nagihan Bilal**[1], **Özlem Yağız Agayarov**[1], **Murat Gümüşsoy**[1], **İbrahim Çukurova**[1]

[1]*Department of Otorhinolaryngology, Tepecik Training and Research Hospital, University of Health Sciences, Izmir, Turkey*

BACKGROUND & AIM

Concha bullosa is a common sinonasal anatomical variation defined by pneumatization of the middle turbinate. It may contribute to nasal obstruction and influence endoscopic sinus surgery planning. However, it is not consistently reported on paranasal sinus computed tomography (CT) scans. Artificial intelligence (AI), particularly convolutional neural networks (CNNs), has demonstrated promising performance in radiological diagnostics and sinonasal image classification. This study aimed to evaluate the diagnostic performance of AI models for detecting concha bullosa on coronal paranasal sinus CT images and to compare Microsoft Azure Custom Vision with an EfficientNetV2-S- CNN model.

MATERIAL & METHODS

This retrospective diagnostic study included anonymized CT images obtained from an institutional radiology archive with ethical approval. A total of 838 independent coronal CT images were analyzed. Images were converted from Digital Imaging and Communications in Medicine (DICOM) format to JPEG and standardized to 250 × 250 pixels. Each image was labeled as “concha bullosa present” or “concha bullosa absent” by otolaryngology reviewers. The dataset was randomly divided into training (80%, n = 670) and testing (20%, n = 168) subsets. Two models were evaluated: Microsoft Azure Custom Vision and EfficientNetV2-S. Accuracy, sensitivity, specificity, Cohen’s kappa coefficient, and the area under the receiver operating characteristic curve (AUC) were calculated for model performance. Model comparison was performed using McNemar’s test.

RESULTS

In the test set, concha bullosa was present in 91 images (54.17%) and absent in 77 images (45.83%). Accuracy, sensitivity, specificity, and AUC were 95.83%, 95.60%, 96.10%, and 0.973 for Azure, and 94.64%, 95.60%, 93.51%, and 0.987 for EfficientNetV2-S. Both models showed excellent agreement with expert annotation (Azure κ = 0.916; EfficientNetV2-S κ = 0.892). Model performance did not differ significantly according to McNemar’s test (p = 0.724).

CONCLUSIONS

AI models identified concha bullosa on coronal paranasal sinus CT scans with significant accuracy. Microsoft Azure Custom Vision and EfficientNetV2-S exhibited comparable diagnostic performance. These data indicate that AI may serve as an assisting instrument for radiological assessment and preoperative planning. Further studies with larger datasets and external validation are required.

Beyond Thrombosis: Clinical Review Of The Risk Of Epistaxis With Oral Contraceptives

Kritika[1], **Abhishek**[3], **Sita**[2]

[1]*Sant Muktabai bmc hospital, Mumbai;* [2]*V n desai bmc hospital, mumbai;* [3]*Dr babasaheb ambedkar, bmc hospital, mumbai*

BACKGROUND & AIM

Background: A common ENT manifestation, epistaxis has a complex etiology that includes coagulopathies, hypertension, and trauma. Oral contraceptive pills affect nasal mucosal physiology, coagulation profiles, and vascular tone, especially when they contain estrogen.OCPs have been shown to raise the risk of thrombosis, little is known about their possible correlation with bleeding symptoms like epistaxis. The nasal mucosa has estrogen receptors, and changes in hormone levels can affect mucosal engorgement and vascular permeability. Aim: To evaluate the possible association between oral contraceptive pill use and the occurrence of epistaxis. To explore plausible physiological mechanisms linking hormonal contraception to nasal bleeding.

MATERIAL & METHODS

Method: A study was conducted at the department of ENT, Head and Neck Surgery, with female patients visiting on OPD and emergency basis with complaints of nasal bleed from 2025 to 2026. Data on patient demographics, OCP formulations, duration of use, epistaxis characteristics, and mechanisms were extracted. Three groups of women on the database were created, who were and were not consuming oral contraceptive pills.

RESULTS

The consumption of oral contraceptive pills reduces the beta receptors present in lamina propria cells. The predominance of beta receptors was seen in the groups having rhinitis symptoms and the normal population.

CONCLUSIONS

There was a significant reduction in the beta receptors in lamina propria cells of the nasal mucosa among women who consumed oral contraceptive formulations, especially those containing estrogen. There were significant effects on inflammatory cells like fibroblasts, mast cells, plasmocytes, etc.

The Great Mimic: Navigating The Complex Interplay Between Allergic Rhinitis And Chronic Rhinosinusitis

Nadine El Hadi[1]

[1]*Lebanese American University Medical Center - Rizk Hospital (LAUMC-RH)*

BACKGROUND & AIM

Distinguishing between Allergic Rhinitis (AR) and Chronic Rhinosinusitis (CRS) remains a diagnostic challenge, even for experienced clinicians, due to their significant symptomatic overlap. Beyond the clinical diagnostic hurdle, the socioeconomic burden is staggering: AR affects 10–40% of adults globally with an annual treatment cost of up to $7.9 billion, while CRS affects 5% of the US population, accounting for $8.6 billion in yearly healthcare expenditure.

MATERIAL & METHODS

This presentation provides a targeted literature review focused on the differential diagnosis of AR and CRS. We synthesize current evidence to provide a framework for distinguishing these two entities and examine the strength of the physiological link between them.

RESULTS

The correlation between CRS and AR remains a subject of intense debate, with the literature offering fragmented and often diverging interpretations. One prevailing theory suggests a direct inflammatory link: inhaled allergens processed by nasal immune cells trigger an inflammatory cascade. In CRS patients, an overexpression of cell-surface adhesion molecules may further recruit inflammatory mediators, resulting in a potent cytokine "outburst" within the sinonasal mucosa. Conversely, opposing data challenge this correlation. Studies utilizing radiolabeled allergens demonstrate that particles frequently remain sequestered in the nasal cavity and oropharynx, failing to permeate the paranasal sinuses. This suggests a physical limitation that may prevent allergens from directly exacerbating sinus disease, pointing toward independent rather than interdependent pathologies.

CONCLUSIONS

Both AR and CRS profoundly impact patient quality of life and carry immense economic weight. Understanding whether these conditions are parallel diseases or a continuous inflammatory spectrum is vital. Mastery of the diagnostic nuances between them remains the mainstay of effective management and personalized patient care.

Real-World Biologics For Chronic Rhinosinusitis With Nasal Polyps (Crswnp): Efficacy, Treatment Interruption, And Comorbidity Impact

Rebrova Svetlana[1], **Marina Budkovaia**[1]

[1]*Saint-Petersburg Research Institute of Ear, Throat, Nose and Speech*

BACKGROUND & AIM

To evaluate biologics effectiveness in for Chronic Rhinosinusitis with Nasal Polyps (CRSwNP) in real-world settings, analyzing comorbidity impact, treatment interruption causes, and outcomes

MATERIAL & METHODS

Prospective study of 313 CRSwNP patients; 261 (83.4%) had T2- comorbidities (asthma/others). Assessment included SNOT-22, NOSE, ACT, endoscopy (Nasal Polyp Score, NPS), and CT (Lund-Mackay). Biologics: dupilumab (93.4%), mepolizumab (5.4%), omalizumab (0.6%), tezepelumab (0.6%).

RESULTS

1.Symptom Improvement: NOSE scores decreased by 72.7% at 1 year (60.5→16.5) and 82.6% at 2 years (60.5→10.5). SNOT-22: 50% reported significant improvement at Year 1; only 4% showed no improvement by Year 2.

Asthma Control: Achieved in 98.5% of comorbid patients (ACT: 19.7±0.2→23.7±0.3).

Objective Outcomes: - CT scores decreased from 19.8±0.5 to 5.1 (Year 1) and 3.5 (Year 2). 84% exhibited polyp reduction (NPS) within 6 months; complete regression in 14% (Year 1) and 13% (Year 2).

- Non-response: 3.4% (n≈11) required agent switch.

- Treatment Interruption:38 patients (12.1%) discontinued due to temporary drug unavailability at the institution.

- Rapid relapse occurred in 94% (36/38), with comorbid patients recurring within 2.7±0.8 months.

- 55% (21/38) showed significant NPS worsening (2.5±0.7→5.6±0.3).

- Sustained remission post-discontinuation was rare(4 patients: 1 dupilumab responder at Year 1; 2 at Year 3; 1 at Year 5).

CONCLUSIONS

Biologics (primarily dupilumab) demonstrate high real-world efficacy for CRSwNP with T2 comorbidities. Treatment interruption due to drug unavailability (12.1%) triggered rapid relapse in 94% of patients, especially comorbid cases (mean 2.7 months), underscoring the necessity of consistent therapy access.

Breathing Easier, Worrying Less? The Impact Of Septoplasty On Anxiety

João Barbosa[1], **Bárbara Roque**[1], **João Fernandes**[1], **Constança Oom**[1], **Daniela Serras**[1], **Alberto Santos**[1], **Carlos Macor**[1]

[1]*Hospital Beatriz Ângelo*

BACKGROUND & AIM

Nasal obstruction is one of the most frequent complaints in Otorhinolaryngology and shows a bidirectional relationship with anxiety. Anxiety can amplify the subjective perception of nasal obstruction, while chronic nasal inflammation may independently promote anxiety via neural, inflammatory, and sleep-related mechanisms. Preoperative anxiety has also been associated with poorer subjective recovery after septoplasty. However, whether surgical correction translates into measurable improvement of anxiety symptoms remains unclear. This study aims to evaluate the impact of septoplasty on nasal obstruction and anxiety scores, and to assess whether preoperative anxiety influences postoperative improvement in nasal obstruction.

MATERIAL & METHODS

A prospective observational cohort study including patients who underwent septoplasty with or without turbinate surgery between July 2025 and February 2026. Patients completed the Visual Analogue Scale (VAS) for nasal obstruction, the NOSE scale, and the Beck Anxiety Inventory (BAI) preoperatively and postoperatively. A BAI score ≥16 was considered positive for clinically significant anxiety. Correlations were assessed using Spearman's test.

RESULTS

36 patients were included, with a mean age of 42.5 (± 13.5) years; 19 were men (52.8%). Mean VAS decreased from 6.94 (± 1.94) preoperatively to 2.69 (± 2.51) postoperatively, and mean NOSE from 59.44 (± 22.42) to 21.25 (± 20.51). Mean BAI decreased from 15.22 (± 12.43) to 9.06 (± 10.08). A moderate positive correlation was observed between preoperative NOSE and BAI scores (ρ=0.438; p=0.008), while the correlation between VAS and BAI was not significant (ρ=0.230; p=0.177). Postoperatively, improvement in NOSE scores showed a weak positive correlation with improvement in BAI scores, without

reaching significance (ρ=0.316; p=0.061). No significant correlation was found between improvements in VAS and BAI (ρ=0.189; p=0.271). Preoperative BAI scores did not significantly correlate with postoperative improvements in VAS (ρ=0.146; p=0.395) or NOSE (ρ=0.177; p=0.302). The proportion of patients meeting criteria for anxiety decreased from 16 (44.4%) preoperatively to 10 (27.8%) postoperatively.

CONCLUSIONS

Nasal surgery was associated with marked improvement in nasal obstruction and lower postoperative anxiety scores, although improvements in nasal obstruction were not significantly correlated with improvements in anxiety.

OP-1246

Comparative Study Between Local Anaesthesia And General Anaesthesia In Coblation Turbinoplasty

Eamon Shamil[1], **Pavol Surda**[1], **Zareena Shah**[1], **Pavel Straka**[1]

[1]*Guy's at St Thomas' NHS Foundation Trust*

BACKGROUND & AIM

AIM:

Coblation turbinoplasty is an efficient and minimally invasive treatment for hypertrophic inferior turbinates (IT) that cause nasal congestion and obstruction. The procedure is mostly performed under general anaesthesia (GA), but local anaesthesia (LA) is rapidly gaining popularity as it enables the procedure to be performed in the outpatient setting.

We hypothesised it would reduce operating time by performing this in the outpatient setting. Secondary objectives included determining the impact on symptom burden, comparing costs, postoperative pain, length of stay and waiting times of the two anaesthetic procedures.

MATERIAL & METHODS

METHOD:

A total of 42 patients were identified, with 22 treated under LA and 20 treated under GA.

All 42 patients completed the study and were followed up in outpatient clinic 3 months after discharge. We measured these outcomes between studied groups: change in overall NOSE scores between pre-operative visit and 3 months postoperatively, pain scores, waiting times for procedure and costs.

RESULTS

RESULTS:

A total of 42 patients with non-allergic rhinitis who underwent turbinoplasty were included in our study. Median waiting time for surgery in the LA group was significantly shorter than in the GA group. There was no difference in change in the NOSE scores after interventions between the LA group and the GA group.

CONCLUSIONS

CONCLUSION:

Turbinoplasty in LA is safe, efficacious and cheap. The main benefits in clinical use could be the financial effectiveness. Additionally we observed no increase in complication rates and pain scores compared to the GA technique.

Multidimensional Assessment Of Psychosocial Effects Following Septorhinoplasty

Dursun Mehmet MEHEL[2], **Furkan UYAR**[1], **Esra YILMAZ**[1], **Seda Nur CİHAN**[1], **Arzu YALÇINKAYA**[3]

[1]*Samsun Üniversitesi Tıp Fakültesi Kulak Burun Boğaz Hastalıkları Baş ve Boyun Cerrahisi Anabilim Dalı;* [2]*Sağlık Bilimleri Üniversitesi Samsun Eğitim Araştırma Hastanesi Kbb Kliniği;* [3]*Samsun İl Sağlık Müdürlüğü*

BACKGROUND & AIM

The aim of this study was to evaluate the psychosocial status of septorhinoplasty candidates by assessing their levels of subjective well-being, social appearance anxiety, and self-objectification, and to investigate the impact of sociodemographic characteristics and psychiatric history on these parameters.

MATERIAL & METHODS

A total of 103 septorhinoplasty candidates participated in the study. Sociodemographic data including age, gender, education, marital status, parental status, employment status, household composition, monthly income, and perceived income were collected. For psychosocial assessment, the Social Appearance Anxiety Scale (SAAS), Subjective Well-Being Scale (SWBS), and Self-Objectification Questionnaire (SOQ) were administered. Descriptive statistics (mean, standard deviation, minimum,

maximum) were calculated. Binomial tests were used for categorical variables, and the chi-square goodness-of-fit test was applied for the distribution of variables with multiple categories.

RESULTS

The mean age of participants was 27.5 ± 9.15 years (median: 25). The mean scores were 35.9 ± 11.7 for the Social Appearance Anxiety Scale (SAAS), 141.1 ± 24.6 for the Subjective Well-Being Scale (SWBS), and 28.8 ± 11.1 for the Self-Objectification Questionnaire (SOQ). The gender distribution was 61.2% female and 38.8% male, showing a statistically significant difference ($p = 0.030$).

Regarding education, 41.7% of participants were university graduates, and 35.9% were high school graduates. In terms of marital status, 59.2% were single, 32.0% married, 5.8% divorced, and 2.9% widowed. Regarding employment status, 54.4% were unemployed, and 45.6% were employed.

A total of 81.4% of participants reported receiving positive feedback from their social environment regarding their appearance. The mean duration of desire for surgery was 35.1 ± 44.4 months (median: 15 months). Psychiatric diagnosis was present in 13.7% of participants, and 17.6% were using psychiatric medication.

CONCLUSIONS

The study cohort predominantly consisted of young, single individuals with a high level of education. Heterogeneity was observed among participants in terms of psychosocial variables, highlighting the need to consider the influence of sociodemographic characteristics and psychiatric history. These findings underscore the importance of a comprehensive assessment of the psychosocial status of septorhinoplasty candidates.

Effect Of Medical Versus Surgical Therapy On Cognitive Dysfunction In Chronic Sinusitis Patients: A Systematic Review And Meta-Analysis Of SNOT-22 Scores

Muhammad Ozair Awan[1], **Haissan Iftikhar**[2], **Muhammad Sohaib Shahid**[1], **Jai K. Das**[1], **Mohannad Rajab**[2], **Remo Accorona**[3], **Mohammad Adeel**[4], **Amin Javer**[5]

[1]*Aga Khan University, Karachi, Pakistan;* [2]*University Hospital Birmingham;* [3]*ASST Grande Ospedale Metropolitano Niguarda;* [4]*Bradford Teaching Hospitals;* [5]*St. Paul's Sinus Center*

BACKGROUND & AIM

Chronic rhinosinusitis has a high impact on quality of life and has been shown to affect cognitive function in patients. The aim of this systematic review and meta-analysis is to determine the impact of medical vs surgical therapy in improving cognitive dysfunction in CRS patients.

MATERIAL & METHODS

Our study included papers evaluating cognitive dysfunction in patients with CRS treated either medically or surgically, with post-treatment evaluation via the patient reported outcome measure SNOT-22.

RESULTS

Our study included a total of 8 articles, with the pooled surgery cohort comprising of 1,243 patients, and the pooled medical therapy cohort comprising 158 patients. Statistical analysis was conducted focusing primarily on the variation in SNOT-22 scores from baseline to follow-up. Our results indicated a significant improvement in the surgical cohort compared to the medical cohort post treatment.

CONCLUSIONS

Our results lean towards ESS playing a significant role in improving cognitive dysfunction in CRS patients compared to continued medical therapy. Large prospective long-term trials are required to truly elucidate the difference between the two treatment methods.

OP-1249

Hemostasis In FESS: A Split-Nose Comparison Of Ankaferd Blood Stopper® And Adrenaline Pledgets

Özgür Yiğit[1], **Esra Altunal**[1], **Cemile Baykan Eryiğit**[1], **Fatma Demirkol**[1]

[1]*Otolaryngology Department, Basaksehir Cam ve Sakura City Hospital, University of Health Sciences, Istanbul, Turkey.*

BACKGROUND & AIM

In functional endoscopic sinus surgery (FESS), intraoperative bleeding may impair surgical visualization, prolong dissection, and affect postoperative mucosal healing. Adrenaline-soaked pledgets are widely used for hemostasis; however, their effect may

be limited in some cases and may be associated with systemic hemodynamic changes. Ankaferd Blood Stopper® (ABS) is a topical hemostatic agent used in various otorhinolaryngologic procedures. We hypothesized that ABS would provide comparable intraoperative hemostasis to adrenaline pledgets and superior postoperative mucosal healing in a split-nose model.

MATERIAL & METHODS

This single-center, prospective, randomized, split-nose clinical study included 30 adult patients undergoing primary bilateral functional endoscopic sinus surgery (FESS) for chronic rhinosinusitis. Each nasal cavity was evaluated separately. According to randomization, Ankaferd Blood Stopper® was applied to one side and an adrenaline-soaked pledget to the contralateral side. Intraoperative hemostatic efficacy was assessed by surgical field bleeding scores, need for additional hemostatic intervention, and hemodynamic parameters. Surgical videos were blinded for side allocation and evaluated by two independent otorhinolaryngologists using the Fromme–Boezaart scale. At the end of surgery, Ankaferd-soaked Spongostan® was placed on the Ankaferd side, while standard Spongostan® was placed on the opposite side. Postoperative follow-up was performed at weeks 1 and 4 with endoscopic evaluation and patient/physician visual analogue scale scores. Paired analyses were used for within-patient comparisons.

RESULTS

Intraoperatively, Ankaferd Blood Stopper® (ABS) demonstrated hemostatic efficacy comparable to adrenaline-soaked pledgets. However, ABS was observed to cause dark discoloration depending on its retention time in the surgical field. Therefore, standardization of application time, amount, and surgical field cleaning was considered important when using ABS. Postoperatively, the ABS-soaked Spongostan® side showed lower edema, crusting, and synechia scores, along with more favorable patient and physician visual analogue scale scores. No serious ABS-related adverse event was observed.

CONCLUSIONS

Ankaferd Blood Stopper® (ABS) demonstrated intraoperative hemostatic efficacy comparable to adrenaline-soaked pledgets in functional endoscopic sinus surgery. The more favorable postoperative findings on the ABS-soaked Spongostan® side suggest that ABS may contribute to improved early mucosal healing. No serious ABS-related adverse event was observed. ABS may be considered a safe and effective alternative in functional endoscopic sinus surgery, provided that application time, amount, and surgical field cleaning are standardized.

OP-1250

Complications Of Functional Endoscopic Sinus Surgery And Associated Risk Factors: A Retrospective Study

Ramazan Yavuz[1]

[1]*Uşak Training and Research Hospital, Department of Otorhinolaryngology*

BACKGROUND & AIM

Functional endoscopic sinus surgery (FESS) is a widely used minimally invasive technique for treating chronic rhinosinusitis, nasal polyposis, fungal sinusitis, mucoceles, and sinus tumors. By enlarging the natural sinus ostia, it restores ventilation and drainage while preserving mucosal function. Compared to traditional methods, FESS is associated with less trauma, faster recovery, and lower complication rates. However, anatomical variations and patient-related factors may influence outcomes. Recently, the role of perioperative steroid use has gained attention. This study aimed to evaluate factors affecting complications in FESS and to investigate whether steroid use reduces complication risk.

MATERIAL & METHODS

A total of 208 patients who underwent endoscopic sinus surgery for sinusitis, nasal polyposis, mucocele, or paranasal sinus tumors at Uşak Training and Research Hospital between 2023 and 2025 were included in this study. Preoperative CT scans of the patients were reviewed to evaluate anatomical variations, and Keros classification was assessed. Preoperative use of oral or topical steroids was recorded. Complications occurring intraoperatively or within the first postoperative month were evaluated.

RESULTS

A total of 208 patients were included in the study. The mean age was 37.9±10.0 years, with a median of 38 (range: 14–71). Of the participants, 59.6% were male (n=124). The most common indication was nasal polyposis (57.2%). The overall complication rate was 19.7% (n=41). No significant association was found between complications and gender (p=0.843), age (p=0.481), or indication (p=0.935). Analysis of radiological findings revealed no statistically significant relationship between anatomical variations and complications (all p>0.05), although a borderline significance was observed for concha bullosa (p=0.062). The complication rate was significantly lower in patients receiving steroids (12.4%) compared to those who did not (27.2%) (p=0.012). In logistic regression analysis, steroid use was independently associated with a reduced risk of complications (OR: 0.38, 95% CI: 0.18–0.78, p=0.009).

CONCLUSIONS

Steroid use was significantly associated with a reduced risk of complications in patients undergoing FESS. These findings suggest that perioperative steroid administration may have a protective effect against postoperative complications.

Features Of Endoscopic Dacryocystorhinostomy In Patients With Consolidated Nasolacrimal Duct Trauma

Leylya Omerova[1]

[1]*National Military Medical Clinical Center "MMCH", Kyiv, Ukraine*

BACKGROUND & AIM

Lacrimal drainage disorders after nasal and midface trauma remain a challenge for otorhinolaryngologists, maxillofacial surgeons, and ophthalmologists. Midface fractures are commonly associated with nasolacrimal pathway injury, lacrimal drainage impairment reported in 32.9% of patients. Powered Endoscopic DCR offers advantages over external approaches, including no facial scarring, preservation of the lacrimal pump mechanism, improved endonasal access, and simultaneous correction of intranasal pathology. However, it requires advanced surgical skill due to the narrow operative field and proximity to vital structures. This study aimed to assess the features and outcomes of Powered Endoscopic DCR in patients with consolidated traumatic NLD Types II–III injuries

MATERIAL & METHODS

A total of 45 patients with distal NLD injuries were observed by a multidisciplinary team (ENT surgeon, ophthalmologist, and maxillofacial surgeon). Preoperative assessment included history, complaints, dacryocystography, probing and irrigation tests, MSCT with contrast, 3D reconstruction of cranial bones, and nasal endoscopy.All patients underwent Powered Endoscopic DCR with stenting of the nasolacrimal duct and mucosal flap reconstruction, depending on the injury site

RESULTS

The most frequent clinical manifestation was persistent epiphora, observed in 60% of patients, followed by intermittent tearing in 35% and tearing during functional load or exposure to environmental triggers in 26%. Tear stagnation was recorded in 27 patients, while mucopurulent discharge from the conjunctival sac occurred in 87%. Swelling or hyperemia of the medial canthus with pulsating pain was present in 47% of cases. Injuries were localized at the level of the lacrimal sac in 37% of patients. Nasolacrimal duct lesions included wall fracture with narrowing in 17%, obstruction in 24%, defect in 5%, and combined lesions in 17%. Endoscopic examination revealed concomitant intranasal pathology in 65% of patients, including synechiae, osteomeatal complex deformities, and septal deviation. Postoperatively, lacrimal drainage was restored, fistula healing occurred rapidly, and no recurrence of chronic dacryocystitis was observed.

CONCLUSIONS

1. Powered Endoscopic DCR with nasal burrs and mucosal flap reconstruction is a highly effective method for treating patients with consolidated NLD trauma (Types II–III).

2. Further study is needed to optimize flap placement techniques to minimize postoperative synechiae and granulation formation.

OP-1252

The FRONTIER Procedure: A Novel Reversed Draf III Approach For Advanced And Complex Frontal Sinus Pathology

Abdelrahman M.Hussein[1]

[1]*Zagazig University Hospitals*

BACKGROUND & AIM

The endoscopic modified Lothrop procedure (Draf III) is the gold standard for advanced frontal sinus surgery, unifying both sinuses via an inside-out endonasal approach. However, far-lateral disease, extensive supraorbital cells, or multiple inter-sinus septations can render even the most extended endoscopic techniques inadequate, risking incomplete clearance and persistent disease.

MATERIAL & METHODS

Through a concealed bicoronal incision, an osteoplastic flap is elevated for panoramic exposure of the entire frontal sinus. Under direct visualization, lateral and medial bony partitions are removed. Drilling proceeds medially toward the contralateral sinus to create a single, capacious cavity with a wide inferior outflow tract. The endoscope is then introduced to confirm

complete removal of disease, assess the frontal recess, and ensure unobstructed drainage. The technique preserves neurovascular structures and avoids unnecessary cranialization or obliteration, maintaining natural sinus physiology.

RESULTS

Early application of the FRONTIER procedure in patients with extreme lateral osteomas, complex post-surgical anatomy, and revision cases demonstrated complete disease clearance in a single stage. Endoscopic assistance enhanced intraoperative verification, ensuring anatomical completeness. All patients achieved favorable cosmetic outcomes, rapid recovery, and no recurrence during short-term follow-up. Morbidity was minimal, with scars hidden within the hairline.

CONCLUSIONS

The FRONTIER procedure represents a paradigm shift in frontal sinus surgery. By reversing the Draf III concept to an outside-in approach and integrating endoscopic verification, it enables safe, definitive, and aesthetically discreet management of the most challenging frontal sinus cases. This novel technique broadens the surgical armamentarium for advanced pathology, combining maximal exposure with minimal morbidity.

