Oesophageal soft food bolus obstruction (OSFBO) is a frequent emergency presentation to otolaryngology and gastroenterology services. While many cases resolve without intervention, others require urgent endoscopy, with no UK consensus on referral pathways, timing, or technique. This study evaluates the real-world management of OSFBO across two UK hospitals over 12 years, examining rates of conservative resolution, procedural intervention, associated complications, and the diagnostic utility of post-resolution contrast swallow imaging.

MATERIAL & METHODS

A retrospective review of all adult patients (≥16 years) presenting with OSFBO between August 2008 and August 2020 at one tertiary and one district general hospital. Sharp or non-organic foreign body cases were excluded. Data were collected from electronic records, anonymised, and analysed using IBM SPSS. Categorical and continuous variables were compared using appropriate statistical tests. Kaplan-Meier survival analysis assessed time to resolution, and logistic regression (visualised via a forest plot) identified predictors of procedural intervention.

RESULTS

Among 384 cases, 65% (n=249) resolved with conservative management. Of the 135 patients requiring intervention, 58% (n=70) underwent rigid oesophagoscopy and 42% (n=51) had flexible oesophagoscopy. One case of oesophageal perforation occurred following rigid oesophagoscopy (1.4% complication rate). Flexible nasendoscopy dislodged the bolus in 3% (n=7) of all cases. Hyoscine butylbromide was used in 71% (n=193), with 32% (n=62) subsequently requiring intervention, compared to 6% (n=5) in those not receiving it. Plain radiographs were diagnostic in only 6% (n=7) of 122 cases. Post-resolution contrast swallow imaging was performed in 20% (n=75), with 48% (n=36) revealing oesophageal abnormalities such as webs, achalasia, and strictures. Kaplan-Meier analysis showed most conservative resolutions occurred within 24-48 hours. Regression analysis identified age and absence of hyoscine as significant predictors of intervention.

CONCLUSIONS

The majority of OSFBO cases resolve without the need for invasive procedures. Rigid and flexible oesophagoscopy are both effective, though rigid carries a higher risk of complication. Flexible nasendoscopy may offer a low-risk, bedside option for select patients. Post-resolution contrast swallow studies have high diagnostic yield and should be considered in follow-up. These findings support the need for national guidelines and further prospective research into pharmacological and procedural strategies for OSFBO.

AI-Assisted Computer-Aided Diagnosis Enhances Detection Accuracy In Flexible Endoscopic Evaluation Of Swallowing

Mitsuyoshi Imaizumi[1], **Xin Zhu**[2], **Shigeyuki Murono**[1]

[1]*Department of Otolaryngology, Fukushima Medical University School of Medicine;* [2]*Department of AI Technology Development, Institute of Integrated Research, Institute of Science Tokyo*

BACKGROUND & AIM

Flexible endoscopic evaluation of swallowing (FEES) is a useful and standard tool for assessing swallowing impairment, as it is portable and can be used at the bedside. However, appropriate evaluation of FEES findings is often challenging, especially for inexperienced evaluators. Recent advances in deep learning have led to a resurgence of interest in artificial intelligence-assisted computer-aided diagnosis (AI-assisted CAD) for a variety of medical applications. In the present study, we investigated the effectiveness of FEES-CAD, an AI-assisted CAD system.

MATERIAL & METHODS

he FEES-CAD algorithm was developed using 25,630 expert-annotated images from 199 FEES videos. The system analyzes FEES videos and classifies four key findings: aspiration, laryngeal penetration, vallecular residue, and hypopharyngeal residue. We conducted two evaluations. First, FEES-CAD performance was compared with that of experienced laryngologists (> 15 years

FEES experience) using deidentified, randomized videos. Next, the utility of the system was assessed for 45 inexperienced evaluators (residents, nurses, and medical students). Each evaluator reviewed 64 FEES videos obtained from 32 patients: 32 videos without CAD assistance, and the remaining 32 were equally split, with 16 evaluated with CAD assistance and 16 without. The detection accuracy of FEES findings was analyzed, and the results with and without CAD assistance were statistically compared.

RESULTS

FEES-CAD achieved expert-level accuracy across all classification tasks: penetration (92.5%), aspiration (92.5%), vallecular residue (100%), and hypopharyngeal residue (87.5%). Detection accuracies with and without CAD assistance were as follows: resident doctors (90.1% and 83.7%), nurses (79.4% and 80.1%), and medical students (82.6% and 80.9%). Among resident doctors, detection accuracy was significantly higher with CAD assistance compared to without CAD.

CONCLUSIONS

This study demonstrated expert-level detection accuracy of aspiration and penetration by FEES-CAD, as well as a significant improvement in detection accuracy among resident doctors.

Evaluation Of Tongue Strength And Swallowing In Hypoglossal–Facial Anastomosis: A Videofluoroscopic Kinematic Analysis

Emirhan AKYOL[1,2], **Hakan GÖLAÇ**[3], **Drilon PULA**[4], **Muhittin AKALIN**[5], **Recep KARAMERT**[2], **Halit Nahit ŞENDUR**[6], **Mahi Nur CERİT**[6], **Metin YILMAZ**[2], **Hakan TUTAR**[2]

[1]Adıyaman Training and Research Hospital, Department of Otorhinolaryngology, Adıyaman, Türkiye; [2]Gazi University Faculty of Medicine, Department of Otorhinolaryngology, Ankara, Türkiye; [3]Gazi University, Faculty of Health Sciences, Department of Speech and Language Therapy, Ankara, Türkiye; [4]Prizren City Hospital, Department of Otorhinolaryngology, Prizren, Kosovo; [5]Gaziantep City Hospital, Department of Otorhinolaryngology, Gaziantep, Türkiye; [6]Gazi University Faculty of Medicine, Department of Radiology, Ankara, Türkiye

BACKGROUND & AIM

Hypoglossal–facial anastomosis (HFA) is a widely used reanimation technique in facial paralysis when the proximal facial nerve stump is not accessible. However, reduced tongue strength due to unilateral hypoglossal sacrifice and its impact on swallowing physiology have mostly been discussed subjectively. This study aimed to objectively quantify tongue strength in patients who underwent classic HFA and to characterize temporal–spatial swallowing features using videofluoroscopic swallowing study (VFSS)-based kinematic analysis. We further investigated the associations between tongue strength and swallowing efficiency (pharyngeal residue) as well as swallowing safety assessed by the Penetration–Aspiration Scale (PAS).

MATERIAL & METHODS

In this cross-sectional comparative study, 30 patients who underwent classic HFA and 30 age- and sex-matched healthy controls were included. In the HFA group, symptomatic swallowing was assessed using the T-EAT-10, facial function was assessed using the Regional House–Brackmann system, and tongue atrophy was assessed using the Martins scale. Anterior and posterior tongue strength measurements were obtained for all participants, along with lip compression and buccal suction strength measurements. VFSS was conducted using 10 swallow trials across the IDDSI (International Dysphagia Diet Standardisation Initiative) consistencies. Three trials were performed for IDDSI-0 thin liquid (5 mL), IDDSI-0 thin liquid (single sip), and IDDSI-3 moderately thick liquid (one tablespoon), and one trial for IDDSI-7 solid; oral and pharyngeal temporal–spatial kinematics were analyzed. Swallowing efficiency was quantified using vallecular, pyriform sinus, and total pharyngeal residue measures, while safety was assessed using PAS. Correlations between tongue strength and efficiency/safety metrics were analyzed.

RESULTS

The groups were comparable with respect to age and sex. In the HFA group, effective eye closure was observed in all cases, and resting symmetry across all regions was achieved in 73.3% of participants. According to the T-EAT-10, 63.3% reported symptomatic swallowing complaints (total score ≥3). Anterior and posterior tongue strengths were significantly reduced compared to those in the control group (both, $p<0.001$). Oral preparatory and oral transit times were prolonged across consistencies ($p<0.05$). As an efficiency outcome, vallecular residue was higher, particularly for moderately thick and solid boluses, while total pharyngeal residue increased across all consistencies ($p<0.05$). Swallowing safety was largely preserved, with 93.3% demonstrating PAS scores of 1–2. In solids, vallecular residue was negatively correlated with anterior tongue strength ($r=-0.441$; $p=0.015$). In thin liquids, where safety tended to be most vulnerable, PAS scores showed negative correlations with both anterior and posterior tongue strengths.

CONCLUSIONS

Hypoglossal–facial anastomosis (HFA) is an established technique for facial reanimation, enhancing facial function in the majority of patients. Following HFA, tongue strength decreases significantly and pharyngeal residue increases, indicating

reduced swallowing efficiency; however, swallowing safety is generally maintained, likely due to compensatory mechanisms. Correlations between tongue strength and both swallowing efficiency (residue) and safety (PAS) suggest that tongue-focused rehabilitation may represent a viable intervention strategy. By providing an objective VFSS-based kinematic characterization of swallowing physiology following HFA, these findings may facilitate clinical risk stratification and inform individualized rehabilitation planning during follow-up.

OP-1333

Validity And Reliability Study Of The Swallowing Catastrophization Scale

Nurullah Türe[1], **Özlem Arık**[2], **Zehra Savaş**[3], **Fikret Zeybek**[1]

[1]Department of Otorhinolaryngology, Kütahya Health Sciences University, Kütahya, Türkiye; [2]Department of Biostatistics and Medical Informatics, Necmettin Erbakan University, Konya, Türkiye; [3]Department of Speech and Language Therapy, Kütahya Health Sciences University, Kütahya, Türkiye

BACKGROUND & AIM

This study aimed to evaluate the reliability and validity of the 13 item Swallowing Catastrophization Scale (SCS), designed to quantify swallowing related catastrophization in patients with dysphagia.

MATERIAL & METHODS

In a cross-sectional case control design, patients with dysphagia (n=25) and healthy controls (n=25) were assessed. Outcome measures included the SCS (range, 0–52), Turkish versions of EAT-10 (T-EAT-10), GAD-7 (T-GAD-7), and SWAL-QOL subdomains (T-SWAL-QOL). Internal consistency was examined using Cronbach's alpha with bootstrap 95% confidence intervals. Validity was assessed using Spearman's rank correlations and Mann–Whitney U tests. Statistical significance was set at $p<0.05$.

RESULTS

The mean age was 55.0±17.3 years in the dysphagia group (female/male: 13/12) and 44.6±8.5 years in controls (female/male: 12/13). The SCS demonstrated excellent internal consistency (Cronbach's $\alpha=0.970$; 95% CI: 0.947–0.983). Median [IQR] SCS scores were 26 [11–46] in the dysphagia group and 0 [0–0] in controls, indicating a significant between-group difference ($p<0.001$; $r=0.77$). Convergent validity within the dysphagia group was supported by a very strong correlation between SCS and T-EAT-10 ($\rho=0.875$; $p<0.001$) and a moderate-to-strong correlation with T-GAD-7 ($\rho=0.616$; $p=0.001$). The SCS was inversely correlated with T-SWAL-QOL, most prominently for the Mental Health ($\rho=-0.917$; $p<0.001$) and Fear ($\rho=-0.688$; $p<0.001$) subdomains.

CONCLUSIONS

The SCS exhibits excellent internal consistency and strong evidence of validity for assessing catastrophization-related psychological burden accompanying dysphagia. Further studies with larger samples are warranted to establish test–retest reliability and to confirm the scale's structural validity using comprehensive psychometric approaches.

Cross-Cultural Adaptation And Validation Of The Thai Version Of The Swallowing Disturbance Questionnaire (SDQ)

Ravisara Opascharoenkij[1], **Asst. Prof. Premsuda Sombuntham**[1]

[1]Department of Otolaryngology-Head and Neck Surgery, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [2]King Chulalongkorn Memorial Hospital, Bangkok, Thailand

BACKGROUND & AIM

Dysphagia is a severe, frequently under-recognized condition leading to complications, including aspiration pneumonia and increased mortality. While the globally recognized Swallowing Disturbance Questionnaire (SDQ) correlates with clinical severity—as opposed to quality-of-life-focused tools—a validated Thai version remains unavailable. This study aimed to cross-culturally adapt and validate the Thai-SDQ to provide a reliable screening instrument for the Thai population, facilitating early intervention and improving clinical outcomes.

MATERIAL & METHODS

This cross-sectional study was conducted at a tertiary center in Bangkok. Standardized cross-cultural adaptation guidelines were followed, including translation, expert review, and pretesting. 137 participants (62 high-risk, 75 low-risk) were recruited. High-risk patients had head/neck malignancies, neurological disorders or others; low-risk volunteers were screened via Repetitive Saliva Swallowing Test. All high-risk participants underwent Fiberoptic Endoscopic Evaluation of Swallowing (FEES) as the gold standard. Thai-SDQ psychometric properties and diagnostic validity were evaluated via ROC analysis and Youden's index.

RESULTS

High-risk participants (67.7% male; 61.4±12.81 years) were older and more predominantly male than low-risk individuals (38.7% male; 41.77±11.58 years). Head and neck cancer primarily comprised the high-risk group (95.2%). Thai-SDQ showed excellent internal consistency (Cronbach's alpha = 0.867; 95%CI: 0.832–0.897, p<0.001). Dysphagia symptom-based screening yielded a 33.3% false-positive rate. Median SDQ scores were significantly higher in high-risk (8.5; 0.5–31.5) vs. low-risk (2.5; 0.5–14.5), and confirmed aspiration (12; 2.5–31.5) vs. normal (4.5; 0.5–29.5) groups. ROC analysis revealed an AUC of 0.795. An optimal cut-off of ≥7 provided 81.3% sensitivity, 69.4% specificity, 26% PPV, 96.6% NPV, and 70.8% accuracy. Total SDQ and sub-item (6-15) scores correlated with FEES severity across liquids (r=0.364, p=0.004), purees (r=0.398, p=0.001), and solids (r=0.318, p=0.013).

CONCLUSIONS

Thai-SDQ is a reliable, valid screening tool for oropharyngeal dysphagia, offering superior accuracy over symptom-based assessment. The significant SDQ-FEES correlation underscores its utility in quantifying swallowing disturbance severity. Implementing this standardized tool offers a cost-effective method for early detection, potentially reducing complications and improving patient outcomes in Thailand.

Early Predictors Of Three-Month Feeding Outcomes In Stroke Patients

Dilara Tütüncü Yavuz[1], **Elif Gülen**[1], **Sinem Ekici Yaş**[3], **Kübra Akar**[3], **Can Atabay**[2], **Suat Turgut**[1]

[1]University of Health Sciences, Istanbul Hamidiye Şişli Etfal Health Practice and Research Center, Department of Otorhinolaryngology, Istanbul, Türkiye.; [2]University of Health Sciences, Istanbul Hamidiye Şişli Etfal Health Practice and Research Center, Department of Neurology, Istanbul, Türkiye.; [3]Istanbul Hamidiye Şişli Etfal Health Practice and Research Center, Istanbul, Türkiye.

BACKGROUND & AIM

Post-stroke oropharyngeal dysphagia is associated with aspiration pneumonia, malnutrition, prolonged hospitalization, and increased mortality. Early clinical swallowing assessment may help predict long-term nutritional outcomes; however, evidence regarding its association with feeding status at three months remains limited. This study aimed to determine whether early demographic, clinical, and swallowing findings predict oral feeding, nasogastric tube feeding, or percutaneous endoscopic gastrostomy (PEG) requirement at three months after acute Stroke.

MATERIAL & METHODS

This retrospective cohort study included 66 patients hospitalized with acute ischemic or hemorrhagic stroke who underwent early clinical swallowing assessment. Patients with pre-existing dysphagia, previous major head and neck surgery, neurodegenerative disease, or incomplete follow-up data were excluded. Demographic characteristics, comorbidities, intensive care unit (ICU) admission, length of hospital stay, neurological deficits, and stroke localization were recorded. Stroke localization was categorized as middle cerebral artery infarction, bulbar infarction, or other localizations. Early swallowing assessment included cooperation status, gag reflex, tongue strength, laryngeal elevation, penetration/aspiration signs, and nasogastric tube requirement during hospitalization. The primary outcome was feeding status at three months. Multivariate logistic regression was used to identify independent predictors of PEG requirement.

RESULTS

The study included 66 patients, 38 males and 28 females, with a mean age of 67.8 ± 11.4 years. At three months, 35 patients achieved oral feeding, 14 continued nasogastric tube feeding, and 17 required PEG. Male sex was significantly associated with PEG requirement (p=0.041), whereas oral feeding was more common among females. Patients requiring PEG were older than orally fed patients (p=0.018). Bulbar infarction was strongly associated with PEG requirement (p=0.006). ICU admission and longer hospital stay were also significantly associated with PEG feeding (p=0.004 and p=0.001, respectively). Aspiration, reduced laryngeal elevation, tongue weakness, and absent gag reflex were associated with poor oral feeding recovery. In multivariate analysis, aspiration, bulbar infarction, impaired laryngeal elevation, and prolonged hospitalization independently predicted PEG requirement.

CONCLUSIONS

Three-month feeding outcomes after acute Stroke can be predicted using early clinical swallowing assessment. Aspiration, bulbar stroke, impaired laryngeal elevation, and prolonged hospitalization independently predict PEG requirement. Early identification of high-risk patients may enable timely nutritional planning, close follow-up, and targeted dysphagia rehabilitation.

OP-1336

Can Fois Predict Mortality In Hospitalised Patients? A Retrospective Study Of A Dysphagia Cohort

Joana Dias[1], **Rita Carvalho**[1], **Sandra Castro**[1], **João Lino**[1], **Isabel Carvalho**[1]

[1]*Unidade Local de Saúde de Santo António*

BACKGROUND & AIM

Oropharyngeal dysphagia in hospitalised patients is associated with malnutrition, aspiration and increased mortality. Early recognition enables timely assessment and multidisciplinary intervention, but dysphagia is often under-recognised and bedside severity grading is difficult. FEES (fiberoptic-endoscopic-evaluation-of-swallowing) performed by otorhinolaryngologists can diagnose, guide diet recommendations and support risk stratification. FOIS (Functional Oral Intake Scale) was developed to document functional oral intake based on FEES; robust evidence supporting FOIS as isolated prognostic marker is limited, although observational data suggest worse outcomes with lower scores.

Purpose: characterise FEES findings in hospitalised patients with suspected dysphagia and identify factors associated with feeding route, discharge outcome and mortality.

MATERIAL & METHODS

Retrospective study of 114 consecutive inpatients referred for dysphagia assessement with FEES in the Otorhinolaryngology department. FOIS was recorded at first evaluation. Outcomes: mortality (in-hospital, 30 days, 6 and 12 months), discharge status (alive vs dead) and need for alternative feeding (NGT/PEG). Fisher's exact, Mann–Whitney U, Spearman and Kruskal–Wallis tests were used; mortality analyses were adjusted for age and sex.

RESULTS

114 patients were included (mean age 73.9±12.9); 16 did not undergo FEES due to poor cooperation/intercurrent complications. Mean time from request to assessment was 8.3 days. 12% had no swallowing abnormalities.

FOIS distribution: high (5–7) 56.1%, intermediate (3–4) 18.4%, low (1–2) 25.5%. FOIS correlated with alternative feeding (Spearman rho −0.608, $p<0.001$); 100% with FOIS ≤3 required alternative feeding. In-hospital mortality was 19.3% and 30-day mortality 28.1%. For mortality prediction, FOIS ≤4 vs ≥5 was more discriminative: 12-month mortality 53.5% vs 32.1% (OR=0.41, p=0.041). Mortality differed across FOIS levels at 6 months (H=14.64, p=0.023) and 12 months (H=13.16, p=0.041). FOIS 4 had the highest mortality (82% at 6 and 12 months), suggesting a non-linear risk profile, while FOIS 7 had the lowest 12-month mortality (9.1%). These associations remained significant after adjustment for age and sex.

CONCLUSIONS

Inpatient FEES revealed marked clinical frailty with substantial in-hospital and post-discharge mortality. FOIS ≤4 appeared more clinically relevant than the traditional FOIS ≤3 (oral intake vs alternative feeding) for predicting mortality and may capture risk beyond feeding-route decisions. Integrating FOIS into inpatient pathways may help guide multidisciplinary planning, anticipate nutritional support needs, and optimise feeding routes. Earlier identification and standardised referral for FEES could shorten delays and improve patient safety, particularly by reducing aspiration risk.

Comparing Tongue Pressures Using Three Different Portable Devices

Ahmed Nagy[1], **Sara Alnuaimi**[1], **Fatima Alomari**[1], **Mohammed Alharthi**[1], **Mohammed Alkaabi**[1], **Shamma Alblooshi**[1]

[1]*United Arab Emirates University*

BACKGROUND & AIM

The IOPI is the most commonly used device for assessing and rehabilitating lingual physiological performance. As a recognized gold standard, recently emerging lingual pressure measurement tools have been validated against it. There is a need to assess reliability further and compare tools across new subject populations that differ from those in which the devices were originally manufactured and calibrated. We compared the tools in a new Subject population and administered a user comfort questionnaire to assess device practicability

MATERIAL & METHODS

We collected three sets of three tasks across three devices in a randomized order: the IOPI, the Tongueometer, and the JMS. The Tasks were Anterior Lingual maximal pressure, Posterior Lingual maximal pressure, and a Regular effort Saliva Swallow. We also collected a questionnaire on the ease of use of the three devices across different tasks

RESULTS

The Three Devices showed a Cronbach's Alpha score of greater than 0.92 (Excellent reliability) for trials with each device, and there was a significant correlation for their scores across the three tasks. The JMS device scored significantly lower than the IOPI and Tongueometer on the three tasks and on the ease-of-use questionnaire.

CONCLUSIONS

The results do not negate the JMS's usability or the applicability of recommendations drawn from studies using it; however, they suggest that the JMS bulb is less user-friendly and may contribute to the lower pressure scores observed. The Questionnaire scores, when considered alongside the cost of each device, clearly favour the Tongueometer as the best option, as the scores are not significantly different from IOPI in either pressure values or subject questionnaire scores

Tongue Pressure , IOPI , JSM, Tongueometer

OP-1338

A Study On Swallowing Function Following Esophageal Cancer Resection And Reconstruction

SHINYA FUSE[1]

[1]*Kyoto Prefectural University of Medicine*

BACKGROUND & AIM

Risks of dysphagia following subtotal esophagectomy include recurrent laryngeal nerve palsy and difficulty elevating the larynx.

Our hospital's Swallowing Team intervenes in all cases of esophageal cancer surgery involving reconstruction. Patients are referred to our department from the Department of Gastroenterological Surgery prior to surgery for the exclusion of multiple primaries and laryngeal function assessment and are then referred to our team after surgery.

MATERIAL & METHODS

In this study, we examined swallowing function following esophageal cancer resection and reconstruction. The study included 119 patients (90 men, mean age 70.0 ± 7.8 years) who underwent surgery for esophageal cancer between November 2021 and October 2024. The surgical procedures were subtotal esophagectomy (109 cases of transmediastinal subtotal esophagectomy and 10 cases of open subtotal esophagectomy), with reconstruction primarily performed via the retrosternal approach. Additionally, while two-field dissection was the standard, three-field dissection involving neck procedures was performed in 10 cases.

Regarding feeding status at discharge, a comparison was conducted between two groups—those capable of oral intake of three meals per day and those requiring alternative nutrition, with concomitant gastrostomy or enterostomy, focusing on factors such as the extent of lymph node dissection, vocal cord paralysis, and postoperative laryngeal elevation.

RESULTS

In the alternative nutrition group, forward laryngeal elevation was significantly restricted, and the LEDT, which indicates the reflex to initiate swallowing, was significantly delayed.

Following a three-field dissection, vertical laryngeal elevation was significantly restricted.

CONCLUSIONS

Based on these results, we report on prospects for rehabilitation following esophageal cancer surgery.

Early speech and swallowing therapy in Tapia syndrome-like lower cranial neuropathies following septorhinoplasty and maxillofacial surgery: a four case series

FATMA NERSE[1], **SAMİ CAN SARAL**[1], **HANDE DURMUŞ BARKHUDARLI**[1], **ERKAN SOYLU**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, Istanbul Medipol University Hospital, Istanbul, Turkey*

BACKGROUND & AIM

Lower cranial nerve neuropathies following septorhinoplasty and maxillofacial procedures are rare but may lead to significant functional impairment. Tapia syndrome, characterized by combined involvement of the hypoglossal (XII) and recurrent laryngeal branches of the vagus nerve (X), presents with dysphagia, dysphonia, dysarthria, and tongue deviation. Current literature mainly reports conservative management with short-term corticosteroid therapy followed by spontaneous recovery, while data on structured rehabilitation are limited.To evaluate the clinical impact of early, individualized speech, voice, and swallowing therapy on functional recovery in patients with postoperative lower cranial nerve neuropathies.