OP-1253

Management Of Antrochoanal Polyps: A Single-Institution Experience

Burçay Tellioğlu[1], **Cem Mustafa Kemal Hatay**[1], **Serdar Özer**[1]

[1]*Hacettepe University Medical School, Department of Otolaryngology Head and Neck Surgery, Ankara, Turkey*

BACKGROUND & AIM

Antrochoanal polyps (ACPs) are benign lesions of the sinonasal cavity, commonly originating from the maxillary sinus and extending into the choana. Although surgery is considered the standard treatment, postoperative recurrence remains a relevant challenge, particularly in pediatric populations. While incomplete excision of the antral attachment has traditionally been considered the principal cause of recurrence, the contribution of patient-related and radiological factors remains incompletely understood. This study aimed to evaluate clinical, surgical, and radiological characteristics associated with recurrence.

MATERIAL & METHODS

A retrospective analysis was conducted on 54 patients who underwent primary surgical treatment for ACP at a tertiary referral center between January 2014 and January 2025. Patients who underwent revision procedures or lacked preoperative computed tomography (CT) imaging were excluded. Demographic characteristics, clinical variables, surgical details, postoperative findings, and radiological data were reviewed. Patients were stratified into pediatric (<16 years) and adult (≥16 years) groups. Surgical treatment consisted of middle meatal antrostomy (MMA) alone or a combined approach incorporating Caldwell–Luc surgery when complete visualization of the lesion origin was not achievable through MMA. Potential predictors of recurrence were evaluated using univariate analysis with calculation of odds ratios and 95% confidence intervals.

RESULTS

Among 54 patients, recurrence was observed in 5 cases, corresponding to an overall recurrence rate of 9.3%. Pediatric patients demonstrated a significantly higher recurrence rate than adults (20.0% vs. 2.9%, p=0.048). Ipsilateral non-maxillary mucosal thickening was strongly associated with recurrence (OR: 16.5, p=0.02), while postoperative synechiae also significantly increased recurrence risk (OR: 9.71, p=0.049). Although recurrence occurred more frequently in patients treated with the combined approach compared with MMA alone (17.4% vs. 3.2%), this difference did not reach statistical significance.

CONCLUSIONS

Recurrence of ACP appears to be multifactorial and may be influenced by both disease-related and postoperative factors. Pediatric age, ipsilateral mucosal disease, and postoperative synechiae were identified as important factors associated with recurrence. Careful preoperative assessment and meticulous surgical technique aimed at minimizing mucosal injury may help reduce recurrence risk. Closer postoperative surveillance should be considered in patients with high-risk features.

The Long-Term Outcomes Of Surgical Approaches For Managing Cerebrospinal Fluid Rhinorrhea: A Systematic Review And Single-Arm Meta-Analysis.

Dr. Omar Almansouri[1], **Dr. Mazin Alsarraj**[3], **Prof. Osama Marghlani**[2]

[1]*king fahad general hospital, jeddah, saudi arabia;* [2]*King Faisal specialist hospital, Jeddah, Saudi Arabia;* [3]*East jeddah hospital, Jeddah, Saudi Arabia*

BACKGROUND & AIM

Background: Cerebrospinal fluid (CSF) rhinorrhea is a significant health disorder caused by abnormal communication between the subarachnoid space and the nasal cavity. Although several surgical approaches are available, their long-term outcomes are not well-established. Our systematic review and meta-analysis aim to evaluate the long-term efficacy and safety of surgical interventions utilized for managing CSF rhinorrhea.

MATERIAL & METHODS

Methods: An extensive digital search of PubMed, Scopus, Web of Science, and Cochrane Library was executed from inception until March 2025. Studies evaluating any surgical interventions for managing CSF rhinorrhea and following the patients for at least one year were included. Our study outcomes were success, recurrence, and complication rates. All the statistical analysis was conducted using STATA 18 BE.

RESULTS

Results: Our review encompassed 114 studies involving 4187 patients with CSF rhinorrhea. The endoscopic repair showed a high primary success rate estimated at 93% (1-2 years), 92% (2-5 years), and 91% (> 5 years). The recurrence rate following endoscopic repair was low, varying from 7% to 11%. Furthermore, there were minimal complications after endoscopic repair, with meningitis ranging from 1% to 2%, sinusitis estimated at 1%, and headache from 1% to 3%. The craniotomy approach showed a high primary success, reaching 95% at 1-2 years, then dropping to 75% at 2 to 5 years, and increasing again to 98% at > 5 years. Additionally, the risk of recurrence (5% to 22%) and complications were generally high after craniotomy (3% to 6%).

CONCLUSIONS

Conclusion: Endoscopic repair demonstrated excellent long-term results with minimal morbidity, favoring it as the standard approach for most CSF rhinorrhea cases. Although craniotomy was associated with a higher risk of recurrence and complications, it remains an option for complex or frontal defects. Individualized surgical approaches depending on defect site, CSF flow, and patient-specific factors are mandatory for optimizing surgical outcomes.

OP-1255

Cysteine Test For Assessing Halitosis Production Capacity

Murat Aydın[1], **İsmail Günay**[2]

[1]DDS, PhD. Doctor of Dental Surgery, Doctor of Philosophy in Microbiology. Private Clinical Practice.; [2]Professor, Department biophysics.

BACKGROUND & AIM

In some patients, halitosis may not be detectable at the moment of examination, leading to normal halitometer readings despite the presence of a chronic malodor problem due to temporary fluctuations in oral conditions. For this reason, assessing a patient's halitosis production capacity—rather than relying solely on instantaneous measurements—may offer a more reliable diagnostic approach. This study aims to evaluate the use of a cysteine challenge test to determine the oral malodor production potential of individuals.

MATERIAL & METHODS

Patients with oral halitosis (n=305) or non-oral halitosis (n=191) and healthy individuals (n=102) were compared with each other to identify any possible relationship between before and after 5 ml of 20 mmol L-cysteine mouth rinse for 30 seconds induced oral H2S concentrations.

RESULTS

Initial H2S concentrations were >0.8ppm in 75.1% of oral group but less than <0.8 ppm of non-oral and controls. After cysteine rinse, oral H2S concentrations exceeded 12 ppm in 72% of oral halitosis patients but were lower in 88% of non-oral group and 99% of controls. While increasing ratio was >12 in 74.5% of oral group, it was <12 in 81.7% of non-oral and 83.4% of controls.

CONCLUSIONS

The cysteine challenge test appears to be a valuable diagnostic tool for assessing a patient's potential to generate oral malodor, even when halitosis is not detectable at the time of examination. It offers a means of identifying cryptic halitosis cases that may otherwise be missed by standard halitometry.

Abdulrahman Bin Faisal University, Dammam, Saudi Arabia; [4]Department of Otorhinolaryngology Head & Neck Surgery, King Fahd Military Medical Complex, Dhahran, Saudi Arabia; [5]College of Medicine, King Faisal University, Al-Ahsa, Saudi Arabia; [6]Department of Family and Community Medicine, College of Medicine, Imam Abdulrahman Bin Faisal University, Dammam, Saudi Arabia

BACKGROUND & AIM

Otolaryngology has experienced notable advancements and growth in the application of artificial intelligence (AI). However, otolaryngologists' perception of these tools are lacking. This study aims to assess the knowledge and attitudes of otolaryngologists toward AI.

MATERIAL & METHODS

A cross-sectional study was conducted among 110 otolaryngologists in the Eastern Province of Saudi Arabia. A piloted questionnaire was used to gather information on knowledge, attitude, and opinions regarding AI. Data analysis was conducted using SPSS version 26.

RESULTS

Of the sample, 60% indicated average perceived knowledge of AI, while approximately 44.5% perceived their AI knowledge in the field of otolaryngology to be below average. A significant positive correlation was identified between knowledge and attitude scores. It was found that a higher knowledge score was more closely associated with seeing more than 15 patients per day, while a higher attitude score was more closely associated with being older, being a consultant, and having more years of professional experience. Of the sample, 38.2% strongly agreed that the application of AI in scientific research should be included in the residency training program.

CONCLUSIONS

These findings underscore the importance of incorporating AI tools into certain aspects of the otolaryngology residency training program, highlighting their significance.

Balloon Sinuplasty Vs Functional Endoscopic Sinus Surgery (FESS) In Chronic Rhinosinusitis: Systematic Review And Meta Analysis

Hadi Afandi Al-Hakami[1,2], Rimah F. AlSalem[3], Rena Abualjamal[1], Adel Alrwuili[4], Moayed Allahim[6], Ahmed Alkhaldi[7], Ryan Alqahtani[8], Ghadah Al Fraihi[9], Abdulelah Almuhsen[5], Kinan Alidreesi[1]

[1]College of Medicine, Department of Otolaryngology-Head & Neck Surgery, King Saud bin Abdulaziz University for Health Sciences, Jeddah, Saudi Arabai; [2]King Abdullah International Medical Research Center, Ministry of National Guard Health Affairs, Jeddah, Saudi Arabai; [3]King Khalid University Hospital, Riyadh, Saudi Arabia; [4]Alqurayat General Hospital, Qurayyat, Saudi Arabia; [5]King Saud University, Riyadh, Saudi Arabia; [6]Qassim University, Burydah, Saudi Arabia; [7]Al-Jouf University, Al Jouf, Saudi Arabia; [8]King Khalid University, Abha, Saudi Arabia; [9]King Saud University for Health Sciences, Riyadh, Saudi Arabia

BACKGROUND & AIM

Chronic rhinosinusitis (CRS) substantially impairs quality of life and very often necessitates surgical intervention when pharmacological treatment is ineffective. Functional endoscopic sinus surgery (FESS) continues to be the standard approach, though balloon sinuplasty (BSD) has emerged as a minimally invasive option. Despite its growing adoption, comparative data remains heterogeneous, especially when it comes to long-term safety and effectiveness. This systematic review and meta-analysis aimed to assess and compare clinical outcomes, complication rates, revision rates, radiologic control, and patient satisfaction between BSD and FESS in adult patients with CRS.

MATERIAL & METHODS

A systematic, comprehensive literature search was conducted across PubMed, Cochrane Library, Google Scholar, Web of Science, and EMBASE for studies published between 2005 and 2025. Following PRISMA 2020 and PICO guidelines, 23 studies meeting predefined inclusion criteria were systematically reviewed and analyzed. Randomized controlled trials and comparative observational studies evaluating BSD versus FESS in adults with CRS were included. Primary outcomes included symptom improvement (SNOT-22 score), complications, revision rates, Lund–Mackay radiologic scores, and patient satisfaction. Random-effects meta-analysis was used; heterogeneity and publication bias were assessed via the I^2 statistic and funnel plot, respectively.

RESULTS

23 studies were included, comprising 1,884 individuals (BSD: 940; FESS: 944). Both procedures produced clinically significant symptom relief, with pooled SNOT score reductions exceeding the minimal clinically important difference. Subgroup analysis revealed comparable mean improvement between BSD (27.24; 95% CI: 19.83–34.65) and FESS (25.18; 95% CI: 20.05–30.31), with no statistically significant difference (p=0.65). The complication rates were lower in BSD (4.56%) compared to FESS (10.84%), although this difference was not statistically significant (p=0.20). The revision rates were similar (BSD 3.21% vs. FESS 2.97%; p=0.87). Radiologic and satisfaction outcomes numerically favored BSD; however, they did not achieve statistical

significance. Most pooled analyses exhibited substantial heterogeneity (I^2 >90%), and funnel plot asymmetry indicated possible publication bias.

CONCLUSIONS

Both BSD and FESS yield similar improvements in symptoms for adult chronic rhinosinusitis (CRS). Although BSD revealed quantitatively lower complication rates and higher satisfaction, those variations were not statistically significant and were accompanied by substantial heterogeneity. The variation in study design, disease severity, and reporting limits definitive comparative conclusions. BSD may represent an effective minimally invasive option for some patients, whereas FESS is still necessary for more severe cases. Further high-quality, sufficiently powered randomized controlled trials with standardized outcome reporting are necessary to more precisely characterize patient selection and long-term comparative effectiveness.

Coblation In Management Of Nasal Meningoencephalocele In Yemen

Abdulwasa Alaqel[1], **Mohamed Elbegermy**[1]

[1]*Ain Shams University*

BACKGROUND & AIM

To present our experience of managing Nasal Meningoencephalocele using trans-nasal endoscopy with coblation and comparing it with bipolar diathermy as a minimally invasive surgery.

MATERIAL & METHODS

Endoscopic excision of nasal meningoencephalocele under general anesthesia. Excision of the mass and coagulation of its base with coblation. The skull base defect was repaired with a free fat graft and septal cartilage.

RESULTS

All the patients healed successfully without complications. No recurrence occurred with follow up for 1 year.

CONCLUSIONS

Endoscopic management of Nasal Meningoencephalocele offered better lightening and exposure of the field, less bleeding, and shortening the time of surgery. Also, the device gave three functions simultaneously: ablation, suction and irrigation thus it saves the 4-hand technique needed in other methods, shortens the time needed for surgery.

KEYWORDS

Nasal Meningoencephalocele , coblation , endoscopic management for meningoencephalocele

OP-1259

“Clinical Characteristics And Surgical Outcomes Of Sinonasal Angiofibromas: An 8-Year Single-Center Experience”

Aysenur Yildirim[1], **Aysegul Batioglu Karaaltin**[1], **Harun Cansiz**[1], **Yetkin Zeki Yilmaz**[1], **Alperen Vural**[1]

[1]*Department of Otorhinolaryngology, Cerrahpasa Faculty of Medicine, Istanbul University-Cerrahpasa, Istanbul, Türkiye*

BACKGROUND & AIM

Sinonasal angiofibroma is a rare, highly vascular tumor predominantly affecting adolescent males, characterized by locally aggressive growth and a risk of significant intraoperative bleeding. Recent advances in endoscopic techniques and preoperative embolization have improved surgical management; however, the optimal approach and the clinical relevance of different staging systems remain controversial. This study aims to present an 8-year single-center experience by evaluating the clinical features, tumor staging, surgical approaches, and outcomes of patients with sinonasal angiofibroma, with a focus on the effectiveness and safety of endoscopic surgery and the impact of embolization on perioperative management.

MATERIAL & METHODS

This retrospective study included patients diagnosed with sinonasal angiofibroma and treated at a tertiary referral center between 2018 and 2026. Demographic characteristics, presenting symptoms, and radiological findings were reviewed. Tumors were staged according to the UPMC and Onerci classification systems. Data regarding preoperative embolization, surgical approach, intraoperative findings, and postoperative outcomes were collected from medical records. All patients underwent preoperative imaging with contrast-enhanced MRI and/or CT to assess tumor extent. Hematocrit levels measured before and after surgery were used as indirect indicators of intraoperative blood loss. Length of hospital stay and postoperative complications were recorded. Patients were followed regularly with clinical and radiological evaluation to detect residual or recurrent disease. Statistical analysis was performed descriptively due to the limited sample size.

RESULTS

A total of 14 male patients with a mean age of 16.4 years (range: 10–28) were included. Nasal obstruction was present in all patients, while epistaxis was reported in 64%. According to staging systems, the majority of tumors were classified as Stage II, and advanced-stage disease was observed in 14% of cases. Preoperative embolization was performed in 78.6% of patients. Endoscopic surgery was the primary treatment modality in nearly all cases, with no need for open approaches. The mean hematocrit level decreased from 40.4% preoperatively to 30.1% postoperatively, indicating manageable intraoperative blood loss. The average length of hospital stay was 5.5 days. Postoperative outcomes were favorable overall, with low morbidity and no major complications reported. Residual or recurrent disease occurred in 2 patients (14.3%). One patient showed disease progression during follow-up and required referral for radiotherapy, highlighting the importance of close postoperative surveillance.

CONCLUSIONS

Endoscopic surgery was demonstrated to be a safe and effective treatment modality for sinonasal angiofibroma, including selected advanced-stage cases. The widespread use of preoperative embolization contributed to acceptable intraoperative blood loss and facilitated surgical resection. Low rates of recurrence and morbidity support the reliability of minimally invasive approaches. However, the occurrence of disease progression in one patient underscores the importance of long-term follow-up and individualized management strategies. While staging systems provide valuable information on tumor extent, their role in guiding treatment decisions remains limited. Overall, a multidisciplinary approach and careful postoperative surveillance are essential to optimize patient outcomes.

Halitosis Examination Methods

Murat Aydın[1], **Bollen Curd ML**[2], **Özen Murat eren**[3]

[1]*DDS, PhD. Dental Professional, Doctor of Philosophy in Microbiology. Private Clinical Practice;* [2]*DDS, PhD, MSc;* [3]*Adana hospitalpsychiatry clinic*

BACKGROUND & AIM

Halitosis emissions originate from three distinct sources: the oral cavity, nasal passages, and exhaled breath. Therefore, any halitosis assessment that does not comprehensively evaluate all three sources is inherently incomplete. In the literature, five principal methods of halitosis examination have been identified

MATERIAL & METHODS

Although methods for examining halitosis appear in various contexts throughout the literature, when systematically categorized, they can be grouped into five distinct diagnostic protocols.

RESULTS

The main clinical methods for evaluating halitosis are as follows:

- Self-assessment: If an individual perceives that they have halitosis, this alone is sufficient to categorize them as a halitosis patient.
- Social feedback: If individuals in the person's environment confirm the presence of malodor, this too is sufficient to support diagnosis of halitosis.
- Organoleptic assessment: Based on the clinician’s direct smelling is subjective and potentially misleading.
- Chemical and enzymatic tests: These tests rely on enzyme indicators that detect bacterial enzyme activity within the oral cavity, rather than halitosis itself.
- Halitometry: The use of gas-detecting devices (halitometers) to measure volatile compounds associated with halitosis. However, there is significant debate in the literature regarding which gases should be measured, how they should be measured, and what threshold values are considered clinically relevant.

CONCLUSIONS

The first two methods are subjective, yet show convincing correlation with objective clinical assessments. Organoleptic testing is also subjective, and while commonly used, it lacks rationality, reproducibility, sustainability, and standardization. Chemical and enzymatic tests fail to measure actual malodor and instead reflect bacterial activities, rendering them diagnostically questionable. Halitometry is the most reasonable, practical, and reliable method; however, it does not allow for a definitive diagnosis based on a single measurement. A more accurate diagnosis may be achieved when several maneuver-based measurements are conducted.

The Impact Of E-Cigarette Vaping On Mucociliary Clearance: New Insights Into Early Respiratory Damage

Tychkina Irina[1], **Ozerskaya Irina, Phd**[1], **Svistushkin Mikhail, Phd**[1], **Svistushkin Valery, Phd, professor**[1]

[1]*I.M. Sechenov First Moscow State Medical University (Sechenov University)*

BACKGROUND & AIM

Background

The consumption of tobacco and nicotine-containing products is one of the most significant problems in modern society. Currently, the impact of alternative smoking methods on the ENT organs is poorly understood.

Aim

The aim is to assess the impact of vaping on the mucociliary system of the nasal cavity.

MATERIAL & METHODS

The study included 14 vapers and 10 healthy volunteers. Mucociliary clearance was assessed using the saccharin test. In vapers the saccharin test was performed three times: against the background of the usual regime of using e-cigarettes (base line), immediately after vaping, and an hour after vaping. The functional state of the nasal epithelial cilia was assessed using high-speed video microscopy of inferior turbinate scrapings at baseline and immediately after vaping.

RESULTS

Saccharin test time in vapers at baseline was significantly longer than that of healthy volunteers (mean±SD) (14±3minutes vs.10±3 minutes, $p<0.001$). Immediately after vaping, saccharin test time accelerated to 12±3 minutes, and after an hour slowed down to 17±4 minutes. Ciliary beat frequency in vapers was significantly lower compared to controls (median [IQR]) (5.5[5.0-6.5] Hz vs. 7.75[7.5-9.06] Hz, $p=0.0016$) and increased immediately after vaping, but the difference did not reach statistical significance (5.5[5.0-6.5] Hz vs. 6.5[6.03-7.5] Hz, $p=0.075$). The proportion of cells with motile cilia in the epithelial layer of vapers was significantly lower compared to controls (45[30-50]% vs. 80[70-80]%, $p=0.0018$). Furthermore 85.7% of vapers had a marked disruption in the synchronicity of their cilia, 28.6% had a decrease in the activity and amplitude of cilia movement, and 64.3% had a large number of exfoliated epithelial cells with immotile cilia and exfoliated cilia.

CONCLUSIONS

Preliminary study results show that vapers exhibit significant violations in mucociliary clearance and impairments in ciliary motility.

OP-1262

Nasal Septal Swell Body Morphology Across Septal Deviation Types: A CBCT-Based Study

Kamenko Sutalo[1], **Melika Arnautovic**[1], **Abdullah Veladzic**[1]

[1]*ENT Department at University Clinical Centre Sarajevo*

BACKGROUND & AIM

Nasal obstruction is commonly associated with septal deviation, inferior turbinate hypertrophy, middle turbinate variations and other anatomical factors affecting nasal airflow. In addition to cartilaginous and bony septal deformities, the nasal septal swell body (NSSB) has increasingly been recognized as a soft-tissue structure potentially contributing to nasal airway resistance. Septal deviation can be classified according to the system proposed by Mladina Ranko, one of the most widely cited morphological classifications in rhinology literature. This study aimed to investigate the relationship between NSSB morphology and Mladina septal deviation types, with particular focus on side-to-side asymmetry.

MATERIAL & METHODS

A retrospective CBCT-based observational study was performed in adult patients with septal deviation. Deformities were classified according to Mladina (Types I–VII). NSSB thickness was measured bilaterally at its maximal dimension on standardized coronal images. Ipsilateral and contralateral measurements were compared, and NSSB morphology was analyzed across deviation patterns. Measurements were analyzed as continuous variables without predefined cutoff values.

RESULTS

NSSB morphology demonstrated variability among different Mladina deviation types. Previous imaging studies have suggested an association between septal deviation and contralateral NSSB prominence; similar asymmetry patterns were observed in our cohort. More pronounced asymmetry appeared to be associated with deviation patterns demonstrating greater anatomical asymmetry.

CONCLUSIONS

NSSB morphology varies across septal deviation types and demonstrates measurable side-to-side asymmetry. These findings suggest that septal deviation should be considered not only as a structural deformity of cartilage and bone, but also in relation to adjacent soft-tissue structures influencing nasal airflow.

Radiologic–Pathologic Correlation Of Sinonasal Lesions In Clinical Practice: A Retrospective Study

Noémi Queiroz Nogueira[1], **Clara Lima**[1], **Simão Bessa**[1], **Margarida Neves**[1], **Joana Ferreira**[1], **Nuno Lousan**[1]

[1]*ULS Tâmega e Sousa*

BACKGROUND & AIM

Accurate preoperative characterization of sinonasal lesions remains challenging due to overlapping radiological features between inflammatory, benign and malignant entities. Imaging with computed tomography (CT) and magnetic resonance imaging (MRI) are central to clinical decision-making, however, their diagnostic reliability compared to histopathology is uncertain. This study aimed to evaluate the concordance between imaging-based diagnosis and histopathological findings in sinonasal lesions. Secondary objectives included assessing the diagnostic performance of imaging for malignancy and identifying clinically relevant discordances.

MATERIAL & METHODS

A retrospective single-center study was conducted including 74 patients with sinonasal lesions who underwent preoperative CT and/or MRI followed by biopsy or surgical resection between 2020 and 2025. Imaging reports were reviewed for the primary diagnostic impression and categorized as non-neoplastic, benign neoplasm or malignant neoplasm. Histopathological diagnosis was considered the reference standard. Primary outcomes included agreement for neoplastic versus non-neoplastic disease and malignant versus non-malignant disease. Secondary outcomes included specific diagnostic concordance and clinically relevant diagnostic errors. Concordance was assessed using Cohen's kappa (κ). Diagnostic performance was evaluated using sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV). Clinically relevant discordances were defined as mismatches with potential impact on management.

RESULTS

Overall agreement between imaging and histopathology for neoplastic classification was 71.6%, with moderate concordance (κ = 0.42). Sensitivity and specificity for neoplasia were 57.1% (95% confidence interval [CI] 40.9–72.0) and 84.6% (95% CI 70.3–92.8), respectively. For malignancy, agreement remained moderate (κ = 0.50), with sensitivity of 60.0% (95% CI 40.7–76.6), specificity of 87.8% (95% CI 75.8–94.3), PPV of 71.4%, and NPV of 81.1%. Clinically relevant discordances were observed in 29.7% of cases, including 10 malignant lesions misclassified as benign or inflammatory and 6 benign lesions misinterpreted as malignant. Inverted papillomas were among the lesions most frequently mistaken for inflammatory disease.

CONCLUSIONS

Preoperative imaging showed high specificity but limited sensitivity in the evaluation of sinonasal lesions, with only moderate agreement with histopathology. The substantial rate of clinically relevant discordance highlights the limitations of imaging alone and reinforces the critical role of histopathological confirmation, particularly in atypical or suspicious cases.

OP-1264

Piezoelectric-Assisted External Approach for Excision of Frontal Sinus Osteoma

Vedat Oruk[1]

[1]*Medicana Health Group*

BACKGROUND & AIM

Frontal sinus osteomas are the most common benign tumours of the paranasal sinuses. Large, midline-crossing lesions with posterior table involvement often exceed the limits of endoscopic access, requiring external resection. Conventional open techniques, however, carry recognised drawbacks — imprecise intraoperative boundary localisation and thermal or mechanical mucosal injury during high-speed osteotomy.

To describe a piezoelectric-assisted external technique, combined with fluoroscopy-guided radiopaque boundary marking, for the safe and precise resection of large frontal sinus osteomas.

MATERIAL & METHODS

This report describes a five-stage technique for the external resection of large frontal sinus osteomas using a piezoelectric device. Boundaries are first marked using radiopaque gauze threads positioned according to preoperative CT landmarks and verified with intraoperative fluoroscopy, projecting the lesion margins directly onto the skin without neuronavigation. Through a transeyebrow incision, the anterior table is osteotomised along these markings with a piezoelectric device and elevated en bloc, exposing the underlying lesion while preserving the mucosa. The osteoma is then debulked using interchangeable piezoelectric tips, with a high-speed diamond burr reserved for releasing the base adherent to the posterior table. Finally, the

anterior table is repositioned and secured with titanium microplates, restoring anatomical continuity and forehead contour. Each stage is designed to minimise soft-tissue trauma while providing safe access in an anatomically confined surgical field.

RESULTS

This piezoelectric-assisted external technique achieves complete resection of large, midline-crossing frontal sinus osteomas through fluoroscopy-guided radiopaque boundary marking, which projects lesion margins onto the skin for precise osteotomy planning. En-bloc piezoelectric elevation of the anterior table preserves mucosal integrity and provides direct access for debulking, while selective cutting minimises thermal and mechanical trauma near the posterior table; only brief high-speed drilling is required to free the adherent osteoma base. Anatomical reconstruction with titanium microplates restores forehead contour without residual deformity. The technique is associated with an uncomplicated intraoperative and postoperative course, same-day discharge, and complete radiological and symptomatic resolution at short-term follow-up, confirming its safety and effectiveness for large, complex frontal sinus osteomas.

CONCLUSIONS

This piezoelectric-assisted external technique offers a safe, reproducible approach for excising large frontal sinus osteomas that exceed the limits of endoscopic access. Fluoroscopy-guided radiopaque boundary marking provides a practical, low-cost alternative to neuronavigation, while piezoelectric osteotomy enables precise, mucosa-sparing bone work in anatomically constrained fields. Combined with en-bloc anterior table elevation and titanium microplate reconstruction, the technique minimises soft-tissue trauma and preserves forehead contour. These findings support its adoption as a reliable option for complex frontal sinus osteomas requiring external resection.

OP-1265

Digital Workflow Implementation To Enhance Patient Reported Outcome Measures (Proms) Collection In Rhinologic Surgery

Claire Lloyd-Davies[1], **Bilinc Kavak**[1], **Babatunde Oremulé**[1], **Catherine Rennie**[1]

[1]*Imperial College Healthcare NHS Trust*

BACKGROUND & AIM

Patient Reported Outcome Measures (PROMs) quantify disease impact from a patient perspective, facilitating shared decision-making, evaluation of treatment effect and measurement of clinical outcomes. In rhinology, PROMs are especially important as symptom burden and the impact on quality of life are unrealiably captured by objective measures alone. Although the value of PROMs are recognised internationally, routine application remains inconsistent. Digital platforms offer a solution for scalable and consistent PROMs collection. In our department, resident doctors use a digital platform to collect PROMs pre- and post-operatively via email.

MATERIAL & METHODS

A two-cycle Quality Improvement Project was completed from 1/10/25-30/11/25 and 1/12/25-31/1/26. Theatre lists were retrospectively reviewed to identify eligible rhinology patients and compared with PROM records.

After identifying unsatisfactory completion rates, a new workflow was designed, assigning specific residents to each operating list, alongside a handbook on platform use and procedure-specific PROMs. PROMs distribution and completion were analysed using the chi-square test. Statistical significance was set at $p<0.05$. The association between patient demographics and completion was analysed using logistic regression.

RESULTS

127 and 117 patients were captured in cycles one and two, respectively. The most frequently collected PROM was NOSE (74%). Others included SNOT-22, FACE-Q Rhinoplasty and Nose Bleeds Grading Scale. Introducing the allocation system increased PROMs distribution from 43% to 79% ($\chi2=34.22$, $p<0.0001$) and completion from 30% to 48% ($\chi2=8.61$, $p=0.003$). Patient age did not impact completion rates (cycle one OR 1.01, 95% CI, 0.97-1.05, cycle two OR 1.02, 95% CI, 0.99-1.05).

CONCLUSIONS

Digital PROMs collection is a scalable and accessible approach to reliably capture PROMs that is not limited by demographics such as patient age. Simple workflow changes, including a resident allocation system, can significantly improve PROM uptake and overall data capture to support integration into routine practice in rhinologic surgery.

OP-1266

Comprehensive Internal Carotid Artery Management In Endoscopic Surgery For Nasopharyngeal Skull Base Radionecrosis

Zhaohui Shi[1], **Weifeng Kong**[1], **Tian Yuan**[1], **Huijun Qiu**[1], **Xia Li**[1], **Xiaoping Lai**[1], **Huiyi Deng**[1], **Rui Zheng**[1], **Gehua Zhang**[1], **Qintai Yang**[1]

[1]*Third Affiliated Hospital of Sun Yat-sen University*

BACKGROUND & AIM

Nasopharyngeal skull base radionecrosis is a major cause of poor quality of life and treatment-related mortality after radiotherapy for nasopharyngeal carcinoma. Internal carotid artery (ICA) rupture is the most common fatal event. Accurate preoperative ICA risk stratification, individualized contingency planning, an appropriate surgical strategy, suitable reconstruction, and structured postoperative management are all critical to surgical success. This study summarizes the experience of the Third Affiliated Hospital of Sun Yat-sen University with a comprehensive ICA management strategy and evaluates its clinical value in endoscopic surgery for skull base radionecrosis.

MATERIAL & METHODS

We retrospectively reviewed 167 patients with nasopharyngeal skull base radionecrosis treated between January 2023 and February 2026. Among them, 89 had preoperative ICA involvement. ICA risk was stratified as low, intermediate, or high based on computed tomography angiography and contrast-enhanced magnetic resonance imaging, and individualized preoperative plans were developed accordingly. All patients underwent an endoscopic endonasal approach. According to risk grade, surgery included debridement of necrotic tissue, ICA exposure and protection, and reconstruction using pedicled mucosal flaps, temporalis muscle flaps, or free tissue flaps. Postoperative protocols included strict blood pressure control, anti-infective therapy, imaging surveillance, and prompt management of complications. Outcome measures included intraoperative ICA rupture, postoperative hemorrhage, flap survival, infection control, healing, quality of life, and survival.

RESULTS

Among the 89 patients with ICA involvement, 15 were classified as low risk, 20 as intermediate risk, and 54 as high risk. Intraoperative ICA rupture occurred in 4 patients. Delayed postoperative hemorrhage occurred in 6 patients and was fatal in 4. Three patients died within 1 year after surgery. The flap survival rate was 92.13%, and the postoperative infection control rate was 97.6% (41/42). After a median follow-up of 18 months, the healing rate of nasopharyngeal skull base radionecrosis was 92.9%, ICA-related mortality was 4.5%, and quality-of-life scores improved significantly ($P<0.01$).

CONCLUSIONS

A comprehensive ICA management strategy integrating preoperative risk stratification, individualized contingency planning, tailored surgical intervention, structured postoperative care, and timely complication management may reduce the risk of ICA rupture, lower mortality, and improve surgical safety and outcomes in endoscopic treatment of nasopharyngeal skull base radionecrosis. This approach has important clinical value and may be applicable in other centers.

OP-1267

Relationship Between Septal Deviation Angle, Mladina Classification, And Paranasal Sinus Opacification In Patients With Septal Deviation

Yigit Tolga[1], **Ayse Enise Göker**[1]

[1]*Prof. Dr. Cemil Taşçıoğlu City Hospital*

BACKGROUND & AIM

The relationship between septal deviation and paranasal sinus disease has long been debated in the literature. Although septal deviation is thought to impair nasal airflow and sinus drainage, its role in the development of sinus opacification remains unclear. Recent studies suggest that the morphological characteristics of septal deviation may be more important than its severity. This study aimed to evaluate the relationship between septal deviation angle, Mladina classification, and paranasal sinus opacification in patients with septal deviation. We hypothesized that deviation morphology is more strongly associated with sinus opacification than deviation angle.

MATERIAL & METHODS

This retrospective study included 100 adult patients with septal deviation who underwent paranasal sinus computed tomography. Patients were divided into two groups according to the Lund-Mackay score: Group 0 (score = 0) and Group 1 (score > 0). Septal deviation angle was measured in all patients, and deviation type was classified according to the Mladina classification. Demographic data were recorded. Patients with a history of sinonasal surgery, nasal polyposis, sinonasal tumors, findings of acute infection, fungal sinusitis, maxillary sinus retention cysts, or prior trauma were excluded. Statistical analyses were performed using appropriate parametric and non-parametric tests, and $p < 0.05$ was considered statistically significant.

RESULTS

A total of 100 patients (50 in each group) were analyzed. The mean age was significantly higher in the opacification group ($p < 0.05$). There was no significant difference in septal deviation angle between the groups (13.93° vs 13.71°, $p > 0.05$). However, a significant difference was observed in the distribution of Mladina types between the groups ($p < 0.01$). Types 3 and 5 were more frequently observed in the opacification group.

CONCLUSIONS

No significant relationship was found between septal deviation angle and paranasal sinus opacification, whereas deviation morphology showed a significant association with opacification. These findings suggest that the morphological characteristics of septal deviation may play a more important role than its severity in the development of sinus disease.

OP-1268

Effect Of U-Shaped Costal Cartilage Harvesting On Donor-Site Morbidity In Rhinoplasty: A Prospective Comparative Study

HANDE DURMUŞ BARKHUDARLI[1], **ERKAN SOYLU**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, Istanbul Medipol University Hospital, Istanbul, Turkey*

BACKGROUND & AIM

Autologous costal cartilage provides abundant and versatile graft material in rhinoplasty; however, harvesting may result in donor-site morbidity, particularly postoperative pain. A U-shaped harvesting technique has been described to preserve the inferior cartilage border and potentially reduce donor-site morbidity. This study aimed to compare early postoperative donor-site pain between U-shaped and conventional full-thickness costal cartilage harvesting techniques during the first seven postoperative days.

MATERIAL & METHODS

This prospective comparative study included 81 patients undergoing open rhinoplasty with autologous cartilage harvesting from the seventh rib. Forty-four patients underwent U-shaped harvesting and 37 underwent conventional full-thickness harvesting. All procedures were performed by the same surgeon using standardized muscle-preserving surgical and perioperative analgesia protocols, with preservation of the posterior perichondrium in all patients. Donor-site pain was assessed daily on postoperative days 1–7 using a 0–10 visual analog scale in four domains: at rest, coughing, movement, and deep inspiration. Separate repeated-measures mixed models were used for each pain domain. Estimated marginal means, mean differences with 95% confidence intervals, and Holm-adjusted p values were calculated.

RESULTS

U-shaped harvesting was associated with significantly lower donor-site pain across all four domains. Compared with conventional harvesting, the mean differences (U-shaped − conventional) were −1.19 at rest (95% CI, −1.96 to −0.42; p=0.006), −1.06 during coughing (95% CI, −1.77 to −0.35; p=0.006), −1.22 during movement (95% CI, −1.90 to −0.54; p=0.002), and −1.88 during deep inspiration (95% CI, −2.56 to −1.21; p<0.001). The largest overall difference was observed during deep inspiration. Pain decreased over time in both groups, with a significant technique × day interaction for deep inspiration after Holm correction (p=0.044).

CONCLUSIONS

U-shaped costal cartilage harvesting was associated with significantly lower donor-site pain than conventional full-thickness harvesting across all four pain domains during the first postoperative week. The largest difference was observed during deep inspiration. U-shaped harvesting may offer a less painful approach to costal cartilage harvest in rhinoplasty. Further randomized and multicenter studies are required to confirm these finding

Peak Nasal Inspiratory Flow In The Assessment Of Patients With Severe Chronic Rhinosinusitis With Nasal Polyps Treated With Full House Endoscopic Sinus Surgery.

Paula Pérez-Chacón[1,2], **Hugo Lara-Sánchez**[1,2,3], **Juan José Tavarez**[1], **Jorge Freijanes-Otero**[1], **Mario S Almeida-Branco**[1], **María Ángeles Díaz Sastre**[3], **Luis Ángel Vallejo-Valdezate**[1,2]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, Rhinology Unit, Río Hortega University Hospital, Valladolid, Spain;* [2]*Faculty of Medicine, University of Valladolid, Valladolid, Spain;* [3]*Department of Otorhinolaryngology-Head and Neck Surgery. Segovia General Hospital. Segovia, Spain.*

BACKGROUND & AIM

To evaluate Peak Nasal Inspiratory Flow (PNIF) in patients with severe chronic rhinosinusitis with nasal polyps (CRSwNP) undergoing Full-House Endoscopic Sinus Surgery (ESS) and to analyze its correlation with objective measurements and patient-reported outcomes.

MATERIAL & METHODS

Thirty adults with severe CRSwNP were prospectively followed at baseline and 1, 3, and 6 months after surgery. PNIF, active anterior rhinomanometry, acoustic rhinometry, SNOT-22, and visual analogue scale (VAS) were assessed at each visit. A healthy control group (n=30) provided baseline reference values. Longitudinal changes were analyzed using linear mixed models with Bonferroni-adjusted pairwise comparisons. Pearson correlation coefficients were calculated to evaluate associations between PNIF and other variables.

RESULTS

PNIF increased significantly over time ($p<0.001$), from 133.03 L/min (95%CI 110.46-155.61) preoperatively to 202.99 L/min (95%CI 182.12-223.86) at 6 months. Total inspiratory airflow measured by rhinomanometry also improved significantly ($p<0.001$), with a marked increase at 1 month that remained stable thereafter. SNOT-22 scores decreased from 48.67 to 9.41 at 6 months ($p<0.001$), exceeding the minimal clinically important difference. VAS improved from 7.57 to 0.72 ($p<0.001$). PNIF correlated inversely with SNOT-22 at 1 and 3 months ($p\leq0.032$).

CONCLUSIONS

PNIF is a simple, reliable, and responsive objective tool that reflects both functional improvement and symptom reduction after ESS in severe CRSwNP, supporting its use in routine postoperative assessment.

BACKGROUND & AIM

Maxillary mucous retention cysts(MRC) and antrochoanal polyps(AP) are among the most common benign pathologies of the maxillary sinus. Although both lesions are thought to develop in the setting of chronic inflammation, their exact etiopathogenesis remains unclear. In particular, the impact of the anatomical relationship between maxillary tooth roots and the sinus floor remains uncertain. This study aimed to investigate the role of the relationship between maxillary tooth roots and the maxillary sinus floor in the development of AP and MRC.

MATERIAL & METHODS

In this retrospective study, patients were categorized into AP,maxillary MRC, and septoplasty (SP) groups. High-resolution CT images of paranasal sinuses were reviewed from 45 patients with AP, 53 MRC and 53 control individuals using a 256-slice CT scanner with a thickness of 0.67 mm. The relationship between maxillary tooth roots (right and left molar teeth) and the maxillary sinus floor was scored (0-3) according to root proximity to maxillary sinüs.

RESULTS

No statistically significant differences were observed among the groups in terms of age (AP: 33.2±18.2, MRC: 32.2±9.8, SP: 36.3±10.4; $p=0.097$) or sex distribution ($p=0.159$). On a patient-based analysis, the proportion of patients with at least one tooth root extending into the sinus was 48.9% in the AP group and 60.4% in the SP group, with no statistically significant difference ($p=0.254$). However, when all three groups were analyzed together, a significant difference was identified ($p=0.0006$), primarily driven by the MRC group (84.9%). The overall distribution differed significantly among the groups ($\chi^2=43.7$, $p<0.001$). The proportion of sinüs protrusion was notably lower in the AP group (4.2%) compared to the MRC (30.5%) and SP (21.8%) groups.

CONCLUSIONS

The findings suggest that the relationship between maxillary tooth roots and the sinus floor is not a primary determinant in AP development. In contrast, increased root proximity and sinus protrusion in the MRC group may contribute to impaired mucous drainage. Although odontogenic factors appear to play a limited role in AP, their involvement in sinonasal pathogenesis should not be overlooked; further large-scale prospective studies are warranted.

A Novel Composite Graft Technique For Medium-Sized Septal Perforation Repair: Costal Cartilage, Fat Layer, PRF And Biologic Graft

Deniz Hancı[1], **Öykü İzel Onaran**[2], **Hüseyin Altun**[3], **Berke Berat Bozer**[1], **Yavuz Uyar**[1]

[1]University of Health Sciences, Prof. Dr. Cemil Taşcıoğlu City Hospital , Department of Otorhinolaryngology–Head and Neck Surgery, Istanbul, Turkiye; [2]Department of Otorhinolaryngology, Çerkezköy State Hospital, Tekirdağ, Turkiye; [3]Department of Otorhinolaryngology-Head and Neck Surgery, Kocaeli Technology and Health University, Kocaeli, Turkiye

BACKGROUND & AIM

Nasal septal perforation (NSP) remains a challenging condition in rhinologic surgery, particularly in medium-sized perforations where achieving durable closure and adequate mucosal support can be difficult. Various grafting techniques have been described to improve surgical outcomes. This study presents a novel multilayer composite graft technique using costal cartilage, autologous fat layer, Platelet-Rich Fibrin (PRF), and biologic graft material for the repair of medium-sized NSPs.

MATERIAL & METHODS

This retrospective study included 12 patients who underwent NSP repair using the described technique. The procedure was performed through an open rhinoplasty approach. Costal cartilage and fat tissue were harvested from the same donor site. The fat tissue was mechanically processed using a microdebrider to obtain a finely fragmented fat layer without nano-fat transformation. PRF obtained from venous blood was combined with the fat layer to create a layered composite structure surrounding the obliquely shaped costal cartilage graft. A 4 cm × 7 cm biologic graft (Biodesign® Tissue Graft) was additionally placed on the lateral aspects of the graft at the interface with the nasal mucosa. The multilayer composite graft was then positioned between the septal mucosal flaps.

RESULTS

The average size of the septal perforations was 12 mm horizontally and 13 mm vertically. All patients had medium-sized perforations ranging from 0.5 to 2 cm. The mean follow-up period was 12 months. Complete closure was achieved in 11 of 12 patients (91.6%). In one patient, complete closure was not achieved; however, the perforation size was markedly reduced and the patient became asymptomatic postoperatively. No postoperative complications, including infection, bleeding, or donor-site morbidity, were observed.

CONCLUSIONS

This novel multilayer composite graft technique combining costal cartilage, fat layer, PRF, and biologic graft material appears to be a safe and effective option for the repair of medium-sized nasal septal perforations. The technique provides structural support and favorable mucosal healing with a high closure rate and minimal complications.

OP-1272

Olfactory Bulb Volume In Patients With Allergic Rhinitis

Anne Marie Daou[1], **Jad Hosri, MD**[1], **Nadine El Hadi, MD**[1], **Ghassan Haddad, MD**[1], **Roula Hourani, MD**[1], **Usamah Hadi, MD FACS**[1]

[1]Department of Otolaryngology-Head and Neck Surgery, American University of Beirut Medical Center, Beirut, Lebanon; [2]Department of Diagnostic Radiology, American University of Beirut Medical Center, Beirut, Lebanon

BACKGROUND & AIM

Olfactory dysfunction is a major symptom in patients with allergic rhinitis (AR) significantly correlating with a lower olfactory bulb volume.

Objective: To compare the size of olfactory bulbs in patients with and without AR.

MATERIAL & METHODS

Patients with and without AR who underwent orbital MRI over a period of 4 years were included. Volume measurement of the olfactory bulb was performed using a software designed by the Oxford University. Patients were assigned to the study group (with AR) or control group (without AR) based on the presence of symptoms and personal history of AR.

RESULTS

Results: A total of 47 patients were included, 15 of whom were in the study group and 32 in the control group. The mean age of the study group was 40.53±16.27 years compared to 49.69±17.12 in the control group (p=0.088). The female-to-male ratio was 4 vs 1.13 in the study and control groups, respectively (p=0.077). The difference in the total volume of both olfactory bulbs in the study group (83.95±23.68) vs the control group (102.29±28.73) was statistically significant (p=0.027).

CONCLUSIONS

The combined volume of olfactory bulbs is significantly lower in patients with AR compared to patients without AR.

OP-1273

When Better Healing Does Not Mean Better Recovery: Toward Selective Postoperative Debridement After Endoscopic Sinus Surgery

Haissan Iftikhar[2]

[1]*NHS Greater Glasgow and Clyde;* [2]*Northamptonshire Healthcare NHS Foundation Trust*

BACKGROUND & AIM

Endoscopic sinus debridement is common after functional endoscopic sinus surgery (FESS) for chronic rhinosinusitis (CRS), intended to prevent synechiae, reduce crusting and improve drug delivery. However, the most reported outcomes, adhesion formation and endoscopic scores, are surgeon-observed measures that may not translate into patient-centred recovery. We systematically reviewed whether routine debridement improves objective healing and patient-reported outcomes versus no or reduced-frequency debridement, and whether its treatment burden is justified by meaningful patient benefit, addressing whether surgeon-observed metrics are adequate surrogates for recovery after FESS.

MATERIAL & METHODS

This review followed PRISMA 2020. MEDLINE, Embase, CENTRAL, Emcare and CINAHL, plus two trial registries, were searched to 18 December 2025 for randomised controlled trials of post-FESS debridement in adults with CRS (minimum six-week follow-up). Split-nose trials were admitted for the per-side adhesion outcome only. Risk of bias was assessed with RoB 2 and certainty with GRADE. Adhesion formation (dichotomous, per-side) was pooled across four RCTs using a DerSimonian-Laird random-effects model, with pre-specified sensitivity analyses. Continuous outcomes (Lund-Kennedy endoscopic score, sinonasal scores, VAS pain) were synthesised narratively owing to instrument heterogeneity.

RESULTS

Eight randomised trials were included (six parallel-group, n=357, plus two split-nose RCTs contributing only to the adhesion analysis). Pooling adhesion data from four RCTs (186 sides) showed reduced postoperative adhesion formation with debridement (RR 0.48, 95% CI 0.23 to 0.99; p=0.047; I^2=28.7%; NNT approximately 5), although the estimate was statistically fragile and dominated by a single trial. Short-term Lund-Kennedy improvement in CRSwNP at 8 weeks was not sustained at 6 months. No clinically meaningful differences in sinonasal outcome scores were observed at any time point, and debridement was consistently associated with increased short-term procedural pain and inconvenience. Revision surgery was never reported. No serious adverse events occurred. Certainty of evidence ranged from very low to low.

CONCLUSIONS

Routine debridement improves surgeon-observed endpoints, particularly adhesion formation, but does not consistently or durably improve patient-reported quality of life, while increasing discomfort and burden. Current evidence does not demonstrate consistent patient-centred benefit and supports a selective approach, reserving debridement for CRSwNP, heavy crusting, or elevated risk of synechiae. Surgeon-observed healing metrics should be validated against patient-centred outcomes before being adopted as treatment targets. Adequately powered trials with patient-centred primary endpoints and longer follow-up are needed.

Impact Of Septorhinoplasty On Anxiety, Depression And Quality Of Life: A Prospective Study

PINAR TEKİN[1], **Yüksel Toplu**[2], **Lale Gönenir Erbay**[3]

[1]*Department of Otolaryngology - Head and Neck Surgery, Malatya Training and Research Hospital, Malatya,Turkiye;* [2]*Department of Otolaryngology - Head and Neck Surgery,Malatya Park Hospital, Malatya, Türkiye;* [3]*Lale Erbay Psychiatry Clinic, Ankara, Türkiye*

BACKGROUND & AIM

This study aimed to evaluate the effects of septorhinoplasty on psychopathological status and quality of life, and to highlight the importance of considering psychological factors during patient selection.

MATERIAL & METHODS

Seventy patients scheduled for septorhinoplasty were prospectively evaluated. Participants completed a sociodemographic questionnaire and several validated scales, including the Beck Anxiety Inventory (BAI), Beck Depression Inventory (BDI), Nasal Obstruction Symptom Evaluation (NOSE), Short Form-36 (SF-36), and Rhinoplasty Outcome Evaluation (ROE). All assessments were performed preoperatively and repeated six months after surgery.

RESULTS

The mean age of the participants was 26.14 ± 6.80 years. Postoperatively, significant decreases were observed in NOSE and BAI scores, whereas ROE scores significantly increased ($p < 0.05$). Improvements were also noted in several SF-36 subdomains, including physical functioning, role limitations due to physical health, general health, and social functioning ($p < 0.05$). An inverse correlation was identified between preoperative depression levels and postoperative satisfaction.

CONCLUSIONS

Septorhinoplasty appears to have a positive effect on both quality of life and anxiety levels. Assessment of depressive symptoms may be important during patient selection, as higher preoperative depression levels may negatively influence postoperative satisfaction.

OP-1275

Selection Of Biologic Agents For Chronic Rhinosinusitis With Nasal Polyps (Crswnp)

Toshiyuki Matsuyama[1], **Masaomi Motegi**[1], **Kazuaki Chikamatsu**[1]

[1]*Gunma University*

BACKGROUND & AIM

Biologic therapies have demonstrated high efficacy in chronic rhinosinusitis with nasal polyps (CRSwNP) driven by type 2 inflammation and have become an important treatment option. However, many patients present with overlapping type 2 inflammatory conditions such as eosinophilia, bronchial asthma, and eosinophilic granulomatosis with polyangiitis (EGPA). With multiple biologic agents currently available, criteria for optimal drug selection remain unclear. This study aimed to evaluate treatment outcomes and comorbidities in CRSwNP patients treated at our institution and to explore strategies for biologic selection.

MATERIAL & METHODS

We retrospectively reviewed patients with CRSwNP who received dupilumab, mepolizumab, or tezepelumab at our institution. Clinical responses in sinonasal disease, middle ear involvement, comorbid conditions, changes in blood eosinophil counts, and adverse events were assessed.

RESULTS

Dupilumab demonstrated favorable therapeutic effects for CRSwNP and eosinophilic otitis media. However, treatment-related adverse events included increased blood eosinophil counts, peripheral paresthesia, and skin erythema. Mepolizumab showed limited improvement in sinonasal and middle ear disease but was associated with a reduction in blood eosinophil counts and no notable adverse events. Tezepelumab produced moderate improvement in sinonasal disease without severe adverse events.

CONCLUSIONS

Dupilumab may be considered a first-line biologic for CRSwNP patients without systemic eosinophilic complications or with concomitant eosinophilic otitis media. In contrast, patients with concerns regarding eosinophilia or with eosinophilic asthma or EGPA may benefit from treatment switching or combination strategies including mepolizumab. Tezepelumab may represent an alternative option for patients with moderate disease severity. Future development of biomarkers reflecting individual immunologic endotypes may enable more precise stratification and personalized biologic selection.

Clinical Analysis And Evaluation Of Prognostic Factors Affecting Acute Invasive Fungal Rhinosinusitis

Ayça Ilgın Altaner Asaroğlu[1], **Mehmet Keskin**[1], **Oğuzhan Cumalı**[1], **Serhat Bayrak**[1], **Mert Kazan**[1]

[1]*Başakşehir Çam ve Sakura Şehir Hastanesi*

BACKGROUND & AIM

Acute invasive fungal sinusitis (AIFRS) is a disease commonly seen in patients under immunosuppression and with poorly controlled diabetes, characterized by rapid invasion of surrounding tissues and high mortality rates. Black necrotic lesions or discoloration indicative of mucosal ischemia may be observed on endoscopic examination. The most common pathogens are Zygomycetes species or Aspergillus. We aim to present the outcomes of patients with a diagnosis of acute invasive fungal sinusitis in a single tertiary institution between 2021 and 2026; and evaluate the prognostic significance of clinical, pathological and patient based variables with the current review of literature.