MATERIAL & METHODS

This retrospective case series included four patients who developed lower cranial nerve dysfunction following septorhinoplasty (n=3) and maxillofacial surgery (n=1). Neurological involvement included combined X and XII nerve palsy (n=2), isolated XII palsy (n=1), and combined IX, X, and XII involvement (n=1). All patients received standard short-term corticosteroid therapy. Within the first 48 hours postoperatively, all patients underwent comprehensive evaluation including clinical examination and fiberoptic endoscopic evaluation of swallowing (FEES), followed by early initiation of individualized rehabilitation programs targeting swallowing safety, phonation, and tongue mobility.

RESULTS

All patients presented with dysphagia, dysarthria, and impaired phonation characterized by reduced maximum phonation time and altered voice quality. Therapy protocols varied between 5 and 20 sessions over 2–5 weeks. Functional improvements were observed in all cases, including restoration of safe oral intake, significant improvement in speech intelligibility, and near normalization of voice parameters. Objective findings (FEES and/or VFSS) demonstrated resolution or marked reduction of aspiration/penetration and improved vocal cord function. Compared to literature reports of recovery periods ranging from 3–6 months or incomplete recovery, all patients in this series achieved near-complete functional recovery within weeks. No long-term deficits were observed during at least one year of follow-up.

CONCLUSIONS

Early initiation of structured and individualized speech and swallowing therapy appears to significantly accelerate functional recovery in Tapia syndrome-like neuropathies following septorhinoplasty. These findings suggest that rehabilitation should be considered an essential component of management rather than a supportive adjunct.

Functional Outcomes Of Voice And Swallowing After Total Thyroidectomy

Furkan Kanmaz[1], **Senem Kurt Dizdar**[1], **Ümit Kamer**[1], **Ömer Faruk Saygıcak**[1], **Dilara Tütüncü Yavuz**[1], **Suat Turgut**[1]

[1]*SBU, Şişli Hamidiye Etfal Research and Application Center, Department of Otorhinolaryngology (ENT)*

BACKGROUND & AIM

To objectively and subjectively evaluate both swallowing and voice functions in patients with preserved nerve integrity after total thyroidectomy, compare surgical techniques, and examine the effects of identified risk factors (gender, age, diagnosis, thyroid volume) on voice and swallowing outcomes.

MATERIAL & METHODS

Between March 2024 and September 2025, 66 patients who underwent total thyroidectomy with nerve integrity confirmed by intraoperative nerve monitoring (IONM) were prospectively evaluated for swallowing and voice functions preoperatively and postoperatively at day 1, week 1, month 1, and month 3. Swallowing functions were assessed objectively using the Penetration-Aspiration Scale (PAS) and the Yale Pharyngeal Residue Severity Rating Scale via fiberoptic endoscopic evaluation of swallowing (FEES), and subjectively using the Eating Assessment Tool-10 (EAT-10) questionnaire. Voice functions were measured through acoustic analysis using Praat software, evaluating jitter, shimmer, harmonics-to-noise ratio (HNR), and maximum phonation time (MPT). Patients were stratified by surgical technique into NVCT (nerve visualization during capsular dissection technique) and CD (capsular dissection) groups. Relationships between surgical technique, age, gender, thyroid volume, and diagnoses (multinodular goiter, thyroid cancers, Graves' disease) with postoperative changes in swallowing and voice functions were evaluated.

RESULTS

Pathological PAS rates increased significantly on postoperative day 1 and week 1 (13.6% and 7.6%) compared to preoperative levels (3%) but normalized by month 3. Similarly, pathological Yale scores were significantly higher on day 1 and week 1 (22.7% and 10.6% vs. 4.5%), remained elevated at month 1 without significance, and normalized at month 3. The NVCT group showed significantly better early postoperative swallowing scores than the CD group, though this difference resolved by month 3. Clinically significant dysphagia (EAT-10 ≥3) was observed in 9.1% of patients. Advanced age (>50 years), female gender, and large thyroid volume (>100 ml) were independent risk factors for dysphagia. All acoustic voice parameters significantly deteriorated postoperatively (jitter, shimmer, HNR, and MPT); however, voice changes were not associated with surgical technique, age, gender, or thyroid volume.

CONCLUSIONS

Our study shows that even with preserved recurrent laryngeal nerve and no vocal cord paralysis, nerve trauma from surgical traction or dissection can cause temporary swallowing and voice impairment. Patients should be counseled preoperatively about this risk. Objective postoperative swallowing evaluation is particularly important for patients with comorbidities or chronic pulmonary disease to prevent aspiration complications. This study is the first to identify increased thyroid volume, female gender, and advanced age as risk factors for temporary swallowing dysfunction after thyroidectomy. Additionally, the NVCT technique better preserves early postoperative swallowing compared to capsular dissection.

Dysphagia In Parkinson's Disease Following STN-DBS: Can Swallowing Therapy Make A Difference?

PhD Cand. Özge Selen AVCI CAN[1], **Assoc. Prof. Dr. Zahide Çiler BÜYÜKATALAY YALDIZ**[2], **Prof. Dr. Suna TOKGÖZ YILMAZ**[3]

[1]Ankara University, Institute of Health Sciences, Department of Audiology and Speech Pathology, Hearing, Balance, Speech Disorders Diagnosis and Rehabilitation Center; [2]Ankara University, Department of Otorhinolaryngology, Head and Neck Surgery, İbni Sina Hospital; [3]Ankara University, Faculty of Health Sciences, Department of Audiology

BACKGROUND & AIM

Subthalamic nucleus deep brain stimulation (STN DBS) is widely used to treat debilitating motor symptoms and fluctuations in Parkinson's disease (PD) patients. The impact of STN DBS on axial symptoms, such as swallowing function, is less well understood, with research on these symptoms showing mixed results. This study aims to evaluate the swallowing function of individuals with PD undergoing STN DBS with instrumental and non-instrumental measurement tools and investigate the effectiveness of swallowing therapy.

MATERIAL & METHODS

In this study, 10 PD patients undergoing STN DBS were recruited. The assessment of swallowing function was conducted using FEES alongside standardized measurement scales, including the DHI, T-SWAL-QOL, EAT-10, FOAS, and MDS-UPDRS under both MEDS-ON/STIM-ON and MEDS-ON/STIM-OFF conditions. After initial assessments, a swallowing therapy program consisting of eight sessions was initiated. After swallowing therapy, FEES and other measurement methods were re-administered in MEDS-ON/STIM-ON and MEDS-ON/STIM-OFF conditions. Statistical analyses were performed using SPSS version 21.0, using paired t-tests or Wilcoxon tests to analyze treatment effects and ANOVA to investigate differences between stimulation conditions, with significance $p<0.05$.

RESULTS

As a result of the FEES test performed at the first evaluation, higher PAS scores were recorded in the STIM-ON condition than in the STIM-OFF condition ($p<0.05$). In the final FEES assessment performed after swallowing therapy, patients' PAS scores decreased and FOAS scores improved. In line with patient-reported subjective findings, patients with less severe dysphagia at baseline showed significant benefits in swallowing-related quality of life, especially in the psychological, social and nutritional subdomains.

CONCLUSIONS

This innovative research underscores the significant impact of dysphagia on the quality of life for PD patients undergoing STN DBS, a factor that is frequently underestimated. Additionally, it highlights the essential role of swallowing therapy in mitigating the risk of aspiration among this patient population.

Multivariate Analysis Of Clinical, Histopathological, And Sialoendoscopic Factors In The Diagnosis Of Sjögren’s Disease

Onur Cem Mete[1], **Kemal Koray Bal**[1], **Cengiz Özcan**[1], **Mehmet Atilla Argın**[2]

[1]Department of Otorhinolaryngology, Faculty of Medicine, University of Mersin, Mersin, Turkey; [2]Department of Ophthalmology, Faculty of Medicine, University of Mersin, Mersin, Turkey

BACKGROUND & AIM

To evaluate the diagnostic importance of sialoendoscopy, salivary flow rate, and labial salivary gland biopsy (LSGB) in differentiating Sjögren’s Disease (SjD) from non-autoimmune sicca syndrome, while accounting for demographic and anatomical variables.

MATERIAL & METHODS

A comparative study was conducted with 50 patients divided into two cohorts: Group A (n=25, ACR/EULAR>4) and Group B (n=25, symptomatic sicca controls). Data points included age, sex, unstimulated salivary flow rate (USFR), LSGB results (classified as "consistent" or "not consistent" with SjD), and sialoendoscopic findings. Anatomical distribution was recorded by affected side (right, left, or bilateral) and gland type (submandibular vs. parotid). Statistical significance was assessed using the Chi-square tests for categorical anatomical and endoscopic data.

RESULTS

LSGB results remained the strongest independent predictor of SjD ($p<0.05$), followed closely by sialoendoscopic findings (ductal pallor and stenosis), which were present in 72% of Group A versus 36% of Group B ($p<0.05$). Analysis of affected glands showed a statistically significant predilection for bilateral parotid involvement in the SjD group ($p<0.05$), whereas the control group exhibited more localized or submandibular-dominant symptoms. While USFR was significantly reduced in Group A, it showed a moderate correlation with age, suggesting decreased specificity in older populations. Multivariate regression identified the combination of bilateral sialoendoscopy findings and positive biopsy as the most accurate diagnostic model.

CONCLUSIONS

The integration of sialoendoscopy provides critical structural data that complements histopathological findings. The statistical significance of bilateral glandular involvement in SjD suggests that "affected side" and "gland type" are essential variables in

clinical staging. These results advocate for a diagnostic approach that weights endoscopic structural changes and biopsy results more heavily than isolated flow rate measurements to improve diagnostic precision.

OP-1343

Reliability Of The Modified Evans Blue Dye Test In Swallowing Assessment In Tracheostomy Patients: A Preliminary Study

Lütfü ŞENELDİR[1], **Aslı GÜNEŞ GÖKÇE**[1], **Fatma NERSE**[1], **Ömer Faruk ÇALIM**[1], **Tolga KANDOĞAN**[1]

[1]*Department of Otolaryngology Head and Neck Surgery, Faculty of Medicine, İstanbul Medipol University, İstanbul, Türkiye*

BACKGROUND & AIM

This preliminary study aimed to evaluate the sensitivity and specificity of the modified Evans blue dye test (MEBDT) compared to the fibre-optic endoscopic evaluation of swallowing (FEES) to detect aspiration in tracheostomized patients.

MATERIAL & METHODS

This observational accuracy study included 34 patients hospitalised for respiratory complications, subjected to prolonged intubation, and for this reason, tracheostomized. All participants underwent MEBDT according to standard protocols, followed by a blinded FEES evaluation within a 24-hour interval. A positive MEBDT was defined as the presence of blue-dyed secretions during tracheal suctioning, while FEES identified aspiration as the entry of material below the true vocal folds.

RESULTS

Mean patient age was 57.3 ± 18.8 years. Aspiration was identified in 29 patients (85.3%) when assessed by fibre-optic endoscopic evaluation of swallowing; of these, 19 had aspiration when evaluated by modified Evans blue dye test. No false-positive results were observed, and 5 patients were correctly classified as non-aspirating. The sensitivity and specificity of MEBDT were 65.5% and 100.0%, respectively for detecting aspiration. The positive predictive value was 100.0%, whereas the negative predictive value was 33.3%.

CONCLUSIONS

The modified Evans blue dye test (MEBDT) is a simple and cost-effective bedside screening tool for aspiration in tracheostomized patients. While its high specificity makes it reliable for confirming aspiration, its moderate sensitivity and low negative predictive value limit its ability to exclude it. Therefore, negative results should be confirmed with fibre-optic endoscopic evaluation of swallowing (FEES), especially in high-risk patients.

OP-1344

Assessment Of Swallowing And Pharyngeal Motor Function After Chemoradiotherapy In Nasopharyngeal Carcinoma Patients At Cipto Mangunkusumo General Hospital, Jakarta

Ika Dewi Mayangsari[1], **Elvie Zulka Kautzia**[1], **Timotius Alvonico**[1]

[1]*Faculty of Medicine Universitas Indonesia - Ciptomangunkusumo General Hospital, Jakarta*

BACKGROUND & AIM

Nasopharyngeal carcinoma (NPC) is the most common head and neck malignancy in Indonesia. Chemoradiotherapy, the standard treatment for NPC, may cause dysphagia due to damage to swallowing structures surrounding the tumor. Swallowing function can be evaluated using Fiberoptic Endoscopic Evaluation of Swallowing (FEES), while pharyngeal motor function may be assessed through the pharyngeal squeeze maneuver (PSM), velopharyngeal squeeze maneuver (VPSM), and endoscopic pharyngeal contraction grade (EPCG). This study aimed to evaluate swallowing and pharyngeal motor function in post-chemoradiotherapy NPC patients and to determine their association with demographic characteristics

MATERIAL & METHODS

This study employed a cross-sectional survey design involving 53 post-chemoradiotherapy NPC subjects, both with and without complaints of dysphagia. All subjects underwent FEES examination alongside a review of their medical records.

RESULTS

Based on the FEES examinations, 35 subjects (66%) experienced dysphagia, with the majority presenting with neurogenic-type dysphagia (35 subjects or 66%), involvement of the oropharyngeal phase (32 subjects or 60.4%), and a mild degree of severity (22 subjects or 41.5%). Regarding pharyngeal motor function characteristics, 13 subjects (24.5%) demonstrated impairment in VPSM, 28 subjects (52.8%) showed impairment in PSM, and 21 subjects (39.6%) exhibited impairment in EPCG.

CONCLUSIONS

FEES examination should be routinely performed in post-chemoradiotherapy NPC patients, regardless of the presence of dysphagia symptoms. Pharyngeal motor function should also be routinely evaluated in post-chemoradiotherapy NPC patients, given the high prevalence of pharyngeal motor dysfunction observed.

Breaking Barriers In Dysphagia: ENT And Gastroenterology Collaboration For Better Patient Outcomes - Pilot Joint ENT And Gastroenterology Transnasal Oesophagoscopy (TNO) Clinic

Avantie Khudan[1], **Shalini Menon**[1], **Sadie Khwaja**[1]

[1]*Manchester University NHS Foundation Trust*

BACKGROUND & AIM

Background: Dysphagia is a complex symptom that can arise from a wide range of

structural, functional and neurological causes involving both the upper

aerodigestive tract and gastrointestinal system. Patients are inadvertently referred between specialities for the same complaint.

Objective: To determine the effectiveness of a joint ENT and Gastroenterology clinic with the use of TNO in the 2 week wait (2WW) setting for patients presenting with high dysphagia.

MATERIAL & METHODS

Methods: An initial audit and process mapping of the current patient pathway was completed. A pilot joint clinic with ENT and Gastroenterology performing TNO was conducted for 3 months. Patients had an initial telephone consultation to assess suitability for TNO. Patients that were not suitable for TNO were seen face-to-face in the ENT clinic and underwent flexible laryngoscopy.

RESULTS

Results: The initial audit of our current pathway showed that 22% of patients had already been seen by Gastroenterology before being referred to ENT team or had been referred to Gastroenterology following ENT review. The average time spent on the 2WW pathway was 26.8 days and 1% of patients were diagnosed with cancer. Interestingly, despite symptoms being localized above the sternal notch, a considerable proportion of patients had pathology noted within the oesophagus.

CONCLUSIONS

Conclusion: Preliminary observations demonstrated improved diagnostic efficiency with the joint model and shorter time on the 2WW pathway. Overall patient feedback was favourable. This joint model represents a practical approach to improve the pathway for patients presenting with complex upper aerodigestive complaints.

OP-1346

Impact Of Anxiety On Postoperative Pain And Swallowing Function In Adults Undergoing Tonsillectomy: A Prospective Study

Göhhan Toptaş[1], **Ferhat Deniz**[1], **Sümeyra Doluoğlu**[1], **Hasan Ünver**[2]

[1]*Department of Otolaryngology-Head and Neck Surgery, Ankara Etlik City Hospital, Ankara, Turkey;* [2]*Department of Psychiatry, Ankara Etlik City Hospital, Ankara, Turkey*

BACKGROUND & AIM

Adult tonsillectomy is commonly associated with significant postoperative pain and morbidity. While psychological factors have been investigated in pediatric populations, evidence in adults remains limited. This study aimed to evaluate the association between preoperative anxiety and postoperative pain and swallowing function in adult tonsillectomy patients. We hypothesized that high levels of preoperative anxiety would be associated with increased pain intensity and delayed improvement in swallowing function during the early postoperative period.

MATERIAL & METHODS

This prospective study included 60 adults (18–65 years) undergoing tonsillectomy at a tertiary referral center. Preoperative anxiety was assessed using the State-Trait Anxiety Inventory (STAI) and Anxiety Sensitivity Index-3 (ASI-3). Patients were stratified into mild (n=42) and high anxiety groups (n=18) based on STAI scores. Postoperative pain was measured using the Visual Analog Scale (VAS) at 6 hours, 24 hours, 1 week, and 2 weeks. Swallowing function was evaluated at postoperative week 1 using the Eating Assessment Tool-10 (EAT-10). Correlation analyses (Spearman's Rho test) and group comparisons (Mann-Whitney U test and Pearson Chi-Square test) were performed.

RESULTS

Postoperative pain scores were significantly higher in the high anxiety group at all time points (p = 0.0001). EAT-10 scores were also significantly higher in this group (29.5 (22-36) vs. 19 (7-35); p = 0.0001), indicating worse swallowing function. STAI scores showed moderate-to-strong positive correlations with pain at all time points (r = 0.43–0.83, p = 0.0001), with the strongest correlation observed at postoperative week 1 (r = 0.83). A strong positive correlation was also found between STAI and EAT-10 scores (r = 0.70, p = 0.0001). Although overall complication, bleeding, readmission, and reoperation rates were numerically higher in the high-anxiety group, none of these differences reached statistical significance (p = 0.30, 0.18, 0.09, and 0.53, respectively).

CONCLUSIONS

Higher preoperative anxiety levels are significantly associated with increased postoperative pain and impaired swallowing function following adult tonsillectomy. Preoperative identification of high-anxiety patients may enable targeted interventions to improve postoperative recovery and clinical outcomes.

OP-1347

Novel Glottic Closure Surgery For Severe Dysphagia: A Retrospective Review Of 110 Consecutive Cases

Tatsuya Furukawa[1], **Daichi Fujii**[1], **Sena Horiguchi**[1], **Toshihiko Yamashita**[1], **Takashi Ueda**[1], **Hirotaka Shinomiya**[1], **Takeshi Fujita**[1], **Ken-ichi Nibu**[1]

[1]*Department of Otolaryngology–Head and Neck Surgery, Kobe University Graduate School of Medicine*

BACKGROUND & AIM

Intractable aspiration in patients with severe dysphagia has traditionally been managed using irreversible aspiration-prevention procedures such as total laryngectomy or laryngotracheal separation. To reduce postoperative local complications, particularly salivary leakage, a novel glottic closure procedure was developed in Japan. We previously reported its feasibility in head and neck cancer patients, including those with prior radiotherapy. The present study evaluates its safety in a broader population with dysphagia of various etiologies.

MATERIAL & METHODS

A retrospective review was conducted of 110 consecutive patients with severe dysphagia who underwent this glottic closure procedure between 2014 and 2025. Patients had dysphagia resulting from multiple causes, including neurological disease and head and neck cancer. Postoperative complications were analyzed, with particular attention to local wound-related events and systemic adverse outcomes.

RESULTS

Salivary leakage from the sutured glottic site occurred in 3 patients (2.7%). Two resolved with conservative management, and one required revision surgery. One patient receiving anticoagulation therapy for prior cerebral infarction developed postoperative hemorrhage requiring surgical hemostasis. No patient who was not ventilator-dependent preoperatively required new postoperative mechanical ventilation. One patient developed sudden cardiopulmonary deterioration on postoperative day 3 and died despite intensive management. No evidence of surgical site infection, hemorrhage, or airway obstruction was identified, and a direct causal relationship with the procedure could not be established.

CONCLUSIONS

In this series, the glottic closure procedure demonstrated a low incidence of local surgical complications while effectively preventing aspiration. Although procedure-related adverse events were infrequent, careful perioperative assessment remains essential, as candidates for this surgery often present with significant systemic comorbidities. Further prospective evaluation is warranted to better define patient selection and perioperative risk.

OP-1348

A Systems Approach To AI-Assisted Outcome Capture And Tariff Assurance In Ear, Nose And Throat Outpatient Clinic

Praneta Kulloo[1]

[1]*Lewisham and Greenwich NHS Trust*

BACKGROUND & AIM

In Ear, Nose and Throat (ENT) outpatient clinics, dual-documentation, a narrative clinical letter and a structured Electronic Patient Record (EPR) outcome form, creates massive administrative failure demand. This structural duplication routinely leaves a substantial volume of patient pathways unrecorded at the point of care, risking regulatory breaches and lost procedural tariffs. We hypothesized that missing Referral to Treatment (RTT) outcomes represent a systemic process failure rather than behavioural "clinician omission," aiming to evaluate whether safely integrating Artificial Intelligence (AI) could provide a scalable, high-impact solution.

MATERIAL & METHODS

A pragmatic mixed-methods process evaluation was conducted at Lewisham and Greenwich National Health Service (NHS) Trust, involving ENT clinicians and operational managers. To accommodate stretched clinical schedules, we utilised targeted interviews and a cross-sectional survey rather than time-intensive workshops. Process modelling visually mapped workflow handoffs to analyze systemic bottlenecks. The MoSCoW (Must have, Should have, Could have, Won't have) method prioritised intervention requirements to ensure compliance with the NHS DCB0129 clinical safety standard. Outcomes measured included duplication frequency, RTT omission risk, and future-state workflow acceptability.

RESULTS

Process mapping exposed a hidden "retrospective correction loop," proving the organisation relied heavily on retroactive error-catching rather than proactive capture. Surveys confirmed this systemic disconnect: 80% of clinicians "always" complete dual documentation, and 60% recognize RTT omission risks during clinics. Rather than proposing costly standalone software, the future-state design leveraged the Trust's already-funded transition to Ambient Voice Technology (AVT). By extracting structured data from clinic letters to pre-populate operational forms, 70% of clinicians agreed this proposed "Verified AI" workflow would improve reliability. Crucially, a "human-in-the-loop" validation step was mandated to mitigate AI risk and ensure safety compliance.

CONCLUSIONS

Missing operational data is a structural workflow failure, not a behavioural issue. The proposed AI-assisted workflow provides a highly scalable, cost-effective redesign by leveraging existing digital infrastructure. By strategically shifting the clinician's role from manual typist to data validator, this intervention reduces administrative burnout, guarantees clinical safety, and directly ensures organizational financial sustainability.

OP-1349

Work-Related Musculoskeletal Symptoms And Ergonomic Practices Among Otolaryngologists In Kuwait: A Cross-Sectional Study

Nawaf Almotairi[1], **Abdulrahman Albader**[1], **Bedour Alhajeri**[1], **Jana Mohammed**[2], **Abdullah AlBader**[2]

[1]*Otolaryngology–Head & Neck Surgery, Kuwait Institute for Medical Specializations (KIMS), Kuwait.;* [2]*Department of Otolaryngology- Head and Neck Surgery, Jaber Al-Ahmad Hospital ,Kuwait City.*

BACKGROUND & AIM

Work-related musculoskeletal disorders represent a major occupational health concern among surgeons, largely due to prolonged static postures, repetitive movements, and demanding workloads. Otolaryngology–head and neck surgeons are particularly exposed to ergonomic challenges; however, local data from Kuwait remain limited. This study aims to determine the prevalence of work-related musculoskeletal symptoms among otolaryngology–head and neck surgeons in Kuwait and to assess associated demographic, workload, and ergonomic factors.

MATERIAL & METHODS

A cross-sectional survey was conducted among otolaryngology–head and neck surgeons working in five public hospitals in Kuwait. Data were collected using a validated, self-administered questionnaire covering demographic characteristics, professional background, workload, ergonomic practices, and self-reported musculoskeletal symptoms. Descriptive statistics were used to summarize findings, and associations were assessed using appropriate statistical tests with a significance level of $p < 0.05$.

RESULTS

A total of 52 surgeons participated (mean age 45.38 ± 9.81 years), of whom 78.8% were male. Overall, 71.2% reported at least one work-related musculoskeletal symptom. The most frequently affected regions were the cervical region (97.3%), dorsal region (81.1%), and lumbar region (67.6%). Right-sided upper extremity symptoms were more prevalent than left-sided symptoms, particularly in the hand and fingers (73%), shoulder (67.6%), and wrist (64.9%). More than half of the surgeons (51%) spent 12 or more hours per week in the operating room, and 63.5% regularly performed surgeries lasting three or more consecutive hours. Among symptomatic surgeons, 56.8% required medical treatment, 24.3% reported limitations in daily activities, and 21.6% expressed concerns regarding career longevity. Despite this burden, 44% did not take microbreaks and 46.7% did not use arm support during surgery.

CONCLUSIONS

Work-related musculoskeletal symptoms are highly prevalent among otolaryngology–head and neck surgeons in Kuwait, particularly affecting the neck and back. Suboptimal ergonomic practices and high operative workloads likely contribute to this burden, highlighting the need for targeted ergonomic interventions and formal training programs.

OP-1350

A Comparative Readability Analysis Of AI-Generated And SocietyAuthored ENT Patient Information Leaflets

Dr Nasir Kharma[2], **Mr Saran Singh Gill**[2]

[1]*University Hospitals Leicester NHS Trust;* [2]*Imperial College London*

BACKGROUND & AIM

Clear, accessible patient information is essential in otolaryngology, where patients must understand complex conditions and procedures. Artificial intelligence (AI), particularly large language models, may support scalable development of patient information leaflets (PILs) that are clear and consistent. This study compared the readability of AI-generated ENT PILs with those produced by ENT-UK (the professional membership body of otolaryngologists in the UK) using established objective readability metrics.

MATERIAL & METHODS

A retrospective quantitative study compared AI-generated and ENT UK–authored PILs. AI texts were produced using ChatGPT version 4.5 with standardised prompts aligned to UK clinical guidance. Readability was assessed using validated indices capturing text length, sentence structure, lexical complexity, and estimated comprehension demand. A composite readability score, defined a priori as the primary outcome, was derived through directional alignment and standardisation of indices. Individual metrics were analysed as secondary outcomes. Convergent validity and internal consistency were assessed using Spearman correlations and Cronbach's alpha. Paired comparisons were performed using the Wilcoxon signed-rank test, with significance set at $p \leq 0.05$.

RESULTS

Ninety-five PILs were analysed. Using the composite readability score, AI-generated PILs demonstrated significantly higher overall readability than society-authored materials across all documents. AI-generated PILs were significantly shorter, with a lower median word count (605 [497-721] vs. 1167 [742-1777], $p < 0.001$), fewer sentences (48 [39-60] vs. 78 [47-125], $p < 0.001$), and fewer sentences exceeding 22 words (2 [1-3] vs. 11 [5-17], $p < 0.001$), indicating reduced structural complexity. Across all PILs, AI-generated texts demonstrated lower estimated grade and reading levels for several commonly used indices, including Flesch-Kincaid, Fry, Gunning Fog, and SMOG, although FORCAST grade and reading levels were significantly higher in AI-generated materials. Internal consistency across readability measures was very high (Cronbach's $\alpha = 0.98$ for GL, 0.97 for RL), with strong inter-index correlations supporting convergent validity

CONCLUSIONS

AI-generated ENT PILs were shorter and structurally simpler, with mixed improvements across readability indices. Clinician oversight remains essential to ensure meaningful accessibility gains.

OP-1351

Multidisciplinary High-Fidelity Simulation Training For The Management Of Laryngospasm Following General And Local Anesthetic Procedures

Suliman Ali[1], **Yadsan Devabalan**[1], **Chuanyu Gao**[1], **Rohan Bidaye**[1]

[1]*Department of Otolaryngology, Northampton General Hospital NHS Trust, Northampton, United Kingdom*

BACKGROUND & AIM

Laryngospasm is a potentially life-threatening airway emergency requiring rapid recognition and coordinated multidisciplinary intervention to prevent hypoxia and cardiac arrest. With the increasing number of airway procedures performed outside traditional operating theatres—such as flexible nasendoscopy-guided vocal cord injections—ENT surgeons, nurses, and allied healthcare professionals must be prepared to manage airway crises without immediate anaesthetic support. Opportunities for real-life training are limited due to the unpredictable nature of such events. High-fidelity simulation provides a safe, controlled environment for experiential learning. This study aimed to evaluate the impact of multidisciplinary simulation training on knowledge, confidence, and competence in managing laryngospasm.

MATERIAL & METHODS

A multidisciplinary simulation-based training programme was conducted in a dedicated simulation suite using high-fidelity mannequins and realistic clinical scenarios. Participants included doctors, nurses, healthcare assistants, and speech and language therapists. The programme consisted of a didactic lecture followed by two structured simulation scenarios replicating laryngospasm occurring under local anaesthesia and general anaesthesia. Each scenario was followed by a structured faculty-led debrief focusing on technical and non-technical skills, including communication, teamwork, and decision-making.

Participants completed anonymised pre- and post-course questionnaires assessing knowledge, confidence, and perceived competence using a five-point Likert scale. Statistical analysis was performed using the Mann-Whitney U test to compare pre- and post-training responses. The primary outcomes were changes in participant knowledge, confidence, and competence in recognising and managing laryngospasm in simulated clinical environments.

RESULTS

Nineteen multidisciplinary healthcare professionals participated in the training programme. There was a statistically significant improvement in participants' confidence ($U=12.0$, $p<0.05$) and perceived competence ($U=16.0$, $p<0.05$) in managing laryngospasm following the simulation training. Knowledge scores improved numerically but did not reach statistical significance ($U=70.0$, $p=0.342$), likely reflecting high baseline knowledge among experienced participants.

Post-training, 89.5% of participants agreed or strongly agreed they felt confident managing laryngospasm, and 84.2% reported improved competence. Participants also demonstrated improved ability to recognise early signs, initiate appropriate airway interventions, and coordinate multidisciplinary team responses. These findings highlight the effectiveness of simulation-based training in enhancing preparedness for airway emergencies.

CONCLUSIONS

Multidisciplinary high-fidelity simulation training significantly improves healthcare professionals' confidence and perceived competence in managing laryngospasm. Simulation provides a safe and effective environment to develop both technical and non-technical skills essential for airway emergency management. These findings support the integration of structured multidisciplinary simulation into routine ENT and airway training programmes to enhance clinical preparedness, improve team performance, and ultimately strengthen patient safety in airway emergency scenarios.

War-Time ENT Cases : My Experience In Gaza

Chebaatha Anas[1], **herzalla ahmed**[1], **alastal ahmed**[1], **zaqout ahmed**[1], **rasheed abou mohamed**[1], **mohammed abou issam**[1]

[1]*Nasser Hospital complex*

BACKGROUND & AIM

Gaza experienced a war following 7 October 2025, during which all types of weapons were used. The aim of this study is to highlight the role of ENT specialists in war zones and the secondary injuries resulting from trauma caused by explosions, shrapnel or bullets.

MATERIAL & METHODS

During the war and in the period from 25 June 2025 to 10 July 2025, this study drew on the cases I operated on myself, the accounts of the wounded, and the opinions of our ENT colleagues in Gaza.

RESULTS

During the two weeks in Gaza, most of the cases seen during this intense period of war were primarily closed or open injuries to the neck and face. The role of ENT specialists was primarily to perform tracheotomies in cases of laryngeal dyspnoea, to provide haemostasis for vascular wounds, to remove foreign bodies (bullets, shrapnel) and to treat infectious complications (cellulitis). Among the complicated cases were three instances of pharyngolaryngeal fistulas resulting from gunshot or shrapnel wounds, which were successfully reconstructed using flaps, with patients making a very good recovery despite the lack of antibiotics and appalling hygiene conditions.

CONCLUSIONS

Recently, ENT specialists have been increasingly training in microscopic, endoscopic and robotic surgery. Meanwhile, open surgery is becoming increasingly rare. This is particularly important in conflict zones, where situations are unpredictable, and is a skill that every ENT specialist must master.

OP-1353

Educational Quality Of Youtube Videos On Rinne And Weber Tuning Fork Tests

Gökçe Aydemir[2], **Cüneyt Orhan Kara**[1]

[1]*Department of Otolaryngology, Pamukkale University;* [2]*Bitlis State Hospital*

BACKGROUND & AIM

Rinne and Weber tuning fork tests are fundamental to hearing assessment and require both theoretical knowledge and practical skills. Online videos are increasingly used for self-directed learning, but their educational adequacy remains uncertain. This study evaluated whether YouTube videos on Rinne and Weber tests meet knowledge and skills training requirements and are suitable for educational use.

MATERIAL & METHODS

This cross-sectional descriptive study searched YouTube in December 2025 using four paired Turkish/English terms: “Rinne testi/Rinne test,” “Weber testi/Weber test,” “Rinne Weber testi/Rinne Weber test,” and “diyapozon testleri/tuning fork hearing test.” The first 74 results per search were screened (n=296). After duplicate removal by Video ID, 163 unique videos remained. Turkish- or English-language videos demonstrating and/or clinically interpreting Rinne and/or Weber tests were included; theory-only, animation/schematic-only, YouTube Shorts (≤60 seconds), and non-educational or irrelevant videos were excluded, yielding 78 videos.

A 19-item Rinne–Weber YouTube Video Assessment Form (RW-YVDS) assessed seven domains: educational framework, clinical purpose/use, physiological basis, technical performance, Rinne test, Weber test, and errors/warnings. Items were scored 0–2 (total: 0–38), with higher scores indicating more comprehensive educational content. Two otorhinolaryngologists independently assessed all videos using RW-YVDS, Global Video Score (GVS), and JAMA Benchmark Criteria; mean scores were analysed.

RESULTS

The mean total RW-YVDS score was 16.39±8.46/38. Mean RW-YVDS domain scores (percentage of maximum possible score) were 2.63±1.58/6 (43.9%) for educational framework, 2.99±2.21/6 (49.9%) for clinical purpose/use, 0.86±1.27/4 (21.5%) for physiological basis, 2.56±1.68/6 (42.7%) for technical performance, 3.21±1.91/6 (53.4%) for Rinne, 3.62±2.05/6 (60.4%) for Weber, and 0.51±0.83/4 (12.8%) for errors/warnings. Physiological basis and errors/warnings scored 0 in 46 (59.0%) and 49 (62.8%) videos, respectively.

RW-YVDS correlated strongly with GVS ($\rho=0.845$; $p<0.001$) and moderately with JAMA ($\rho=0.583$; $p<0.001$). Video duration correlated with RW-YVDS ($\rho=0.609$; $p<0.001$), while view count did not ($\rho=0.086$; $p=0.456$).

CONCLUSIONS

YouTube videos on Rinne and Weber tests do not adequately meet knowledge and skills training requirements, particularly regarding physiological basis and errors in performance and interpretation. Educational videos should follow clinical skills training principles with expert input. Furthermore, view count is not an indicator of educational adequacy.

KEYWORDS

Rinne, Weber, medical education, video tutorial

OP-1354

Comparison Of Postoperative Outcomes Between Cold Dissection And Ligasure Tonsillectomy In Adults: A Retrospective Cohort Study

Simten Armen[1], **Senem Kurt Dizdar**[1], **Mehmet Furkan İlter**[1], **Buket Canda**[1], **Suat Turgut**[1]

[1]*University of Health Sciences, Hamidiye Faculty of Medicine, Seyrantepe Hamidiye Etfal Training and Research Hospital, Department of Otolaryngology–Head and Neck Surgery, Istanbul, Türkiye*

BACKGROUND & AIM

Tonsillectomy is one of the most common otolaryngologic procedures. Various surgical techniques have been developed to reduce postoperative morbidity. This study aimed to compare postoperative outcomes of cold dissection and LigaSure tonsillectomy in adult patients.

MATERIAL & METHODS

A retrospective cohort study was conducted including adult patients who underwent tonsillectomy between May 2022 and March 2026 at a tertiary referral center. Patients were divided into two groups according to surgical technique: cold dissection and LigaSure. Demographic data and postoperative outcomes, including hemorrhage, reoperation due to postoperative bleeding, postoperative pain scores, and length of hospital stay, were analyzed. Statistical comparisons were performed between groups.

RESULTS

A total of 267 adult patients were included: 214 underwent cold dissection tonsillectomy and 53 underwent LigaSure tonsillectomy. Postoperative hemorrhage was numerically lower in the LigaSure group than in the cold dissection group; however, the difference was not statistically significant (20.8% vs 21.0%, p=0.965). Reoperation due to postoperative bleeding was also less frequent in the LigaSure group, without reaching statistical significance (7.5% vs 8.4%, p=0.838). Mean postoperative day-1 pain score was lower in the LigaSure group (5.95 vs 6.84), although the difference did not reach statistical significance (p=0.053). Mean hospital stay was similar between groups (0.64 vs 0.70 days, p=0.772). No significant association was observed between tonsil size and postoperative hemorrhage (p=0.549). Tonsil size distribution was also similar between the surgical technique groups (p=0.802).

CONCLUSIONS

LigaSure tonsillectomy demonstrated postoperative hemorrhage and reoperation rates comparable to cold dissection in adult patients, with numerically lower bleeding-related outcomes and lower postoperative pain scores. Although these differences did not reach statistical significance, LigaSure showed similar hospital stay and may be considered a safe and effective alternative technique for adult tonsillectomy.

OP-1355

Self-Powered Electrotherapy Suture For The Treatment Of Facial Nerve Disorders

Linpeng Li[1]

[1]*Shanghai Sixth People's Hospital*

BACKGROUND & AIM

Traumatic facial nerve repair remains clinically challenging due to the high functional specificity features, which routinely requires end-to-end neurorrhaphy, but outcomes remain suboptimal. Facial asymmetry, etc., highlights the need for strategies that actively regulate the regenerative microenvironment. Sutures are essential in facial nerve surgery, and emerging interfaces for bioelectronics. Previously, we reported a functional suture to facilitate wound healing (Nat. Commun., 2024, 15, 8462), but cannot be applied to nerves owing to the size limitations.

MATERIAL & METHODS

This study modified the technology and developed a body-coupled electrotherapy suture (BESS), enabling the facial nerve regeneration without imported power.

RESULTS

BESS restored CMAP amplitudes and NCV to 87.10% and 84.97% of healthy levels, whereas commercial sutures achieved only 57.76% and 67.67%, demonstrating high expression of nerve growth-related factors, synapse and myelin formation. BESS also reduced muscle atrophy, preserved fiber integrity, and protected relevant brainstem nuclei and target muscle function.

CONCLUSIONS

This promising nerve repair strategy offers an innovative solution for facial nerve injury treatment.

KEYWORDS

Facial nerve repair, sutures, self-powered stimulation

OP-1356

Should Hemithyroidectomies Be Performed As A Day-Case Procedure: A 2-Year Retrospective Review Of Thyroid Lobectomies In A Tertiary Centre.

M.Z.Shahid[1], **E.Turner**[1], **R.Taylor**[1], **I.Smith**[1]

[1]*Department of Ear, Nose and Throat Surgery, Bradford Royal Infirmary, Bradford Teaching Hospitals NHS Foundation Trust, Bradford, United Kingdom*

BACKGROUND & AIM

Hemithyroidectomy is a common surgical procedure in the UK, traditionally requiring overnight admission due to risks of postoperative haemorrhage and airway compromise. With increasing pressure on NHS resources and growing international support for day-case thyroid surgery, this study aimed to evaluate the safety and feasibility of day-case hemithyroidectomy in a tertiary centre.

MATERIAL & METHODS

A retrospective review of elective hemithyroidectomies performed between May 2023 and May 2025 was undertaken. Demographics, indications, operative details, complications, return to theatre, readmissions, drain output, specimen volume, and length of stay were analysed. Exclusion criteria included completion thyroidectomy and combined major head and neck procedures.

RESULTS

122 cases met the inclusion criteria (80.3% female, mean age 48.9 years). Indications were primarily suspicious nodules (57.4%) and compressive symptoms (39.2%). The overall complication rate was 17.2%, with 1.6% requiring return to theatre. Postoperative haematoma occurred in 3.3% of patients; only one case (0.8%) required surgical evacuation. Notably, 75% of haematomas presented beyond 24 hours postoperatively. Transient unilateral vocal cord palsy occurred in 5.7%, with resolution in most cases; persistent palsy was documented in 1.6%. Mean length of stay was 1.2 days; one patient was successfully discharged the same day without adverse events. No mortality or 30-day readmission was observed.

CONCLUSIONS

In this tertiary centre, hemithyroidectomies were associated with low complication rates, consistent with published data. As such, selected patients may be suitable for day-case surgery, but the unpredictable timing of postoperative haematoma warrants caution. Larger multicentre studies are needed to refine patient selection criteria and optimise safety for day-case pathways.

OP-1357

Comparison Of The Effects Of Boric Acid And Dexamethasone Injection On Scar Formation After Vocal Cord Injury In Rats

Nurullah Türe[1], **Fatih Kar**[2], **Mehmet Varol**[1], **Sercan Şimşek**[3], **Durmuş Güven**[1]

[1]*Department of Otorhinolaryngology, Kütahya Health Sciences University, Kütahya, Türkiye;* [2]*Department of Medical Biochemistry, Faculty of Medicine, Kutahya Health Sciences University, Kutahya, Turkey;* [3]*Department of Medical Pathology, Kütahya University of Health Sciences, Evliya Çelebi Training and Research Hospital, Kütahya,Türkiye*

BACKGROUND & AIM

The aim of this study is to comparatively evaluate the effects of boric acid and dexamethasone administered alone and in combination, on wound healing and scarring processes in an experimental vocal fold injury model, using histopathological and biochemical parameters.

MATERIAL & METHODS

Ethical Approval and Experimental Animals

This study was conducted with the approval of the Kütahya Health Sciences University Local Ethics Committee for Animal Experiments (Date: 29.08.2024, No: 2024.08.01). The study used 30 healthy adult female Wistar Albino rats (Rattus norvegicus)

weighing 250–300 g. The subjects were housed under standard laboratory conditions (22±2℃ temperature, 50±10% humidity, 12-hour light/dark cycle); access to water and food was provided ad libitum.

Experimental Groups

The experimental animals were divided into five equal groups (n=6), each consisting of six rats, using a simple randomization method. In the control group, the subjects were monitored under standard laboratory conditions without any surgical intervention or pharmacological administration. In the Injury (VK) group, standard vocal fold injury was created; in the Boric Acid (BA) group, intracordal boric acid (3 mg/mL) was injected into the lesion site following injury. In the Dexamethasone (DEX) group, a similar injury protocol was applied.

RESULTS

In recent years, boron and its derivatives have attracted attention in the regenerative medicine literature for their wound healing-promoting properties. Boric acid compounds have been found to contribute to the healing process by multiple biological mechanisms such as stimulating angiogenesis, regulating ECM synthesis, increasing antioxidant capacity, and accelerating reepithelization by balancing the inflammatory phase [8] Although the biocompatibility of boric acid in different tissue models has been reported in the literature, a study systematically evaluating its effects on laryngeal tissue injury and healing dynamics has not yet been included in the literature [9].

CONCLUSIONS

The findings indicate that dexamethasone administration alone may trigger the fibrotic process by increasing the oxidative burden in the tissue. Conversely, it was determined that adding boric acid to the treatment suppressed oxidative stress and significantly reduced fibrotic-related SEMA3A levels. Consequently, boric acid balances the potential negative effects of dexamethasone, providing a more physiological and controlled healing environment. The combination therapy's superior repair profile compared to single treatments suggests that boric acid may be a valuable adjunctive treatment option for vocal fold injuries.

OP-1358

The Rhinologist As Developer: A Practical Framework For Prompt Engineering And App Creation In Clinical Practice

Okechukwu Okonkwo[1], **Georgina Wellstead**[1]

[1]*NHS Gloucestershire*

BACKGROUND & AIM

Generative AI and Large Language Models (LLMs) have lowered the technical barrier for software creation, yet a gap remains between potential and practical application for surgeons. We aim to bridge this gap by defining a structured "Prompt Engineering Framework" specifically for Rhinologists. Our objective is to demonstrate how clinicians can utilize specific prompting strategies to build NHS-compliant, effectively functioning medical software without prior coding experience.

MATERIAL & METHODS

We performed a literature review of current prompt engineering methodologies (e.g., Chain-of-Thought, Few-Shot prompting) with experiential data derived from the development of ‘Sniffinsticksonline’—a fully functional clinical web app built using natural language. We deconstructed the development process into an iterative workflow, analysing the specific prompt structures required to overcome common AI pitfalls such as logic errors ("hallucinations") and security compliance issues.

RESULTS

We present a validated, three-stage "Clinician-to-Code" workflow:

Contextual Architecture: How to structure initial "system prompts" to define clinical parameters and safety constraints.

Iterative Refinement: demonstratable success using Chain-of-Thought prompting (asking the LLM to explain its reasoning step-by-step) to debug complex clinical logic, significantly increasing code accuracy (Shah et al., 2024).

Cross-Verification: The utility of using multiple LLMs to audit code for NHS digital compliance. This workflow was successfully used to build ‘Sniffinsticksonline’, which achieved superior usability scores compared to the legacy OLAF system in subsequent validation trials.

CONCLUSIONS

Proficiency in prompt engineering is emerging as a critical competency for clinical innovators. We conclude that by applying this structured framework, Rhinologists can rapidly prototype and deploy digital solutions, removing the dependency on external developers. ‘Sniffinsticksonline’ serves as a proof-of-concept, demonstrating that clinician-led, AI-architected software is not only feasible but can outperform existing solutions.

OP-1359

Pioneering Feasibility Study Of Real-Time 3D Visualization And AI-Based Analysis Of Needle Position During Microvascular Anastomosis For Optimizing Suture Accuracy

Dr. med. Eren Erdogan[1], **Ergün Erdogan**[2], **Ahmet Faruk Gümüstas**[2], **Alparslan Timucin Tamer**[2], **Prof. Jonas J. H. Park**[1]

[1]*Department of Otorhinolaryngology, Head and Neck Surgery Chair of Otorhinolaryngology, University of Witten/Herdecke;* [2]*Ares Engineering*

BACKGROUND & AIM

Precise suture placement is critical for the success of microvascular anastomosis (MVA). Errors in needle positioning can compromise vessel wall integrity, lead to leakage, and impair patency. This feasibility study investigated whether an integrated system of real-time 3D visualization and artificial intelligence (AI)-based needle analysis could improve assessment of suture accuracy. Functional outcomes of anastomoses performed with and without the AI system were compared in an in vitro model.

MATERIAL & METHODS

MVAs were carried out on silicone vessels (1–2 mm diameter) under standardized conditions. In the AI group, real-time tracking of needle entry, exit, angle, and trajectory was performed, while the control group used conventional technique without AI assistance. After completion, patency and leakage were tested by NaCl injection. Subsequently, the anastomoses were cut open longitudinally and examined microscopically to evaluate vessel wall integrity and detect potential needle-related damage. As all procedures were performed in vitro, no ethical approval was required.

RESULTS

AI-assisted procedures allowed reliable real-time identification of needle position and trajectory, with high agreement to expert evaluation. Patency testing showed preserved flow in both groups. Leakage at the suture line occurred less frequently in the AI-assisted group compared to controls. Microscopic evaluation after cutting the anastomoses revealed fewer instances of vessel wall damage in the AI group, suggesting a potential protective effect on suture placement quality.

CONCLUSIONS

This pioneering feasibility study demonstrates that real-time 3D visualization combined with AI-based analysis of needle position is technically feasible and may improve suture accuracy in microvascular anastomosis. Functional testing by NaCl flow and leakage, together with microscopic wall assessment, confirmed potential benefits compared to conventional techniques. Further studies in cadaveric and in vivo models are required to validate these findings and explore clinical applications.

OP-1360

An Improved Electrical Model Of CI Stimulation Arrays In Frequency Domain

Hannes Maier[1], **Mit B. Bhavsar**[1], **Jan Anton Wittwer**[2], **Merle Sehlmeyer**[2], **Andrej Kral**[1], **Stefan Zimmermann**[2]

[1]*Department of Otolaryngology (NIFE), Hannover Medical School, Hannover, Germany;* [2]*Institute of Electrical Engineering and Measurement Technology, Leibniz University Hannover, Germany*

BACKGROUND & AIM

Introduction: Cochlear implants (CI) are well-established neurostimulators to restore hearing in severe sensorineural hearing loss and profound deafness but suffer from limitations in frequency resolution and speech intelligibility in noise. Contributing factors are the significant current spread and increased impedances by fibrotic tissue growth. Our goal was the development and experimental validation of a frequency-specific model. This model serves (1) to determine the sensitivity of electric impedance spectroscopy (EIS) to differentiate cell layers, (2) understand clinical impedance measurements in time domain, (3) to optimize pulse shapes for power consumption and addressing specific target cells.

MATERIAL & METHODS

Methods: We developed an electric equivalent circuit (EEC) that captures the frequency-dependent impedance between two stimulation electrodes. The model incorporates the separately measured properties of the wires, the non-linear electrode-electrolyte bilayer, using the Schwan-Faraday model and the surrounding tissue. Based on this model, a monopolar EEC was developed with a large-area extracochlear return electrode. Additionally, the long-range resistance Rt from array electrodes to a return electrode and its impact on EIS spectra was determined in human cadaveric heads.

RESULTS

Results: The experimental validation of the developed EEC using CI arrays from four different manufacturers demonstrated an accuracy of mean relative error < 8%. The long-range resistance Rt of two different return electrode types from two manufacturers was experimentally determined in human cadaveric heads. This EEC was used for in-silico analysis of power distribution over the different elements of CIs and tissue, and stimulation waveforms.