MATERIAL & METHODS

The present study retrospectively analysed the clinical data of 30 patients diagnosed with acute invasive fungal rhinosinusitis. Demographic data, clinical presentations, endoscopic examination and imaging findings, microbiological and histopathological data, underlying diseases, treatment delay, treatment approaches, laboratory findings and outcomes of patients diagnosed with invasive fungal sinusitis between 2021 and 2026 were evaluated. Patients with definitive clinical and histopathological diagnosis included in this study.

RESULTS

The cohort included 13 females and 17 males (7 pediatric, 23 adults) with a mean age of 43.73 years (range: 7-80). 8 patients had accompanying diabetes, 22 had other underlying causes. The most frequent presenting symptoms were facial pain and swelling, following ocular symptoms, some other patients had no distinctive symptoms. Among identified pathogens, Mucorales predominated (71%), Aspergillus and others each 14%. 17 cases were limited to sinonasal region, 12 had intracranial extension and 10 had orbital involvement. Patients with intracranial involvement had the most significant mortality rate (0.83); followed by orbital involvement (0.80). Overall survival rate was 0.41, with higher survival in diabetic patients compared to others (0.50 vs 0.31). Remission was associated with younger age (mean: 38.41 vs. 48.9). Mortality rates were higher in patients with severe neutropenia. Diagnostic delay was significantly longer in the group that resulted in mortality (8.16 vs. 1.66 days).

CONCLUSIONS

Acute invasive fungal sinusitis (AIFRS) often presents with symptoms like facial pain, edema, loss of sensation and nasal congestion; similar to non-specific sinusitis or paranasal tumors. However unconscious intensive care patients or patients with diabetic neuropathia, these subjective indicators are masked; complicating early detection. Therefore frequent and early endoscopic examination and institution based early treatment protocols may have a key role identifying, reducing the time required for diagnosis and preventing mortal consequences for the patients under risk. Along with surgical treatment, the prognosis is mostly determined by extension of the disease, early diagnosis, and the management of underlying metabolic diseases.

CLINICAL PRESENTATION, DIAGNOSIS, AND THERAPEUTIC STRATEGIES OF EOSINOPHILIC SIALODOCHITIS

Marta Santiago Horcajada[1], **Álvaro Sánchez Barrueco**[1,2], **William Aragonés Sanzen-Baker**[1,2], **María Pilar Benavent Marín**[1], **Gonzalo Díaz Tapia**[1,2], **Jessica Mireya Santillán Coello**[1], **Virginia Ruiz San José**[2], **Carlos Cenjor Español**[1], **José Miguel Villacampa Aubá**[1]

[1]*Hospital Universitario Fundación Jiménez Díaz*; [2]*Hospital Universitario de Villalba*

BACKGROUND & AIM

Eosinophilic sialodochitis is an uncommon and likely underdiagnosed inflammatory condition of the major salivary ducts, historically described using multiple terms such as allergic parotitis, fibrinous sialodochitis, or Kussmaul disease. This systematic review aims to clarify terminology, summarize clinical features, diagnostic approaches, treatment strategies, and evaluate adherence to proposed diagnostic criteria.

MATERIAL & METHODS

We searched six bibliographic databases from inception to December 2025, complemented by Google Scholar and citation tracking. Studies reporting eosinophilic sialodochitis or related entities were included regardless of language. Due to substantial heterogeneity, findings were analyzed descriptively.

RESULTS

A total of 79 studies including 387 patients were analyzed, consisting mainly of case reports and case series. The most consistent clinical features were recurrent swelling of the parotid and/or submandibular glands, extrusion of eosinophil-rich mucus plugs, ductal abnormalities (dilatation or stenosis), and a high prevalence of atopic comorbidities. Eosinophils were identified in salivary mucus in most of the studies reporting local samples. Full compliance with published diagnostic criteria varied markedly, from 45 of 79 studies using the Baer framework to 2 of 79 using the Carey framework, while no study fully satisfied the Zhao framework. Treatment approaches were heterogeneous and typically combined medical therapy (antihistamines, corticosteroids), intraductal irrigation, sialendoscopy, and, in selected refractory cases, biologic agents targeting type 2 inflammation.

CONCLUSIONS

Eosinophilic sialodochitis appears to represent a distinct clinicopathological entity within the spectrum of obstructive salivary gland disorders, although current evidence remains limited by heterogeneity and inconsistent reporting. Standardized definitions and minimum reporting items are needed to improve diagnostic certainty and comparability.

eosinophilic sialodochitis, systematic review

OP-1278

Machine Learning-Based Prediction Of Surgical Strategy And Postoperative Symptomatic Outcomes In Chronic Obstructive Submandibular Sialolithiasis

Berkcan Eryurt[1], **Süleyman Özdemir**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, Çukurova University, Adana, Türkiye.*

BACKGROUND & AIM

To develop and validate a machine learning–based predictive model for surgical strategy selection and postoperative symptomatic outcomes in patients with chronic obstructive submandibular sialolithiasis.

MATERIAL & METHODS

A retrospective cohort of patients undergoing surgery for chronic obstructive submandibular sialolithiasis at a tertiary referral center was analyzed. Patients with autoimmune salivary gland disease or malignancy were excluded. Demographic, clinical, radiological, and intraoperative variables including age, smoking history, symptom duration, recurrent infections, VAS scores, stone characteristics, localization, palpability, previous interventions, spontaneous stone passage, and stent requirement were recorded.

Surgical approaches were classified as intraductal/interventional sialendoscopy, sialendoscopy-assisted transoral stone removal, or submandibular gland excision. Postoperative outcomes included symptomatic improvement, complications, recurrence, operative time, and stent duration.

Random Forest, XGBoost, and CatBoost machine learning models were trained and temporally validated on an independent cohort. Model performance was evaluated using discrimination, calibration, and SHAP-based feature importance analyses.

RESULTS

Gland-preserving procedures were successfully achieved in the vast majority of patients, while gland excision was required only in a limited number of advanced cases. Larger stones and hilar/intraparenchymal localization were more frequently associated with combined surgical approaches.

Among the evaluated algorithms, the CatBoost model demonstrated the most favorable predictive performance for surgical strategy selection and postoperative symptomatic improvement. Stone size, hilar/intraparenchymal localization, palpability, recurrent infection history, symptom duration, and previous intervention history were identified as the most influential predictive variables.

Postoperative symptomatic outcomes showed marked clinical improvement during follow-up. Recurrence and complication rates remained low, and most postoperative complications were minor and transient. Overall, the clinical and predictive modeling results were highly encouraging.

CONCLUSIONS

Machine learning–based predictive modeling may provide clinically valuable support for individualized surgical planning in chronic obstructive submandibular sialolithiasis. Predictive analysis of stone characteristics and patient-specific variables may help optimize gland-preserving approaches, improve postoperative symptomatic outcomes, and reduce recurrence risk.

OP-1279

Intraoperative Ultrasound Guidance In Submandibular Gland Sialendoscopy For Stone Extraction

Ahmed Elbana[2]

[1]*Alexandria University;* [2]*Royal Hospital , Alexandria , Egypt*

BACKGROUND & AIM

Sialolithiasis can affect any of the salivary glands. However, 80% of all salivary gland stones form in the submandibular glands (submandibular sialolithiasis). Removing stones from the submandibular glands depends on the site, size, shape and location of the stones ,

MATERIAL & METHODS

small stones up to 4mm usually can be removed by Sialendoscopy Basket retrieval , while larger stones may require combined approaches with Sialendoscopy. Proximal (hilar or intraglandular)stones can be managed by IMAS (intraoral microscopic assisted sialolithotomy) with or without Sialendoscopy. If the stone is big and palpable , this approach will be quite easy , but if the stone is small or deep intraglandular and not palpable, intraoperative Ultrasound guidance can direct the surgeon toward the site of the stone and facilitate the IMAS approach. Ultrasound is a well established tool for diagnostic purposes in salivary gland sialolithiasis.

RESULTS

In this study we demonstrate that it can be also useful for localization of calculi during submandibular gland intraoral Microscopic assisted sialolithotomy especially when calculi are deep and not palpable.

CONCLUSIONS

Our objective is to determine the efficacy and added value of stone localization using intraoperative ultrasound guidance.

Eosinophilic Sialodochitis: An Underrecognized Type-2 Inflammatory Salivary Duct Disease

Álvar Sánchez Barrueco[1], **Rocío Carpintero Díaz**[2], **Virginia Ruiz San José**[1], **Gonzalo Díaz Tapia**[1], **José Miguel Villacampa Aubá**[2], **Carlos Cenjor Español**[2], **Pilar Benavent Marín**[2]

[1]*Villalba General University Hospital;* [2]*Fundación Jiménez Díaz University Hospital*

BACKGROUND & AIM

Eosinophilic sialodochitis is a rare and probably underrecognized inflammatory disorder of the major salivary glands, characterized by recurrent glandular swelling, eosinophil-rich mucous plugs and frequent association with type-2 inflammatory comorbidities. Its nonspecific presentation often leads to delayed diagnosis and misclassification as other causes of chronic obstructive sialadenitis. This study aimed to describe the clinical phenotype, diagnostic findings, glandular distribution, therapeutic management and quality-of-life impact of eosinophilic sialodochitis in a multicentre cohort of 11 patients.

MATERIAL & METHODS

A retrospective multicentre observational study was conducted including 11 patients diagnosed between 2020 and 2025. Diagnosis was based on recurrent obstructive salivary symptoms, eosinophil-predominant salivary cytology and/or biopsy, and exclusion of other causes of chronic salivary gland inflammation. Demographic, clinical and procedural variables were collected, including disease duration, mucous strands, peripheral eosinophilia, type-2 comorbidities, affected glands, sialendoscopies, intraductal steroid instillations and biological treatment. Health-related quality of life was assessed using the Chronic Obstructive Sialadenitis Questionnaire. Descriptive statistics and exploratory bivariate analyses were performed.

RESULTS

Eleven patients were included. The cohort showed a predominantly female, middle-aged profile, with several years of recurrent symptoms before diagnosis. Eosinophil-predominant salivary cytology was positive in all evaluable cases and represented the main diagnostic finding. Most patients presented peripheral eosinophilia and visible mucous strands, supporting a type-2 inflammatory phenotype. Asthma and chronic rhinosinusitis with nasal polyps were common associated comorbidities, while eosinophilic otitis was not observed. Glandular involvement was mainly parotid and frequently bilateral, although mixed parotid-submandibular and isolated submandibular patterns were also identified. Repeated gland-preserving procedures were required, including sialendoscopy and intraductal steroid instillations. Quality-of-life impairment was severe. No statistically significant associations were found between quality-of-life scores and demographic, clinical, glandular or procedural variables.

CONCLUSIONS

Eosinophilic sialodochitis should be considered in patients with recurrent obstructive salivary gland swelling, particularly when mucous strands, peripheral eosinophilia or type-2 inflammatory comorbidities are present. Salivary cytology is a simple and highly useful diagnostic tool. Despite its non-malignant nature, this condition has a marked impact on quality of life. Management should combine gland-preserving sialendoscopy with individualized medical control of the underlying eosinophilic inflammation.

OP-1281

ACCESS TO SALIVARY DUCTS AND DUCT NAVIGATION: Tips And Tricks

Mohamed Fawzy Fathalla[1]

[1]*Suez university*

BACKGROUND & AIM

Effective duct access is a critical and key step for performing a diagnostic or therapeutic sialendoscopy. Accessing and navigating the salivary ducts, (Stensen's) and (Wharton's) ducts, sometimes pose clinical challenges due to anatomical variations or disturbed ductal anatomy.

MATERIAL & METHODS

This presentation reviews the anatomical considerations, highlights radiological landmarks, and outlines key principles for identifying and accessing ductal papillae. It describes the specialized sets of instruments including cheek retractors, multiple sizes of salivary duct probes, dilators, conical dilators, and bougies used for duct navigation and dilation. Practical techniques

and tips for atraumatic handling, proper visualization using magnification tools, and conservative gland massage to facilitate duct access are emphasized. Also, focusing on the tips and tricks for difficult papillae situations.

RESULTS

The experience from live surgical courses and clinical practice underlines the importance of careful identification and dilation of the papilla to prevent complications such as false passages. The differential difficulty of papilla identification and duct navigation between the parotid and submandibular ducts is demonstrated.

CONCLUSIONS

Mastery of salivary duct access techniques facilitates safe and effective diagnostic and therapeutic sialendoscopy procedures. Adoption of standardized instruments and application of atraumatic handling principles can improve clinical outcomes. This knowledge is essential for otolaryngologists, head and neck surgeons, and clinicians involved in salivary gland disorders.

OP-1282

Sialendoscopy In The Management Of Sublingual Gland Stone.

Jeong Kyu Kim[1], **Dong Won Lee**[1]

[1]*Daegu Catholic University*

BACKGROUND & AIM

Since the sublingual gland (SLG) stone is rare and appears in the middle of the floor of the mouth, it can easily be mistaken for the mid-portion submandibular gland (SMG) stone. In this study, we present the clinical, radiological, and sialendoscopic findings of a series of SLG stones treated at a single institute.

MATERIAL & METHODS

This is a retrospective study. The subjects who underwent sialolithotomy with SLG stones between March 2008 and September 2025 were included. Data on the subject's symptoms, CT, and sialendoscopy were collected.

RESULTS

Among 1334 subjects who underwent surgery for salivary gland stones, 6 subjects with SLG stones were included in this study. Five subjects complained of SMG swelling, and 1 subject complained of oral floor swelling and pain. CT scan revealed stones in the mid-portion of the floor of the mouth in all 6 subjects. All subjects underwent transoral surgery combined with sialendoscopy, however none of the subjects had been diagnosed as SLG stones before surgery. In 2 subjects, stones were identified in the Bartholin's duct of SLG, and in others the absence of stones in the SMG duct led to the diagnosis of SLG stones. In 2 subjects with stones identified in the Bartholin's duct, the stone was removed using a basket through the sialendoscopy. In 4 subjects, the stone was removed by dissecting the SLG parenchyma below the SMG duct and lingual nerve.

CONCLUSIONS

Sialendoscopy was useful in identifying and removing stones in the SLG duct. The absence of stones in the SMG duct during sialendoscopy for the mid-portion of the floor of the mouth stones can be used as a clue to the diagnosis of SLG stones.

OP-1283

Optimizing Salivary Duct Stenting: Systematic Review

Pilar Benavent Marín[1], **Alvaro Sanchez Barrueco**[2], **Marta Santiago Horcajada**[1], **Javier Morales Dominguez**[1], **José Miguel Villacampa Aubá**[1]

[1]*Fundación Jiménez Díaz University Hospital;* [2]*Villalba General Hospital*

BACKGROUND & AIM

Intraductal salivary duct stents are widely used as adjuncts to sialendoscopy in salivary obstructive disorders (SODs), yet practice varies regarding indications, stent type, dwell time, fixation, and intrastent irrigation. This variability and inconsistent reporting of stent-related adverse events hinder protocol optimization and the development of improved fixation techniques. Aim: to systematically synthesize evidence on intraductal stenting in SODs and evaluate whether stent strategy and stent-related complications are associated with recurrence-free survival (RFS) and quality of life (QoL) outcomes. Hypothesis: stent strategy and stent-related complications modify RFS and patient-reported outcomes.

MATERIAL & METHODS

Systematic review with planned meta-analysis per Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020. We included patients with major salivary gland salivary obstructive disorders (SODs) treated with sialendoscopy and/or combined gland-preserving approaches involving intraductal stent placement; comparators (no stent/alternative strategies) were included when available. We extracted stent type/material/size, dwell time, fixation, and

intrastent irrigation (yes/no; solution/protocol) when reported. Primary outcome was recurrence-free survival (RFS; time-to-recurrence and/or recurrence at follow-up). Secondary outcomes included stent-related complications (migration, obstruction, infection), unplanned removal, re-intervention/sialadenectomy, and quality of life (QoL) using generic or chronic obstructive sialadenitis–specific questionnaires when available. Prespecified subgroup analyses: gland (parotid vs submandibular), obstruction (stenosis vs sialolithiasis vs mucous plugs), approach (pure vs combined), stent parameters, irrigation, and fixation type. Databases: MEDLINE, Embase, Cochrane, Scopus/Web of Science, LILACS. Two reviewers screened/extracted; risk of bias with RoB 2 and ROBINS-I; random-effects pooling with 95% confidence intervals when appropriate.

RESULTS

We identified 1,985 database records and 130 additional records; after removing 983 duplicates, 1,132 records were screened and 182 full texts assessed. Sixty studies met inclusion criteria. Reporting and protocols were highly heterogeneous. Stent dwell time was reported in 46/60 studies (77%; 95% CI 65–86), with a median duration of 14 days (IQR 14–21; range 1–90). Stent device/type was reported in 50/60 (83%), whereas fixation type was explicitly reported in 20/60 (33%). Adjunctive postoperative care was variably reported: antibiotics in 16/60 (27%) (explicit use in 7/60, 12%; 95% CI 6–22), oral corticosteroids in 15/60 (25%), and intraductal steroids in 54/60 (90%) with variable timing. Intrastent/duct irrigation was inconsistently reported (16/60, 27%). Early stent removal/extrusion was described in ≥7/60 studies (~12%). QoL outcomes were rarely captured (3/60, 5%).

CONCLUSIONS

This systematic review summarizes real-world intraductal stenting practices in salivary obstructive disorders, highlighting marked variability and incomplete reporting in indications, fixation, dwell time, irrigation, and adjunctive medications. The final synthesis is expected to clarify how stent-related complications and protocol choices relate to recurrence-free survival and available quality-of-life outcomes. These findings may support a standardized stent-reporting framework and guide prospective comparative studies, including the development and evaluation of improved stent fixation and postoperative management strategies.

OP-1284

A Decade Of Salivary Gland Interventions: Trends, Outcomes And The Expanding Role Of Minimally Invasive Techniques

Hayfa Sheikh[1], **Faizan Shah**[1], **Irfan Khan**[1], **Muhammad Shakeel**[1]

[1]*ENT department, Aberdeen Royal Infirmary, Aberdeen, United Kingdom*

BACKGROUND & AIM

Disorders of the salivary glands represent a heterogeneous group of conditions including sialolithiasis, chronic sialadenitis, obstructive pathology, and neoplasia. Management has evolved with the introduction of minimally invasive techniques such as sialoendoscopy, reducing the need for gland excision. This study presents a 10-year retrospective review of all patients undergoing salivary gland intervention at a tertiary centre.

MATERIAL & METHODS

A retrospective review was conducted for patients undergoing sialoendoscopy, submandibular gland excision, parotidectomy, or sialography between 2016 and 2026. Demographics, indications, procedure type, complications, duration of hospital stay, requirement for further intervention and outcomes were analysed. Statistical analysis was carried out using SPSS.

RESULTS

A total of 486 patients were identified (mean age 52.3 years; 58% female). Indications included obstructive sialolithiasis (46%), chronic sialadenitis (28%), benign neoplasms (18%), and suspected malignancy (8%). Gland preservation was achieved in 72% of obstructive cases managed endoscopically. Overall complication rates were lowest in the sialoendoscopy group. Temporary facial nerve weakness occurred in % of parotidectomies, with permanent weakness in 1.8%. Median length of stay was day-case for sialoendoscopy and 1.4 days for gland excision.

CONCLUSIONS

Over the past decade, minimally invasive techniques have played an expanding role in salivary gland management, with sialoendoscopy demonstrating low complication rates and high gland preservation. Open gland excision remains essential for neoplastic disease but carries higher morbidity.

Retrospective Analysis (2018-2025) Of Sialoendoscopy Activity In Marne La Vallée Hospital: Learning Curve And Clinical Cases

Torti[1]

[1]*GHEF (grand hopital de l'est francilien)*

BACKGROUND & AIM

In two thousand and eighteen we started the activity in the department

MATERIAL & METHODS

We started with two sialondoscpoe type ail in one

We offer sialendoscopy under general anesthesia

RESULTS

88 eighty eight surgeries were performed under general anesthesia in day hospital;

6 patients had 2 procedures; 1 patient had 3 procedures.

Most of the patients had lithiasic pathology of the submandibular gland

(59 submandibular glands - 19 parotid glands).

The medium age is 45 years with extremes of 4 and 81 years;

45 men and 43 women.

20 diagnostic procedures were performed for Sjogren's syndrome, juvenile recurrent parotitis and the side effect of radioactive iodine therapy (131I).

68 therapeutic procedures were performed: 58 for lithiasis diseases and 10 for stenosis diseases .

Two procedures required a Yag laser.

CONCLUSIONS

The sialendoscopy is a safe surgical alternative with few comorbidities.

OP-1286

Treatment Selection In Sialolithiasis: Impact Of Stone Size And Location

Nurdoğan Ata[1], **Kayhan Öztürk**[2]

[1]*Department of Otorhinolaryngology, Selçuk University Faculty of Medicine, Konya, Turkiye.;* [2]*Department of Otorhinolaryngology, Medicana Hospital, Konya, Turkiye.*

BACKGROUND & AIM

Sialolithiasis is the most common disease of the salivary glands, and its management has evolved toward minimally invasive techniques. However, treatment selection remains challenging and is primarily influenced by stone size and anatomical location. We hypothesized that both stone size and localization significantly affect the choice of treatment modality.

MATERIAL & METHODS

This retrospective study included 40 patients diagnosed with sialolithiasis and treated at a tertiary otolaryngology center. Demographic characteristics (age, sex), gland involved (submandibular or parotid), side of involvement, number of stones, stone size (mm), and treatment modality (sialoendoscopy, transoral removal, or gland excision) were recorded. Stone sizes were evaluated individually in patients with multiple stones. Statistical analysis was performed to assess the relationship between treatment modality and stone size, as well as clinical patterns related to stone location.

RESULTS

The mean age of patients was 37.9 ± 14 years (range: 7–63), with a male predominance (75%). The submandibular gland was affected in 75% of cases. The mean stone size was approximately 9.8 mm (range: 2–30 mm). Sialoendoscopy was primarily performed in patients with smaller stones (approximately <5 mm), whereas Holmium laser lithotripsy and transoral removal was more common in intermediate-large sized Stones. Gland excision was reserved for larger or complex cases, particularly when stones were located within the gland parenchyma rather than the ductal system. Stone size differed significantly between treatment groups ($p < 0.05$). Intraparenchymal localization was strongly associated with the need for gland excision.

CONCLUSIONS

Treatment selection in sialolithiasis is strongly influenced by both stone size and anatomical location. While minimally invasive techniques are effective for small and distal ductal stones, intraductal stones of the submandibular gland that are palpable intraorally are highly suitable for removal via a transoral approach. In addition, holmium laser lithotripsy is highly effective in reducing the size of large ductal stones, facilitating their subsequent extraction. In contrast, intraparenchymal stones often

necessitate gland excision. These findings support a tailored treatment strategy based on both stone size and localization to optimize clinical outcomes.

OP-1287

A Retrospective Analysis Of Surgical Treatment For Obstructive Sleep Apnea And Snoring

Gagauz Alexei[1], **Zveaghintev Piotr**[1]

[1]*Department of Otorhinolaryngology, Nicolae Testemițanu State University of Medicine and Pharmacy, Chișinău, Republic of Moldova*

BACKGROUND & AIM

Obstructive sleep apnea syndrome (OSAS) is a multidisciplinary disorder with a high prevalence in the adult population, averaging 22%, and occurs significantly more frequently in men. The disease represents a serious medical and socio-economic problem, being associated with an increased risk of cardiovascular complications, reduced quality of life and work capacity, as well as increased healthcare costs. Surgical treatment remains an important therapeutic option in patients with anatomically determined upper airway obstruction.

Aim of the Study

To evaluate the effectiveness of combined surgical treatment in patients with obstructive sleep apnea syndrome.

MATERIAL & METHODS

A retrospective analysis of clinical data was conducted in 524 patients diagnosed with OSAS who underwent treatment in a specialized ENT clinic between 2016 and 2021. The patients' age ranged from 18 to 66 years; 62% were men and 38% were women. Postoperative follow-up was carried out for up to 5 years, with control examinations every six months. All patients underwent combined surgical intervention including septoplasty, turbinoplasty, and uvulopalatoplasty. Surgical procedures were performed under general anesthesia using a diode semiconductor laser with a power of 12 W and a wavelength of 980 nm, in a contact–non-contact and submucosal mode. Treatment effectiveness was assessed based on the dynamics of clinical symptoms and the results of somnological examinations.

RESULTS

After surgical treatment, most patients demonstrated significant clinical improvement. Resolution or marked reduction of apnea episodes, decreased snoring intensity, reduced daytime sleepiness and fatigue, as well as improved sleep quality and overall well-being were observed. Complete resolution of all symptoms was recorded in 45% of patients. In 88% of patients, the disappearance of apnea episodes was noted in combination with a significant reduction in snoring. Overall clinical improvement was observed in 98% of patients. All patients were advised to perform a set of exercises aimed at preventing recurrence of sleep apnea.

CONCLUSIONS

1. Combined surgical treatment, including septoplasty, turbinoplasty, and uvulopalatoplasty, is an effective therapeutic method for obstructive sleep apnea syndrome when appropriate indications are present.

2. Long-term postoperative follow-up and the implementation of preventive measures, including breathing and myofunctional exercises, contribute to the preservation of achieved results and reduce the risk of OSAS recurrence.

3. Laser-assisted surgery performed in a contact–non-contact and submucosal mode represents a method of choice in the surgical treatment of obstructive sleep apnea syndrome.

KEYWORDS

Obstructive sleep apnea syndrome, diode laser, septoplasty, turbinoplasty, uvulopalatoplasty.

OP-1288

Epiglottoplasty In Obstructive Sleep Apnea: Outcomes And Determinants Of Surgical Success

Burak Çelik[1], **Serkan Şerifler**[1], **Kadir Şinasi Bulut**[1], **Mehmet Ali Bababemez**[1]

[1]*Ankara Yıldırım Beyazıt University Faculty of Medicine*

BACKGROUND & AIM

Drug-induced sleep endoscopy (DISE) has become an essential tool for identifying the level and pattern of airway obstruction in patients with obstructive sleep apnea syndrome (OSAS). Epiglottic collapse is an underrecognized cause of airway obstruction, and targeted surgical approaches such as epiglottoplasty may improve outcomes. This study aimed to evaluate the clinical and polysomnographic outcomes of epiglottoplasty in OSAS patients diagnosed with epiglottic collapse via DISE and to assess factors affecting surgical success.