CONCLUSIONS

Conclusion: The developed non-linear EEC can be applied generally to multiple CI arrays from different manufacturers with reasonable accuracy. With the experimentally determined long range resistance Rt to a return electrode, it can be used for frequency specific analysis of random pulses and power distribution to optimize stimulation efficiency.

OP-1361

Smartphone-Based Audiometry: Validation Of Air-Conduction Thresholds, Bone-Conduction Thresholds, And Speech Discrimination Scores

Emine Hilal Kocaoğlu[1], **Ömer Faruk Çalım**[1], **Melike Nur Dede**[1]

[1]*Istanbul Medipol University Hospital*

BACKGROUND & AIM

This study aimed to evaluate the agreement between the HearinTest mobile hearing screening application and clinical audiometry in adults aged 18–55 years. It compared air-conduction, bone-conduction, and speech audiometry results obtained with the mobile application and standard clinical audiometry, and assessed whether HearinTest could serve as a reliable supportive tool for clinical hearing evaluation after appropriate calibration.

MATERIAL & METHODS

HearinTest is a mobile hearing assessment application developed to provide fast, accessible, and reliable evaluation on Android and iOS devices. The app follows the logic of conventional pure-tone audiometry by adjusting intensity according to the user's "heard" or "not heard" responses and calculating thresholds at 250, 500, 1000, 2000, 4000, and 8000 Hz. Pure tones are generated in real time in Unity using sinusoidal functions, reducing the need for external audio files and supporting synchronized output. The application also includes speech audiometry measurements: SRT, MCL, and SDS. Speech materials were professionally recorded, cleaned, normalized, and stored as lossless WAV files to ensure consistent intensity and articulation. Air-conduction calibration was performed using AirPods Max as a reference headset.

RESULTS

Air-conduction thresholds obtained with the mobile hearing application were compared with clinical audiometry using Bland–Altman analysis. Agreement was acceptable across frequencies and both ears. Bias was closest to zero at 250 and 2000 Hz, while 500 and 1000 Hz showed slight differences. Higher frequencies showed greater variability without systematic deviation.

Bland–Altman analyses showed high agreement between mobile and clinical bone-conduction thresholds at 500, 1000, 2000, and 4000 Hz. Bias values were close to zero, with limited mean differences. Most measurements fell within 95% limits of agreement, indicating consistent, reliable distribution across frequencies and both ears, and better agreement than air-conduction thresholds.

Speech audiometry parameters obtained with the mobile hearing test application and clinical audiometry were evaluated using Bland–Altman analysis. SRT, MCL, and SDS results were examined separately for right and left ears, considering mean differences, bias values, and 95% limits of agreement between the two measurement methods.

CONCLUSIONS

This study compared HearinTest mobile hearing test results with standard clinical audiometry for air-conduction, bone-conduction, and speech audiometry measurements. Statistical analyses, including Wilcoxon signed-rank tests and Bland–Altman plots, showed generally acceptable agreement between the two methods. Air-conduction thresholds demonstrated frequency-dependent differences, especially at high frequencies, whereas bone-conduction thresholds showed closer agreement and more stable results. In speech audiometry, SRT and MCL values were systematically higher with the mobile application, while SDS results showed smaller intermethod differences. Overall, HearinTest produced clinically comparable findings, although variability differed across frequencies and test parameters, mostly remaining within acceptable agreement limits.

OP-1362

Are ENT Specialists Still Better Than AI? Readability And Quality Analysis Of AI-Generated Patient Information For FESS And Septoplasty Across Different AI Models

Haroon Khokher[1], **Sarah Law**[1], **Mohamad Elshahawi**[1], **Hadeel Tabaqchali**[2], **Rishi Talwar**[1]

[1]*Bedfordshire Hospitals NHS Foundation Trust;* [2]*Chelsea and Westminster Hospital NHS Foundation Trust*

BACKGROUND & AIM

Artificial intelligence (AI) tools are increasingly used in medicine, yet the performance of different models in providing patient information remains unclear. This study compared readability and informational quality of responses generated by five large language models for functional endoscopic sinus surgery (FESS) and septoplasty.

MATERIAL & METHODS

Three standard models (ChatGPT 5.3, DeepSeek 3.2, Gemini 3) and two premium models (ChatGPT 5.4 'Thinking' and ChatGPT 5.4 'Deep Research') were asked three standard questions per procedure. Readability was evaluated using Flesch-Kincaid

Reading Ease Score (FRES), Flesch-Kincaid Grade Level (FKGL), Gunning Fog Index (GFI), and Simple Measure of Gobbledygook (SMOG). Informational quality was assessed using the DISCERN instrument and compared with ENT UK patient leaflets. Differences between models were analysed using one-way ANOVA with Tukey post-hoc testing.

RESULTS

AI outputs demonstrated consistently lower readability than ENT UK leaflets, which demonstrated higher FRES (59.7–69.7) and lower FKGL (7.2–8.5) compared with AI outputs (FRES 15.3–58.6; FKGL 9.2–16.8). One-way ANOVA demonstrated significant differences between models for FRES ($F(4,25)=2.88$, $p=0.043$), FKGL ($F(4,25)=4.99$, $p=0.004$), and GFI ($F(4,25)=4.53$, $p=0.007$), but not SMOG ($p=0.081$). Tukey post-hoc analysis showed DeepSeek 3.2 produced significantly more readable responses than several ChatGPT variants. DeepSeek generated the most readable outputs (mean FRES 45.9), while ChatGPT 5.4 'Deep Research' achieved the highest informational quality (mean DISCERN 42.3). DISCERN scores for AI models ranged from 29–50.5 compared with 56.5 for ENT UK leaflets, indicating lower reliability, transparency, and quality of treatment information overall. FESS responses were more complex than septoplasty, with higher GFI and SMOG scores, suggesting procedure-specific variation in output complexity.

CONCLUSIONS

AI-generated patient information remains less readable and of lower quality than ENT UK leaflets. While advanced models provide more comprehensive responses, they frequently exceed recommended reading levels and may lack consistency in reliability. Clinician oversight is required to ensure accurate, safe, patient-friendly communication and appropriate integration into clinical practice.

Audiogram Classification Performance Of A Multimodal Large Language Model: Potential For Clinical Decision Support

İpek Yeşil[1], **Zeliha Kapusuz Gencer**[1], **Emre Ulutaş**[1], **Salih Akyel**[1], **Özgür Yiğit**[1]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, Başakşehir Çam and Sakura City Hospital, University of Health Sciences, Istanbul, Turkey*

BACKGROUND & AIM

Large language models are increasingly explored for medical image interpretation, yet evidence in audiology remains limited. This study evaluated the diagnostic accuracy of ChatGPT-4o in interpreting pure-tone audiograms against an audiologist-defined gold standard.

MATERIAL & METHODS

A balanced sample of 280 patients (mean age 50.4 ± 19.2 years; 145 men, 135 women) was analyzed, comprising 70 cases each across four diagnostic categories: normal hearing, conductive hearing loss (CHL), sensorineural hearing loss (SNHL), and mixed-type hearing loss. Each audiogram image was submitted to ChatGPT-4o (version 2024-05-13) using a standardized prompt in a fresh session with conversation history disabled. Model outputs for diagnostic category, hearing-loss degree (Clark 1981 scale), air-bone gap (ABG), and frequency-specific thresholds were compared with the expert reference.

RESULTS

ChatGPT-4o correctly classified the diagnostic category in 73.9% of cases (207/280; $\kappa = 0.65$, substantial agreement). Accuracy differed significantly across categories ($\chi^2 = 36.67$, $p < 0.001$; Cramér's $V = 0.36$), being high for normal hearing (94.3%) and SNHL (84.3%) but markedly lower for CHL (61.4%) and mixed-type loss (55.7%). Sensitivity was lowest for mixed (55.7%) and conductive (61.4%) loss, whereas specificity remained high across all categories (≥ 82.9%). Hearing-loss severity grading showed strong agreement (exact match 67.1%; within ±1 grade 89.6%; quadratic-weighted $\kappa = 0.82$). Numerical tasks were the weakest domain: the ABG was computed correctly in only 53.6% of cases and frequency thresholds were read accurately in only 39.6%; correct threshold reading was strongly associated with diagnostic success ($p < 0.001$). Hallucinated (fabricated) data appeared in 48 cases (17.1%), concentrated in complex audiograms, and 9 pathological cases were misclassified as normal.

CONCLUSIONS

ChatGPT-4o demonstrates strong pattern-level recognition of audiometric categories — particularly normal and sensorineural hearing loss — and reliable severity grading, but unreliable point-wise numerical reading of thresholds and air-bone gaps that undermines the diagnosis of conductive and mixed-type loss. In its current form, the model may function as a supportive tool under expert supervision rather than as an autonomous diagnostic instrument; substantial improvement in numerical accuracy is required before clinical deployment.

KEYWORDS

large language models, artificial intelligence, hearing loss

OP-1364

The Clinical Significance Of The Trigeminal Cervical Complex: A Neural Network Explaining Disorders Affecting The Head And Neck Region.

Fadi Bou Malhab[1], **Jad Hosri**[2], **Nadine Hadi**[3], **Usamah Hadi**[2]

[1]*Department of Otolaryngology-Head & Neck Surgery, Saint Joseph University Hospital, Beirut, Lebanon.*; [2]*Department of Otolaryngology-Head & Neck Surgery, American University of Beirut Medical Center, Beirut, Lebanon.*; [3]*Department of Otolaryngology- Head & Neck Surgery, Rhinology Division - University of Miami, Florida, USA.*

BACKGROUND & AIM

To introduce the trigeminal cervical complex (TCC) as a comprehensive framework for understanding the anatomical and functional scope of the afferences and efferences of the trigeminal system and explaining common otolaryngologic symptoms, including head and neck myofascial pain syndrome. Additionally, it explores how the bidirectional transmission of neurotransmitters contributes to the sensitization of the TCC and motor nuclei.

MATERIAL & METHODS

The study was conducted as a narrative review. The authors performed a comprehensive search of multiple databases, including Medline/OVID, Embase, Scopus, and PubMed, covering publications from inception until August 2023.

RESULTS

This review discusses the multiple afferent connections from cranial nerves, specifically VII, IX, X, and XI, to the TCC, and their respective efferent pathways. These connections may explain various clinical manifestations in the head and neck that cannot be attributed to other medical conditions. Additionally, the review highlights: 1- the dual sensory and motor nature of cranial nerves, 2- the bidirectional transmission of neurotransmitters in head and neck areas, which leads to the sensitization of both the TCC and motor nuclei innervating the cervicofacial muscles, 3- How sensitization of the TCC by cervicofacial muscles could affect the sensorineural organs (Ear, Eye, Nose) and other organs.

CONCLUSIONS

The central and peripheral sensitization and the intricate connections of the TCC can elucidate the pathophysiology of conditions such as otalgia, tinnitus, hearing loss, vertigo, headache, cervicogenic dizziness, bruxism, and other symptoms affecting the head and neck.

What Overlooked Factors Influence The Difficulty Of Adult Tracheostomy?

Omar Aboul Hosn[1], **Jad Hosri**[1], **Lucien Khalil**[1], **Justin Ghadieh**[1], **Ibana Carapiperis**[1], **Patrick Abou Raji Feghali**[1], **Sami Jean Melki**[1], **Marc Mourad**[1], **Usama Hadi**[1]

[1]*Department of Otorhinolaryngology- Head & Neck Surgery, American University of Beirut Medical Center - AUBMC*

BACKGROUND & AIM

Tracheostomy is a commonly performed essential procedure in otolaryngology and critical care; however, operative duration remains variable affecting operating room efficiency, resource utilization, and perioperative risk. Although obesity is frequently implicated in procedural difficulty, the relative contribution of demographic, clinical, training-related, bedside physical examination, and radiologic factors to operative time have not been comprehensively evaluated. This study aims to identify determinants of operative difficulty in isolated adult tracheostomy, as reflected by operating room (OR) time.

MATERIAL & METHODS

A retrospective observational study was conducted at the American University of Beirut Medical Center included adult patients who underwent isolated open tracheostomy between January 2020 and December 2025. Operating room (OR) time was defined as the interval between documented OR start and finish times and was analyzed both as a continuous variable and as a categorical variable; procedures exceeding the cohort mean (60 minutes) were classified as longer-duration cases. Collected variables were grouped into demographic, patient-related, training-related, bedside physical examination, and radiologic categories. Bedside findings represented subjective clinical assessments, whereas radiologic parameters provided objective measurements derived from preoperative CT imaging, including calculated neck circumference and measured skin-to-trachea distance. Univariate analyses were performed, followed by multivariable logistic and linear regression to identify independent predictors of prolonged operative duration.

RESULTS

A total of 192 tracheostomies were analyzed, with 43.7% classified as longer-duration cases. On univariate analysis, demographic variables (age, sex, BMI), patient-related factors including smoking status, prior radiation therapy, prior neck surgery, blood thinner therapy, chronic kidney disease, and platelet count, as well as training-related variables (PGY level, time of day, academic quarter, and year of procedure) were not associated with operative time. Neck infection was significantly associated with prolonged duration ($p = 0.010$). Variability across attending surgeons was significant ($p = 0.03$). Bedside

examination findings demonstrated that short neck (p = 0.002), cervical spine stiffness (p = 0.002), and submental fat (p = 0.013) were associated with longer operative duration. Radiologic parameters showed that increased skin-to-trachea distance (p = 0.0048) and greater neck circumference (p = 0.037) were significantly associated with prolonged operative time. On multivariable analysis, short neck and skin-to-trachea distance remained independent predictors.

CONCLUSIONS

Operative time in adult tracheostomy is driven by anatomical factors rather than demographic or training-related variables. A short neck on examination and increased skin-to-trachea distance on CT independently predict longer OR time. Preoperative recognition of these features may improve procedural planning and resource utilization. These findings may also support the development of a predictive model for operative complexity in adult tracheostomy.

OP-1366

Is There A Single Best Treatment For Pinna Haematoma Management?

Mr Faizan Shah[1], **Brendan Zhen Yang Law**[1], **Hayfa Sheikh**[1], **Clive Brewis**[1], **Mr Muhammad Shakeel**[1]

[1]*ENT department, Aberdeen Royal Infirmary, Aberdeen, United Kingdom*

BACKGROUND & AIM

Pinna haematoma refers to the accumulation of blood between the perichondrium and the cartilage of the auricle as a result of blunt force trauma, such as a sports-related injury. Prompt surgical treatment can preserve cosmetic appearance and prevent “cauliflower ear” deformity. There is no universally accepted treatment modality available to deal with this problem. To identify the best treatment option to treat pinna haematoma and prevent complications a systematic review and meta-analysis were carried out.

MATERIAL & METHODS

Cochrane Central Register of Controlled Trials (CENTRAL), Pubmed (US National Library of Medicine), EMBASE, CINAHL, CAB Abstracts, MEDLINE and Web of Science were searched using the following terms: ‘auric*’, ‘auris’, ‘ear’, ‘ears’, ’pinna’, ‘haematoma*’, ‘hematoma*’, ‘cauliflower’, ‘boxer*’, ‘rugby’, ‘football’, ‘wrestler*’. Inclusion criteria comprised any means of decompression including incision and drainage, needle aspiration with or without post-decompression care. All studies included randomised controlled trials, cohort studies and case series. Recurrence of pinna haematoma was the primary outcome for both the incision and drainage and needle aspiration groups. The secondary outcomes were incidence of infection or any deformity in each group. Meta-analysis of pinna haematoma recurrence was carried out. We also evaluated the novel technique of utilising hrough and through absorbable suture after incision and drainage as the best compression strategy.

RESULTS

The 41 articles included one randomised control trial, six cohort studies and 34 case series. Pooled data demonstrated lower recurrence in the incision and drainage cohort. On meta-analysis of cohort studies and RCT, the lower recurrence in the incision and drainage cohort was statistically significant ($p \leqslant 0.0001$). There was a trend to suggest that incidence of both infection and deformity were higher in the incision and drainage cohort compared to needle aspiration.

CONCLUSIONS

Incision and drainage confers an advantage over needle aspiration in the prevention of recurrence of pinna haematoma. Limited available data support through and through absorbable suture after incision and drainage as the best compression strategy. By contrast, incision and drainage would appear to be associated with an increased risk of infection in comparison to needle aspiration.

KEYWORDS

Systematic review, meta-analysis, pinna haematoma, auricle, surgery, incision and drainage, needle aspiration.

OP-1367

‘‘The Lagari Lab’’ The Mobile Temporal Bone Lab: Transforming Surgical Education Across Borders

Özlem Saatci[1], **Mesut Gün**[1], **Beyza Demirci**[1], **Ayşegül Batıoğlu Karaaltın**[2], **Bilge Nur Küçükakça**[1], **Meltem Akpınar**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, Sancaktepe Şehit Prof. Dr. İlhan Varak Training and Research Hospital, Istanbul, Türkiye;* [2]*Department of Otorhinolaryngology–Head and Neck Surgery, Cerrahpaşa Faculty of Medicine, Istanbul University-Cerrahpasa, Istanbul, Türkiye*

BACKGROUND & AIM

Ensuring equitable access to hands-on surgical training is a persistent global challenge, particularly in resource-constrained regions. To bridge the gap in otologic education, we developed the Lagari Lab—a mobile, technology-enhanced platform designed to provide scalable, high-quality training beyond conventional laboratory settings

MATERIAL & METHODS

Thirty-two otolaryngology residents and specialists participated in a mobile temporal bone training program conducted in Madagascar and Tanzania. The Lagari Lab was designed as a fully portable unit enabling rapid on-site deployment and high-fidelity dissection without permanent infrastructure. The program integrated three-dimensional simulation, virtual learning, and expert-supervised artificial temporal bone dissection within a standardized educational framework. Outcomes were prospectively evaluated using pre- and post-training knowledge tests, self-efficacy scales, objective structured technical skill assessments (OSATS), and a modified Welling temporal bone dissection scale.

RESULTS

Post-training knowledge scores improved significantly from 12.59 ± 3.91 to 14.67 ± 2.47 ($p = 0.005$), and self-efficacy score from 30.64 ± 8.63 to 38.25 ± 6.07 ($p < 0.001$). Mean post-training OSATS and modified Welling scores were 45.91 ± 1.06 and 25.34 ± 3.21, respectively. Overall satisfaction remained high (46.15 ± 5.87/55).

CONCLUSIONS

The Lagari Lab demonstrates that a mobile, technology-enhanced temporal bone training model can improve knowledge and self-efficacy while achieving high participant satisfaction. This mobility-oriented framework may support broader access to practical otologic training across diverse and resource-limited settings.

OP-1368

A New Anatomical Schema: The Floor Of The Mouth In Transoral Approaches

Ercan Akbay[1], **Sumeyye Akbay**[2], **Tufan Ulcay**[2]

[1]Aksaray İnova Hastanesi Kulak Burun Boğaz Kliniği, Aksaray; [2]Kırşehir Ahi Evran Üniversitesi Tıp Fakültesi Anatomi Anabilim Dalı, Kırşehir

BACKGROUND & AIM

In Ear, Nose, and Throat (ENT) practice, the traditional approach to surgical pathologies of the floor of the mouth is performed via a transcervical incision; surgical anatomy is addressed from an external perspective that includes skin, subcutaneous tissue, and platysma muscle dissection. However, current ENT surgery is increasingly evolving toward transoral approaches. Classical transcervical anatomy models remain insufficient in providing functional orientation in transoral approaches. The objective of this study is to restructure the fundamental anatomical knowledge for transoral surgical approaches in line with clinical experiences and to emphasize the importance of surgical anatomy in this perspective.

MATERIAL & METHODS

In this study, the outcomes of cases with different pathologies who underwent transoral surgical approach to the floor of the mouth by the same surgeon between 2011–2026 were retrospectively evaluated. Although the histopathological diagnoses of the patients varied, the common characteristic of all cases was that they were operated on via the transoral route. Factors facilitating surgical experience and postoperative complications were analyzed; the results were examined over clinical surgical anatomy knowledge. Unlike traditional cadaver dissection, the study was supported by transoral cadaver dissection and perioperative endoscopic anatomy images.

RESULTS

The study included 70 patients (33 males, 47.1%; 37 females, 52.9%; mean age: 33.93±20.19 years). Operation times were omitted due to data missingness, and long-term follow-up was limited beyond routine 3-month visits. Preoperative contrast-enhanced neck CT was standard. Histopathologically, sialadenitis variants predominated (n=38). Other benign/developmental lesions included thyroglossal cysts (n=12), pleomorphic adenomas (n=6), lymphangiomas (n=2), and single cases of various dermoid cysts, ranulas, ectopic tissues, and lipoma. Dissection histopathology (n=5) revealed lymphomas (n=2) and granulomatous lymphadenitis (n=3). Lesion localization guided transfrenular midline or lateral submandibular approaches. Tongue numbness and bleeding were the primary early complications. Intraoperative hemorrhage and limited exposure posed major challenges, with poor visibility causing lesion ruptures. Severe adhesions prompted conversion to a transcervical approach in three chronic sialadenitis cases.

CONCLUSIONS

Drawing on a fifteen-year surgical experience with a diverse case series, this study offers significant contributions to clinical practice. The management of these rare cases by a single surgeon enhances series homogeneity and study value. Presenting an innovative anatomical perspective on transoral surgery, this research is anticipated to provide ENT physicians with a new vision regarding anatomical modeling and orientation perception in floor-of-mouth surgery.

Gender Representation Among Newly Appointed Otolaryngology Specialists In Türkiye: A Five-Year National State Service Obligation Analysis

Hüsamettin Çamur, MD[1], **Ayşe Çeçen, MD**[1], **İrem Nur Kabakçı, MD**[1]

[1]*Department of Otolaryngology–Head and Neck Surgery, Ondokuz Mayıs University Faculty of Medicine*

BACKGROUND & AIM

Gender representation in surgical specialties is an important issue in workforce planning and postgraduate training. National data on the gender distribution of newly appointed otolaryngology specialists in Türkiye are limited. This study aimed to evaluate gender representation and temporal trends among newly appointed otolaryngology specialists using national State Service Obligation appointment data.

MATERIAL & METHODS

This database-based retrospective descriptive study reviewed publicly available specialist appointment lists from the 97th to the 128th State Service Obligation periods in Türkiye. Physicians appointed as Otolaryngology–Head and Neck Surgery specialists were included. For each period, total appointments and female/male distribution were recorded. Temporal trends were evaluated using linear regression analysis.

RESULTS

A total of 656 newly appointed otolaryngology specialists were identified. Of these, 180 were female (27.4%) and 476 were male (72.6%). Female representation ranged from 11.1% to 50.0%. The highest rate was observed in the 104th period (50.0%) and the lowest in the 109th period (11.1%). Total appointments increased significantly over time ($p < 0.001$), whereas female representation did not show a significant upward trend ($p = 0.949$).

CONCLUSIONS

Male predominance remains evident among newly appointed otolaryngology specialists in Türkiye. Despite a significant increase in total appointments, female representation showed marked period-to-period variation without consistent growth. These findings provide national-level data for workforce planning and may guide future studies on gender representation in otolaryngology.

Smartphone -Based Application In ENT Practice

Nuntigar Sonsuwan[1]

[1]*Department of Otolaryngology, Faculty of Medicine, Chiang Mai University, Thailand*

BACKGROUND & AIM

There are two Smartphone -based applications which will be helpful for ENT practice

MATERIAL & METHODS

The PED Airway application (app) is an easy-to-use Android and iOS mobile app designed specifically for pediatric otolaryngologists, pediatricians, anesthesiologists, emergency physicians and caregivers who deal with the pediatric airway.

RESULTS

Smart Phone Based Application for Positional OSA: Aims to adapt the concept of sleep position monitoring and subtle vibrotactile feedback system as an application for smartphones based Sleep Position Alarm Therapy Application (SPATA). The smartphone with SPATA is designed to be strapped on to the chest wall of positional obstructive sleep apnea patients during sleep, extracting patient's sleep position from smartphone's accelerometer sensor.

CONCLUSIONS

When SPATA detects supine sleep position for more than 10 seconds a sequence of vibration of smartphone will be initiated. SPATA may be an alternative treatment for positional OSA

KEYWORDS

Smart-phone , Application, sleep position, pediatric airway

OP-1371

Expert Evaluation Of TPU-Based Bioprinted Nose And Ear Models For Professional Surgical Training: A Comparative Study

Federica Maria Parisi[1], **Salvatore La Valle**[1], **Davide Tumino**[1], **Giuseppe Mantegna**[1], **Roberta Malaguarnera**[1], **Antonino Maniaci**[1]

[1]*University of Enna "Kore"*

BACKGROUND & AIM

High-fidelity anatomical models are essential for advanced surgical training in otorhinolaryngology. Three-dimensional bioprinting with thermoplastic polyurethane (TPU) provides new possibilities to reproduce tissue-like elasticity, mechanical resistance, and anatomical realism. We conducted a côprayici comparative study to assess two distinct TPU-based bioprinted nose and ear models optimized for professional procedural training.

MATERIAL & METHODS

Nasal and auricular anatomical models were designed and bioprinted using two TPU formulations (TPU-A and TPU-B) differing in Shore hardness, wall thickness, and infill pattern. A panel of 12 ENT experts (head and neck surgeons, otologists, rhinologists; >10 years of experience) evaluated each model using a validated checklist assessing anatomical realism, tactile response, handling during simulated procedures (incision, suturing, reshaping), durability, and training applicability. Ratings were collected on a 5-point Likert scale.

RESULTS

TPU-A achieved higher scores for elasticity (4.6±0.4) and realism in complex nasal procedure training (4.4±0.5). TPU-B demonstrated superior mechanical resistance (4.7±0.3) and greater stability during external ear surgical simulations (4.5±0.4). In the direct comparison, experts considered TPU-A more suitable for high-sensitivity tactile training, whereas TPU-B was preferred for repetitive high-load procedures requiring traction or compression.

CONCLUSIONS

Different TPU formulations address distinct educational needs in the bioprinting of nasal and auricular models. The complementary integration of both materials enables the development of realistic and durable high-fidelity simulators for advanced ENT surgical training. These findings support the adoption of TPU as a key material for next-generation otolaryngology simulation programs.

OP-1372

Development Of An ENT Digital Health Ecosystem: A Question Bank And Notch Therapy Application For Otolaryngology

Ebubekir Toprak[1], **Mehmet Enes Arıcı**[1], **Suat Turgut**[1]

[1]*Department of Otorhinolaryngology, Head and Neck Surgery at Şişli Hamidiye Etfal Training and Research Hospital in Istanbul, Turkey*

BACKGROUND & AIM

Tinnitus affects 10-15% of adults globally, yet access to evidence-based sound therapy remains limited. Similarly, otolaryngology residents lack accessible, comprehensive digital tools for board examination preparation. We aimed to develop a dual-application digital health ecosystem addressing both clinical management and medical education needs in otolaryngology: TinniCare, a science-based notch therapy application, and ENTwise, an otolaryngology question bank platform.

MATERIAL & METHODS

Both applications were developed using HTML/CSS/JavaScript with Capacitor iOS framework by an ENT resident. TinniCare implements notch sound therapy based on lateral inhibition principles, featuring a 7-step binary search frequency finder (2AFC method), five tinnitus sound type simulations (pure tone, narrow-band ringing, cricket, hum, whistle), six therapy sounds including nature sounds with real-time notch filtering, sound layering, and longitudinal severity tracking using a Visual Analog Scale (VAS). ENTwise contains 1,550 peer-reviewed questions across four subspecialties (otology, rhinology, laryngology, head and neck surgery) with bilingual support, session-based practice, and performance analytics. A prospective pilot study with 20 tinnitus patients is planned using TinniCare for 12 weeks, with weekly VAS severity scores and Tinnitus Handicap Inventory (THI) measurements at baseline, 4, 8, and 12 weeks.

RESULTS

Both applications have been successfully developed and deployed on iOS App Store. TinniCare incorporates evidence from a 2025 meta-analysis of 14 randomized controlled trials (n=793) demonstrating significant reductions in tinnitus severity with notch therapy. ENTwise provides comprehensive coverage across all ENT subspecialties with 1,550 bilingual questions. Preliminary pilot data from the first enrolled patients will be presented, including VAS score trends, therapy adherence rates, and user engagement metrics.

CONCLUSIONS

This ENT digital health ecosystem demonstrates that evidence-based clinical tools and educational platforms can be developed and deployed by otolaryngology residents. TinniCare offers an accessible, science-based approach to tinnitus management, while ENTwise addresses the need for comprehensive board preparation. Preliminary clinical data and user engagement metrics will provide initial validation for the notch therapy implementation.

OP-1373

Transoral Anatomy And Submandibular Gland Ganglion Neurectomy

Sumeyye Akbay[1], **Ercan Akbay**[2], **Tufan Ulcay**[1]

[1]*Kırşehir Ahi Evran Üniversitesi Tıp Fakültesi Anatomi Anabilim Dalı, Kırşehir;* [2]*Aksaray İnova Hastanesi Kulak Burun Boğaz Kliniği, Aksaray*

BACKGROUND & AIM

Parasympathetic denervation of the submandibular gland significantly reduces the amount of resting saliva. Drooling (uncontrolled saliva flow) is treated through denervation. The objective of this study is to explain the details of the surgical technique through clinical outcomes in patients undergoing "Transoral Submandibular Gland Ganglion Neurectomy" and to emphasize the critical importance of deep anatomical knowledge belonging to this region. The classic anatomical approach and orientation, on which traditional submandibular surgeries rely, are completely inverted (turned upside down) in the transoral technique and reconstructed with a brand-new anatomical perspective.

MATERIAL & METHODS

Operations performed by the same surgeon in different clinics between the years 2013-2026 were retrospectively evaluated. When patients came for follow-ups, the reduction rates in saliva flow observed by their relatives were questioned as percentages and recorded. Clinical outcomes and the surgical technique were subjected to a comprehensive evaluation.

Surgical Technique: Transoral submandibular ganglion neurectomy is an advantageous surgery with its low complication risk and its safe anatomical localization far from arterial structures. Entering with an incision parallel to Wharton's duct, the lingual nerve medial to the duct is preserved and dissection is performed up to the crossing point. Transection of the parasympathetic fibers splitting from the lingual nerve to the submandibular gland constitutes the main surgical step of the operation. Following hemostasis, the mucosal incision line is closed with absorbable sutures.

RESULTS

Of the 16 patients included in the study, 7 were male and 9 were female, with their ages ranging between 7 and 27 (mean = 12.56 ± 4.74; variance = 22.52). For the bilateral surgical procedure, the operation time was calculated between 20-45 minutes (mean = 32.25 ± 6.73; variance = 45.40); and the postoperative follow-up period was calculated between 1-12 months (mean = 7 ± 3.54; variance = 12.53). The reduction rate in saliva flow ranges between 70% and 100%, and it was found as mean = 89.37 ± 8.53 (variance = 72.91). In the postoperative period, no significant complication was observed except for a mild bleeding in 1 patient that stopped spontaneously with follow-up, and difficulty swallowing in 1 patient that lasted for 2 weeks and passed.

CONCLUSIONS

Transoral submandibular ganglion neurectomy is a minimally invasive, permanent, and alternative surgical treatment performed for parasympathetic denervation while preserving the sympathetic functions of the submandibular gland. In the literature review, only two articles showing anatomical feasibility studies on cadavers were found, but there is no comprehensive clinical study. This paper is a study in which clinical experiences are successfully presented. Furthermore, the transoral anatomical detail, which includes a different configuration of traditional anatomical structures, has been re-revealed starting from the nuclei in the brain to the end organ.

OP-1374

Medical Illustration In Otolaryngology–Head And Neck Surgery: Enhancing Surgical Education, Communication, And Dissemination Of Innovative Techniques

Mohammed Alwabili[1]

[1]*King Fahad Specialized hospital, Al-Qassim, Saudi Arabia*

BACKGROUND & AIM

Otolaryngology–Head and Neck Surgery encompasses anatomically complex regions characterized by intricate three-dimensional relationships, limited operative exposure, and highly specialized surgical approaches. Traditional methods of surgical communication, including textual descriptions and intraoperative photography, may not always adequately convey critical anatomical details or operative nuances. Medical illustration has emerged as a powerful educational and communication tool capable of simplifying complex surgical concepts while maintaining anatomical accuracy.

MATERIAL & METHODS

The objective is to highlight the role of medical illustration in facilitating the understanding of complex otolaryngologic surgical procedures, improving surgical education, and enhancing the dissemination of innovative operative techniques.

A narrative review of the educational applications of medical illustration in surgical disciplines was performed, with particular emphasis on otolaryngology and head and neck surgery. The utility of illustrations in preoperative planning, resident education, surgical publications, conference presentations, and communication of novel surgical techniques was examined.

RESULTS

Medical illustrations provide visual abstraction that emphasizes key anatomical structures and procedural steps while eliminating unnecessary visual distractions commonly encountered in operative photographs and videos. In otolaryngology, illustrations facilitate comprehension of endoscopic sinus surgery, skull base approaches, otologic procedures, airway surgery, and head and neck reconstruction. Furthermore, they serve as effective tools for communicating innovative surgical techniques, standardizing procedural descriptions, and enhancing educational materials for trainees and practicing surgeons. Recent advances in digital illustration and three-dimensional visualization have further expanded their educational value.

CONCLUSIONS

Medical illustration represents an underutilized yet highly effective adjunct in otolaryngology education and scientific communication. By transforming complex surgical information into clear visual narratives, medical illustration enhances learning, supports knowledge dissemination, and facilitates the adoption of novel surgical techniques. Greater collaboration between surgeons and medical illustrators may contribute to improved surgical education and communication within the specialty.

OP-1375

Danish Prehospital Cricothyroidotomy Investigation A Nationwide Investigation Of Prehospital Emergency Cricothyroidotomy During Cardiac Arrest Between 2016 And 2023

Theo Walther Jensen[2], **Mathias G. Holgersen**[1], **Stig Nikolaj Blomberg**[1], **Jacob Foghsgaard**[2], **Jacob Steinmetz**[2], **Mikkel Porsborg Andersen**[1], **Michael Howitz**[2], **Helle C. Christensen**[1]

[1]*Prehospital Center Region Zealland;* [2]*Copenhagen University Hospital, Righospitalet.*

BACKGROUND & AIM

Emergency cricothyrotomy (EC) is a rare but potentially life-saving procedure performed when conventional airway management fails. Evidence on its epidemiology, indications, and outcomes in the prehospital setting, particularly in out-of-hospital cardiac arrest (OHCA), remains limited. The aim of this study is to present a comprehensive epidemiological analysis of EC procedures performed during cardiac arrest in the prehospital setting in Denmark.

MATERIAL & METHODS

We conducted a nationwide registry-based follow-up study including all patients who underwent prehospital EC in Denmark between 2016 and 2023. Cases were identified through prehospital medical records, the Danish Helicopter Emergency Medical Services database, and the Danish Cardiac Arrest Register. All cases were manually validated. The primary outcome was 30-day survival. Multivariable logistic regression was used to examine factors associated with survival.

RESULTS

Preliminary results show taht a total of 71 prehospital EC cases were identified, of which 48 (67.6%) occurred in patients with cardiac arrest. Preliminary results show that the overall procedural success rate was high, achieved in 83.3% of cardiac arrest cases and 95.6% of non-cardiac arrest cases. Preliminary results show that the most common indications were aspiration and oropharyngeal bleeding. Among patients with OHCA, return of spontaneous circulation was achieved in 25%, while 30-day survival was 4.5% and one-year survival 2.3%. In multivariable analysis preliminary results show that EC was associated with lower odds of 30-day survival (OR 0.15, 95% CI 0.02–0.53), whereas shockable rhythm and bystander-witnessed arrest were associated with improved survival.

CONCLUSIONS

Preliminary results show that prehospital EC is a rare but highly effective procedure for establishing a definitive airway in critically ill patients. Despite high procedural success, survival in patients undergoing EC during cardiac arrest remains low and appears primarily driven by underlying disease severity rather than the intervention itself. Preliminary results suggests that EC should be regarded as an essential rescue procedure in extreme airway emergencies, although its impact on overall survival is limited.

THE THERAPEUTIC POTENTIAL FOR SIALORRHEA: RADIOFREQUENCY ABLATION OF THE SUBMANDIBULAR GLANDS IN A RAT MODEL

Beyza Nur Ulaş[1], **Nihal Seden Boyoglu**[2], **Özgür Yiğit**[3], **Kenan Barış Bingül**[4]

[1]Department of Otorhinolaryngology – Head and Neck Surgery, Istanbul Training and Research Hospital, Istanbul, Turkey; [2]Department of Otorhinolaryngology – Head and Neck Surgery, Yeditepe University Kozyatağı Hospital, Istanbul, Turkey; [3]Department of Otorhinolaryngology – Head and Neck Surgery, Başakşehir Çam and Sakura City Hospital, Istanbul, Turkey; [4]Department of Pathology, Istanbul Training and Research Hospital, Istanbul, Turkey

BACKGROUND & AIM

Sialorrhea is a clinical condition frequently associated with neurological disorders and can significantly impair quality of life. This study aimed to evaluate the histopathological and volumetric effects of radiofrequency ablation (RFA) applied to the submandibular gland in a rat model and to investigate whether this technique may serve as a minimally invasive and durable treatment option for sialorrhea.

MATERIAL & METHODS

A total of 28 rats were divided into four groups and underwent RFA with either 5 Joules or 10 Joules of energy. Sacrifice times were set at 3 weeks and 3 months for each energy level. RFA was applied to the right submandibular gland, while the left gland was preserved as an internal control. Following sacrifice, glands were assessed macroscopically, and histopathological evaluation was performed using H&E, Masson Trichrome, and PAS-AB staining to assess atrophy, fibrosis, inflammation, and ductal changes.

RESULTS

All RFA-treated glands showed significant volume reduction compared to controls ($p < 0.05$). Both 5 Joule and 10 Joule applications resulted in decreased gland weights, with the reduction more pronounced at 3 months than at 3 weeks. Histopathological examination revealed coagulative necrosis, marked atrophy, fibrosis, ductal proliferation, and a characteristic zonal pattern of tissue damage. Mucinous components appeared relatively more resistant than serous acini. No complications were observed during or after the procedures.

CONCLUSIONS

Radiofrequency ablation induces progressive, time- and energy-dependent atrophy and volume reduction in the rat submandibular gland. Given the direct relationship between gland size and salivary output, RFA demonstrates potential as a minimally invasive, long-lasting, and systemically safe treatment option for sialorrhea. This study represents the first experimental model applying RFA to the rat submandibular gland and provides foundational insight for future human studies.

KEYWORDS

Sialorrhea, submandibular gland, radiofrequency ablation, rat model, salivary gland, minimally invasive treatment.

Preliminary Results On Equivalence Of Water Based And Chemical Pre-Cleaning Of Thermolabile Endoscopes In Otorhinolaryngology

Sara Chantal Werner[1], **Marvin Rausch**[2], **Klaus Eichhorn**[1], **Sebastian Strieth**[1], **Stefan Alexander Rudhart**[1]

[1]Department of Otolaryngology, Head and Neck Surgery, University Hospital Bonn, University of Bonn, 53127 Bonn, Germany; [2]Department of Medical Microbiology and Hygiene, University Hospital Bonn, University of Bonn, 53127 Bonn, Germany

BACKGROUND & AIM

The hygienic reprocessing of flexible, thermolabile endoscopes without working channel (FE) in otorhinolaryngology (ENT) is subject to demanding requirements to ensure patient safety. In Germany and internationally, UV-based disinfection is increasingly implemented in hospitals, outpatient clinics and private practice with consistently convincing outcomes. With regard of the precleaning process, however, requirements currently vary depending on the responsible regulating authority. The aim of this study is to investigate whether a de-escalated, water-based precleaning followed by UV-C is equivalent to chemical precleaning.

MATERIAL & METHODS

50 clinically used ENT endoscopes were swap-tested from the entire surface. Samples were immediately plated on tryptic soy agar (TSA) and incubated at 30°C for five days. Visually distinct colonies were subcultured onto separate Columbia agar plates, incubated for an additional night at 37°C, and subsequently analyzed using MALDI-TOF-MS analysis determining baseline contamination.

Using the same method, 50 endoscopes were examined after pre-cleaning with mikrozid® universal wipes followed by UV-C disinfection for 60 seconds.

In addition, 13 endoscopes were analyzed after water-based pre-cleaning followed by UV-C disinfection. Data are presented as mean ± standard deviation (SD) and standard error of mean (SEM); group differences were analyzed using the Kruskal-Wallis test with Dunn´s multiple comparisons correction.

RESULTS

Baseline contamination demonstrated a high microbial load, with mean values of 33,7 ± 84,5 colony-forming units (CFU) (SEM 15.7) on the handle site and 161,38 ± 185,2 CFU (SEM 34.4) on the insertion tube. Predominantly bacteria belonging to the physical flora of the upper respiratory tract were detected. After precleaning with mikrozid® universal wipes followed by UV-C

disinfection, 48 of 50 (96%); minimal contamination in two endoscopes resulted in an overall mean residual contamination of 0,19 ± 0,45 CFU (SEM 0.06).

After water-based pre-cleaning followed by UV-C disinfection, 13 out of 13 endoscopes (100%) showed no detectable microbial growth (0 CFU). Both chemical and water-based pre-cleaning resulted in a significant reduction of CFU counts compared with baseline (adjusted p<0.0001 for all comparisons). No statistically significant differences were observed between chemical and water-based pre-cleaning for either handle or insertion tube (adjusted p >0.9999).

CONCLUSIONS

Water-based pre-cleaning demonstrated microbiologically equivalent results compared with chemical pre-cleaning. Considering these findings, there are justified indications for a reassessment and possible adjustment of existing precleaning algorithms.

KEYWORDS

Hygiene, endoscopes, UV-C, precleaning

Shaye**[8], **Charles Nkurunziza**[9], **Natalie McCall**[10], **Jonathan Abaho**[10], **Eric Uwizeyimana**[11], **Ornella Masimbi**[10], **Sarah Nuss**[12], **Trinithas Boyi**[13], **Mary Jue Xu**[2]

[1]Harvard Medical School; [2]University of California San Francisco Department of Otolaryngology; [3]University of California, Los Angeles Department of Head and Neck Surgery; [4]Rwanda Military Hospital; [5]King Faisal Hospital, Rwanda; [6]University of Rwanda, Department of Otolaryngology; [7]University of Rwanda, Kigali, Rwanda; [8]Harvard Medical School / Massachusetts Eye and Ear Infirmary, Boston, MA, USA; [9]University Teaching Hospital of Kigali, Rwanda; [10]University of Global Health Equity, Rwanda; [11]Saint Paul's Hospital Millennium Medical College, Ethiopia; [12]Massachusetts Eye and Ear Infirmary, Boston, MA, USA; [13]Southern Illinois University, Department of Otolaryngology

BACKGROUND & AIM

In Rwanda's health system, otolaryngology care is structured such that patients are first evaluated at district hospitals, where general practitioners (GPs) play a central role in assessment and triage. As GPs serve as the primary point of contact for many otolaryngology presentations, ongoing professional development in otolaryngologic skills is particularly relevant to their scope of practice. We sought to develop, implement, and evaluate a hands-on training curriculum for GPs to learn and practice foundational skills in otolaryngologic care.

MATERIAL & METHODS

In this Type II hybrid effectiveness-implementation study, an 8-hour curriculum was developed and led by 9 Rwandan OHNS clinicians. The course taught essential skills for GPs including head and neck exam (lecture and hands-on practice), laceration repair (simulation), anterior rhinoscopy and nasal packing (simulation), and ear foreign body removal (simulation). Pre- and post-intervention surveys evaluated clinical outcomes (knowledge and confidence/comfort) and implementation outcomes (appropriateness and acceptability). Data were analyzed using descriptive statistics and paired t-tests.

RESULTS

Forty GPs collectively representing 19 of 30 Rwandan districts attended the training. The curriculum was appropriate, with 93% of GPs agreeing that otolaryngology skills are relevant to their practice. The training was associated with significant improvement in self-reported confidence in all surveyed areas, with anterior rhinoscopy yielding the greatest mean increase of 2.66 out of 5 (p<0.001). Knowledge assessment scores also demonstrated a mean score improvement of 18.55% (p<0.001). Finally, the training was acceptable. All participants agreed the training would improve their ability to manage and treat otolaryngology conditions, and all participants were interested in attending future training sessions.

CONCLUSIONS

This study describes one of the first documented hands-on otolaryngology training session focused on Rwandan GPs. The combined lecture- and simulation-based format was appropriate, effective, and acceptable. This model demonstrates that participants place great value on simulation-based education with associated improvements in both confidence and knowledge. Given the current scope of CME programs focused on otolaryngologic topics in Rwanda, this model could be utilized to further support ongoing professional development to strengthen GPs, knowledge, confidence, and skills, therefore promoting the provision of high-quality otolaryngologic care across healthcare levels.

OP-1379

Comparative Evaluation of the 4K 3D VITOM® EAGLE Exoscope in Otorhinolaryngology: Surgical Workload, Ergonomics, and Feasibility

Alper Tanrısever[1], **Allahverdi Aghayev**[1], **Emre Ocak**[1], **Selcuk Mulazimoglu**[1], **Zahide Ciler Buyukatalay**[1], **Mustafa Kursat Gokcan**[1], **Cem Meco**[1]

[1]*Department of Otorhinolaryngology and Head and Neck Surgery, Ankara University School of Medicine, Ankara, Türkiye*

BACKGROUND & AIM

Surgical visualization in otorhinolaryngology–head and neck surgery is evolving toward heads-up, digitally mediated 4K-3D platforms. However, evidence regarding the surgeon-centered ergonomic and workload impact of the VITOM® EAGLE exoscope remains limited. This study aimed to comparatively evaluate the robotic arm–assisted 4K-3D VITOM® EAGLE exoscope across otologic, microlaryngeal, and head and neck procedures, focusing on surgical workload, postural ergonomic risk, and feasibility.

MATERIAL & METHODS

This single-center observational feasibility study included 21 elective procedures performed by five surgeons: 11 otologic, six microlaryngeal, and four head and neck operations. The VITOM® EAGLE 4K-3D exoscope mounted on the ARTip™ CRUISE robotic arm was compared with the conventional visualization modality routinely used for each procedure type: operating microscope for otologic and microlaryngeal surgery, and surgical loupes for head and neck surgery. Surgical workload was assessed using the National Aeronautics and Space Administration Task Load Index (NASA-TLX), and ergonomic risk using the Rapid Upper Limb Assessment (RULA). Paired comparisons, Holm-adjusted analyses, subgroup analyses, and sensitivity models were performed.

RESULTS

Overall, total NASA-TLX was modestly lower with exoscopic visualization than with the conventional comparator (31.82 ± 15.80 vs 33.51 ± 15.00, $p = 0.044$), mainly driven by otologic procedures (22.24 ± 7.02 vs 30.97 ± 11.37, $p < 0.001$). The exoscope produced a consistent ergonomic advantage, with significantly lower total RULA scores overall (3.52 ± 0.81 vs 5.76 ± 0.44, $p < 0.001$). RULA Group A and Group B scores were also significantly reduced (both $p < 0.001$). Workload-domain analysis showed redistribution away from physical-demand dominance toward relatively higher cognitive and temporal components, rather than uniform global workload reduction.

CONCLUSIONS

The robotic arm–assisted 4K-3D VITOM® EAGLE exoscope is feasible across selected otorhinolaryngology procedures and provides a clinically meaningful reduction in postural ergonomic risk, particularly in otology. Its principal benefit appears to be ergonomic optimization and workload redistribution rather than simple reduction of total perceived workload. These findings support further prospective, procedure-specific human-factors studies.

DECELLULARIZED XENOGENEIC CARTILAGE AS A BIOSCAFFOLD: A RABBIT MODEL STUDY

Miyase ORHAN[1], **Mehmet Akif ERYILMAZ**[2], **Fahriye KILINÇ**[3], **Fakih Cihat ERAVCI**[2], **Hamdi ARBAĞ**[2]

[1]*Ereğli State Hospital, Ear Nose and Throat Clinic, Konya, Turkey;* [2]*Necmettin Erbakan University, Medical Faculty, Department of Otorhinolaryngology, Konya, Turkey;* [3]*Necmettin Erbakan University, Medical Faculty, Department of Pathology, Konya, Turkey*

BACKGROUND & AIM

Autologous cartilage grafts remain the gold standard in reconstructive surgery; however, donor-site morbidity and limited graft availability continue to drive the search for alternative biomaterials. This study aimed to histopathologically evaluate host tissue response to decellularized xenogeneic cartilage and to compare its time-dependent biological behavior with autologous auricular cartilage grafts in an experimental rabbit model.

MATERIAL & METHODS

Chicken-derived sternal cartilage underwent lipid extraction, sodium dodecyl sulfate–based detergent decellularization, enzymatic processing, and ethylene oxide sterilization. In twelve New Zealand rabbits, xenogeneic grafts were implanted into subcutaneous pockets on one side, while fresh autologous auricular cartilage grafts were placed contralaterally as controls. Specimens were harvested at 1 week, 1 month, 3 months, and 4 months. Histopathological evaluation included cellularity, glycosaminoglycan (GAG) preservation, inflammatory response, peripheral proliferative activity, collagen matrix integrity, calcification, and bone metaplasia. Assessments were performed using standardized scoring criteria by a pathologist blinded to implantation time points.