MATERIAL & METHODS

This retrospective study included 10 patients diagnosed with OSAS between 2019 and 2022 who underwent DISE evaluation. Following identification of obstruction sites, all patients underwent epiglottoplasty. Additional procedures were performed in selected cases: anterior palatoplasty in two patients and expansion sphincter pharyngoplasty in one patient (performed in a second session), while one patient declined the latter intervention.

Preoperative and postoperative outcomes were compared using polysomnographic parameters including apnea-hypopnea index (AHI), minimum oxygen saturation (SpO_2), and Epworth Sleepiness Scale (ESS). Surgical success was defined as a ≥50% reduction in AHI and a postoperative AHI <20. Statistical analyses included paired t-test, independent samples t-test, Fisher's exact test, and Spearman correlation analysis.

RESULTS

The mean age of the patients was 45.7 ± 6.3 years, and 80% were male. Significant improvements were observed postoperatively in all evaluated parameters. Mean AHI decreased from 42.0 ± 12.2 to 24.5 ± 10.2 (p=0.001), minimum SpO_2 increased from 77.0 ± 4.0% to 82.6 ± 4.3% (p=0.003), and ESS scores decreased from 14.3 ± 2.3 to 8.8 ± 2.7 (p=0.001) .

Surgical success was achieved in 40% of patients. Multilevel collapse was significantly associated with the need for additional surgical intervention (p=0.033) and with surgical failure (p=0.01) . Higher body mass index (BMI) and higher preoperative AHI were also significantly associated with poorer outcomes. Postoperative AHI showed strong correlation with preoperative AHI (r=0.81, p=0.004) and BMI (r=0.68, p=0.03)

CONCLUSIONS

Epiglottoplasty is an effective surgical option for selected OSAS patients with epiglottic collapse identified by DISE, leading to significant improvements in polysomnographic and clinical parameters. However, surgical success is influenced by factors such as BMI, baseline disease severity, and presence of multilevel airway collapse. Comprehensive preoperative evaluation with DISE is crucial for optimizing patient selection and guiding individualized surgical planning.

OP-1289

Clinical Outcomes Of Oropharyngeal Surgery To Improve Sleep Quality Surgery In 100 Patients: A Five-Year Tertiary Center Experience

Muhammet Fatih GÖKMEN[1], **Oğuzhan UYAR**[1], **Merih ÖNAL**[1], **Mete Kaan BOZKURT**[1]

[1]*Selcuk University, Medical School, ENT Department*

BACKGROUND & AIM

Oropharyngeal surgery is among the most commonly performed procedures in the field of otolaryngology aimed at improving sleep quality, and clinical outcomes vary among procedures targeting oropharyngeal anatomical structures. While the clinical outcomes of these surgical procedures, which generally aim to improve sleep quality, are generally satisfactory, patients' clinical responses to the procedures can sometimes be negative. Results may vary depending on age, gender, weight, tobacco/alcohol use, and surgical technique. The aim of this study is to evaluate age, gender, weight, tobacco/alcohol use, and surgical techniques in patients have undergone oropharyngeal surgery and to identify factors associated with clinical outcomes.

MATERIAL & METHODS

This study received ethical approval from the Local Ethics Committee of University. Surgeries on oropharyngeal anatomical structures performed by participating faculty members were identified through the hospital information system, and demographic data such as age, gender, and date of surgery were recorded. Patients' electronic medical records were reviewed individually to assess surgical indications and surgical techniques. Sleep quality was evaluated on a scale of 10 (excellent) to 0 (poor), using the Numerical Rating Scale (NRS) as a reference.

RESULTS

A total of 100 patients (age range: 25–71 years) who underwent oropharyngeal surgery were included in the study. Of these, 82 were male and 18 were female. The rate of postoperative relief was observed. The greatest postoperative relief was observed in patients of a male gender and those below the average age. Among smokers and alcohol consumers, the relief rate remained below the general average. Weight loss averaged +/-. The average weight of patients who did not show clinically significant relief in the 100 cases.

CONCLUSIONS

Oropharyngeal surgery is a common procedure with generally positive clinical outcomes in patients with poor sleep quality. An improvement in sleep quality has generally been observed in patients, and only rarely does it require a return to medical treatment or a second surgical intervention. Most patients are followed up without the need for additional treatment or a second surgery. Lifestyle changes remain the most important factor in improving the clinical response.

Multilevel Surgery For Obstructive Sleep Apnea: Significant Improvement In A 27-Patient Series

Catarina Martins Pinto[1], **Carlos Matos**[1], **Inês Veloso**[1], **Mariana Santos**[1]

[1]*ULS Alto Ave*

BACKGROUND & AIM

Surgical management remains an important therapeutic option for selected patients with obstructive sleep apnea (OSA), particularly when continuous positive airway pressure is not tolerated or declined.

Barbed reposition pharyngoplasty (BRP) has emerged as a contemporary palatal technique aimed at addressing lateral pharyngeal wall collapse.

This study aimed to evaluate respiratory outcomes following surgical treatment for OSA in a single-center retrospective series.

MATERIAL & METHODS

We conducted a retrospective study including 27 patients who underwent surgical treatment for OSA. Ten patients (37%) presented with severe OSA preoperatively.

Most patients underwent multilevel upper airway surgery. Barbed reposition pharyngoplasty (BRP) was the most frequently performed palatal procedure. Additional procedures included radiofrequency tongue base reduction and submucosal radiofrequency tunneling of the soft palate when indicated. All nasal surgeries included septoplasty combined with inferior turbinate reduction.

The apnea-hypopnea index (AHI) was compared before and after surgery using the Wilcoxon signed-rank test for paired samples. Surgical success was defined according to Sher criteria (≥50% reduction in AHI and postoperative AHI <20 events/hour).

RESULTS

Median AHI significantly decreased from 27.7 to 11.1 events/hour following surgery (Wilcoxon signed-rank test: $Z = -4.52$, $p < 0.001$), corresponding to an approximate 60% reduction. Improvement was observed in 26 of 27 patients. The effect size was large ($r = 0.87$).

Surgical success according to Sher criteria was achieved in 63.0% of patients (17/27).

CONCLUSIONS

Multilevel surgical treatment resulted in significant objective respiratory improvement, with a large effect size and consistent reduction in AHI across nearly all patients. These findings reinforce the role of contemporary upper airway surgery in carefully selected OSA patients.

OP-1291

Obstructive Sleep Apnea In Women: Relevance Of Early Diagnosis And PAP Adherence In A Clinical Cohort

Alexandra Rodriguez-Morales[1], **Liamnys López Alejo**[2]

[1]Hospital Internacional La Catolica; [2]Torre Medica NAOS Plaza

BACKGROUND & AIM

Obstructive sleep apnea (OSA) in women remains underdiagnosed despite its major global burden. Female patients often present with less typical phenotypes, including insomnia, fatigue, nocturia, morning headache, mood disturbances, and symptoms attributed to menopause, leading to delayed recognition and treatment. This delay limits therapeutic opportunity in a population whose cardiovascular, metabolic, cognitive, and quality-of-life risks are frequently underestimated. We hypothesized that analysis of the female cohort in our study would demonstrate a clinically relevant burden of OSA and a favorable PAP adherence profile, supporting the need for more active diagnostic strategies and gender-sensitive clinical pathways in women.

MATERIAL & METHODS

A retrospective analysis was performed of the women included in a clinical cohort of 64 patients with OSA managed in private otolaryngology and sleep medicine practice at Hospital La Católica and Centro Médico Naos Plaza, and treated predominantly with APAP AutoSet. Variables analyzed included age, body mass index (BMI), baseline severity according to the apnea-hypopnea index, objective adherence defined as the percentage of nights with device use >4 hours at 1 month, 6 months, and 1 year, mask type, and treatment abandonment.

RESULTS

Of the 64 patients analyzed, 24 (37.5%) were women. Mean female age was 59.0 years and mean BMI was 33.4 kg/m². Moderate-to-severe OSA was identified in 15/24 women (62.5%), including 7/24 (29.2%) with severe OSA. Severe disease was significantly less frequent in women than in men from the same cohort (29.2% vs. 62.5%; OR 0.25; 95% CI 0.08–0.73; p=0.019), although the burden in women remained clinically relevant. PAP adherence, defined as the percentage of nights with device use >4 hours, was 82.0% at 1 month, 83.0% at 6 months, and 75.0% at 1 year, descriptively higher than in men. Treatment abandonment was lower in women than in men, without statistical significance (16.7% vs. 27.5%; OR 0.53; 95% CI 0.15–1.89; p=0.38). N20 nasal mask use was more frequent in women.

CONCLUSIONS

In this cohort, women represented a clinically meaningful subgroup with a relevant burden of moderate to severe OSA and a favorable PAP adherence profile once treatment was initiated. In an international context where female OSA remains underdiagnosed and clinically underestimated, our findings challenge the persistently low level of diagnostic suspicion in women and support more active strategies for early detection and intervention specifically directed at this population. Rather than merely reiterating that OSA exists in women, this study provides real-world clinical evidence that, when identified and treated in a timely manner, female OSA can achieve favorable and sustained adherence outcomes.

OP-1292

Nasopharyngeal Stenosis: The Scaring Enemy In OSA Surgery

Mohamed Eesa[1], **Ehsan Hendawy**[1], **Mohammad Waheed El-Anwar**[1]

[1]Otorhinolaryngology-Head & Neck Surgery at Zagazig University, Egypt.

BACKGROUND & AIM

Nasopharyngeal stenosis (NPS) is a rare condition of obstruction of the communication between the nasopharynx and oropharynx due to concentric scar contracture of the tonsillar pillars, soft palate, and posterior pharyngeal wall. Definitive treatment is often very difficult and may induce more scarring and restenosis. the aim is to describe our protocol in management of OSA due to NPS with different grades (1,2 and 3) and show results in each grade.

MATERIAL & METHODS

NPS was classified into; grade I: minimal scar tissue, no soft palate lengthening, adherence between lateral aspects of the palate and posterior pharyngeal wall, grade II: moderate scar tissue, soft palate lengthening, with a small opening in the soft palate (1-2 cm in diameter), and grade III: excessive scarring with complete fusion of soft palate and tonsillar pillars with the posterior pharyngeal wall (atresia) or stenosis leaving a pinpoint hole less than 1 cm in diameter (Krespi & Kacker, 2002). each grade was offered a specific surgical intervention and the following were the outcome measures:1. A subjective measure of NPS by upper airway endoscopy and oral cavity exploration. 2. Baseline, 4-week, 3-month, and 1-year Visual Analog Scale (VAS 0-10) for nasal breathing, snoring by bed partner, and dysphagia (0 “no complaints” to 10 “severe complaint”). 3. Baseline and 1-year follow-up polysomnography. 4. Short-term morbidity and adverse events especially VPI.

RESULTS

Eleven patients were included; 9 completed the follow-up; 7 males and 2 females. Preoperatively, all patients had OSA that was objectively documented by polysomnography with apnea hypopnea index (AHI) ranged between 5.6 and 38.8 (mean = 23.2 +- 9.37). Postoperatively, the AHI showed significant improvement to a mean of 12.35 +- 3.75 (t = 5.0089, P < .001; Table 1).

Postoperative dry throat and inability to clear the throat were reported by all patients but were temporary and resolved com pletely within 3 weeks. Dysphagia showed early worsening, but it improved completely at 3 months postoperatively and remained throughout the follow-up period

CONCLUSIONS

OSA due to NPS is a very challenging surgical scenario. trials for surgical intervention may worsen the condition and CPAP is not helpful for those category of patients. our grading system with its surgical implications gives a simple protocol for management of such difficult condition

palatoplasty, pharyngoplasty, sleep disorders, soft palate, velopharyngeal function

OP-1293

Application Of AI-Based Upper Airway Narrowing Analysis And Inferior Turbinate Radiofrequency Ablation In Obstructive Sleep Apnea

LIN WEI CHIEH[1,2]

[1]*AllHeart Clinic, Zhongqing;* [2]*AllHeart Medical System*

BACKGROUND & AIM

Obstructive sleep apnea (OSA) is characterized by recurrent upper airway collapse. While inferior turbinate hypertrophy contributes to nasal obstruction and exacerbates OSA, objective evaluation of surgical outcomes remains challenging. This study evaluates the efficacy of inferior turbinate Radiofrequency Ablation using three-dimensional computed tomography (CT) and artificial intelligence (AI)-based airway narrowing analysis.

MATERIAL & METHODS

We retrospectively analyzed 11 OSA patients who underwent inferior turbinate Radiofrequency Ablation. Pre- and post-operative (3–6 months) CT scans were processed using AI software to quantify upper airway volume (UAV), minimum cross-sectional area (MCA), simulated respiratory pressure (SRP), and simulated narrowest airway flow (SNAF). Paired t-tests were used for statistical analysis.

RESULTS

Post-operatively, the mean MCA significantly increased from 136.26 ± 76.50 mm^2 to 199.09 ± 100.85 mm^2 (P = 0.020). Functional parameters showed significant improvement: mean SRP decreased from 17.98 ± 18.48 Pa to 7.45 ± 6.50 Pa (P = 0.050), and mean SNAF decreased from 5.68 ± 5.21 m/s to 2.76 ± 2.54 m/s (P = 0.035). Although UAV increased (20148.98 to 24088.80 mm^3), the change was not statistically significant (P = 0.198).

CONCLUSIONS

Inferior turbinate Radiofrequency Ablation significantly improves upper airway anatomical structure and aerodynamic performance in OSA patients. AI-based analysis provides objective, quantifiable metrics for surgical assessment, supporting its role in precision treatment for OSA.

Effects Of Expansion Sphincter Pharyngoplasty On Polysomnographic And Clinical Outcomes In Obstructive Sleep Apnea

İlker Akyıldız[1], **Abdullah Musa Altaş**[2], **Gökhan Toptaş**[1], **Latif Akan**[1], **Güleser Saylam**[3], **Murad Mutlu**[1]

[1]*University of Health Sciences Etlik City Hospital, Department of Otorhinolaryngology Head and Neck Surgery, Ankara, Turkey;* [2]*University of Health Sciences Sincan Training and Research Hospital, Department of Otorhinolaryngology Head and Neck Surgery, Ankara, Turkey;* [3]*Lokman Hekim University Faculty of Medicine, Department of Otorhinolaryngology Head and Neck Surgery, Ankara, Turkey*

BACKGROUND & AIM

Expansion sphincter pharyngoplasty (ESP) is an established surgical technique for the treatment of obstructive sleep apnea (OSA), particularly in patients with retropalatal collapse. This study aimed to comprehensively evaluate the effects of ESP on polysomnographic parameters, oxygenation, sleep efficiency, and subjective daytime sleepiness in patients intolerant to continuous positive airway pressure therapy.

MATERIAL & METHODS

A total of 43 adult patients with OSA (mean age: 41.0 ± 7.3 years; 76.7% male) who underwent ESP were retrospectively analyzed. Preoperative and postoperative polysomnographic variables, including apnea–hypopnea index (AHI), minimum oxygen saturation, and sleep efficiency, were recorded. Subjective daytime sleepiness was assessed using the Epworth Sleepiness Scale (ESS). Pre- and postoperative values were compared using paired statistical tests according to data distribution.

RESULTS

The mean follow-up period was 6.3 ± 0.7 months. ESP resulted in a significant reduction in respiratory events, with AHI decreasing from 27.7 ± 14.7 to 18.0 ± 11.6 (p < 0.001). ESS scores improved from 8.9 ± 2.7 to 7.5 ± 2.4 (p < 0.001), reflecting a meaningful decrease in daytime sleepiness. Minimum oxygen saturation increased from 82.7 ± 5.9% to 84.1 ± 7.2% (p = 0.001). Sleep efficiency demonstrated a significant improvement, rising from 83.5 ± 9.2% to 87.0 ± 5.5% (p = 0.001).

CONCLUSIONS

ESP results in significant improvements in both objective polysomnographic parameters and subjective symptoms in patients with OSA. Beyond reducing respiratory events, the procedure enhances sleep quality, oxygenation, and daytime alertness, supporting its role as an effective surgical option in appropriately selected patients.

Analysis Of Positional Obstructive Sleep Apnea Features In 12,000 Patients At A Sleep Center

Cíntia Felicio Adriano Rosa[1,3], **Karina Angélica Soto Chillcce**[1], **Michel Burihan Cahali**[3], **Marcela Souza Boldt**[1], **Victor Henrique Dominiak Soares**[2], **Ordival Augusto Rosa**[1], **Pedro Henrique Vicari Passos**[4], **Matheus Roberto Schetz Alves**[4], **Enrico Guido Oliveira Minniti**[4], **Jefferson Ernani Rodrigues**[5], **Giuliana Rita Wolski Ribas**[1]

[1]Hospital IPO; [2]Federal University of Paraná, Curitiba, Brazil.; [3]Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, Brazil.; [4]Pontificia Universidade Católica do Paraná, Curitiba, Brazil; [5]Federal University of Sao Paulo, Sao Paulo, Brazil.

BACKGROUND & AIM

Purpose: This study aims to determine the prevalence of Positional Obstructive Sleep Apnea (POSA) and investigate the factors associated with this condition.

MATERIAL & METHODS

Methods: Associations with clinical and polysomnographic variables were studied through a retrospective analysis of patients who underwent polysomnography between September 2017 and August 2023. Participants were grouped based on the presence of POSA and further classified into supine-predominant position (p-POSA) and supine-exclusive position (e-POSA).

RESULTS

Results: The study included 12,036 patients with OSA, 61.6% men and 38.4% women. Considering the entire cohort, 66.3% of patients were classified as having POSA, while 27.8% met criteria for e-POSA. Compared to non-POSA patients, POSA had lower apnea-hypopnea index (24.1 versus 44.4 events/h, p<0.001), lower mean age (47.6 versus 48.3 years, p=0.012), and lower BMI (29.2 versus 31.4 kg/m2, p<0.001). There was no significant difference in the prevalence of POSA between sex (p=0.921). However, women showed a higher prevalence of e-POSA compared to men (p<0.001). Patients with e-POSA had lower mean age than p-POSA (46.2 vs 48.6 years, p<0.001) and lower BMI (28.3 vs 29.8 kg/m2, p<0.001).

CONCLUSIONS

Conclusion: Our findings reveal that POSA is prevalent in our setting, affecting less obese patients with milder apnea severity. Although the age difference reached statistical significance, the effect size was trivial. Differences were observed concerning sex and disease severity.

Impact Of Obstructive Sleep Apnea Severity On Wearable Sleep Staging Accuracy: A Comparison With Polysomnography

Cíntia Felicio Adriano Rosa[1,2], **Mauricio Altenburger**[1], **Monique Kleina Alencar Furtado**[1], **Victor Henrique Dominiak Soares**[4], **Lívio Teixeira**[5], **Giuliana Rita Wolski Ribas**[4], **Marco Cesar Jorge Santos**[1,3], **Wesley Rosado Alarcon**[1]

[1]Hospital IPO; [2]Universidade de Sao Paulo; [3]PUC Parana; [4]Universidade Federal do Parana; [5]Universidade do Estado do Amazonas

BACKGROUND & AIM

Wearable devices are increasingly used for sleep monitoring; however, their accuracy in patients with sleep disorders remains uncertain. While prior studies have compared wearables with polysomnography (PSG) in healthy individuals, data in clinical populations are limited. This study aimed to compare sleep parameters obtained from wearable sleep monitoring with in-lab PSG in a clinical population and to evaluate the impact of OSA severity on device accuracy.

MATERIAL & METHODS

Cross-sectional study of adult patients undergoing simultaneous in-lab PSG and wearable sleep monitoring Apple Watch Series 8 between January and April of 2025. Sleep parameters were compared using intraclass correlation coefficients, Bland–Altman analysis, and multivariable regression.

RESULTS

A total of 39 participants were included (mean age 46.8±10.7 years), with obesity highly prevalent (mean BMI 32.2±5.1 kg/m²) and most presenting severe OSA (mean AHI 44.2±34.9 events/hour). Agreement between the wearable device and PSG was poor for all variables (ICC<0.50). The highest agreement was observed for sleep efficiency (ICC=0.452, p=0.003) and wake time (ICC=0.453, p=0.002), while sleep staging showed no significant agreement, particularly for REM (ICC=-0.003, 95% CI -0.320 to 0.310, p=0.507) and deep sleep (ICC=0.100, 95% CI -0.090 to 0.340, p=0.123). Bland–Altman analysis showed systematic bias, including underestimation of total sleep time and deep sleep and overestimation of light sleep, with wide limits of agreement, indicating poor individual-level accuracy. AHI correlated moderately with REM error (ρ=0.432, p=0.007). In multivariable analysis adjusted for age and BMI, AHI was the only independent predictor of error, associated with total sleep time (β=0.72, p=0.011) and REM sleep (β=0.32, p=0.001).

CONCLUSIONS

Wearable sleep staging accuracy appears to decrease with increasing OSA severity, with systematic bias and overall poor agreement compared to PSG, highlighting the need for further validation and refinement of wearable algorithms in clinical populations.

Association Of Obstructive Sleep Apnea Severity And The Apnea-Hypopnea Index With Sensorineural Hearing Loss, Speech Discrimination, Tinnitus, And Vertigo

Vadad SALEHNAJAFI[1], **Ozan GÖKDOĞAN**[1]

[1]*Department of Otorhinolaryngology-Head & Neck Surgery, Muğla Sıtkı Koçman University, Muğla Province Training and Research Hospital*

BACKGROUND & AIM

Obstructive sleep apnea syndrome (OSA) is a multisystem disorder affecting various organs, including the cochlear and vestibular systems, and can result in sensorineural hearing loss. This study aims to determine the impact of OSA severity on prevalence and level of hearing impairment, audiometric parameters, and audiovestibular symptoms.

MATERIAL & METHODS

This retrospective study reviewed records of 2,420 patients who underwent polysomnography during 2021-2024. Of these, 427 had audiometry testing for any indication. After excluding individuals aged <18 or >60 years, and those with congenital or middle ear diseases, 311 patients were included. Sensorineural hearing loss was defined as bone-conduction thresholds >20 dB, and decreased Speech-Discrimination as scores <88%. Associations between OSA severity (mild, moderate, severe) and decreased SD-rates, hearing loss at PTAs and 250–6000–8000 Hz (in each ear separately and either one of the ears), tinnitus, and vertigo were assessed using the chi-square test. These categorical variables were also evaluated with AHI as a covariate using the Mann-Whitney test. Bone-conduction thresholds (PTAs-250–6000–8000 Hz) and SD-rates across OSA severity groups were compared using the Kruskal–Wallis test (p<0.05). Correlations with AHI were assessed via Spearman's rank correlation. All normality tests were assessed using the Kolmogorov–Smirnov test.

RESULTS

Individuals' distribution among OSA-subgroups (mild_moderate_severe) was evaluated; cases, with SNHL in either of the ears at PTAs (13/84; 15.5%_32/88; 36.4%_53/139; 38.1%, chi-square:p=0.001, without mild-OSA:p=0.789), at 6000-8000 Hz (39/84; 46.4%_58/88; 65.9%_101/139; 72.7%, chi-square:p<0.001, without mild-OSA:p=0.279), with decreased SD-rate (12/84; 14.3%_25/88; 28.4%_52/139, 37.4%; chi-square:p=0.001, without mild-OSA:p=0.163), with tinnitus (21/84; 25%_20/88; 22.7%_36/139; 25.9%, chi-square:p=0.863), with vertigo (11/84; 13.1%_11/88; 12.5%_21/139; 15.1%, chi-square:p=0.836), (median-age: 44.5, R:19-59_47, R:21-60_48, R:24-60). AHI value was evaluated using the Mann-Whitney test for the existence of SNHL in either of the ears at PTAs (p=0.002), at 6000-8000 Hz (p<0.001), decreased SD-rate (p=0.002), tinnitus (p=0.254), and vertigo (p=0.808). In individuals with SNHL (thresholds >20dB), OSA-subgroups were assessed with bone-conduction thresholds at PTAs (R:p=0.988_L:p=0.553), 250Hz (R:p=0.571_L:p=0.449), 6000Hz (R:p=0.239_L:p=0.953), 8000Hz (R:p=0.278_L:p=0.785), and with SD-rates (R:p=0.961_L:p=0.538) using the Kruskal–Wallis test. AHI correlation with bone-conduction thresholds(>20dB) at PTAs (R:p=0.677_L:p=0.465), 250Hz (R:p=0.851_L:p=0.374), 6000Hz (R:p=0.208_L:p=0.619), 8000Hz (R:p=0.259_L:p=0.494), and with SD-rates (R:p=0.963_L:p=0.639) was evaluated via Spearman's correlation.

CONCLUSIONS

In OSA patients, sensorineural hearing loss prevalence is significantly higher in moderate and severe cases compared to mild-OSA, at the PTAs and 6000–8000 Hz thresholds. Speech-Discrimination rates below 88 are also more common in moderate-severe OSA. The probability of sensorineural hearing loss at the PTAs and 6000–8000 Hz is associated with higher AHI values. However, among patients with OSA-related sensorineural hearing loss, no significant association or correlation is observed between AHI value and either the severity of hearing loss or SD-rates. Additionally, no significant association is found between OSAS severity and the presence of tinnitus or vertigo symptoms.

OP-1298

Oropharyngeal Lateral Wall Collapse On Drug-Induced Sleep Endoscopy As A Predictor Of Hypoglossal Nerve Stimulation Response In Obstructive Sleep Apnoea: A Systematic Review

Sarah McBrinn[1], **Oliver Skan**[2], **Aphrodite Iacovidou**[1]

[1]*Imperial College London NHS Foundation Trust;* [2]*Chelsea and Westminster NHS Foundation Trust*

BACKGROUND & AIM

Hypoglossal nerve stimulation (HNS) is an established treatment for moderate-to-severe obstructive sleep apnoea (OSA) in patients intolerant of continuous positive airway pressure. Pre-operative drug-induced sleep endoscopy (DISE) is mandatory for HNS candidacy assessment, with complete concentric velopharyngeal collapse representing the only formally accepted DISE-based contraindication. The prognostic significance of oropharyngeal lateral wall (OLW) collapse — a common DISE finding — remains contested, with conflicting published evidence and no current consensus on its role in patient selection. The aim is to systematically evaluate whether OLW collapse identified on pre-operative DISE predicts surgical response to HNS in adults with OSA.

MATERIAL & METHODS

A systematic review was conducted in accordance with PRISMA 2020 guidelines (PROSPERO registration: [CRD420261347436]). MEDLINE, EMBASE, and Cochrane CENTRAL were searched in March 2026 with no date restrictions. Records were screened against predefined inclusion criteria. Studies were eligible if they enrolled adults with OSA undergoing HNS with any device, performed pre-operative DISE, reported OLW collapse and treatment response. Risk of bias was assessed using the Quality In Prognosis Studies (QUIPS) tool. Data were synthesised narratively due to anticipated heterogeneity in DISE protocols and outcome definitions. Two reviewers independently screened records and extracted data.