RESULTS

Absence of chondrocyte nuclei confirmed successful decellularization in xenogeneic grafts. Both graft types demonstrated a time-dependent reduction in GAG content, which occurred earlier and was more pronounced in xenogeneic grafts ($p < 0.001$).

Inflammatory response was significantly higher in the xenograft group compared with autografts ($p < 0.001$), without evidence of progressive increase over time. Peripheral proliferative activity was observed in both graft types. At the earliest evaluation point, proliferative activity was significantly greater in autografts ($p < 0.001$); however, no statistically significant differences were identified between graft types at subsequent time points ($p > 0.05$). Peripheral proliferation within the xenogeneic graft group demonstrated a progressive increase over time ($p = 0.005$). No significant intergroup differences were observed in collagen matrix preservation, calcification, or bone metaplasia ($p > 0.05$).

CONCLUSIONS

Decellularized xenogeneic cartilage preserved structural collagen matrix integrity but exhibited greater glycosaminoglycan loss and persistent inflammatory response compared with autografts. Nevertheless, progressively increasing cellular proliferation suggests ongoing host–tissue interaction over time. These findings indicate that decellularized xenogeneic cartilage may represent a potential bioscaffold candidate warranting further experimental and translational investigation in reconstructive cartilage surgery.

OP-1381

Implementing Ambient Voice Technology Into Ear, Nose And Throat Outpatient Clinics: A Workflow Analysis

Praneta Kulloo[1]

[1]*Lewisham and Greenwich NHS Trust*

BACKGROUND & AIM

Ear, Nose, and Throat (ENT) outpatient clinics face severe clinical documentation inefficiencies. Current workflows require clinicians to duplicate effort through brief electronic notes and full manual dictaphone recordings, contributing heavily to clinician fatigue and delayed patient correspondence. We hypothesized that integrating Ambient Voice Technology (AVT), an artificial intelligence (AI) scribe, would eliminate manual rework loops, reduce documentation turnaround times, and alleviate clinical administrative burdens

MATERIAL & METHODS

Study design: Mixed-methods business process analysis. Subjects: ENT clinicians and medical secretaries. Setting: Outpatient clinics at Lewisham and Greenwich National Health Service (NHS) Trust. Intervention(s): Simulated integration of an AVT-powered AI scribe to passively capture consultations and generate structured Electronic Health Record (EHR) notes. Outcome measurement(s): Process handoff frequency, documentation turnaround time, and projected clinician time saved. Independent variables: Documentation method (Manual dictation vs. AVT). Analyses: Data were collected via clinician surveys and one-to-one interviews to capture specific workflow pain points. Workflows were mapped using Business Process Model and Notation (BPMN) swimlanes. Root-cause analysis utilised the 'Five Whys' technique.

RESULTS

Baseline BPMN mapping revealed a fragmented process requiring seven manual handoffs per clinic letter and a frustrating rework loop. Clinical surveys indicated complex letters require up to 10 minutes of manual clinician processing. The modelled AVT intervention successfully consolidated the workflow to a single, same-day clinician review at the point of care. To ensure clinical safety and usability, acceptance criteria established for the pilot mandate a strict AI transcription accuracy of ≥ 99% (Word Error Rate) and a system latency under 10 seconds. However, root-cause analysis identified that outdated legacy EHR systems and rigorous NHS data governance compliance pose significant systemic barriers to immediate integration.

CONCLUSIONS

Replacing manual dictation with AVT presents overwhelming positive potential to streamline ENT documentation workflows, significantly reducing clinician burnout and returning valuable time to direct patient care. However, successful translational implementation is negatively impacted by legacy technology, necessitating strategic alignment with future hospital-wide EHR migrations to sustain these clinical benefits

OP-1382

Enhancing Confidence And Knowledge In Vertigo Management: Outcomes Of A Primary Care Training Course For General Otorhinolaryngologists

Catherine Marie D. Yabut, MD[1], **Angelo Augusto M. Sumalde, MD**[1], **Rosario R. Ricalde, MD**[1]

[1]*Department of Otolaryngology-Head and Neck Surgery, University of the Philippines - Philippine General Hospital;* [2]*Philippine National Ear Institute, National Institutes of Health, University of the Philippines Manila*

BACKGROUND & AIM

Background. Dizziness is a common complaint seen in hospital practice, yet diagnosis and management remains a challenge to most physicians. In 2024, ORL HNS experts from the Philippines developed a two-day course consisting of lectures and workshops on proper diagnosis and management of vertigo in the primary care setting.

Objectives. This study aims to evaluate the preceptorship program for general otolaryngologists through pre- and post-training program questions about confidence in dealing with patients complaining of vertigo as well as pre-and post-test exams on theoretical and practical knowledge on vertigo.

MATERIAL & METHODS

Methods. This is a cross-sectional study design used to compare pre and post test scores of PBO-HNS certified otorhinolaryngologists who attended the two day vertigo training course. This includes the pre- and post-test questionnaire scores on confidence in dealing with dizzy patients and pre- and post-test questionnaires on theoretical knowledge and practices on vertigo and dizziness.

RESULTS

Results. Results showed that there was a significant improvement in the overall confidence of participants dealing with vertigo patients and vertigo specific scenarios. Confidence also scores improved across all vertigo-related scenarios in the questionnaire, with the most significant increase in performing H.I.N.T.S exam, followed by performing canalolith repositioning maneuvers and positional tests. Similarly, the total theoretical knowledge score of participants also increased after the course,

CONCLUSIONS

Conclusion. Our study demonstrated that following a two-day vertigo training course, participants exhibited a significant increase in both confidence and theoretical knowledge in the diagnosis and management of vertigo, thereby improving efficacy and efficiency of primary care for patients.

OP-1383

Enhancing Artificial Intelligence Responses In Healthcare: Assessing Chatgpt Models In Addressing Common Pharyngitis Inquiries

Remzi Doğan[1], **Behlül Güran**[1], **Ramazan Bahadır Küçük**[1], **Orhan Özturan**[1], **Fadlullah Aksoy**[1], **Sabri Baki Eren**[1], **Alper Yenigün**[1], **Erol Şentürk**[1]

[1]*Department of Otolaryngology, Bezmialem Vakif University, Istanbul, Turkey*

BACKGROUND & AIM

Pharyngitis is an inflammation of the mucosa of the oropharynx. In most cases, it is caused by a bacterial or viral infection. Approximately 50 to 80 percent of pharyngitis or sore throat symptoms are of viral origin. The most common bacterial cause is Group A beta-haemolytic streptococci.This study evaluates and compares the accuracy, comprehensiveness, and readability of responses generated by ChatGPT-3.5 and ChatGPT-4 to common patient questions regarding pharyngitis

MATERIAL & METHODS

Thirty patient-oriented questions about pharyngitis, based on guidelines from the American Academy of Otolaryngology and the American Academy of Pediatrics, were posed to both ChatGPT-3.5 and ChatGPT-4. A total of five Ear Nose Throat specialists and three residents were tasked with evaluating the responses for accuracy and comprehensiveness. The readability of the responses was evaluated using the Flesch-Kincaid Grade Level and Flesch Reading Ease scores.

RESULTS

Out of 480 responses, ChatGPT-4. provided significantly more comprehensive and accurate answers compared to ChatGPT-3.5, with 88% of ChatGPT-4. responses rated as comprehensive and accurate versus 79% for ChatGPT-3.5 ($p = 0.01$). Readability analysis showed that both versions required a high educational level for comprehension

CONCLUSIONS

ChatGPT-4 demonstrated superior performance in providing more accurate and comprehensive information on pharyngitis compared to ChatGPT-3.5. However, the complex language used by both models may limit accessibility for the general patient population. Future Artificial Intelligence models should aim for simpler language to improve accessibility and comprehension. Ongoing testing and feedback are essential for refining these Artificial Intelligence based tools in healthcare settings.

OP-1384

Ergonomic Impact Of Robotic-Assisted Microvascular Anastomosis: An EMG-Based Comparison

Dr. med. Eren Erdogan[1], **Prof. Jonas J.-H. Park**[1]

[1]Department of Otorhinolaryngology, Head and Neck Surgery Chair of Otorhinolaryngology, University of Witten/Herdecke

BACKGROUND & AIM

Microvascular anastomoses represent a key element in plastic and reconstructive head and neck surgery. These demanding procedures are often performed at the end of lengthy tumor resections, when the surgeon is already physically and mentally fatigued. This study aimed to demonstrate the feasibility of robot-assisted microvascular anastomosis and to evaluate whether robotic technology can reduce the surgeon's physical workload during microsurgical procedures.

MATERIAL & METHODS

A master–slave robotic system was used, in which the surgeon's hand movements were transmitted via joysticks and replicated in near real-time by the robotic arms. To assess ergonomic advantages, wireless electromyography (EMG) measurements were performed while conducting microanastomoses on silicone vessels with a diameter of 1–2 mm. Muscular load and fatigue were analyzed, particularly in the shoulder girdle, upper arms, and hands.

RESULTS

Microanastomoses using the robotic system were successfully completed on silicone vessels. EMG analyses revealed significant differences in muscular strain compared to conventional free-hand techniques. A structured training and adaptation phase was required to ensure efficient and precise use of the robotic system.

CONCLUSIONS

This study provides first evidence that robot-assisted microvascular anastomosis is technically feasible. Successful completion of the anastomosis on a non-living model supports the potential of robotic systems in microsurgery. Further studies are needed to validate the clinical applicability of this technique in real surgical scenarios, particularly in head and neck reconstruction.

OP-1385

From Free Text To Real-World Evidence: Standardizing Voice-Care Data In ENT Clinics (Apdvoice)

Ramil Hashimli[1]

[1]Faculty of Medicine and Health Sciences, Karabakh University, Khankendi, Azerbaijan

BACKGROUND & AIM

Voice-care documentation in ENT clinics is predominantly narrative and fragmented, limiting outcome measurement, comparability, and evidence generation. As phoniatrics increasingly demands multidisciplinary decision-making and multi-center collaboration, the absence of standardized, analyzable datasets represents a critical barrier. This presentation introduces APDVoice (apdvoice.com) as an integrated digital framework that not only standardizes voice-care documentation but also enables structured consilium-based case discussion and research-ready data generation for single- and multi-center clinical studies (Figure 1).

MATERIAL & METHODS

APDVoice was designed as a structured clinical data ecosystem tailored to ENT–phoniatric workflows. At its core is the Minimum Voice Dataset (MVD), capturing standardized information on symptoms, risk modifiers, endoscopic findings, acoustic and perceptual parameters, diagnosis, treatment decisions, and longitudinal outcomes (Figure 2).

Beyond routine documentation, the platform incorporates dedicated Consilium and Research modules. The Consilium module enables structured discussion of complex or hard cases by linking standardized clinical data, multimedia findings, and expert input (Figure 3). The Research module transforms routine clinical data into curated datasets suitable for single-center analyses and scalable multi-center studies (Figure 4).

The system architecture supports longitudinal tracking, cross-clinician comparability, and future interoperability with external research and analytics infrastructures, forming a scalable ecosystem for real-world evidence generation (Figures 1 and 4).

RESULTS

Structured data capture improved documentation consistency, completeness, and analytical usability across clinical encounters. The Consilium module facilitated standardized discussion of complex voice cases, supporting transparent decision-making and reproducible clinical reasoning.

The Research module enabled efficient transformation of routine clinical data into analyzable datasets, reducing manual data extraction and supporting both retrospective and prospective research workflows. Standardized variables allowed reliable aggregation of cases across clinicians and centers, enabling comparative analyses and hypothesis-driven research.

Together, these modules established a practical pathway from everyday clinical documentation to real-world evidence generation, supporting both clinical excellence and scientific productivity in phoniatric practice.

CONCLUSIONS

Transforming narrative documentation into structured, standardized datasets is essential for advancing voice care from anecdotal practice to measurable, evidence-driven precision medicine. APDVoice illustrates how digital workflow redesign can generate high-quality real-world evidence directly from routine clinical activity. Beyond documentation, such platforms move phoniatrics beyond isolated clinical narratives toward a shared, data-driven ecosystem that supports precision care, reproducible science, and future AI-assisted clinical intelligence.

OP-1386

Linking Long Covid With GNRH Neurons Invasion

Prabhsimran Kaur[1], **Talha Siddiqi**[1], **Prof Nirmal Kumar**[1]

[1]*WWL Wrightington, Wigan and Leigh NHS Foundation Trust*

BACKGROUND & AIM

Anosmia is a common manifestation of COVID-19, affecting approximately 50% of patients, with 68–73% recovering olfactory function. However, a substantial proportion develop persistent anosmia as part of long COVID, a syndrome characterised by prolonged fatigue, cognitive dysfunction, headaches, and sensory deficits. Long COVID represents an increasing healthcare and economic burden, with emerging evidence suggesting sustained viral neuroinvasion and hypothalamic dysfunction.

This study aims to explore the potential mechanisms linking SARS-CoV-2 neuroinvasion, olfactory dysfunction, and disruption of the hypothalamic–pituitary–gonadal (HPG) axis, with particular focus on gonadotropin-releasing hormone (GnRH) neuronal integrity.

MATERIAL & METHODS

A narrative review of current neuropathological, molecular, and clinical studies was undertaken, including post-mortem analyses, translational research, and longitudinal cohort data (e.g. GoCOVID study), to evaluate evidence of SARS-CoV-2 neurotropism and its impact on hypothalamic and endocrine function.

RESULTS

Neuropathological studies demonstrate SARS-CoV-2 neuroinvasion associated with loss of GnRH neurons, suggesting disruption of the HPG axis. The virus infects olfactory sensory neurons and hypothalamic tanycytes, while GnRH neurons express ACE2, TMPRSS2, and neuropilin-1 (NRP1), facilitating direct viral entry. Infection of hypothalamic structures, particularly the median eminence, impairs GnRH neuronal signalling, leading to apoptosis and reduced GnRH transcript expression.

Clinical data from the GoCOVID study indicate heterogeneous endocrine outcomes. While some patients recover normal HPG axis function within one year, others develop delayed or persistent hypogonadotropic hypogonadism, associated with testosterone deficiency and impaired reproductive function.

Additionally, fetal and neonatal GnRH neurons express viral entry receptors, suggesting vulnerability during critical developmental periods, with potential long-term implications for pubertal and reproductive function.

CONCLUSIONS

SARS-CoV-2–associated anosmia may reflect broader neuroendocrine involvement, including disruption of GnRH neurons and the HPG axis. Persistent hypothalamic dysfunction may contribute to long COVID manifestations and endocrine sequelae. Further longitudinal and mechanistic studies are required to clarify causality and long-term clinical implications.

OP-1387

The Pamukkale Operative Performance Scale (Paops): A Competency-Based Tool For Structured Operative Performance Assessment

Cüneyt Orhan Kara[1], **Erdem Mengi**[1], **Fazıl Necdet Ardıç**[1]

[1]*Pamukkale University*

BACKGROUND & AIM

To develop the Pamukkale Operative Performance Scale (PaOPS) and present preliminary evidence supporting its validity and reliability as a structured instrument for assessing resident competence during real surgical procedures.

MATERIAL & METHODS

The PaOPS was developed based on the key steps that trainees are expected to perform during routine surgical procedures. The scale comprises five domains: (1) integration of patient-specific information into the planned procedure, (2) procedural

knowledge, (3) technical skill and appropriate handling of surgical instruments, (4) management of operative flow, and (5) teamwork and communication. In addition, operative autonomy was evaluated as a separate item. The validity, reliability, and generalizability of the PaOPS were examined using statistical analyses. Ethical approval was obtained.

RESULTS

A total of 738 surgical performances by 22 otolaryngology residents were assessed by five supervising surgeons across 85 procedures.

Validity: Spearman correlation analyses showed that higher PaOPS scores were strongly associated with greater operative autonomy across all procedures ($r = 0.773$, $p < 0.001$), indicating that performance improvements paralleled increased surgical independence. For adenotonsillectomy/tonsillectomy, the most frequently assessed procedure, the number of cases performed correlated positively with PaOPS scores ($r = 0.819–0.934$, $p < 0.001$) and with attainment of operative autonomy ($r = 0.619–0.847$, $p < 0.001$), supporting the scale's sensitivity to experience-related gains and its validity in competency-based training.

Reliability: The PaOPS demonstrated good internal consistency (Cronbach's $\alpha = 0.785$). Interrater reliability showed moderate agreement across performance domains ($\kappa = 0.425–0.597$, $p < 0.001$) and excellent agreement for operative autonomy ratings ($\kappa = 0.892$, $p < 0.001$). Generalizability analysis yielded a reliability coefficient of 0.91, indicating high measurement generalizability..

CONCLUSIONS

The PaOPS demonstrated satisfactory preliminary validity and reliability as a concise, competency-based instrument for assessing resident performance in real operative environments. It may serve as a practical tool in otolaryngology training programs to assess operative competence, deliver structured feedback, and track progression toward surgical autonomy.

OP-1388

Workplace Harassement, Family Planning, Parental Leave And Lactation Experiences Among Otorhinolaryngologists In Turkiye: A National Cross-Sectional Survey

Zuhal Zeybek Sivas[1], **Demet Ozdemir**[1], **Fatmanur Sahin Akinci**[1], **Betul Ozdemir**[2]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, Antalya City Hospital, Antalya, Turkiye;* [2]*Republic of Turkey Ministry of Health, General Directorate of Public Health*

BACKGROUND & AIM

This study aimed to assess family planning, reproductive decision making, occupational harrassment and workplace bullying, parental leave and lactation experiences among otorhinolaryngologists practicing in Turkiye. Furthermore it is endeavored to evaluate potential differences according to gender and occupational status (resident physician or specialist).

MATERIAL & METHODS

A web-based, anonymous, cross-sectional survey was conducted among actively practicing otorhinolaryngology specialists and residents throughout Turkiye region. The questionnaire was adapted to Turkish setting from the survey developed by Naismith et al. to assess family planning, parental leave, fertility and lactation experiences among otorhinolaryngologists in Canada. The survey was distributed to approximately 3000 otorhinolaryngologists via professional networking and digital platforms. Through the survey 202 completed responses were obtained. Categorical variables were compared using the Pearson's chi-square test whereas continuous and ordinal variables were analyzed utilizing the Mann-Whitney U test. A p value of <0.05 was accepted as statistically significant.

RESULTS

A total of 202 otorhinolaryngologists participated in the study ; 46.5% were women whereas 53.5% were men. The mean age was 34.86± 8.66 years. Overall, 60.9% of participants reported delaying parenthood due to career related impacts. Infact this rate was significantly higher among women then men (71.3% vs. 51.9% respectively, p=0.007) Women were also more likely to state that otorhinolaryngology training had influenced their decision regard to having a child compared to men. (55.3% vs 29.6% respectively, p=0.003) During residency training, exposure to workplace harrassment and bullying were reported more frequently by women than men (59.6% vs 38.0% respectively, p=0.007) Moreover this difference remained significant after completion of residency (25.5% vs 5.6% respectively, p<0.001) Among female physicians who needed to express breast milk in the occupational era, 72.2% reported inadequate timing , 83.3 % reported deprivation of adequate space and 66.7% reported inadequate storage facilities.

CONCLUSIONS

Otorhinolaryngologists in Turkiye, particularly women physicians cope with substantial challenges and obstacles related to occupational harassement, family planning, lactational support and parental leave.These findings highlight the need for secure reporting systems for workplace mistreatment, parental leave policies that don't impose career or financial disadvantages, and improved workplace infrastructure supportive of lactation.

OP-1389

4K-3D Video Microscopy Vs. Conventional Microscope In Head And Neck Microsurgery: Objective Ergonomic Analysis Using EMG

Dr. med. Eren Erdogan[1], **Prof. Jonas J.-H. Park**[1]

[1]*Department of Otorhinolaryngology, Head and Neck Surgery Chair of Otorhinolaryngology, University of Witten/Herdecke*

BACKGROUND & AIM

One of the main ergonomic challenges in conventional microvascular anastomosis (MVA) is the prolonged use of an operating microscope, which often leads to strain in the shoulder, neck, and back muscles. The Mitaka® HawkSight 4K-3D video microscope provides an alternative by offering high-resolution 4K-3D visualization on a monitor placed away from the operating table. This setup allows for greater freedom of movement of the head and neck muscles, reducing dependence on a traditional operating microscope. The present study aimed to evaluate whether the Mitaka® HawkSight 4K-3D video microscope offers ergonomic advantages for the surgeon during MVA.

MATERIAL & METHODS

MVA procedures were performed using both the Mitaka® HawkSight 4K-3D video microscope and a conventional optical microscope. Electromyographic (EMG) measurements were recorded with a wireless system to analyze and compare muscle activity in the shoulder, neck, and back regions of the operating surgeon.

RESULTS

In vivo MVA performed with digital 4K-3D video microscopy demonstrated excellent visualization of microvessels. EMG analysis revealed significant differences in muscular workload between digital and conventional microscopy. In particular, mean frequency values in the cervical muscles were higher during 4K-3D video microscopy, suggesting reduced muscle fatigue compared to conventional techniques. A structured training and familiarization phase was required to optimize handling of the digital 3D system.

CONCLUSIONS

This study demonstrates the feasibility of performing microvascular anastomosis using the Mitaka® HawkSight 4K-3D video microscope. The enhanced freedom of movement in the neck and shoulder regions, independent of the microscope's position, offers clear ergonomic benefits for the surgeon. However, further technological development and refinement of the digital video microscopy system are required to maximize its ergonomic potential in clinical practice.

OP-1390

Preventing Early Musculoskeletal Injury in Surgical Training: A Novel PGY-1 Ergonomics Curriculum with Measurable Behavioural Impact

Ikeade Adeyinka[1], **Dr. Darren deSa**[1], **Dr. Smriti Nayan**[1]

[1]*Michael G. DeGroote School of Medicine, McMaster University*

BACKGROUND & AIM

Musculoskeletal (MSK) strain affects more than 75% of surgeons over their careers, with otolaryngologists at particularly high risk due to prolonged static posture and fine motor demands. Despite this burden, structured ergonomics education is rarely embedded in early surgical training. To our knowledge, no standardized ergonomics curriculum has been implemented at the PGY-1 level. We developed and evaluated a structured ergonomics program for first-year surgical residents to characterize baseline MSK symptoms and assess the impact of early targeted training.

MATERIAL & METHODS

Twenty-four PGY-1 surgical residents participated in a structured ergonomics session consisting of: (1) a didactic module addressing ergonomic principles, neutral posture, microbreak implementation, and operating room setup; and (2) a six-station hands-on workshop providing real-time posture coaching and targeted core-stabilization exercises relevant to operative positioning.

Pre-session voluntary surveys assessed MSK symptoms using a visual analogue scale (VAS 0–10; 0 = no pain, 10 = worst imaginable pain), ergonomic knowledge, and microbreak behaviours. Post-session voluntary surveys evaluated educational value, confidence in applying ergonomic principles, comfort requesting intraoperative adjustments, and intention to adopt ergonomic practices. Data was summarized descriptively.

RESULTS

Twenty-one residents (88%) completed the pre-session survey. Over 90% reported experiencing MSK discomfort during or after surgery. Mean intraoperative VAS scores ranged from 1.2–3.1/10 (range 0–8), with postoperative discomfort comparable or higher in several domains, suggesting persistent symptom burden. No respondents reported prior formal ergonomics training.

Eighteen residents (75%) completed the post-session survey. Session quality was rated highly (mean 4.6/5), with 94% reporting high relevance to surgical training. Post-session understanding of surgical ergonomics was high (89% rating 4–5/5). Confidence in recognizing ergonomic risk factors improved (89% rating 4–5/5), and 83% reported high confidence in applying ergonomic principles.

Eighty-three percent felt more comfortable requesting microbreaks, and 83% intended to use a microbreak routine during their next operative day. Eighty-nine percent planned to implement at least one ergonomic modification in their next case.

CONCLUSIONS

Even early in residency, trainees demonstrate measurable MSK symptoms without prior formal ergonomics education. Early implementation of structured ergonomics training represents a proactive strategy to prevent ingrained postural dysfunction and long-term occupational morbidity. This novel pilot supports integration of specialty-specific ergonomics curricula to promote surgeon longevity and sustainable surgical careers.

Evaluation Of The Efficacy Of Exosome-Rich Plasma And Selenium Applications On Nerve Regeneration In A Traumatic Facial Nerve Injury Model

ONUR OZSAHIN[1], **MELEK KEZBAN GURBUZ**[1], **MEHMET OZGUR PINARBASLI**[1], **MUHAMMED SEFA UYAR**[1], **ARZU HAZAL AYDIN**[2], **CIGDEM CENGELLI UNEL**[3]

[1]*Eskişehir Osmangazi University, Department of Otorhinolaryngology, Eskişehir;* [2]*Eskişehir Osmangazi University, Department of Pathology, Eskişehir;* [3]*Eskişehir Osmangazi University, Department of Medical Pharmacology, Eskişehir*

BACKGROUND & AIM

The aim of this study is to compare the effects of steroid treatment, Exosome-Rich Plasma (ERP), and selenium on nerve recovery in a traumatic facial nerve injury model through electrophysiological and histopathological evaluation

MATERIAL & METHODS

This study utilized 50 male Wistar Albino rats (3 months old, 300–400 g) randomized into five equal groups (n=10). Under anesthesia, the buccal branch of the facial nerve was exposed, and baseline electrophysiological recordings, including nerve stimulation thresholds (starting at 0.01 mA) and motor unit action potentials from the orbicularis oris and buccal muscles, were obtained. Except for the sham group (Group 1) all subjects underwent a 10-minute nerve compression trauma using microvascular clamps. The control group (Group 2) received no treatment, while experimental groups received methylprednisolone (Group 3: 28 days,1 mg/kg,im), ERP (Group 4: intraneuronal, only first day) and selenium (Group 5: 28 days, sodium selenit 0,17 mg/kg,ip). ERP was prepared from intracardiac blood of five donor rats. After four weeks, final electrophysiological measurements were recorded, and the traumatized nerve segments were excised for histopathological examination prior to sacrifice

RESULTS

This study is my medical specialty thesis. The experimental process and data collection phases are currently ongoing. The efficacy of ERP and selenium in the treatment of facial nerve injury will be evaluated based on the statistical analysis of the obtained electrophysiological and histopathological data.

CONCLUSIONS

All histopathological and electrophysiological data acquired throughout the study will be statistically analyzed to evaluate the therapeutic efficacy of exosome-rich plasma and selenium in facial nerve injury, both of which currently lack a defined role in clinical practice. Consequently, these findings are expected to facilitate the development of novel therapeutic protocols for the management of facial nerve paralysis

Pixel-Wise Otoscopy Planning With Patient-Specific Graft Templates: Quantified Tympanic Membrane Perforation Assessment Applied To Endoscopic Tympanoplasty

Letícia Rosito[1], **Fabio Selaimen**[1], **Alice Lang Silva**[1], **Vinícius Nitz**[1]

[1]*Hospital de Clínicas de Porto Alegre, affiliated with the Federal University of Rio Grande do Sul*

BACKGROUND & AIM

Tympanic membrane (TM) perforation repair—especially with cartilage grafts—often depends on subjective intraoperative estimation of defect size and shape, leading to repeated trimming, longer operative time, and unnecessary cartilage removal. This is particularly relevant in endoscopic tympanoplasty, where precision and efficiency are essential. We developed a practical, low-cost pixel-wise otoscopy workflow with scale calibration (mm/pixel) to objectively quantify perforation geometry (perforation-to-TM area ratio, areas in mm^2, and major/minor axes in mm) and generate a patient-specific graft template. The template can be used as a 2D blueprint and optionally converted into a 3D-printable cutting mold to standardize cartilage shaping.

MATERIAL & METHODS

A browser-based application (Streamlit) with a Python/OpenCV backend was developed for preoperative otoscopy planning. Standard otoscopic images were imported and scale-calibrated to millimeters using either (i) speculum diameter (mm) with automatic circle detection, or (ii) manual calibration by defining a known distance, yielding mm/pixel. The tympanic membrane (TM) and perforation were segmented pixel-wise by manual mask delineation (touch/pen input), generating binary masks. The perforation mask was constrained within the TM mask to avoid overestimation. Areas were computed by pixel counting and converted to mm^2 using the calibration factor; perforation-to-TM area ratio (%) was calculated. Perforation major/minor axes were estimated from contour geometry (ellipse fitting or minimum-area rectangle) and converted to millimeters. A patient-specific graft template was created from the perforation mask and exported as (1) an annotated 2D blueprint with scale bar and metrics, and (2) an optional 3D-ready contour for extrusion and STL mold generation for cartilage trimming guidance.

RESULTS

The workflow successfully generated calibrated, objective perforation measurements and a patient-specific graft template from a single otoscopic image. In the representative case, scale calibration yielded a consistent mm/pixel factor, enabling conversion of pixel-based metrics to clinically interpretable dimensions. The total tympanic membrane area was 68.68 mm^2, with a perforation area of 51.94 mm^2, corresponding to a perforation-to-TM ratio of 75.63%. Perforation geometry analysis demonstrated a major axis of 8.81 mm and a minor axis of 8.33 mm, with an equivalent diameter of 8.13 mm. The system produced two standardized outputs: (1) a blue graft “blueprint” showing the perforation-derived graft shape with embedded dimensions and a scale bar, and (2) an overlay visualization of the graft on the otoscopic image, allowing immediate verification of expected coverage and edge control. The template contour was also compatible with export for optional 3D mold generation to guide cartilage trimming.

CONCLUSIONS

A scale-calibrated, pixel-wise otoscopy planning workflow can objectively quantify tympanic membrane perforation size and geometry and generate a patient-specific graft template for endoscopic tympanoplasty. By providing perforation-to-TM area ratio, absolute areas (mm^2), and major/minor axes (mm) preoperatively, the approach supports accurate graft sizing and improves control of perforation margins and full coverage. This can reduce intraoperative trial-and-error, shorten operative time, and minimize excessive cartilage removal, with potential to increase anatomical closure success. The optional conversion of the template into a 3D-printable cutting mold may further standardize cartilage shaping and enhance reproducibility.

The Role Of Chatgpt-4 In Otorhinolaryngology: A Narrative Review

Talal Alharbi[1]

[1]*King Abdulaziz Medical City, MNGHA, Riyadh , Saudi Arabia*

BACKGROUND & AIM

Background:

Artificial intelligence (AI) and large language models (LLMs) such as ChatGPT-4 have rapidly gained attention for their potential to transform clinical practice, medical education, and patient communication. However, their specific utility in otorhinolaryngology (ENT) remains underexplored.

Objective:

To review current literature and assess ChatGPT-4’s potential applications, benefits, and limitations in otorhinolaryngology across patient education, medical education, and clinical practice domains.

MATERIAL & METHODS

Methods:

A narrative review was conducted using PubMed, Google Scholar, and EMBASE databases with keywords including “ChatGPT-4,” “artificial intelligence,” “ENT,” and “otorhinolaryngology.” Relevant English-language studies were evaluated. Additionally, ChatGPT-4 was prompted across multiple ENT-related scenarios to assess its response accuracy and practicality.

RESULTS

Results:

ChatGPT-4 demonstrated strong potential in improving patient education by enhancing readability and accessibility of medical information, and by providing clear peri-operative guidance. In medical education, it served effectively as a virtual tutor, generating structured learning objectives, assessment materials, and procedural simulations. Clinically, ChatGPT-4 supported documentation tasks such as operative notes and consent forms, aligning with guideline-based standards. However, limitations included inconsistent diagnostic accuracy, occasional factual errors, and ethical concerns regarding data security and medico-legal responsibility.

CONCLUSIONS

Conclusion:

ChatGPT-4 can complement otorhinolaryngology practice by enhancing patient communication, educational efficiency, and administrative workflow. Nonetheless, its use should remain adjunctive, with continued validation and ethical oversight to ensure safe and accurate clinical integration.

Noise-Induced Vestibular Dysfunction In Rats: A Synaptic Mechanism

Fatma Nur Komur[1,2], **Luis Roberto Cassinotti**[2], **Bugra Genc**[3], **Yavuz Gundogdu**[4], **Dila Sener Akcora**[5], **Ozlem Tugce Cilingir Kaya**[5], **Ali Cemal Yumusakhuylu**[4], **Gabriel Corfas**[2], **Cagatay Oysu**[4], **Ayse Ayca Ciprut**[6]

[1]Institute of Health Sciences, Department of Audiology and Speech Disorders, Marmara University, Istanbul, Türkiye; [2]Kresge Hearing Research Institute and Department of Otolaryngology Head and Neck Surgery, University of Michigan, Ann Arbor, Michigan, USA; [3]Department of Laboratory Animals, Faculty of Veterinary Medicine, Ondokuz Mayis University, Samsun, Türkiye; [4]Department of Otolaryngology, Faculty of Medicine, Marmara University, Istanbul, Türkiye; [5]Department of Histology and Embryology, Faculty of Medicine, Marmara University, Istanbul, Türkiye; [6]Department of Audiology, Faculty of Medicine, Marmara University, Istanbul, Türkiye

BACKGROUND & AIM

The cochlea and vestibular organs share the membranous labyrinth, close anatomical proximity, similar hair cell structures, and a common vascular supply, suggesting that both systems may be susceptible to noise-induced damage. Therefore, this study aimed to characterize the impact of low-frequency noise (LFN) exposure on vestibular function and utricular synaptic integrity using electrophysiological, behavioral, and histological assessments.

MATERIAL & METHODS

Sprague-Dawley rats were exposed to 6 hours of continuous LFN at either 110 dB SPL or 120 dB SPL. Auditory function was assessed using auditory brainstem responses (ABRs), while vestibular function was evaluated using cervical vestibular-evoked myogenic potentials (cVEMPs), the balance beam-walking test, and the rotarod test. Utricular synaptic organization was examined by immunofluorescence staining and confocal microscopy.

RESULTS

Exposure to 120 dB SPL LFN resulted in permanent auditory and vestibular functional deficits, whereas the effects of 110 dB SPL LFN were temporary and limited. In the 120 dB SPL group, increased ABR thresholds, reduced wave I amplitudes, elevated cVEMP thresholds, decreased cVEMP amplitudes, and prolonged latencies were observed. These electrophysiological results were accompanied by poorer behavioral performance. Histological analysis revealed selective synaptic loss in the striolar region of the utricle following exposure to 120 dB SPL LFN, while no comparable synaptic loss was observed after 110 dB SPL exposure.

CONCLUSIONS

Noise exposure represents an important environmental risk factor that can directly affect vestibular function. The present findings indicate that noise-induced vestibular damage is intensity-dependent and associated with utricular synaptopathy, with the striolar region particularly vulnerable. Vestibular synaptopathy may therefore play an underlying role in noise-induced balance dysfunction.

OP-1395

Reaching One Billion At Risk: Evaluating A Clinician-Led Youtube Intervention For Hearing-Loss Prevention In Young Audiences

Esh Tatla[1], **Ishika Kamat**[1], **Jade Miller**[2]

[1]West Hertfordshire Teaching Hospitals NHS Trust, United Kingdom; [2]St George's University Hospitals NHS Foundation Trust

BACKGROUND & AIM

Hearing loss is a growing global public-health challenge affecting over 1.5 billion people worldwide, with prevalence projected to increase substantially by 2050 (WHO, 2021). Up to 1 billion adolescents and young adults are at risk of preventable noise-induced hearing loss due to unsafe listening practices (WHO 2025; Dillard et al. 2022). Despite this preventability, hearing-health literacy remains low and engagement with traditional public-health resources is limited. To address this gap, we independently developed and produced a WHO-informed educational YouTube video designed to translate evidence-based hearing-loss prevention guidance into accessible, narrative-driven digital content. This study evaluated its reach and public-health impact.

MATERIAL & METHODS

A mixed-methods observational evaluation was conducted of a 7-minute clinician-authored educational video translating key messages from the WHO World Report on Hearing into clear explanations of auditory physiology, cumulative noise exposure, and preventive behaviours. The video was designed using evidence-based science communication principles to engage adolescents and young adults. Quantitative analytics were extracted from YouTube Studio (27/07/2024–05/02/2026), including impressions, views, watch time, retention, engagement, and audience demographics. A qualitative thematic analysis of 1,421 de-duplicated public comments was performed using an inductive–deductive framework aligned with public-health outcomes (knowledge gain, risk perception, behavioural intention, barriers, misinformation). Only publicly available anonymised data were analysed.

RESULTS

The video generated 421,022 views and 17,232 watch-hours from 3,752,747 impressions (CTR 7.43%), with 79.96% of views occurring within 28 days. Engagement included 23,379 likes and 1,425 comments. Viewers were predominantly aged 18–34 years (86.7%), the highest-risk demographic for unsafe listening, and globally distributed (91.9% of views outside the UK). Thematic analysis identified prevention awareness, risk recognition, and lived experience as dominant themes. Fifteen percent of comments expressed self-reported preventive behaviour change or intent, and prevention-focused comments attracted 34% of total comment likes.

CONCLUSIONS

A clinician-led, WHO-informed digital intervention achieved rapid global reach and engagement among high-risk young audiences. While sustained behavioural change cannot be directly inferred, findings demonstrate that clinician-created digital media can function as a scalable, low-cost adjunct to traditional hearing-loss prevention strategies and highlight the potential for healthcare professionals to directly translate evidence into impactful global public-health communication.

Cognitive Load Effect On Intraoperative Learning – A Randomized Trial In Simulation-Based Settings

Abdulrahman Alhabeeb MBBS[2], Fareeda Mukhtar MBBS[3], Jawad Alhabeeb MBBS[1], Moustafa Alhamadh MBBS[1], Meshal Alothri MBBS[6], Rakan Saad Aldusari MBBS[1], Raghad Mansour Almunyif MBBS[8], Saleh Alnasser MSc[1], Mohammed F. Shaheen MD[2,4]

[1]College of Medicine, King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia; [2]College of Medicine, King Abdullah International Medical Research Center, King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia; [3]College of Medicine, Alfaisal University, Riyadh, Saudi Arabia; [4]Hepatobiliary Sciences Department and Organ Transplant Center, King Abdulaziz Medical City, Ministry of the National Guard Health Affairs, Riyadh, Saudi Arabia; [5]College of Medicine, King Abdullah International Medical Research Center, King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia; [6]Division of Orthopaedic Surgery, Department of Surgery, McMaster University, Hamilton, ON, Canada; [7]Department of Surgery, KAMC, MNGHA, Riyadh, Saudi Arabia; [8]Department of Physical Medicine & Rehabilitation, Rehabilitation Hospital, King Fahad Medical City, Riyadh Second Health Cluster, Riyadh, Saudi Arabia

BACKGROUND & AIM

Surgical trainees in the operating room (OR) face numerous stressful distractions, that increase cognitive load (CL) and potentially hinder learning. While the challenging nature of the OR environment is known, its specific effects on CL and knowledge acquisition in the setting of intraoperative teaching remain underexplored. This study addresses this gap.

MATERIAL & METHODS

A randomized controlled trial was conducted with 61 medical students at King Saud bin Abdulaziz University for Health Sciences. Participants were divided into a control group (CG), exposed to a low-stress simulation, and an experimental group (EG), subjected to a noisy OR simulation. Both groups participated in a chest tube insertion scenario with intraoperative teaching. CL was measured subjectively using the Modified Multidimensional Cognitive Load Scale (m-MCLS) and objectively via heart rate monitoring and a tactile response task (TRT). Postsimulation quiz scores assessed knowledge acquisition.

RESULTS

The EG exhibited significantly higher extraneous CL due to environmental noise ($p < 0.001$). Objective measures supported this; the EG showed more skipped TRT responses (19% vs. 5.3%, $p < 0.001$), indicating attentional lapses. Quiz scores were also

lower in the EG (57.4% vs. 67.5%, p = 0.02), reflecting impaired knowledge acquisition. Prior meaningful hands-on exposure improved performance on univariate analysis but lost significance after accounting for group assignment.

CONCLUSIONS

Simulating a realistic OR environment intensified cognitive load and trainees impaired knowledge acquisition. Incorporating CL management strategies into surgical training may enhance trainee performance and adaptability in similar real-time encounters. Further research should explore optimal simulation realism levels and interventions to mitigate negative impacts on OR knowledge acquisitions.

OP-1397

Quantum Physics - Theoretical Voice Evaluation: A Review Of Emerging Perspectives And Applications

Mette Pedersen[1]

[1]*The Medical center, Østergade 18, 1100 Copenhagen*

BACKGROUND & AIM

Traditional acoustic analysis of the human voice often relies on classical linear models, which struggle to capture the non-linear, stochastic nature of vocal production and pathological turbulence. Recent theoretical developments, most notably: Quantum Vocal Theory of Sound, have proposed that the mathematical quantum mechanics, specifically linear operators in Hilbert spaces, offer a superior framework for describing sounds as an embodied representation. This review is of current knowledge on how quantum principles can be applied to voice evaluation and pathology detection.

MATERIAL & METHODS

We conducted a systematic review of the literature (2018-2025) focusing on quantum signal processing, quantum-inspired algorithms, and vocal state superpositions. The review examines the use of quantum-mechanical postulates (observables, measurement, and time evolution) to show phonetic elements like phonation and turbulence.

RESULTS

The literature reveals that mapping vocal signals onto a Hilbert space allows for a more nuanced representation of vocal states. Research into quantum-enhanced analysis (e.g., the QuantumMelody framework) demonstrates that hybrid quantum-classical models can activate higher agreement with expert clinical graders up to 74% in singing assessment compared to classical baselines. Quantum-inspired denoising and entanglement-based feature extraction have also shown potential in improving signal-to-noise ratios in pathological voice recordings.

CONCLUSIONS

While still in its infancy, a quantum-informed perspective on sound provides a robust mathematical toolkit for addressing complexity in phoniatrics. Future clinical applications may leverage quantum machine learning to enhance the sensitivity of automated voice grading systems, though practical implementation remains tied to advancements in quantum hardware.

Neck Abscesses And Phlegmons – A Continuing Challenge: The Use Of Vacuum-Assisted Closure (VAC) Therapy In Exceptionally Difficult Clinical Cases

Natalia Cicha-Markiewicz[1], **Krystian Mania**[1], **Paweł Golusiński**[1]

[1]*Department of Otolaryngology and Laryngological Oncology, Provincial Hospital in Poznan, Poland*

BACKGROUND & AIM

Although advances in diagnostic imaging and widespread antibiotic use have significantly reduced the incidence of extensive purulent infections of the neck, deep neck abscesses and phlegmons remain potentially life-threatening conditions. Comorbidities often further influence the patient's general condition and clinical outcome. The aim of this study was to analyze the clinical characteristics and management of deep neck infections treated at a tertiary otolaryngology center, with particular emphasis on the role of vacuum-assisted closure (VAC) therapy in exceptionally advanced necrotizing cases.

MATERIAL & METHODS

A retrospective analysis was conducted of patients hospitalized in the Department of Otolaryngology of the Provincial Hospital in Poznan between 2010 and 2023. Demographic data (age, sex), comorbidities, localization and extent of inflammatory lesions, radiological and microbiological findings, and treatment modalities were evaluated. Particular attention was given to cases requiring advanced wound management techniques - the role of vacuum-assisted closure (VAC) therapy in exceptionally advanced necrotizing cases.

RESULTS

Between 2010 and 2023, 203 patients aged 20–88 years were hospitalized due to neck abscesses or phlegmons, predominance of male patients. The time from symptom onset to hospital admission ranged from several days to several months. The most common symptoms included fever or subfebrile temperature, neck pain, and cervical swelling. The submandibular and lateral cervical regions were the most frequently affected sites; other locations included the anterior neck, submental, parapharyngeal, prevertebral spaces. Multispace infections with extension to the mediastinum, and even the chest wall with soft tissue necrosis were also observed. Staphylococci and Streptococcus pyogenes were the most commonly identified pathogens. The majority of patients were treated with wide surgical incision and drainage combined with systemic antibiotic therapy. In two patients with extensive necrotizing soft tissue involvement, negative pressure wound therapy (VAC) was successfully implemented.

CONCLUSIONS

Deep neck abscesses and phlegmons are relatively rare but remain serious, potentially life-threatening conditions. Computed tomography plays an important role in diagnostic evaluation by providing precise information on the location and extent of infection. Wide surgical drainage combined with appropriate systemic antibiotic therapy remains the standard of care and significantly improves patient outcomes. In particularly extensive or necrotizing infections, adjunctive negative pressure wound therapy (VAC) can support wound healing and reduce local infection. Careful monitoring and timely intervention are essential to prevent severe complications and ensure optimal recovery.

Clinical Outcomes And Complications Of Tonsil Surgery In 2,537 Patients: A Fifteen-Year Tertiary Center Experience

Muhammet Fatih Gökmen[1], **Hidayet Giray Soy**[1], **Merih Önal**[1], **Bülent Ulusoy**[1], **Ömer Erdur**[1], **Çağdaş Elsürer**[1], **Mete Kaan Bozkurt**[1]

[1]*Selcuk University Faculty of Medicine Hospital*

BACKGROUND & AIM

Tonsil surgery is among the most commonly performed procedures in otorhinolaryngology, with indications varying between pediatric and adult populations. Although generally safe, postoperative complications—particularly hemorrhage—remain clinically significant and may require readmission to the hospital or surgical intervention. Complication rates may differ according to age, indication, surgical technique, and comorbidities. This study aimed to evaluate the demographic characteristics, surgical indications, operative techniques, and postoperative complication rates of pediatric and adult patients who underwent tonsil surgery, and to identify factors associated with minor and major complications in a large single-center cohort.

MATERIAL & METHODS

This study received ethical approval from the Local Ethics Committee of Selçuk University Faculty of Medicine (approval no. 2025/674). Tonsillectomies performed by participating faculty members were identified through the hospital information system, and demographic data such as age, gender, and date of surgery were recorded. Patients' electronic medical records were reviewed separately to assess surgical indications, comorbidities, surgical techniques, hemostasis methods, and postoperative complications. Readmission or hospitalization due to pain, feeding difficulties, or deterioration of general health status was defined as a minor complication, while postoperative bleeding was classified as a major complication. Data were tabulated using Microsoft Excel and analyzed using IBM SPSS Statistics version 29.0 (IBM Corp., Armonk, NY, USA). Parametric variables were analyzed using Student's t-test, and nonparametric variables were evaluated using the Mann–Whitney U test. A p-value < 0.05 was considered statistically significant.

RESULTS

A total of 2,537 patients (age range: 14 months–72 years) who underwent tonsil surgery were included. Of these, 1,860 (73.3%) were pediatric and 677 (26.7%) were adults. Obstruction was the leading surgical indication (1,683; 66.3%), followed by infection (755; 29.8%), with obstructive causes predominating in children and infectious indications in adults. Most patients (2,335; 92%) had no comorbidities, with respiratory and cardiovascular disorders being the most frequent among those affected. Tonsillectomy was performed in 2,194 cases (86.5%) and tonsillotomy/biopsy in 343 (13.5%), with the cold knife technique used in 1,890 patients (74.5%). Minor complications occurred in 52 patients (2.1%), and major hemorrhage in 87 (3.4%). Reintervention was required in 21 patients (24.1%). There was one pediatric mortality (0.04%); all other patients were discharged without sequelae.

CONCLUSIONS

Tonsil surgery is a common and generally safe procedure in both pediatric and adult populations. Obstructive indications predominated in children, whereas infectious causes were more frequent in adults. The overall rates of minor and major complications were low; however, postoperative hemorrhage remains the most significant adverse event and may require surgical intervention. Although most patients were discharged without sequelae, rare but serious outcomes can occur. Careful patient selection, meticulous surgical technique, and close postoperative monitoring are essential to minimize complications and improve clinical outcomes.

OP-1400

COVID-19 Policy Change And Otolaryngologic Surgery In Japan: A Nationwide Interrupted Time-Series Study

Yoshinori Taguchi[1], **Mizuo Ando**[1]

[1]*Okayama University Hospital*

BACKGROUND & AIM

The COVID-19 pandemic disrupted surgical services worldwide. In Japan, a national state of emergency was declared in April 2020, and COVID-19 was reclassified as a Class 5 infectious disease (seasonal influenza–equivalent) in May 2023, marking a shift from emergency countermeasures to routine infectious-disease management. We quantified the impact of these two policy milestones on nationwide otolaryngology–head and neck surgery activity, capturing both surgical volume and surgical reimbursement.

MATERIAL & METHODS

We used publicly available aggregated monthly data from Japan's National Database (NDB) Open Data. Otolaryngological surgeries were identified using K-codes from April 2019 through March 2024. Outcomes were (1) total surgical volume and (2) total surgical fees in Japanese yen (JPY); for interpretability, fees were also approximately converted to USD using the publicly available average USD/JPY exchange rate for Japan fiscal year 2019. We performed segmented interrupted time-series regression with two intervention points (April 2020 and May 2023), estimating incidence rate ratios (IRRs) with 95% confidence intervals for immediate level changes.

RESULTS

In the pre-emergency period (April 2019–March 2020), the mean monthly surgical volume was 35,157 (SD 3,499), and mean monthly surgical fees were JPY 4.56×10^{9} (SD 3.27×10^{8}), approximately US$42 million/month. For all surgeries combined, a large immediate level change was observed only after the April 2020 emergency declaration, corresponding to a 26% reduction in volume (IRR 0.74, 95% CI 0.62–0.89; p<0.01) and a 19% reduction in surgical fees (IRR 0.81, 95% CI 0.68–0.95; p<0.01). Most procedure categories showed a similar abrupt decline; however, head and neck cancer surgery and foreign body removal showed little to no immediate level change.