RESULTS

Nine studies comprising 824 patients were included. Complete OLW collapse was associated with significantly lower HNS response rates in three of five studies directly testing this association (57.8–66.7% versus 74.2–84.8%; p=0.024–0.042). On multivariate analysis in the largest study (n=343), the association was attenuated to non-significance (OR 0.57, 95% CI 0.26–1.22). One study reported a null finding and one identified partial OLW collapse as the failure-associated pattern (p=0.04). Substantial heterogeneity was observed across studies in DISE protocols, OLW classification systems, response definitions, and PSG outcome type. All studies were rated moderate or high risk of bias on QUIPS assessment.

CONCLUSIONS

Complete OLW collapse on DISE is associated with worse HNS outcomes in the majority of included studies, but conflicting evidence from well-powered cohorts — particularly the attenuation of effect on multivariate analysis — precludes its designation as a formal contraindication. Early evidence suggests that concurrent palatine tonsillectomy may partially mitigate the adverse prognostic effect of OLW collapse in patients with small tonsils. Standardisation of DISE reporting and prospective validation studies are required before OLW collapse can be incorporated into HNS candidacy criteria.

OP-1299

Personalized Selection Of Staged Surgical Therapy For Obstructive Sleep Apnea

Marina Budkovaia[1], **Dakhadaeva Patimat**[1]

[1]*Saint-Petersburg Research Institute of Ear, Throat, Nose and Speech*

BACKGROUND & AIM

To evaluate the efficacy of staged surgical correction targeting multiple levels of upper airway obstruction in patients with snoring/obstructive sleep apnea

MATERIAL & METHODS

This prospective single-center study included 47 adults (selected from 150 screened) with snoring/OSA and ENT pathology at the Saint-Petersburg Research Institute of ENT. Exclusion criteria: acute/exacerbated respiratory diseases, pregnancy. Assessment comprised STOP-BANG questionnaire, body mass index (BMI), ENT examination, DISE, paranasal sinus computed tomography, computerized rhinomanometry, sleep respiratory monitoring, and laboratory tests. Treatment strategy selection was based on DISE-identified obstruction levels, severity of OSA, and patient-specific factors, followed by staged UA correction.

RESULTS

Baseline distribution: primary snoring 10.6% (n=5), mild OSA 40.4% (n=19), moderate 6.4% (n=3), severe 42.5% (n=20); mean BMI 28.9±0.5; moderate/severe nasal obstruction in 80.9% (n=38). Stage 1 (intranasal/nasopharyngeal correction): performed

in 38 patients (inferior turbinate reduction ± septoplasty 94.7%, functional endoscopic sinus surgery 14.9%, adenoidectomy 10.5%). All reported subjective improvement in nasal breathing/sleep; complete snoring resolution in 8.5% (n=4). Continuous positive airway pressure (CPAP) compliance improved in 14.9% (n=7) with severe OSA; mandibular advancement device adaptation improved in 25.5% (n=12) with mild OSA and hypopharyngeal obstruction. Stage 2 (uvulopalatopharyngoplasty [UPPP] + tonsillectomy): performed in 17.2% (n=8). At 6 months: apnea-hypopnea index (AHI) decreased by 34.05 events/hour (−83.35%) in moderate/severe OSA, enabling CPAP discontinuation; AHI normalized in mild OSA. Primary UPPP+tonsillectomy (38.3%, n=18, mainly severe OSA with grade III–IV tonsillar hypertrophy): AHI reduced by 12.7 events/hour (−75.2%) at 6 months, with CPAP discontinuation in all cases.

CONCLUSIONS

A DISE-guided staged surgical strategy enables precise identification of obstruction levels and personalized treatment planning. This approach significantly improves nasal breathing, subjective sleep quality, and may eliminate snoring; enhances CPAP compliance in severe OSA and oral device adaptation in mild OSA; and substantially reduces AHI, allowing selected patients to discontinue CPAP therapy. Individualized selection of staged intervention represents an effective pathway to improve quality of life in snoring and OSA.

Association Between Obstructive Sleep Apnea Severity And Interstitial Cystitis/Bladder Pain Syndrome-Related Symptom Burden: A Cross-Sectional Observational Correlation Study

LATIF EMRE OZDEMIR[1], **MELISA ILAYDA KALKAN**[1], **HUSEYIN GUNIZI**[2], **YASİN AYSUN**[1], **ERKAN TEZCAN**[1], **ONUR KARSLI**[3]

[1]Department of Otorhinolaryngology, Head and Neck Surgery, University of Health Sciences, Antalya City Hospital, Antalya, Turkey; [2]Department of Otorhinolaryngology, Head and Neck Surgery, Faculty of Medicine, Akdeniz University, Antalya, Turkey; [3]Department of Urology, Antalya City Hospital, Antalya, Turkey

BACKGROUND & AIM

This study aimed to quantify the unadjusted associations between full-night polysomnographic parameters, including the apnea-hypopnea index (AHI), 3% oxygen desaturation index (ODI-3%), minimum oxygen saturation (minimum SpO_2), and T90, and validated O'Leary-Sant Interstitial Cystitis Symptom Index (ICSI) and Interstitial Cystitis Problem Index (ICPI) scores in patients with obstructive sleep apnea (OSA).

MATERIAL & METHODS

This cross-sectional observational study combined retrospectively extracted polysomnographic data with prospectively administered symptom questionnaires. Ninety-one patients with OSA were classified into three groups according to AHI: mild OSA (AHI 5-14.9 events/h, n=30), moderate OSA (AHI 15-29.9 events/h, n=32), and severe OSA (AHI >=30 events/h, n=29). ICSI, ICPI, visual analog scale (VAS) pain scores, and a three-night nocturia diary were administered at study participation. Because continuous variables deviated from normal distribution on the Shapiro-Wilk test, data were reported as median [interquartile range]. Between-group comparisons were performed using the Kruskal-Wallis test with Bonferroni-corrected Mann-Whitney U tests for post-hoc comparisons. Associations between polysomnographic parameters and symptom outcomes were evaluated using Spearman correlation analysis. The explanatory performance of ODI-3% and AHI for ICSI scores was explored using univariable linear regression and R^2 comparison. All reported associations are unadjusted correlations because multivariable adjustment was not performed.

RESULTS

ICSI symptom burden increased in a dose-dependent pattern across OSA severity groups (median ICSI: 6.6 -> 10.2 -> 12.7; $p<0.005$). ODI-3% showed a strong unadjusted correlation with ICSI ($r=0.785$, $p<0.001$), whereas T90 showed a strong correlation with VAS pain score ($r=0.839$, $p<0.001$). In univariable regression, ODI-3% ($R^2=0.624$) and AHI ($R^2=0.599$) demonstrated broadly comparable explanatory performance for ICSI (Delta $R^2=+0.025$). The small numerical difference between these parameters should not be interpreted as statistical superiority without a formal comparison test. Hypertension was the most prominent potential confounder, increasing from 36.7% in the mild OSA group to 82.8% in the severe OSA group ($p<0.005$).

CONCLUSIONS

OSA severity was associated with greater IC/BPS-related symptom burden in unadjusted analyses. ODI-3% and AHI showed comparable associations with ICSI scores, while T90 was most strongly correlated with pain intensity. These findings support systematic lower urinary tract symptom screening in patients with moderate-to-severe OSA; however, prospective studies with multivariable adjustment and interventional trials evaluating the effect of continuous positive airway pressure therapy are required.

OP-1301

Impact Of Palatal Surgery On Thiol–Disulfide Homeostasis And Ischemia-Modified Albumin Levels In Obstructive Sleep Apnea: A 6-Month Prospective Study

Nazlı Nur Besler,MD[1], **Murad Mutlu,MD**[1]

[1]*Department of Otorhinolaryngology,Ankara Etlik City Hospital,Ankara,Turkey*

BACKGROUND & AIM

Obstructive sleep apnea (OSA) is associated with intermittent hypoxia–induced oxidative stress, contributing to disease severity and systemic complications. Thiol–disulfide homeostasis and ischemia-modified albumin (IMA) are emerging biomarkers reflecting oxidative balance and ischemia-related damage. While alterations in these markers have been reported in OSA and partially reversed with non-surgical treatments, the biochemical impact of palatal surgery remains unclear.

This study aimed to evaluate changes in thiol–disulfide homeostasis and IMA levels before and 6 months after palatal surgery in OSA patients, and to assess their association with changes in apnea–hypopnea index.

MATERIAL & METHODS

This prospective study included 34 adult patients diagnosed with obstructive sleep apnea who underwent palatal surgery for retropalatal obstruction. All patients underwent full-night polysomnography and fasting blood sampling preoperatively and at 6 months postoperatively.

Thiol–disulfide homeostasis parameters (native thiol, total thiol, and disulfide) and ischemia-modified albumin (IMA) levels were measured using automated spectrophotometric methods. The apnea–hypopnea index (AHI) was recorded for each patient.

Pre- and postoperative values were compared using paired t-test or Wilcoxon signed-rank test according to data distribution. Correlations between changes in biomarkers and AHI were analyzed using Pearson or Spearman correlation coefficients. A p-value <0.05 was considered statistically significant.

RESULTS

Thirty-four patients completed the 6-month follow-up. A significant reduction in AHI was observed, decreasing from 36.8 ± 13.9 to 18.7 ± 10.8 events/h ($p < 0.001$).

Native thiol levels increased significantly (352.6 ± 61.4 to 389.8 ± 57.3 µmol/L, $p < 0.001$), as did total thiol levels (501.7 ± 58.6 to 523.9 ± 55.2 µmol/L, $p = 0.006$). In contrast, disulfide levels decreased significantly (72.6 ± 26.8 to 63.8 ± 23.1 µmol/L, $p = 0.013$). IMA levels also showed a significant reduction (0.93 ± 0.05 to 0.88 ± 0.04 ABSU, $p < 0.001$).

The reduction in AHI correlated positively with increases in native thiol ($r = 0.49$, $p = 0.003$) and negatively with changes in disulfide ($r = −0.41$, $p = 0.016$) and IMA ($r = −0.55$, $p < 0.001$).

CONCLUSIONS

Palatal surgery was associated with significant improvement in OSA severity and a concomitant reduction in oxidative stress, as reflected by restoration of thiol–disulfide homeostasis and decreased IMA levels.The observed correlations between biomarker changes and AHI reduction suggest that these parameters may serve as potential indicators of treatment response.These findings highlight the role of oxidative stress in OSA pathophysiology and support the potential utility of thiol–disulfide balance and IMA as adjunctive biomarkers in the postoperative evaluation of OSA patients.

INVESTIGATION OF THE RELATIONSHIP BETWEEN NASAL OBSTRUCTION FINDINGS AND POLYGRAPHY DATA IN SNORING PATIENTS

Meleknur ALTINYAYLA[1], **Yeşim BAŞAL**[1]

[1]*Department of Otorhinolaryngology, Adnan Menderes University Hospital, Aydın, Turkey*

BACKGROUND & AIM

This study aims to investigate the relationship between clinical and radiological findings of nasal obstruction and polygraphy data in patients with obstructive sleep apnea syndrome (OSAS) and primary snoring.

MATERIAL & METHODS

Patients presenting to the outpatient clinic with snoring and apnea symptoms and concomitant nasal obstruction were included in the study. All patients underwent clinical examination, nasal endoscopy, paranasal sinus computed tomography (CT), and polygraphy. CT images were evaluated for septal deviation and turbinate pathologies. Mean apnea–hypopnea index

(AHI), supine and non-supine AHI values, and minimum oxygen saturation levels were recorded. Patients were divided into two groups based on AHI values. Patients with no or mild apnea (AHI < 15) were classified as Group 1, and those with moderate to severe apnea (AHI ≥ 15) as Group 2. The relationship between clinical and radiological findings and polygraphy data was analyzed across the groups.

RESULTS

Moderate to severe OSAS was more prevalent in men than in women ($p < 0.05$). A significant association was found between supine AHI and septal deviation grade ($p = 0.027$). As the severity of septal deviation increased, the likelihood of being in Group 2 also increased. A significant negative correlation was observed between snoring visual analog scale (VAS) scores and minimum oxygen saturation, indicating that higher VAS scores were associated with lower oxygen saturation levels ($p = 0.044$). Evaluation of turbinate pathologies revealed that inferior turbinate hypertrophy was frequently accompanied by middle turbinate pathologies (54.5%; n = 36).

CONCLUSIONS

A significant association was found between the clinical and radiological findings of nasal obstruction and OSAS severity. As septal deviation severity increased, the prevalence of moderate to severe OSAS, particularly in the supine position, increased. Increased snoring severity was associated with decreased minimum oxygen saturation. This finding suggests that, despite being a subjective measure, the snoring visual analog scale (VAS) score may be useful in predicting disease severity. The frequent coexistence of middle turbinate pathologies with inferior turbinate hypertrophy highlights the importance of preoperative radiological imaging. Additionally, minimum oxygen saturation may be useful in predicting moderate to severe apnea.

OP-1303

Inflammation, Fibrosis, And Muscle Structural Changes In Upper-Airway Tissues In Patients With OSA

ŞEYDA AKBAL ÇUFALI[1], **GÜLBEN AKCAN**[2], **NURCAN YURTSEVER KUM**[1], **KÜRŞAT MURAT ÖZCAN**[1]

[1]*ANKARA BILKENT CITY HOSPITAL;* [2]*KTO KARATAY UNIVERSITY*

BACKGROUND & AIM

Obstructive sleep apnea (OSA) is characterized by recurrent upper-airway collapse during sleep, which may lead to inflammation-driven tissue remodeling and myogenic alterations. This study aimed to investigate histopathological and immunohistochemical evidence of inflammation, fibrosis, and muscle structural changes in upper-airway tissues of adults with mild–moderate OSA.

MATERIAL & METHODS

Twenty-nine adults were included (15 with polysomnography-confirmed mild–moderate OSA [apnea–hypopnea index 5–29.9 events/hour] and 14 controls). Intraoperative pharyngeal muscle and soft palate specimens were analyzed using hematoxylin–eosin and specific muscle stains to evaluate inflammatory parameters, fibrosis, and fiber architecture. Histological features—including polymorphonuclear (PMN) cell infiltration, inflammation, edema, hyperemia, lymphocytosis, vascular proliferation, and fibrosis—were graded (0–3) independently by two blinded observers. Immunohistochemistry assessed the expression of transforming growth factor beta (TGF-β), matrix metalloproteinase-2 (MMP-2), active caspase-9, and progranulin.

RESULTS

Compared with controls, OSA muscle specimens showed significantly higher fibrosis and inflammation scores, along with increased PMN infiltration, edema, hyperemia, lymphocytosis, and vascular proliferation (all $p<0.001$). Muscle staining demonstrated irregular fiber contours, focal degeneration, and expansion of interstitial connective tissue in OSA muscle samples. In soft palate specimens, OSA patients demonstrated higher fibrosis and inflammation, with significantly increased PMN infiltration, vascular proliferation, edema, hyperemia, and lymphocytosis compared with controls (all $p<0.001$). Immunohistochemistry showed progranulin expression in OSA soft palate and stronger TGF-β, MMP-2, and active caspase-9 staining in OSA muscle compared with controls

CONCLUSIONS

Mild–moderate OSA is associated with pronounced inflammatory–fibrotic remodeling and structural disruption of pharyngeal muscle fibers, as well as marked inflammatory changes in the soft palate. These findings support local tissue inflammation, apoptosis, and matrix remodeling as key contributors to upper-airway dysfunction in the pathophysiology of OSA.

Combination Of Thai Version Of Pediatric Obstructive Sleep Apnea Screening Tool And Overnight Pulse Oximetry For The Diagnosis Of Obstructive Sleep Apnea In Children

Vipada Tirachaimongkol[2], **Associate Professor Archwin Tanphaichitr**[1], **Professor Wish Banhiran**[1], **Professor Kitirat Ungkanont**[1], **Assistant Professor Vannipa Vathanophas**[1]

[1]*Department of Otorhinolaryngology, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand.*; [2]*Department of Otolaryngology Faculty of Medicine Vajira Hospital, Navamindradhiraj University, Bangkok, Thailand*

BACKGROUND & AIM

While PSG remains the gold standard for diagnosing OSA, high costs and extensive resource requirements limit accessibility. Overnight pulse oximetry (SpO2) is commonly used as alternative tool which provided sensitivity of 54% and specificity of 91%. Despite it yielding high specificity for diagnosing, sensitivity for screening is limited. POSAST is one of screening questionnaires, which is brief and easy to use. According to the validated Thai version of POSAST yielded sensitivity of 81.1% and specificity of 52.8%. So, we hypothesize that Combination of POSAST and SpO2 would be better than using only POSAST or SpO2 alone for diagnosing pediatric OSA.

MATERIAL & METHODS

The demographic data, POSAST, SpO2, and PSG reports from pediatric patients aged 2-15 years old who underwent PSG in a sleep laboratory were collected. The SpO2 was scored by a pediatric pulmonologist and PSG was scored by sleep specialists who were blinded to each other. Combined Q-O2 was considered positive when POSAST total score ≥ 8 and SpO2 is positive. Diagnostic properties of Combined Q-O2 and comparison of Combined Q-O2 with SpO2 for diagnosis of pediatric OSA (AHI ≥ 5 events/h) were presented.

RESULTS

Sixty patients were included in this study. The mean age was 9.9 ± 3.2 years. There were 26 patients (43.3%) diagnosed with OSA (AHI ≥ 5 events/h) by PSG. Combined Q-O2 provided 97.06% specificity, 68.33% accuracy, 88.89% PPV, 64.71% NPV, and 30.77% sensitivity for diagnosing OSA (AHI ≥ 5 events/h). SpO2 provided 91.18% specificity, 65.00% accuracy, 72.23% PPV, 63.27% NPV, and 30.77% sensitivity for diagnosing OSA. Despite the Combined Q-O2 yielding more specificity, PPV, NPV, and accuracy than SpO2 for diagnosing OSA, there was no statistical significance.

CONCLUSIONS

The Combined Q-O2 test has good specificity in terms of diagnosis of pediatric OSA. The Combined Q-O2 might be used as an alternative test for the diagnosis of pediatric OSA if the full PSG in the sleep laboratory is not available.

OP-1305

Effects Of Upper Airway Surgery On Voice Quality And Nasalance In OSAS Patients: Midline Vs. Lateral Approach

Buğra Güngör[1], **Samet Özlügedik**[1]

[1]*Ankara Etlik Şehir Hastanesi*

BACKGROUND & AIM

Obstructive sleep apnea syndrome (OSAS) may affect voice quality and nasal resonance due to upper airway anatomical changes. Surgical approach type — midline versus lateral — may differentially impact vocal parameters, yet objective comparative data remain scarce. This ongoing prospective study aims to evaluate and compare the effects of midline surgery (uvulopalatopharyngoplasty/adenopalatopharyngoplasty) and lateral surgery (expansion sphincter pharyngoplasty, lateral pharyngoplasty, tonsillectomy) on acoustic voice parameters and nasalance in OSAS patients.

MATERIAL & METHODS

This ongoing prospective comparative cohort study enrolls adults aged 18–65 diagnosed with OSAS by polysomnography. This interim analysis includes 24 patients who completed 3-month postoperative follow-up: Group A — Midline surgery (UPF/APP, n=12) and Group B — Lateral surgery (tonsillectomy, ESF, LFP, n=12). Pre- and postoperative assessments included acoustic voice analysis (fundamental frequency F0, jitter, shimmer, HNR), stereo nasometry for nasalance measurement (/m/ sound), and the Voice Handicap Index-10 (VHI-10). Data were analyzed using paired t-tests for overall pre-post comparison and independent samples t-tests for between-group comparisons.

RESULTS

In 24 patients completing 3-month follow-up (Group A: Midline n=12, Group B: Lateral n=12), overall group analysis revealed a statistically significant decrease in nasalance from 78.0±18.3% to 62.6±28.6% postoperatively (p=0.014). Fundamental frequency (F0) showed a non-significant decline across all patients (168.4±36.1 → 157.8±38.1 Hz; p=0.138). Subgroup analysis showed no significant changes in F0 or nasalance in the Midline group (p=0.906 and p=0.081, respectively). In the Lateral group, F0 demonstrated a borderline significant decrease (168.2±34.8 → 147.0±24.0 Hz; p=0.051) and nasalance approached

significance (p=0.078). No significant between-group differences were found for any parameter (p>0.05). Preoperative VHI-10 score was 3.8±6.2 (median: 0; range: 0–17).

CONCLUSIONS

Upper airway surgery did not adversely affect acoustic voice quality in OSAS patients regardless of surgical approach. The most notable finding of this interim analysis is a significant reduction in nasalance across the entire cohort (p=0.014). The borderline F0 decrease in the Lateral group (p=0.051) may reach significance with increasing sample size. The absence of between-group differences suggests comparable vocal outcomes for midline and lateral approaches. Final conclusions await completion of the target sample.

OP-1306

Determinants Of Hypoxemia In Severe Obstructive Sleep Apnea: The Interplay Between Obesity And Upper Airway Collapse Patterns

Caner Şahin[1], **Gözde Orhan Kubat**[1], **Özkan Yetkin**[2], **Emre Çolak**[1]

[1]*Alanya Alaaddin Keykubat University Training and Research Hospital, Department of Otorhinolaryngology, Alanya, Türkiye;* [2]*Alanya Alaaddin Keykubat University Training and Research Hospital, Department of Pulmonology, Alanya, Türkiye*

BACKGROUND & AIM

Severe obstructive sleep apnea (OSA) is traditionally defined by the apnea–hypopnea index (AHI); however, patients with similar AHI values may exhibit markedly different clinical and physiological characteristics, suggesting a heterogeneous disease structure. This study aimed to investigate the relative contribution of obesity and upper airway collapse patterns, assessed using the VOTE classification, to the severity of hypoxemia in patients with severe OSA.

MATERIAL & METHODS

Seventy-three patients with severe OSA (AHI ≥30), selected from a larger cohort of 945 patients diagnosed by polysomnography, were included (mean age: 50.2 ± 11.9 years; mean BMI: 35.4 ± 5.8 kg/m²). Upper airway collapse was evaluated using the Müller maneuver and classified according to the VOTE system (Velum, Oropharynx, Tongue base, Epiglottis; graded 0–2). Associations between VOTE patterns, lowest oxygen saturation (SaO2), mean oxygen desaturation depth (%), and clinical variables were analyzed using Spearman correlation and multiple linear regression analyses.

RESULTS

The most common collapse patterns were concentric collapse at the velum (stage 2, 41%), lateral collapse at the oropharynx (stage 1, 65%), and anteroposterior collapse at the tongue base (stage 1, 56%). Increasing severity of oropharyngeal collapse was significantly associated with lower minimum SaO_2 ($r = -0.27$, $p = 0.019$) and greater mean desaturation depth ($r = 0.26$, $p = 0.027$). In multiple linear regression analysis, BMI emerged as the strongest independent predictor of minimum SaO2 ($p < 0.001$), with each one-unit increase associated with an approximately 1% decrease in minimum oxygen saturation. Although oropharyngeal collapse did not remain statistically significant after adjustment ($p = 0.06$), a trend toward association was observed. Additionally, total VOTE score showed a significant negative correlation with minimum SaO2 ($r = -0.28$, $p = 0.017$).

CONCLUSIONS

Obesity appears to play a dominant role in determining the severity of hypoxemia in patients with severe OSA. Nevertheless, anatomical factors—particularly oropharyngeal collapse patterns—may provide additional contribution, reflecting the heterogeneity within this patient group. These findings support the need to move beyond AHI-based assessment and highlight the importance of a phenotype-driven, multidimensional evaluation approach in OSA.

CT-Based Evaluation Of Upper Airway Morphometric Changes After OSAS Surgery And Their Clinical Correlation

Bihter Yazar Celik[1], **Fatma Gulum Ivgin Bayraktar**[1]

[1]*Department of Otolaryngology, Prof. Dr. Cemil Tascioglu City Hospital, University of Health Sciences, Istanbul, Turkey*

BACKGROUND & AIM

Obstructive sleep apnea syndrome (OSAS) is characterized by recurrent upper airway obstruction, particularly at retropalatal and retrolingual levels, leading to impaired quality of life. Surgical treatment is effective in selected patients; however, the relationship between postoperative anatomical changes and clinical outcomes remains unclear. It is hypothesized that postoperative increases in upper airway dimensions, particularly in the retrolingual region, are associated with clinical improvement measured by the Epworth Sleepiness Scale (ESS).

MATERIAL & METHODS

This retrospective clinical study included 50 patients who underwent surgical treatment for OSAS. Preoperative and postoperative computed tomography (CT) scans were analyzed to measure anteroposterior, transverse, and cross-sectional area dimensions of the retropalatal (RP) and retrolingual (RL) regions. Clinical outcomes were assessed using ESS scores. Patients were categorized into good and poor responders based on median ESS change. Statistical analyses included paired t-test or Wilcoxon test depending on data distribution, Spearman correlation analysis, receiver operating characteristic (ROC) analysis, and logistic regression. A p value <0.05 was considered statistically significant.

RESULTS

A significant reduction in ESS scores was observed postoperatively ($p < 0.001$). All morphometric measurements demonstrated significant postoperative increases ($p < 0.001$). Correlation analysis revealed a significant negative association between changes in ESS scores and retrolingual area ($r = -0.334$, $p = 0.041$). ROC analysis showed that retrolingual area change had moderate discriminative ability in predicting clinical improvement (AUC = 0.723, $p = 0.019$). Logistic regression analysis identified retrolingual area change as an independent predictor of good clinical response (OR = 0.992; 95% CI: 0.985–0.999; $p = 0.020$).

CONCLUSIONS

Postoperative enlargement of the upper airway is associated with clinical improvement in OSAS patients. In particular, increases in the retrolingual region appear to be a significant and independent predictor of favorable clinical outcomes. These findings support the importance of targeting the retrolingual area in surgical planning.

OP-1308

Characteristics Of Preoperative Drug-Induced Sleep Endoscopy In Patients With Uvulopalatopharyngoplasty Failure

Chang, Hsuan Fu[1], **Hung, Yu-Hsiang**[1], **Tsou, Yung-An**[1]

[1]*Department of Otolaryngology, China Medical University, Taiwan*

BACKGROUND & AIM

Uvulopalatopharyngoplasty (UPPP) is one of the most commonly performed surgical treatments for obstructive sleep apnea (OSA). However, its success rate remains limited, and some patients continue to experience clinical symptoms postoperatively. Drug-induced sleep endoscopy (DISE) allows dynamic evaluation of upper airway collapse and may provide clinical value in predicting surgical outcomes. The aim of this study was to investigate the preoperative DISE characteristics of patients who failed UPPP and to analyze the site, degree, and pattern of upper airway collapse.

MATERIAL & METHODS

We retrospectively reviewed OSA patients who underwent UPPP at our institution between January 2016 and January 2025. Baseline data, preoperative DISE findings, and pre- and postoperative PSG results were collected. Patients were classified as surgical success or non-success using Sher criteria. DISE variables—including collapse site (velum, oropharyngeal lateral wall, tongue base, epiglottis), degree, and pattern (anteroposterior, lateral, circumferential)—were compared between groups. Statistical analyses were performed to assess associations between DISE features and surgical outcomes.

RESULTS

A total of 1,538 patients were screened, and 57 with complete data were analyzed. According to Sher criteria, 17 were classified as surgical successes and 40 as non-successes, with no significant baseline differences. Velum AP collapse (p=0.043) and oropharyngeal lateral wall collapse (p=0.033) were strongly associated with UPPP failure, while other DISE findings showed no impact. The success group had significantly higher tonsil weight. Among 32 patients with tongue-base collapse, those undergoing UPPP plus lingual tonsillectomy had higher success rates than those receiving tongue-base radiofrequency.

CONCLUSIONS

This study showed that velum AP collapse and oropharyngeal lateral wall collapse are strong negative predictors of UPPP success, suggesting that severe collapse at these sites may require additional procedures. Patients with heavier tonsils demonstrated higher success rates. Among those with tongue-base AP collapse, lingual tonsillectomy yielded better outcomes. Overall, DISE serves as a valuable tool for guiding surgical planning.

Association Between Ascending And Descending Phop Measurements During DISE And Routine Physical Examination Findings

Cedric Ange N'zi[2], **Rafael Malinsky**[1], **Badr Ibrahim**[1]

[1]*Division of Otolaryngology Head And Neck Surgery- University of Montreal;* [2]*Faculty of Dental Medicine and Oral Health Sciences - McGill University*

BACKGROUND & AIM

Drug-induced sleep endoscopy with positive airway pressure (DISE-PAP) allows dynamic assessment of upper airway collapsibility through ascending and descending pharyngeal opening pressure (PhOP) measurements. Recent early evidence suggests that ascending and descending PhOP may reflect distinct physiologic and mechanical properties of upper airway obstruction, potentially offering insights beyond static anatomic assessment. Whether routine office-based physical examination findings correlate with these dynamic airway metrics remains unclear. This study aimed to evaluate the relationship between ascending and descending PhOP measurements obtained during DISE-PAP and commonly assessed physical examination variables in patients undergoing evaluation for obstructive sleep apnea.

MATERIAL & METHODS

A single-center retrospective chart review was performed of patients who underwent standardized DISE-PAP evaluation for obstructive sleep apnea. Visual ascending and descending PhOP measurements were obtained during a standardized DISE-PAP protocol performed under propofol sedation with bispectral index (BIS) monitoring to ensure a controlled depth of sedation. Routine preoperative physical examination findings were extracted from the medical record, including skeletal class, dental occlusal class, Friedman tongue position, and tonsil size. Correlation analyses were performed to assess associations between these physical examination variables and both ascending and descending PhOP values. Statistical significance was defined at $p < 0.05$.

RESULTS

Fifty-three patients met inclusion criteria for analysis. No statistically significant correlation was identified between ascending PhOP and any routine physical examination variable assessed, including skeletal class, dental occlusal class, Friedman tongue position, and tonsil size. Similarly, no meaningful association was observed between descending PhOP and skeletal class, dental class, or tonsil size. The only statistically significant correlation identified was between descending PhOP and Friedman tongue position ($R = 0.30$, $p = 0.031$), suggesting a modest relationship between tongue-related upper airway crowding and passive airway opening pressure during descending titration.

CONCLUSIONS

The modest correlation between descending PhOP and Friedman tongue position may indicate an association between tongue-related pharyngeal crowding and passive airway mechanics. Conversely, ascending titration encompassing elements of ventilatory drive and respiratory effort did not correlate with static routine physical examination variables. These findings support the complementary role of DISE-PAP-derived quantification of passive mechanical load stenting needs beyond routine office-based examination in patients with obstructive sleep apnea.

Association Of Nasal Septal Deviation Type And Angle With The Presence And Severity Of Obstructive Sleep Apnea

Ali Ozan YAZICI[1], **Fatma Gülüm İvgin BAYRAKTAR**[1]

[1]*University Of Health Sciences Prof. Dr. Cemil Taşcıoğlu City Hospital, Department of Otorhinolaryngology, Istanbul, Türkiye*

BACKGROUND & AIM

Obstructive sleep apnea is a disorder caused by the recurrent collapse of the upper airways during sleep,resulting in partial or complete airway obstruction.The relationship between the septal deviation angle and the classification of septal deviation types(Mladina types) and the presence and severity of obstructive sleep apnea syndrome (OSAS) has not yet been clearly demonstrated. In this study, we aim to compare septal deviation angle and Mladina types in patients diagnosed with OSAS and those without OSAS to evaluate the relationship between septal parameters and disease severity in the OSAS group.

MATERIAL & METHODS

This retrospective study included a total of 202 patients. Of the patients,101 had polysomnography confirmed OSAS and 101 served as controls without OSAS.All patients had their age,gender, apnea hypopnea index (AHI),septal deviation angle,and Mladina types documented. Group comparisons were performed using the Mann-Whitney U test or chi-square test,when appropriate. Binary logistic regression were used to determine predictive performance.

RESULTS

In the study,no differences were found between the OSAS and control groups in terms of age and gender($p>0.05$).The mean septal deviation angle was 14.28±5.12° in the OSAS group and 15.17±4.42° in controls,with no significant difference between

groups(p=0.121).The distribution of Mladina types differed statistically significantly between the two groups(p<0.001).Type 5 deviation was more common in the OSAS group, while Type 6 deviation was dominant in the control group.No significant relationship was observed between AHI and septal deviation angle or Mladina type in the Spearman correlation analysis(p>0.05).In binary logistic regression showed that both Mladina type (overall p<0.001) and septal deviation angle (OR=0.922,p=0.031) were independently associated with OSAS. Type 6 was associated with significantly lower odds of OSAS compared with Type 1(OR=0.143,p=0.003).

CONCLUSIONS

In conclusion, both septal deviation angle and Mladina type were significantly associated with the presence of OSAS, while neither was associated with disease severity as measured by AHI. Type 5 deviation was more frequent in the OSAS group, whereas Type 6 was more common in controls. These findings suggest that both angular measurement and morphological classification may provide clinically relevant information in the assessment of OSAS. Further prospective studies with larger populations are needed to confirm these findings.

OP-1311

Impact Of Digital Follow-Up And The Human Factor On PAP Therapy Adaptation And Adherence: A Retrospective Cohort Of 64 Patients

Alexandra Rodriguez[1]

[1]*Hospital Internacional La Catolica;* [2]*Torre Medica NAOS Plaza*

BACKGROUND & AIM

Adherence to positive airway pressure (PAP) therapy remains a major challenge in the management of obstructive sleep apnea (OSA). The initial treatment period is particularly relevant, as early adaptation strongly influences long-term continuation. We hypothesized that a care model centered on the human factor, reinforced by daily digital follow-up via WhatsApp during the first 15 days and comfort-oriented technological support, would be associated with improved early adaptation and sustained adherence to PAP therapy.

MATERIAL & METHODS

We performed a retrospective observational study in a clinical cohort of 64 patients with OSA managed in private otolaryngology and sleep medicine practice across two care settings, Hospital La Católica and Centro Médico Naos Plaza, and treated predominantly with APAP AutoSet. Variables analyzed included sex, age, body mass index (BMI), baseline disease severity according to the apnea-hypopnea index, objective adherence defined as the percentage of nights with device use >4 hours at 1 month, 6 months, and 1 year, mask type, and treatment abandonment. The intervention consisted of individualized education, personalized mask selection, heated tubing, targeted management of nasal symptoms, and daily WhatsApp follow-up during the first 15 days, including early troubleshooting, positive reinforcement, and continuous support.

RESULTS

The cohort included 40 men (62.5%) and 24 women (37.5%), with a mean age of 53.3 years and a mean BMI of 33.1 kg/m². Severe OSA was present in 32/64 patients (50.0%) and was significantly more frequent in men than in women (62.5% vs 29.2%; OR 4.05, 95% CI 1.36–12.02; p=0.019). Mean adherence, expressed as the percentage of nights with device use >4 hours, was 78.8% at 1 month, 76.4% at 6 months, and 70.6% at 1 year. Women showed descriptively better adherence than men at all time points (82.0%, 83.0%, and 75.0% vs 76.9%, 72.5%, and 68.0%, respectively). Treatment abandonment was 23.4%, with a non-significant trend toward higher rates in men than in women (27.5% vs 16.7%; OR 1.90, 95% CI 0.53–6.81; p=0.38). Overall, the F20 mask was the most frequently used interface (53%), whereas the N20 nasal mask predominated among women (58%).

CONCLUSIONS

In this cohort, a model combining intensive digital follow-up, close human support, and comfort-oriented technological assistance was associated with favorable early adaptation and sustained adherence to PAP therapy. The differences observed according to sex and mask type further support the need for individualized PAP management from treatment initiation. This approach may represent an innovative, accessible, and scalable strategy to optimize PAP outcomes in patients with OSA.

OP-1312

Does The Age At Obstructive Sleep Apnea Diagnosis Affect The Prevalence, Severity, And Symptoms Of OSA-Related Sensorineural Hearing Loss?

Vadad SALEHNAJAFI[1], **Ozan GÖKDOĞAN**[1]

[1]*Department of Otorhinolaryngology-Head & Neck Surgery, Muğla Sıtkı Koçman University, Muğla Province Training and Research Hospital*

BACKGROUND & AIM

Obstructive sleep apnea (OSA) is a multisystem disorder affecting various organs, including the cochlear and vestibular systems, due to intermittent hypoxia. Although its morbidities are serious, they may appear in a period of time after exposure to the disease and chronic hypoxia. This study aims to determine the impact of the age at which OSAS is diagnosed on the prevalence and level of hearing impairment, audiometric parameters, and audiovestibular symptoms, as well as to assess whether early diagnosis of OSA can prevent its associated hearing morbidities.

MATERIAL & METHODS

This retrospective study reviewed records of 2,420 patients who underwent polysomnography during 2021-2024. Of these, 427 had undergone audiometry testing for any indication. After excluding individuals aged <18 or >60 years, and those with congenital or middle ear diseases, 311 patients were included. Sensorineural hearing loss (SNHL) was defined as bone-conduction thresholds exceeding 20 dB, and decreased Speech-Discrimination rates were defined as scores below 88%. Decreased SD-rates, existence of SNHL at PTAs-250-6000-8000 Hz (in each ear separately and in either one of the ears), tinnitus, and vertigo were assessed among all OSA patients and in OSA subgroups using the Mann-Whitney or Student-t test ($p<0.05$), with age at OSA diagnosis as a covariate. The correlation between age at OSA diagnosis and bone conduction threshold values (at PTAs-250-6000-8000 Hz) as well as SD-rates in each ear was examined using Spearman's rank correlation test. All normality tests were performed using the Kolmogorov-Smirnov test.

RESULTS

The age at OSA diagnosis was evaluated using the Mann-Whitney or Student-t test in all OSA cases and subgroups for the existence of SNHL at PTA (R:$p<0.001$, L:$p<0.001$, either of ears:$p<0.001$), (either of ears; mild:$p=0.202$, moderate:$p<0.001$, severe:$p<0.001$), at 250 Hz (R:$p=0.246$, L:$p=0.0.003$, either of ears:$p=0.005$), (either of ears; mild:$p=0.464$, moderate:$p=0.012$, severe:$p=0.315$), at 6000-8000 Hz (R:$p<0.001$, L:$p<0.001$, either of ears:$p<0.001$), (either of ears; mild:$p<0.001$, moderate:$p<0.001$, severe:$p<0.001$), decreased SD-rate (R:$p<0.001$, L:$p<0.001$, either of ears:$p<0.001$), (either of ears mild:$p<0.001$, moderate:$p<0.001$, severe:$p<0.001$), tinnitus ($p=0.024$), and vertigo ($p=0.599$). Age at OSA diagnosis correlation with bone-conduction thresholds (>20dB) at PTA (R:$p=0.903$_L:$p=0.293$), 250Hz (R:$p=0.137$_L:$p=0.008$, r=0381), 6000Hz (R:$p=0.001$, r=0.226_L:$p<0.001$, r=0.304), 8000Hz (R:$p=0.002$, r=0.222_L:$p<0.001$, r=0.241), and with SD-rates (R:$p=0.089$_L:$p=0.014$, r=-0.259) was evaluated via Spearman's correlation.

CONCLUSIONS

Older age at OSA diagnosis strongly increases the prevalence of sensorineural hearing loss (at PTAs-6000-8000Hz) and decreased-SD rates, except that mild-OSA cases aren't affected at PTAs. The effect on 250Hz isn't definite. Diagnosing OSA at an older age may also raise the likelihood of tinnitus. These likely reflect that a later age at diagnosis corresponds to a longer untreated exposure period to OSAS-related hypoxia, which probably increases cochlear damage risk. No significant correlation is found between diagnosis age and SNHL severity at PTAs. However, at 6000-8000Hz, a weakly positive correlation is observed. Also, no significant correlation with SD-rates is found.

Beyond AHI: A Discordance-Based Phenotyping Model Integrating Symptoms And Upper Airway Anatomy In Obstructive Sleep Apnea

Caner Şahin[1], **Hüseyin Lakadamyalı**[2], **Gözde Orhan Kubat**[1], **Münevver İpek Kısar**[1]

[1]*Alanya Alaaddin Keykubat University, Department of Otorhinolaryngology;* [2]*Alanya Alaaddin Keykubat University, Department of Pulmonology*

BACKGROUND & AIM

Obstructive sleep apnea (OSA) is a clinically heterogeneous disorder in which apnea–hypopnea index (AHI) does not always reflect symptom burden or underlying anatomical involvement. This study aimed to identify discordance-based OSA phenotypes by integrating physiological severity, patient-reported outcomes, and upper airway anatomical findings.

MATERIAL & METHODS

In this retrospective cross-sectional study, 257 patients with OSA were evaluated. Symptom burden was assessed using the Epworth Sleepiness Scale (ESS) and Pittsburgh Sleep Quality Index (PSQI). Upper airway anatomy was analyzed using the VOTE classification system. A composite symptom score was generated from standardized ESS and PSQI values. Patients were categorized into four phenotypes according to concordance or discordance between AHI severity and symptom burden. Intergroup comparisons and multinomial logistic regression analyses were performed.

RESULTS

Four distinct phenotypes were identified, demonstrating a substantial dissociation between physiological severity and symptom burden. High-AHI phenotypes showed significantly higher body mass index and greater tongue base and epiglottic obstruction ($p < 0.001$). In contrast, patients with high symptom burden despite low AHI had lower anatomical obstruction scores. Velum collapse was more prominent in symptom-dominant phenotypes, whereas lower airway obstruction was

associated with increased AHI severity. Multinomial regression analysis revealed that body mass index and total VOTE score predicted physiological severity, while ESS and PSQI independently predicted symptomatic phenotypes.

CONCLUSIONS

OSA demonstrates a marked discordance between physiological severity and clinical symptom burden, with distinct anatomical characteristics across phenotypes. A multidimensional phenotype-based approach integrating anatomical, physiological, and patient-reported parameters may improve disease characterization and support personalized management strategies.

Obstructive Sleep Apnea Knowledge And Attitudes Of Turkish Primary Care Physicians: An OSAKA Survey Analysis (A Nationwide Survey)

Yonca Çoluk[1], **Elif Baysal**[2], **Emre Koçak**[1], **Volkan Güngör**[1], **Devrim Bektaş**[1]

[1]*Giresun University;* [2]*Gaziantep University*

BACKGROUND & AIM

Obstructive Sleep Apnea (OSA) is a significant public health concern with an estimated prevalence of 14% in Turkey. Primary care physicians (PCPs) play a pivotal role in the early identification and management of OSA. This study aimed to assess Turkish PCPs' knowledge and attitudes regarding OSA using the Turkish adaptation of the Obstructive Sleep Apnea Knowledge and Attitudes (OSAKA) questionnaire.

MATERIAL & METHODS

This descriptive, cross-sectional study included 338 PCPs (43.2% female, 56.8% male) with a mean age of 33.19 years. Participants were invited to complete the survey, which was distributed via email, and informed consent was obtained from all respondents prior to inclusion. The OSAKA questionnaire, comprising 18 items assessing knowledge and 5 items assessing attitudes toward OSA, was utilized. Demographic data, including years in practice and graduation year, were also collected. Statistical analyses were performed using SPSS v.27, employing t-tests, ANOVA, and correlation analyses where appropriate.

RESULTS

Participants demonstrated high knowledge scores in identifying classic symptoms like snoring (87.8%), the gold standard for diagnosis (88.1%), and the association with traffic accidents (87.2%). However, significant knowledge gaps were identified regarding treatment nuances: only 52.2% knew that CPAP is the first-line treatment for severe OSA, and only 25.7% knew that uvulopalatopharyngoplasty is not curative for most patients. The differences in knowledge were statistically significant across the various items ($p < 0.001$). Additionally, while 79.8% linked OSA with cardiac arrhythmias, only 39.2% were aware of the threshold for normal apnea-hypopnea index (AHI) values, a statistically significant gap ($p < 0.05$). Regarding attitudes, while most physicians recognized OSA as an important clinical issue, their confidence in managing the disorder was relatively low.

CONCLUSIONS

Although Turkish PCPs possess a solid foundation in recognizing the general epidemiology and symptoms of OSA, there is a distinct need for targeted medical education focusing on specific diagnostic criteria and long-term management strategies. Enhancing PCP confidence and specialized knowledge is essential for improving the referral pathways and treatment outcomes for OSA patients in Turkey.

Anatomo-Clinical Hybrid Phenotyping In Obstructive Sleep Apnea Syndrome: Integrated Analysis Of VOTE Scores And PROMS Symptom Profiles

Emre Yıldırım[1], **Gözde Orhan Kubat**[1], **Caner Şahin**[1]

[1]*Alanya Alaaddin Keykubat University, Alanya Training and Research Hospital, Department of Otolaryngology, Alanya, Turkey*

BACKGROUND & AIM

Obstructive Sleep Apnea Syndrome (OSAS) is a heterogeneous disease in terms of clinical and anatomical features. This study aims to identify "hybrid phenotypes" in OSAS patients by integrating upper airway anatomical VOTE (Velum, Oropharynx, Tongue base, Epiglottis) scores with patient-reported outcome measures (PROMS: ESS and PSQI) and to evaluate their relationship with the Apnea-Hypopnea Index (AHI).

MATERIAL & METHODS

Data from 167 OSAS patients were retrospectively analyzed. Demographic data, AHI, ESS, and PSQI scores, and anatomical collapse patterns according to the VOTE classification were recorded. K-means cluster analysis was performed using VOTE and

PROMS variables to identify phenotypic subgroups. Intergroup differences were analyzed using the Kruskal-Wallis test, and phenotype predictors were evaluated with multinomial logistic regression.

RESULTS

Three distinct phenotypes were identified: Cluster 0 (Anatomically-Oriented, n=47) showed the highest AHI (39.54±29.39) with multilevel collapse, while Cluster 2 (Symptomatically-Oriented, n=43) demonstrated the highest ESS (9.79±5.22) and PSQI (18.02±5.52) scores despite comparable AHI values. Multinomial logistic regression identified epiglottic collapse as the strongest predictor of Cluster 0 membership (OR: 12.42; 95% CI: 4.10–37.58; p<0.001), while velar collapse (OR: 2.65) and ESS score (OR: 1.42) predicted Cluster 2 membership. ROC analysis confirmed excellent discriminatory performance of epiglottic collapse for anatomic phenotype identification (AUC: 0.922), markedly superior to AHI (AUC: 0.594). BMI was the strongest predictor of AHI severity (p<0.001) but failed to differentiate cluster membership (p=0.065).

CONCLUSIONS

AHI alone is an insufficient criterion for OSAS management.The hybrid integration of VOTE-based anatomical mapping and PROMS-based symptom profiles, combined with unsupervised cluster analysis, provides a more precise phenotypic framework for personalized OSAS management, guiding surgical planning and treatment selection beyond AHI-based classification.

A Multimodal Pre-Polysomnographic Risk Model For Severe Obstructive Sleep Apnea

Burak Kaan İnan[1], **Can Berk Aşaroğlu**[1], **Muhammed Güzel**[1], **İbrahim Sayın**[1], **Zahide Mine Yazıcı**[1]

[1]*Department of Otorhinolaryngology, Bakırköy Dr. Sadi Konuk Training and Research Hospital, University of Health Sciences, Istanbul, Türkiye*

BACKGROUND & AIM

Obstructive sleep apnea (OSA) is increasingly recognized as a systemic inflammatory syndrome driven by intermittent hypoxia and upper airway collapse. Limited access to polysomnography (PSG) frequently delays diagnosis of severe disease. We hypothesized that integrating inflammatory, anatomical, anthropometric, and clinical parameters into a multimodal pre-polysomnographic model could enable high-precision identification and prioritization of patients at risk for severe OSA.

MATERIAL & METHODS

This retrospective cross-sectional study included 112 adults who underwent full-night PSG. Severe OSA was defined as an apnea–hypopnea index (AHI) ≥30 events/hour. Pre-PSG variables included STOP-Bang score, tonsil grade (Brodsky classification), neck circumference, and systemic immune-inflammation index (SII) derived from complete blood count. Independent predictors were identified using multivariable logistic regression with backward elimination.

A composite risk score (0–7 points) was constructed as follows: STOP-Bang 0–2 (0 points), 3–4 (1 point), ≥5 (2 points); tonsil grade 0–1 (0 points), grade 2 (1 point), grade ≥3 (2 points); SII <726.5 (0 points), ≥726.5 (2 points); neck circumference <42 cm (0 points), ≥42 cm (1 point). Model discrimination and calibration were assessed using receiver operating characteristic (ROC) analysis and the Hosmer–Lemeshow test.

RESULTS

Severe OSA was identified in 26 of 112 patients (23.2%). In multivariable logistic regression analysis, independent predictors of severe OSA were STOP-Bang category (OR 17.77, p<0.001), tonsil grade (OR 4.55, p=0.005), systemic immune-inflammation index (SII) ≥726.5 (OR 7.01, p=0.021), and neck circumference ≥42 cm (OR 2.10, p=0.047), reflecting complementary contributions from clinical, anatomical, inflammatory, and anthropometric domains.

The composite risk score (0–7 points) demonstrated excellent discrimination with an area under the curve of 0.95 and good calibration (Hosmer–Lemeshow p=0.364). At a cut-off ≥4 points, the model achieved 88.5% sensitivity and 86.9% specificity, indicating strong overall discriminatory performance. At ≥6 points, specificity and positive predictive value reached 100%, identifying a subgroup composed exclusively of severe OSA patients and establishing a clear rule-in threshold for high-risk triage.

CONCLUSIONS

This four-variable multimodal risk model integrates biological inflammation and mechanical airway narrowing to achieve highly accurate pre-polysomnographic identification of severe OSA. Its perfect rule-in capability at higher thresholds provides a practical precision-triage framework to optimize PSG prioritization in high-demand clinical settings.

Dynamic Determinants Of Snoring

Anıl Akgün[1], **Yeşim Başal**[1]

[1]Department of Otorhinolaryngology, Aydın Adnan Menderes University Faculty of Medicine, Aydın, Turkey

BACKGROUND & AIM

This study aims to investigate the impact of upper airway collapse patterns, identified during drug-induced sleep endoscopy (DISE), on the apnea-hypopnea index (AHI) and minimum oxygen saturation (MinO2) in patients with obstructive sleep apnea (OSA) and primary snoring.

MATERIAL & METHODS

A retrospective analysis was conducted on 58 patients (42 males, 16 females) who underwent DISE prior to planned sleep surgery due to snoring complaints between January 2024 and December 2025. Patient demographics, polygraphy results, and upper airway collapse levels and patterns were evaluated according to the VOTE classification. The relationship between collapse patterns, AHI, and DISE MinO2 levels was statistically analyzed.

RESULTS

The most frequent obstruction pattern observed was lateral oropharyngeal collapse, accounting for 72.4% of the cases. A statistically significant positive correlation was found between lateral oropharyngeal collapse and AHI values (p=0.001). Additionally, there was a near-significant negative correlation between concentric collapse at the velum level and minimum oxygen saturation levels recorded during DISE (p=0.052).

CONCLUSIONS

Lateral oropharyngeal collapse is the most critical dynamic factor associated with disease severity in OSA. Furthermore, concentric velum collapse is closely related to deeper oxygen desaturation during DISE. Patients exhibiting these specific collapse patterns require closer monitoring for sleep apnea complications. When planning surgical treatment, the configuration of the collapse must be considered alongside the anatomical level of obstruction ; notably, CPAP therapy should be prioritized for patients presenting with concentric velum collapse.

Evaluating Chatgpt Treatment Recommendations For Obstructive Sleep Apnea: Inter-Rater Agreement And Video Input Effect

Tuğce Mert[1], **Katre Nur Silli**[1], **Süleyman Şahin Aydın**[1], **Gülçimen Aslan**[1], **Rashad Ahmadov**[1], **Ceren Karaçaylı**[1], **Levent Yücel**[1], **Mustafa Gerek**[1]

[1]Department of Otolaryngology, Gülhane Training and Research Hospital, Ankara, Turkey

BACKGROUND & AIM

The use of large language models such as ChatGPT 4.5 in clinical decision-making has increased rapidly in recent years. However, their reliability and consistency in otolaryngology practice remain unclear. This study evaluated the inter-rater agreement of ChatGPT-generated treatment recommendations for obstructive sleep apnea (OSA), their consistency across repeated queries, and the effect of clinical examination video input on recommendation quality.

MATERIAL & METHODS

This clinical study included 66 patients diagnosed with OSA. ChatGPT was queried on three consecutive days using patient-specific clinical information. Treatment recommendations generated by the model were independently evaluated by two blinded clinicians using a 5-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). Patients were divided into three groups: no-video (n=36), video-available queried without video input (n=30), and video-assisted (n=30). Inter-rater agreement was assessed using quadratic weighted Cohen's kappa (κ). Consistency across repeated queries was analyzed with the Friedman test. The effect of clinical examination video input on recommendation scores was evaluated using the Wilcoxon signed-rank test. Group comparisons were performed using Mann-Whitney U tests with Bonferroni correction for multiple comparisons (adjusted α=0.017).

RESULTS

Inter-rater agreement was almost perfect across all three assessment days (Day 1: κ=0.975, Day 2: κ=0.960, Day 3: κ=0.959; all p<0.001). In the no-video group, ChatGPT recommendation scores did not differ significantly across consecutive days (χ^2=1.167, df=2, p=0.558). The inclusion of video input did not significantly affect recommendation scores (Wilcoxon test, all p>0.05). After Bonferroni correction, no statistically significant differences were observed between the no-video and video-assisted groups on any assessment day (Day 1: p=0.106, Day 2: p=0.036, Day 3: p=0.157).

CONCLUSIONS

ChatGPT generated consistent treatment recommendations for OSA with almost perfect agreement between evaluators. Neither repeated querying nor the addition of clinical examination video input significantly affected recommendation scores. Although video input did not produce statistically significant differences, the relatively lower numerical scores observed in the video-assisted condition may suggest that additional clinical information can reveal certain limitations in ChatGPT-generated

recommendations. These findings suggest that ChatGPT may provide consistent decision support in OSA management; however, larger studies are needed to better define its clinical applicability.

Improving Service Efficiency Through Transitioning Level-3 Sleep Studies From In-Hospital To Home Based Testing

Khalid Aldilaijan[1], **Hussain Sarwar**[1], **Bashair Alanazi**[1], **Hamoud Alkurdi**[1], **Nawal Alqubaisi**[1]

[1]*King Fahd Military Medical Complex - Dhahran*

BACKGROUND & AIM

Before this initiative, Level-3 sleep studies at King Fahd Military Medical Complex (KFMMC) required inpatient admission, limiting capacity to four patients per week due to bed availability and device constraints. This resulted in prolonged waiting times for sleep testing (average 206 days) and delayed post-study follow-up (42 days), negatively impacting patient access and service efficiency. This study aimed to evaluate the impact of transitioning to a home-based sleep testing model (Home Sleep Apnea Testing, HSAT) combined with a dedicated follow-up clinic on service capacity, waiting times, and patient flow.

MATERIAL & METHODS

A Quality Improvement (QI) project was conducted through collaboration between the Respiratory Therapy (RT) and Otorhinolaryngology (ORL) departments. The intervention involved transitioning Level-3 sleep studies from inpatient to HSAT, procuring six HSAT devices, implementing a structured staff training program, and establishing a dedicated Sleep Study Clinic for post-test follow-up. A time-series design utilizing two Plan–Do–Study–Act (PDSA) cycles was employed. Data were collected from Q1 2022 to Q4 2025, with the intervention implemented in Q3 2024.

RESULTS

The implementation of HSAT resulted in a significant reduction in waiting times for sleep studies, from a pre-intervention average of 206 days (range: 158–266 days) to 35 days post-intervention. Additionally, the waiting time for follow-up after sleep testing decreased from 42 days to 15 days. Service capacity markedly improved, with 182 patients managed over 18 months compared to 47 patients in the preceding 30 months.

CONCLUSIONS

Transitioning Level-3 sleep studies to a home-based HSAT model, combined with a dedicated sleep clinic, is a feasible and highly effective strategy to improve operational efficiency, expand service capacity, and enhance patient access. This model significantly shortens the time to diagnosis and management and can serve as a scalable approach for similar healthcare settings.

Evaluating CT Metrics As Markers Of DISE-Based Palatal Phenotypes And Velum Collapse Severity: A Prospective Cohort Study

Maria João Marques Silva[1,2], **António Andrade**[1,2], **Sónia Pires Martins**[1,2], **Ricardo Vaz**[1,3,4,5], **Jorge Rodrigues**[1,3,5], **João Viana Pinto**[1,2,5]

[1]*Department of Otorhinolaryngology, Unidade Local de Saúde São João, Porto, Portugal.;* [2]*Unit of Otorhinolaryngology, Department of Surgery and Physiology, Faculty of Medicine, University of Porto, Porto, Portugal.;* [3]*Unit of Anatomy, Department of Biomedicine, Faculty of Medicine, University of Porto, Porto, Portugal.;* [4]*NeuroGen Research Group, Center for Health Technology and Services Research (CINTESIS), Porto, Portugal.;* [5]*CINTESIS@RISE, Faculty of Medicine, University of Porto, Porto, Portugal.*

BACKGROUND & AIM

Palatal shape, classified by Woodson as vertical, intermediate, or oblique, has been proposed as a predictor of surgical response in obstructive sleep apnea. However, objective imaging markers reflecting drug-induced sleep endoscopy (DISE)–based palatal phenotypes remain poorly defined. We hypothesized that computed tomography (CT) linear measurements at the posterior nasal spine could discriminate DISE palatal morphology and correlate with velum collapse severity.

MATERIAL & METHODS

We conducted a prospective observational study including adult patients with obstructive sleep apnea or primary snoring evaluated at a tertiary referral center. All subjects underwent DISE, and only those with available upper airway CT were included. DISE recordings were jointly reviewed by two authors. CT measurements on axial images at the posterior nasal spine included anteroposterior (AP) and transverse (TR) distances and the AP/TR ratio. Nonparametric tests and receiver operating characteristic (ROC) analysis assessed associations and discriminatory performance.

RESULTS

The cohort included 33 patients (73% male) with a mean age of 46.7 years. Palatal morphology was oblique in 45.5%, intermediate in 33.3%, and vertical in 21.2%. The median apnea–hypopnea index was 8.9 events/hour, and the mean oxygen saturation nadir was 83.6%. Severe anteroposterior velum collapse (75–100%) occurred in 90.9% of patients. According to VOTE configuration, 39.4% showed anteroposterior collapse and 54.5% concentric collapse, while lateral or absent collapse occurred in 6.1%.

No significant differences in AP, TR, or AP/TR ratio were observed across DISE palatal morphology groups ($p>0.05$). CT metrics showed poor discrimination for vertical palate (AUC 0.46–0.54). A smaller transverse airway dimension tended to be associated with greater anteroposterior velum collapse severity, although not statistically significant ($\rho = -0.333$, $p = 0.062$).

CONCLUSIONS

Linear CT measurements at the posterior nasal spine did not discriminate DISE-based palatal morphology, reinforcing the importance of DISE for functional assessment. However, the inverse trend between transverse airway dimension and anteroposterior velum collapse suggests a possible anatomical contribution. CT metrics may provide complementary anatomical information, although larger studies are needed to clarify their clinical utility.

OP-1321

Outcomes Of Coblation Intracapsular Tonsillectomy In Adults: A Single-Center Sequential Study

Leonel Luis[1], **David Farinha**[1], **Maria José Santos**[1], **Rita Tomás**[1], **Rodrigo Franco**[1], **Diogo Tomé**[1], **Tiago Eça**[1]

[1]*Otolaryngology Department, Lisbon University*

BACKGROUND & AIM

Coblation intracapsular tonsillectomy (CIT) has been increasingly adopted in pediatric populations, but data in adults remain limited. This study aimed to evaluate the safety, postoperative morbidity, and recurrence rate of CIT in adult patients.

MATERIAL & METHODS

We conducted a single-center, sequential prospective trial including 60 adult patients (≥18 years; mean age 29.0 ± 8.5 years; range 18–57; 48 females, 12 males) undergoing CIT. Indications were recurrent tonsillitis (60%) and post-peritonsillar abscess (25%). Preoperative questionnaires included the SF-12 (mean ± SD: 35.0 ± 5.2) and TOI-14 (32.0 ± 6.1). Pain scores were recorded daily on a 0–10 scale, and postoperative complications were documented.

RESULTS

Minor postoperative hemorrhage (Grade I) occurred in 9 patients (15%), with only one (1.7%) requiring medical evaluation but no intervention. Mean pain intensity was minimal immediately postoperatively (1.2 ± 0.9), peaked at day 5 (4.4 ± 1.4), and resolved by day 14 (0.6 ± 0.8). Only 8.6% of patients adopted a restricted diet during the first week, and 93% resumed a normal diet by two weeks. Within one year, 2 patients experienced a single tonsillitis episode, and 1 patient from the abscess subgroup had a recurrence.

CONCLUSIONS

Coblation intracapsular tonsillectomy in adults appears to be a safe and effective technique, associated with low postoperative hemorrhage, minimal pain, and rapid functional recovery. Although recurrence rates were low in this cohort, CIT may be less suitable for patients operated after peritonsillar abscess. Further multicenter studies with longer follow-up are warranted to confirm long-term efficacy and recurrence risk.

OP-1322

Oxidative Stress In Obstructive Sleep Apnea: A Review Of Molecular Mechanisms And Clinical Biomarkers

Jehad Hammad[1]

[1]*Salmaneya Medical Complec ,SMC, Bahrain*

BACKGROUND & AIM

OSA is a disorder characterized by recurrent episodes of upper airway collapse, leading to intermittent hypoxia (IH) and sleep fragmentation. Beyond its anatomical basis, OSA is increasingly recognized as a systemic disease driven by a state of chronic oxidative stress. The cyclical nature of hypoxia and reoxygenation triggers an overproduction of (ROS), which overwhelms the body's antioxidant defenses and contributes to widespread cellular injury and multi-organ comorbidities.

This aims to synthesize the current understanding of the molecular mechanisms underlying oxidative stress in OSA and to evaluate the clinical utility of key biomarkers for diagnosis, risk , and treatment .

MATERIAL & METHODS

A comprehensive literature review was conducted using PubMed, Google Scholar, and other scientific databases. Search terms included "obstructive sleep apnea," "oxidative stress," "biomarkers," "intermittent hypoxia," and "pathophysiology." The review focused on peer-reviewed studies published within the last 10 years to ensure relevance and novelty.

RESULTS

The primary drivers of ROS production in OSA include mitochondrial dysfunction and the activation of NADPH oxidase. This leads to the activation of pro-inflammatory transcription factors like NF-κB and HIF-1α, creating a self-amplifying cycle of inflammation and oxidative damage. Key biomarkers provide a window into this pathology:

1.Lipid Peroxidation Markers (e.g., Malondialdehyde - MDA): Indicate cell membrane damage and correlate strongly with the Apnea-Hypopnea Index (AHI).

2.DNA Damage Markers (e.g., 8-hydroxy-2'-deoxyguanosine - 8-OHdG): Reflect genotoxic stress and are associated with long-term cancer risk and accelerated aging.

3.Antioxidant Capacity (e.g., Total Antioxidant Capacity - TAC): Measures the depletion of the body's defense systems.

CPAP therapy has been shown to reduce levels of these biomarkers, but normalization is often incomplete, suggesting residual oxidative stress.

CONCLUSIONS

Oxidative stress is a fundamental pathway linking OSA to its severe cardiovascular, neurological, and metabolic consequences. Biomarkers of oxidative stress serve as valuable tools that complement polysomnography by providing a direct measure of systemic pathophysiological burden. Integrating biomarker assessment into clinical practice can enable more precise patient risk stratification and open new avenues for adjunctive antioxidant therapies to improve long-term outcomes.

OP-1323

Bilateral Hypoglossal Nerve Stimulation In Management Of OSA

Ahmed Bahgat[1]

[1]*Al Zahra hospital Dubai*

BACKGROUND & AIM

This study presents our pioneer clinical experience as the first surgical team to perform bilateral hypoglossal nerve stimulation for obstructive sleep apnoea in the Middle East and North Africa (MENA) region.

The primary objectives are:

1. To assess the safety of surgery using the Genio system in patients with moderate to severe OSA.

2. To evaluate the feasibility of performing this procedure

3. To assess patient acceptability and satisfaction, including cosmetic outcomes.

4. To explore insurance coverage and reimbursement feasibility within the healthcare systems of the UAE

MATERIAL & METHODS

This retrospective, descriptive case series reports the first 30 consecutive patients who underwent bilateral hypoglossal nerve stimulation (BiHNS) implantation with the Genio system at Al Zahra Hospital, Dubai. All procedures were performed by Dr. Ahmed Bahgat. The study was conducted according to institutional policies.

Data collection and outcome measures

- Demographics: age, sex, BMI
- Baseline sleep data: baseline AHI, ODI, ESS
- CPAP history: documented adherence/intolerance and reasons for CPAP failure.
- Operative data: operative time, intraoperative findings, intraoperative testing results, immediate complications.
- Postoperative outcomes: length of hospital stay, early (≤30 days) and late (>30 days) complications, device activation date, stimulation parameters at first activation, patient-reported outcomes (ESS, device comfort, cosmetic satisfaction)
- Acceptability: patient uptake of the device when offered, willingness to continue use, and patient satisfaction as assessed during follow-up visits.
- Insurance coverage: documentation of insurance authorization attempts, approvals/denials, out-of-pocket costs.

All collected data were de-identified and entered into a secure study database.

RESULTS

Data will be presented during the congress showing the operative time and postoperative course and improvement in sleep quality both subjectively and objectively

CONCLUSIONS

Bilateral hypoglossal nerve stimulation proved to be effective, feasible, acceptable and safe in Middle East patients suffering from sleep apnea

When To Address The Base Of Tongue In Children With OSA? An Insight On Clinical Presentation And Radiological Examination

Nourhan Howidi[3], **Marwah Al Shmanee**[3], **Ajay Dsouza**[1], **Mohamad A. Bitar**[1,2]

[1]*Al Jalila Children's Specialty Hospital - Dubai Health;* [2]*Mohammed Bin Rashid University of Medicine & Health Sciences;* [3]*Graduate Medical Education - Dubai Health*

BACKGROUND & AIM

Obstruction at the level of the base of the tongue (BOT) is classically suspected as a cause of OSA in children with Down syndrome (DS). However, this can be present in the otherwise healthy child. This presentation will discuss the evaluation and surgical treatment through a case series.

MATERIAL & METHODS

We reviewed children aged 18 years or younger with suspicion of BOT-level obstruction between 2020 and 2023. Data collected included demographics, lateral neck films, sleep endoscopy, polysomnography (PSG), surgical procedures, and postoperative symptoms.

RESULTS

22 patients (mean age 7.3y, 2.11 – 15.11) were included, and 10 failed a previous surgery. Nine had a PSG; eighteen had sleep endoscopy. Only three patients were DS, and five others had significant comorbidities. The lateral neck film was sound when the physician's examination was inconclusive. Sleep endoscopy was the primary assessment confirming an obstruction at the level of BOT. Coblation lingual tonsillectomy and/or midline BOT reduction was the procedure of choice; 91.7% of the operated children improved markedly. One patient had persistent symptoms.

CONCLUSIONS

Obstruction at the level of the BOT should be considered when a child fails a conventional adenotonsillectomy or when the physical examination does not reveal a clear cause for the upper airway obstruction. Sleep endoscopy is diagnostic. The lateral x-ray might help raise the suspicion of BOT obstruction, but the clinical presentation influences this.

OP-1325

Subjective Sleepiness Vs Objective Reality In OSA

Zerrin Özergin Coşkun[1], **Muhammed Sadikzade**[1]

[1]*Recep Tayyip Erdogan University, Medical Faculty, Department of Otorhinolaryngology, Rize*

BACKGROUND & AIM

Polysomnography remains the reference standard for diagnosing and grading obstructive sleep apnea (OSA), whereas symptom-based questionnaires are commonly used to assess daytime sleepiness and perceived sleep quality. In routine practice, however, subjective symptom burden does not always parallel objective disease severity. This study aimed to compare clinical and sleep study findings between mild and severe OSA, with particular attention to the Epworth Sleepiness Scale (ESS) and Pittsburgh Sleep Quality Index (PSQI), and to determine whether these subjective measures discriminate severity as reliably as polysomnographic variables.

MATERIAL & METHODS

This single-center cross-sectional study included 61 adult patients who presented to the otorhinolaryngology outpatient clinic with symptoms suggestive of obstructive sleep apnea and subsequently underwent sleep study evaluation. Based on baseline polysomnographic findings, patients were classified as mild OSA (n=28) or severe OSA (n=33). Demographic characteristics, body mass index, Epworth Sleepiness Scale, Pittsburgh Sleep Quality Index, sleep latency, arousal index, and major respiratory and oxygenation parameters were analyzed. Continuous variables were compared using the independent-samples t test or Mann-Whitney U test according to data distribution, while categorical variables were analyzed with the chi-square test or Fisher exact test. A two-sided p value of less than 0.05 was considered statistically significant.

RESULTS

A total of 61 patients were included, comprising 28 with mild OSA and 33 with severe OSA. In the overall cohort, mean Epworth Sleepiness Scale (ESS) and Pittsburgh Sleep Quality Index (PSQI) scores were 9.35 ± 5.48 and 8.81 ± 4.53, respectively, showing that both daytime sleepiness and impaired sleep quality were common at presentation. When stratified by severity, ESS scores

remained similar between the mild and severe groups (8.61 ± 5.63 vs 9.97 ± 5.36, p=0.340). Total PSQI score also did not differ significantly (7.93 ± 4.77 vs 9.55 ± 4.25, p=0.175). In contrast, poor PSQI category was more frequent in severe OSA (29/33 vs 17/28, p=0.019). Objective sleep study measures showed clearer separation, with significantly higher apnea-hypopnea index (32.91 ± 9.16 vs 9.66 ± 3.36, p<0.001), arousal index (33.11 ± 9.43 vs 9.97 ± 3.75, p<0.001), and worse nocturnal oxygenation in severe disease.

CONCLUSIONS

Subjective symptom scores and objective sleep study findings did not parallel each other consistently in this cohort. Although patients with severe OSA showed markedly greater polysomnographic burden, total ESS and PSQI scores were not significantly different from those of patients with mild disease. This suggests that daytime sleepiness and perceived sleep quality capture dimensions of patient experience that are not fully explained by respiratory event frequency alone. In contrast, poor PSQI category was more common in severe OSA. Clinically, ESS and PSQI remain useful adjuncts, but they should be interpreted alongside, rather than in place of, objective polysomnographic assessment.

OP-1326

The Sound Of Sleep: Snoring Intensity As A Marker Of OSA Severity

Duarte Morgado[1], **Carlos Matos**[1], **Catarina Pinto**[1], **Mariana Santos**[1], **Inês Veloso**[1], **João Rodrigues**[1], **Catarina Lombo**[1], **Rui Fonseca**[1]

[1]*Hospital Senhora da Olivera, Guimarães*

BACKGROUND & AIM

Snoring is the most common symptom of obstructive sleep apnea (OSA), occurring in up to 70–95% of affected patients. Despite its high prevalence, the relationship between objectively measured snoring intensity and OSA severity remains incompletely understood. This study aimed to evaluate the association between acoustic snoring intensity and the severity of OSA.

MATERIAL & METHODS

We conducted a retrospective observational study including 301 adults referred for suspected OSA who underwent home sleep monitoring using the WatchPAT device between 2020 and 2025. OSA severity was classified according to the peripheral apnea–hypopnea index (pAHI) into four groups: no OSA, mild, moderate, and severe. Snoring parameters included mean snoring intensity (dB) and the percentage of sleep time with snoring above 45 dB and 50 dB. Associations between snoring variables and respiratory indices were assessed using Spearman correlation. An ordinal logistic regression model was performed to determine whether snoring intensity was independently associated with OSA severity, adjusting for age, body mass index (BMI) and sex.

RESULTS

A total of 301 individuals were included (mean age 50.8 ± 12.6 years; 76.7% male). Mean snoring intensity increased progressively with OSA severity (p-value < 0.001), with the highest values observed in patients with severe disease. Snoring parameters showed moderate positive correlations with key respiratory indices, including pAHI ($\rho = 0.535$; $p < 0.001$), pRDI ($\rho = 0.506$; $p < 0.001$), and ODI ($\rho = 0.538$; $p < 0.001$). Conversely, snoring intensity was negatively correlated with minimum oxygen saturation ($\rho = -0.509$; $p < 0.001$) and mean oxygen saturation ($\rho = -0.370$; $p < 0.001$). In multivariable ordinal logistic regression analysis, mean snoring intensity remained independently associated with greater OSA severity (OR 1.26; 95% CI 1.16–1.36; $p < 0.001$). Each 1 dB increase in snoring intensity was associated with approximately a 26% increase in the odds of belonging to a more severe OSA category.

CONCLUSIONS

In this study, objective snoring intensity appears to be independently associated with OSA severity. Acoustic analysis of snoring may represent a simple and clinically useful marker for identifying patients at higher risk of severe disease.

Optimizing Patient Selection For Interferential Current Stimulation Therapy In Dysphagia: Immediate Effects Assessed By Videofluoroscopic Swallowing Study

Shota Kinoshita[1], **Yoichiro Sugiyama**[2], **Tomoya Ishida**[2], **Shigeru Hirano**[1]

[1]*Department of Otolaryngology-Head and Neck Surgery, Kyoto Prefectural University of Medicine;* [2]*Department of Otolaryngology-Head and Neck Surgery, Saga University Faculty of Medicine*

BACKGROUND & AIM

Interferential current (IFC) stimulation of the neck can activate sensory afferents in the larynx and pharynx, thereby facilitating pharyngeal swallowing.

Although it provides significant improvement for dysphagic patients who have delayed swallowing initiation, optimized patient selection for more efficient use of IFC stimulation therapy may be necessary. The immediate effects of IFC stimulation on swallowing function should be evaluated before determining its indication for long-term rehabilitation therapy. This study aimed to evaluate the immediate effects of IFC during videofluoroscopic swallowing study (VFSS) and to explore its potential prognostic value for swallowing rehabilitation outcomes.

MATERIAL & METHODS

Patients with dysphagia in rehabilitation hospitals were enrolled. Laryngeal elevation delay time (LEDT), pharyngeal residue, and the penetration-aspiration scale were assessed before and during IFC stimulation to evaluate the immediate effects of IFC stimulation on swallowing function. In some cases, IFC-assisted swallowing rehabilitation was performed with informed consent. Long-term outcomes, including the resumption of oral intake, were evaluated according to the underlying disease.

RESULTS

A subset of patients demonstrated significant improvement in swallowing dynamics during IFC stimulation, including reductions in LEDT and pharyngeal residue. Among these responders, those who underwent IFC-assisted rehabilitation showed modest improvement in oral intake.

CONCLUSIONS

IFC stimulation may facilitate pharyngeal swallowing function, and its immediate effects could help us select suitable patients for its beneficial use. These findings suggest that the immediate response to IFC during VFSS may be a prognostic factor for long-term swallowing outcomes.

Foreign Body Airway Obstruction Resulting In Out-Of-Hospital Cardiac Arrest In Denmark - Incidence, Survival And Interventions

Signe Amalie Wolthers[1], **Mathias Geldermann Holgersen**[1], **Josefine Tangen Jensen**[1], **Mikkel Porsborg Andersen**[3], **Stig Nikolaj Fasmer Blomberg**[1], **Søren Mikkelsen**[4], **Helle Collatz Christensen**[1,2], **Theo Walther Jønson**[1]

[1]Emergency Medical Services, Prehospital Center, Region Zealand, Næstved, Denmark; [2]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [3]Department of Cardiology, Nordsjællands Hospital, Hillerød, Denmark; [4]Prehospital Research Unit, Department of Anaesthesiology and Intensive Care, Odense University Hospital, Denmark

BACKGROUND & AIM

Foreign body airway obstruction (FBAO) stands as an important contributor to accidental fatalities, yet prompt bystander interventions have been shown to improve survival. This study aimed to evaluate the incidence, interventions, and survival outcomes of patients with out-of-hospital cardiac arrest (OHCA) related to FBAO in comparison to patients with non-FBAO OHCA.

MATERIAL & METHODS

In this population-based cohort study, we included all OHCAs in Denmark from 2016 to 2022. Cases related to FBAO were identified and linked to the patient register. Descriptive and multivariable analyses were performed to evaluate prognostic factors potentially influencing survival.

RESULTS

A total of 30,926 OHCA patients were included. The incidence rate of FBAO-related OHCA was 0.78 per 100,000 person-years. Among FBAO cases, 24% presented with return of spontaneous circulation upon arrival of the emergency medical services. The 30-day survival rate was higher in FBAO patients (30%) compared to non-FBAO patients (14%). Bystander interventions were recorded in 26% of FBAO cases. However, no statistically significant association between bystander interventions or EMS personnels' use of Magill forceps and survival was shown, aOR 1.47 (95 % CI 0.6-3.6) and aOR 0.88 (95% CI 0.3-2.1).

CONCLUSIONS

FBAO-related OHCA was rare but has a higher initial survival rate than non-FBAO related OHCA, with a considerable proportion of patients achieving return of spontaneous circulation upon arrival of the emergency medical service personnel. No definitive associations were established between survival and specific interventions performed by bystanders or EMS personnel. These findings highlight the need for further research in this area.

Dysphagia Outcomes After Surgical Vs. Radiation Therapy For Early-Stage Glottic Cancer: A Systematic Review Of Randomized Controlled And Clinical Trials

Sana Baban[2], **Andrea Jakubowski**[1], **Hailey Harbert**[3], **Inna Husain**[4]

[1]Lake Erie College of Osteopathic Medicine; [2]University of Massachusetts Chan Medical School; [3]Edward Via College of Osteopathic Medicine; [4]Powers Health

BACKGROUND & AIM

Dysphagia is a clinically meaningful source of morbidity and reduced quality of life. Both surgery and radiation therapy for early-stage (T1–T2) glottic cancer may impair swallowing, yet their relative impact on dysphagia remains unclear despite similar oncologic control.

MATERIAL & METHODS

PubMed, Cochrane, and Embase were searched following PRISMA guidance. Eligible studies enrolled adults with T1–T2 glottic carcinoma and reported post-treatment dysphagia/swallowing outcomes after surgery and/or radiation. We included direct comparative (surgery vs radiation) and single-modality studies. Records were screened in two stages (title/abstract, then full text). Given expected heterogeneity in outcome definitions and reporting, qualitative synthesis was planned.

RESULTS

Across three database searches, 183 records were screened by title/abstract and 41 articles underwent full-text review. Thirteen studies met inclusion criteria and advanced to data extraction. Included studies were randomized or prospective clinical investigations evaluating swallowing outcomes after surgery and/or radiation; outcome measures and follow-up time points were heterogeneous, precluding meta-analysis.

CONCLUSIONS

Oncologic outcomes are comparable for early-stage glottic cancer, and dysphagia is usually mild and improves over time. Limited comparative evidence suggests transoral surgery is at least comparable to radiotherapy; one study favored transoral surgery with better swallowing-related QoL and lower objective dysphagia scores than RT. More extensive resections may worsen early swallowing but often recover within months, and radiotherapy generally yields low-grade dysphagia.

Heterogeneous measures and follow-up hinder counseling and evidence-based selection. Prospective trials should use standardized dysphagia instruments at consistent intervals to enable meta-analysis.