CONCLUSIONS

Nationwide otolaryngological surgery in Japan contracted substantially at the onset of emergency measures, with heterogeneous impacts across categories, while essential/urgent surgery appeared comparatively preserved. In future infectious disease outbreaks, these findings suggest that crisis-time triage can protect essential care but may generate backlogs in elective categories, underscoring the need for recovery-phase reallocation of surgical capacity.

OP-1401

Diagnostic Accuracy Of Fine-Needle Aspiration In Parotid Gland Tumors: A Retrospective Analysis Of 215 Cases

Omer Feti Yildiz[1], **Azer Dadashov**[1], **İlda Tanrısever Pehlivan**[1], **Özgür Sürmelioğlu**[1], **Çağlar Eker**[1]

[1]*Cukurova University*

BACKGROUND & AIM

Parotid gland tumors are predominantly benign and generally associated with a favorableprognosis. However, malignant tumors are also encountered at a considerable frequency andare often associated with poor prognosis and metastatic potential. In addition to primaryparotid malignancies, carcinomas originating from the head and neck region may metastasizeto the parotid gland. Therefore, it is important to define the role of fine-needle aspiration(FNA) in distinguishing different types of parotid malignancies.

MATERIAL & METHODS

This retrospective chart review included 215 patients who underwent parotid surgery at Çukurova University Hospital between January 2015 and December 2025. Medical records of all patients were reviewed, and preoperative FNA findings were

compared with final histopathological diagnoses. The sensitivity, specificity, positive predictive value (PPV), andnegative predictive value (NPV) of FNA in differentiating benign and malignant parotidtumors were calculated.

RESULTS

Among 215 cases, preoperative FNA results were available for 151 patients. Of these, 89 patients had both benign FNA findings and benign final histopathology results. In 9 cases, FNA findings were reported as benign, whereas final pathology revealed malignancy. Twentypatients had both malignant FNA findings and malignant final pathology results. In contrast, 5 patients with malignant FNA findings were found to have benign lesions on final histopathological examination. Among 12 cases categorized as salivary gland neoplasm of uncertain malignant potential (SUMP), final pathology was benign in 4 cases and malignantin 8 cases. Of the 16 cases reported as suspicious for malignancy, 7 were benign and 9 weremalignant on final pathology. The sensitivity of fine-needle aspiration for detectingmalignancy was 68.97%, the specificity was 96.79%, the positive predictivevalue was 80%, and the negative predictive value was 94.38%

CONCLUSIONS

Although FNA demonstrates relatively low sensitivity, it has high specificity in the evaluationof parotid gland tumors. Given its ability to reliably differentiate benign from malignantlesions, we support the routine use of preoperative FNA in all patients with parotid tumors.

parotid gland, SGT, salivary gland tumor, FNA, fine needle aspiration

OP-1402

Haemostatic Agent Use And Associated Complications After Thyroid Surgery: A Retrospective Cohort Study In A Tertiary Head And Neck Centre

M.Z.Shahid[1], **E.Turner**[1], **R.Taylor**[1], **I.Smith**[1]

[1]*Department of Ear, Nose and Throat Surgery, Bradford Royal Infirmary, Bradford Teaching Hospitals NHS Foundation Trust, Bradford, United Kingdom*

BACKGROUND & AIM

Haemostatic agents are increasingly used in thyroid surgery to improve operative outcomes. While randomised controlled trials (RCTs) have demonstrated significant benefits, their real-world efficacy is under-researched. To determine whether these agents may facilitate day-case thyroidectomies in the UK, this study evaluated postoperative outcomes associated with the intraoperative application of topical haemostatic agents.

MATERIAL & METHODS

A single-centre retrospective cohort study analysed patients aged ≥18 years who underwent elective thyroidectomies between May 2023 and May 2025. The primary outcome was the incidence of postoperative complications associated with the use of intraoperative topical haemostatic agents. Complications between patients who received haemostatic agents and those who did not were analysed using Fisher's exact test. Secondary outcomes, including total drain output and length of inpatient stay, were analysed using the Mann-Whitney U test.

RESULTS

In 167 thyroidectomies, haemostatic agents were used in 69 (41.3%) patients. Oxidised regenerated cellulose was used in 41 operations (59.4%) and fibrin sealants in 29 (42.0%); one operation used both. Overall, postoperative complications occurred in 37 (22%) patients. A significantly increased incidence of postoperative complications was observed with the use of haemostatic agents ($p<0.001$). No difference was observed in total drain output or length of stay between the two groups.

CONCLUSIONS

Significant postoperative complications were associated with the use of haemostatic agents. This study highlights the challenge of observing RCT-demonstrated efficacy in routine clinical practice. Further research is necessary before determining the role of haemostatic agents in thyroid surgery. Until then, they cannot be relied upon to facilitate day-case thyroid surgery

KEYWORDS

Surgery, adverse effects, therapeutic use, haemostatic agents, post-thyroid surgery complications

Diagnostic Accuracy Of Imaging Modalities For Precise Localization Of Parathyroid Lesions: A Single-Center Retrospective Study

Enes Fatih GÜNEŞ[1], **Şükrü AYDIN**[1], **Mehmet Turan ÇİÇEK**[1], **Mehmet ASLAN**[1], **Çiğdem FIRAT KOCA**[1], **Ali Murat GÜLLE**[1], **Şeyma YAŞAR**[2]

[1]*Inönü University Faculty of Medicine Turgut Özal Medical Center Department of Otorhinolaryngology;* [2]*Inönü University Faculty of Medicine Department of Biostatistics*

BACKGROUND & AIM

Accurate preoperative localization of parathyroid lesions is critical for minimally invasive surgery. This study evaluated the diagnostic performance of different imaging modalities in determining lesion location at the side and quadrant level, using histopathology as the gold standard.

MATERIAL & METHODS

A retrospective analysis was conducted on 130 patients who underwent surgery for suspected parathyroid neoplasms between January 2021 and January 2026 at İnönü University Faculty of Medicine, Department of Otorhinolaryngology. Histopathological diagnoses included parathyroid adenoma, hyperplasia, carcinoma, normal parathyroid tissue, and thymus.

Preoperative imaging modalities included ultrasonography (US), US-guided PTH washout, parathyroid scintigraphy/SPECT-CT (99mTc-sestamibi), computed tomography (CT), magnetic resonance imaging (MRI), FDG PET, and choline PET.

Localization was defined as correct identification of both side (right/left) and quadrant (superior/inferior). Histopathology was accepted as the gold standard. In hyperplasia, a single gland was used as reference. Negative or non-localizing imaging findings were considered incorrect localization.

Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were calculated for each imaging modality.

RESULTS

For US, accuracy and sensitivity were 60%, with an F1-score of 0.61. The highest sensitivity was observed in the left superior localization (100%), although a low PPV (42.9%) indicated a high false-positive rate. Performance was relatively better in inferior localizations but lower in cases without pathology and hyperplasia.

US-guided PTH washout showed accuracy and sensitivity of 75.4% (F1-score 0.75), with the highest performance in right inferior (90.6%) and left inferior (90.0) localizations.(Fig 1)

Parathyroid scintigraphy/SPECT-CT demonstrated accuracy and sensitivity of 67.5% (F1-score 0.69), with the best performance in inferior localizations.

MRI showed an overall accuracy of 50%. Although the highest sensitivity was observed in left superior localization (100%), this was based on a single case. Performance was moderate in right inferior (62.5%) and low in left inferior (20.0%) localizations.

CONCLUSIONS

Overall, findings were consistent with the literature. US showed moderate performance, while PTH washout provided higher accuracy. SPECT-CT had acceptable performance, whereas MRI contributed limited value. Lower rates may be explained by quadrant-level analysis and a heterogeneous patient population.

KEYWORDS

Parathyroid neoplasms, ultrasonography (US), US-guided PTH washout, parathyroid scintigraphy/SPECT-CT (99mTc-sestamibi), computed tomography (CT), magnetic resonance imaging (MRI), FDG PET, choline PET.

OP-1404

Otovent Balloon: A Cross-Sectional Survey Of UK Consultants

Rivya Mathews[1], **Navdeep Bhamra**[2], **John Mathews**[2], **Mudit Jindal**[2]

[1]*West Birmingham Hospitals, U.K.*; [2]*Royal Wolverhampton Hospitals Trust, U.K.*

BACKGROUND & AIM

To explore the opinions of UK consultants on the use of Otovent balloon in the management of Eustachian tube dysfunction (ETD).

MATERIAL & METHODS

A 10-question online survey using Microsoft forms was distributed to ENT consultants/specialists currently practising in the UK (February – April 2026).

RESULTS

A total of 138 ENT-UK consultants and specialists responded to the survey. Just over half (53%) reported using the Otovent balloon in clinical practice, while 47% did not. Among users, it was most commonly recommended for Eustachian tube dysfunction (ETD) symptoms and otitis media with effusion, with only a small proportion using it for barotrauma-related ETD. It was generally prescribed for children over five years old, as younger patients often struggle to use it effectively. Most clinicians had been using the device for less than a decade. In many cases, it was trialled while patients awaited procedures such as ventilation tube insertion or Eustachian tube balloon dilatation.

Among those who did not recommend Otovent, 19% cited insufficient evidence of effectiveness. Additionally, 19% reported discontinuing its use after previously unsuccessful outcomes in their patients.

CONCLUSIONS

This is the first cross-sectional survey on the practice of Otovent balloon in patients having ETD. The study showed that over half (53 percent) used Otovent balloon. The survey suggests that the uptake of Otovent balloon use is more since the NICE (UK)

guidance was published 10 years ago. National guidance for its use in primary care before patients are referred to secondary care for possible surgical intervention should be considered. An effective multicentre trial of Otovent balloon for eustachian tube dysfunction with strict selection criteria may provide a basis for audit and research and help develop the evidence base.

KEYWORDS

Otovent balloon, Eustachian tube dysfunction, otitis media with effusion

ACUTE IDIOPATHIC VELOPHARYNGEAL INCOMPETENCE: CLINICAL CHARACTERIZATION AND SYSTEMATIC EVIDENCE SYNTHESIS

Diogo Nascimento[1,2], **Miguel Campos Lopes**[1,3], **Raquel Andrade**[1], **Luciana Rodrigues**[1], **Maria Inês Ribeiro**[1], **Sofia Macedo**[4], **Paulo Gonçalves**[1], **Tiago Soares Santos**[1,5]

[1]*Department of Otolaryngology, Unidade Local de Saúde de Entre o Douro e Vouga, Santa Maria da Feira, Portugal.*; [2]*Department of Biomedicine, Experimental Biology Unit, Faculty of Medicine of Porto, University of Porto, Porto, Portugal.*; [3]*Faculty of Medicine of Porto, University of Porto, Porto, Portugal.*; [4]*Department of Pediatrics, Unidade Local de Saúde da Póvoa de Varzim / Vila do Conde, Póvoa de Varzim, Portugal.*; [5]*Multidisciplinary Unit of Biomedical Research, ICBAS, Universidade do Porto, Portugal.*

BACKGROUND & AIM

Acute idiopathic velopharyngeal incompetence (AIVI) is a rare neurogenic disorder characterized by sudden palatal paresis without identifiable structural lesions or systemic involvement. It predominantly affects pediatric patients and can present with hypernasality, nasal regurgitation, and dysphagia. Due to its rarity and broad differential diagnosis, clinical management remains heterogeneous. This study aims to integrate systematic evidence synthesis with clinical characterization of a pediatric case to better define epidemiology, clinical features, differential diagnoses, therapeutic response, and recurrence patterns.

MATERIAL & METHODS

A systematic review was conducted according to PRISMA 2020 guidelines across PubMed, Web of Science, SciELO, and LILACS databases. Case reports and case series describing acute velopharyngeal incompetence were included. A hierarchical exclusion strategy, adapted from systematic review principles for rare diseases, was implemented to delimit the entity and identify differential diagnoses. Epidemiological, clinical, therapeutic, and outcome variables were extracted and analyzed descriptively. Additionally, a pediatric case with documented recurrence was clinically characterized and integrated into the evidence synthesis.

RESULTS

Twenty-nine studies comprising 50 cases were included in this review. AIVI showed male predominance (67.4%) and mean pediatric age of 10.1 years. Hypernasality was universal, frequently accompanied by nasal regurgitation and dysphagia. Preceding infectious symptoms were reported in 43.5% of cases. Palatal paresis was predominantly unilateral. Complete or near-complete recovery occurred in 90.0% of cases, with median recovery time of 28 days. Corticosteroid therapy was associated with a trend toward faster recovery. Recurrence was exceptionally rare (three reported cases). Application of the hierarchical exclusion strategy identified several relevant differential diagnoses, including immune-mediated neuropathies and infectious etiologies (e.g., Guillain-Barré syndrome, diphtheria, Lyme disease). The presented case demonstrated typical clinical and endoscopic findings, negative imaging and laboratory workup, favorable corticosteroid response, and documented recurrence.

CONCLUSIONS

AIVI is a rare but distinct clinical entity with favorable prognosis and possible inflammatory pathophysiology. Careful evaluation is essential to differentiate it from potentially severe neurological conditions. Evidence synthesis supports high recovery rates and suggests a potential benefit from corticosteroid therapy. Recurrence remains exceptional but possible. Although not fully understood, awareness of this likely underdiagnosed condition seems crucial when evaluating patients with sudden velopharyngeal incompetence.

OP-1406

Abscess Volume Versus Inflammatory Markers For Predicting Neck Exploration In Deep Neck Infections

ESMANUR SEÇKİN[1], **AYÇA ARSLAN**[1], **ARZUBETÜL DURAN**[1]

[1]*ANKARA ABDURRAHMAN YURTASLAN ONKOLOJİ EĞİTİM VE ARAŞTIRMA HASTANESİ*

BACKGROUND & AIM

Deep neck infections (DNIs) are potentially life-threatening conditions requiring timely diagnosis and intervention. Although systemic inflammatory markers such as neutrophil-to-lymphocyte ratio (NLR), systemic immune-inflammation index (SII), and C-reactive protein (CRP) are widely used in clinical practice, their role in predicting the need for surgical intervention remains

unclear. We hypothesized that abscess volume measured on computed tomography (CT) is a stronger predictor of the need for neck exploration than inflammatory markers.

MATERIAL & METHODS

This retrospective study included 24 patients diagnosed with DNI at a tertiary care center. The decision for neck exploration was based on clinical and radiological findings, including airway compromise, clinical deterioration, lack of response to antibiotic therapy, presence of multiloculated abscess, and surgeon preference.Abscess volume was calculated on CT using the formula: anteroposterior × transverse × craniocaudal diameters × 0.52 and expressed in cubic centimeters (cm^3). Patients were divided into two groups: those who underwent neck exploration (n=11) and those managed non-surgically (n=13), including medical therapy and/or image-guided drainage.

Inflammatory markers, including neutrophil-to-lymphocyte ratio (NLR), systemic immune-inflammation index (SII), and C-reactive protein (CRP), as well as length of hospital stay, were recorded. Group comparisons were performed using the Mann–Whitney U test. Correlations were assessed using Spearman's rank correlation coefficient. Receiver operating characteristic (ROC) analysis was used to evaluate predictive performance and determine optimal cut-off values with 95% confidence intervals (CI).

RESULTS

Abscess volume was significantly higher in patients who underwent neck exploration (p=0.043). ROC analysis demonstrated that abscess volume had the highest predictive value (area under the curve [AUC]=0.81; 95% CI: 0.63–0.99), with an optimal cut-off value of 53 cm^3.

Although CRP levels and NLR were higher in the surgical group, these differences were not statistically significant (p>0.05). Abscess volume showed a significant positive correlation with length of hospital stay (r=0.59, p=0.002). CRP was also correlated with hospitalization duration (r=0.53, p=0.007), whereas NLR and SII showed no significant association with either neck exploration or length of stay.

CONCLUSIONS

In this cohort, abscess volume demonstrated better discriminatory performance than systemic inflammatory markers in predicting the need for neck exploration in DNIs. Additionally, both abscess volume and CRP were associated with prolonged hospitalization. These findings suggest that radiological assessment of abscess burden may support clinical decision-making; however, larger studies are needed to validate these results.

OP-1407

The Educational Value Of Novel 3D Printed Models In Surgical Airway Skills Teaching

Charlotte Arnold[1,2], **Katie Birt**[3], **William Spencer**[3], **Dr Christopher Summers**[3]

[1]*Morriston Hospital Department of ENT;* [2]*Imperial College London NHS Trust, Medical Education Department;* [3]*Swansea University*

BACKGROUND & AIM

Three-dimensional (3D) printed models have been shown to improve surgical skill acquisition, confidence, and technical ability [1]. This study evaluated the use of 3D-printed airway models, as an alternative to animal or cadaveric specimens, for teaching surgical airway management to medical students.

MATERIAL & METHODS

A multidisciplinary team (MDT) of otolaryngologists and anaesthetists (n=9) delivered a practical workshop in which medical students (n=20) were taught how to perform front-of-neck-airway (FONA) access techniques using 3D-printed models. Students received hands-on practice with the models in a small group setting. To assess the value of the models, pre- and post-workshop surveys were utilised, including qualitative and quantitative components.

RESULTS

All participants rated the workshop as excellent (100%, n=20). Regarding the 3D-printed models, 85% of delegates strongly agreed and 15% agreed that the models allowed them to perform key steps in performing tracheostomy and cricothyroidotomy. All students strongly agreed or agreed that the models improved their understanding of relevant airway anatomy and supported achievement of learning objectives. Self-reported confidence in airway management increased markedly following the session. Thematic analysis of qualitative responses highlighted the value of hands-on practice, limited prior exposure to airway management, and a preference for further MDT-led, workshop-based teaching.

CONCLUSIONS

This 3D-printed model provides an affordable, reproducible, and low-stress solution for teaching surgical airway management. For medical students, 3D models provide an opportunity to further their practical and theoretical understanding of airway management with the benefit of the MDT perspective provided in this workshop.

OP-1408

When The Frontal Sinus Expands: Endoscopic Management Of Pneumosinus Dilatans

Catarina Martins Pinto[1], **Francisco Moreira Silva**[1], **Rui Fonseca**[1]

[1]*ULS Alto Ave*

BACKGROUND & AIM

Pneumosinus dilatans (PSD) is a rare condition characterized by abnormal expansion of a paranasal sinus beyond its normal anatomical boundaries, in the absence of bone destruction. A limited number of cases have been described in the literature. The frontal sinus is most frequently involved. The pathophysiology remains unclear, although altered sinus ventilation and a ball-valve mechanism have been proposed.

To describe the clinical presentation, radiologic findings, and endoscopic management of frontal pneumosinus dilatans in a young patient with progressive deformity and headache.

MATERIAL & METHODS

A 19-year-old male presenting with progressive left frontal headache and deformity was evaluated through clinical examination and nasal endoscopy. High-resolution computed tomography (CT) of the paranasal sinuses was performed for anatomical characterization, differential diagnosis, and surgical planning.

RESULTS

Physical examination revealed left frontal protuberance with facial asymmetry, without sinonasal inflammatory signs. Nasal endoscopy was unremarkable.

Computed tomography (CT) of the paranasal sinuses demonstrated marked hyperpneumatization of the left frontal sinus, extending beyond normal anatomical boundaries. The sinus walls were intact, without bone erosion. Mild mucosal thickening was noted along the inferior wall of the frontal sinus, while the remaining paranasal sinuses were well aerated and free of opacification.

Given the progressive deformity and symptomatic burden, surgical management was undertaken using an extended frontal sinusotomy (Draf III). The postoperative course was uneventful, with improvement of headache and stabilization of the cosmetic deformity.

CONCLUSIONS

Frontal pneumosinus dilatans should be considered in patients presenting with progressive frontal deformity and headache. Imaging is essential for accurate diagnosis and surgical planning. Management should be individualized, ranging from observation, in asymptomatic patients, to endoscopic or combined external surgical intervention.

OP-1409

Retrospective Analysis Of Factors Determining Recurrence In Vocal Fold Leukoplakia

Emre Önal[1], **Arzu Tüzüner**[1], **Gülfem Beyazpınar**[1], **Eda Çakmak Aktan**[2]

[1]*Department of Otorhinolaryngology, Başkent University Faculty of Medicine, Ankara, Turkey;* [2]*Biostatistics, Health Sciences Faculty, Department of Audiology, Başkent University, Ankara, Turkey*

BACKGROUND & AIM

Vocal fold leukoplakia comprises epithelial lesions ranging from benign keratosis to invasive carcinoma, with an often unpredictable clinical course. Although excisional biopsy is widely performed for diagnosis and treatment, postoperative recurrence and histopathological progression remain significant concerns. Clinical variables such as smoking status, lesion localization, and patient characteristics are frequently considered in follow-up planning; however, their impact on recurrence and pathological severity has not been clearly established. This study aimed to retrospectively evaluate surgically treated vocal fold leukoplakia and to identify clinical predictors of recurrence and histopathological severity in order to improve risk stratification and follow-up planning.

MATERIAL & METHODS

This retrospective study included patients who underwent type I cordectomy for vocal fold leukoplakia between 2017 and 2025. Patients with less than six months of follow-up, irregular postoperative attendance, or clinically evident invasive malignancy at initial evaluation were excluded. Demographic characteristics, smoking status, lesion localization, histopathological findings, recurrence, and rebiopsy requirement were recorded. Recurrence was defined as the development of a new leukoplakic lesion during follow-up. Histopathological findings were categorized according to severity: hyperkeratosis, parakeratosis, and acanthosis were classified as Group 1, whereas dysplasia (mild, moderate, high-grade) and microinvasive or invasive carcinoma were classified as Group 2. All procedures were performed by the same surgical team using a standardized type I cordectomy technique. Statistical analyses were conducted using SPSS version 25, and associations between categorical variables were evaluated with Fisher's exact or chi-square tests as appropriate. A p-value <0.05 was considered statistically significant.

RESULTS

A total of 32 patients were included, with a mean age of 59.0 ± 14.5 years. The mean follow-up duration was 48.7 months (SD: 21.8; range: 7–90 months). Histopathological evaluation revealed benign lesions in 44% of patients, mild dysplasia in 24%, moderate/high-grade dysplasia in 18%, and microinvasive or invasive carcinoma in 14%. Recurrence occurred in 46.9% of cases, and all recurrent cases underwent rebiopsy. Among rebiopsied patients, mild dysplasia was identified in 28%, moderate/high-grade dysplasia in 65%, and microinvasive or invasive carcinoma in 7%.

No significant association was observed between recurrence and sex, smoking status, or lesion localization ($p > 0.05$). Rebiopsy rates were also not significantly associated with these variables. In contrast, histopathological severity was significantly associated with male sex ($p = 0.004$) and active smoking ($p = 0.013$). Lesion localization was not associated with histopathological severity.

CONCLUSIONS

Recurrence after surgical management of vocal fold leukoplakia remains largely unpredictable when based solely on routine clinical parameters, as no significant association was observed with gender, smoking status, or lesion localization. However, histopathological severity was significantly associated with male gender and active smoking. These findings suggest that clinical risk assessment should not rely solely on demographic or lesion-based characteristics when estimating recurrence risk. Instead, careful histopathological evaluation and individualized surveillance strategies, particularly in active smokers are essential to optimize long-term management.

OP-1410

The Role Of Preoperative CT-Generated 3D Models In Septorhinoplasty Success In Patients With Nasal Axis

Ekrem Tarık Demir[1], **Bayram Barış Büyük**[1], **Volkan Odabaşı**[1], **Rümeysa Vildan Aydoğan**[1]

[1]*Ankara Dr.Abdurrahman Yurtaslan Oncology Research and Training Hospital - ENT Clinic*

BACKGROUND & AIM

Surgical interventions in the head and neck region require precise spatial orientation and predictable planning. While traditional radiological imaging is standard, translating 2D data into 3D surgical reality remains a challenge, particularly in residency training. The primary aim of this study is to evaluate the operative utility of 3D-printed physical models in endoscopic sinus surgery and axis correction, specifically assessing the operating surgeon's perception of the models' benefit using a standardized evaluation scale.

MATERIAL & METHODS

This prospective observational study included 30 patients requiring surgical axis correction. Utilizing preoperative computed tomography (CT) data, patient-specific high-fidelity physical models were manufactured via a high-resolution 16K resin 3D printer. Prior to the actual procedure, surgical teams conducted tactile rehearsals on these models. Following each operation, the primary surgeons completed a standardized 5-point Likert scale questionnaire (ranging from 1 = Strongly Disagree to 5 = Strongly Agree). The survey evaluated the model's contribution to (I) understanding complex anatomy, (II) planning surgical maneuvers, (III) reducing intraoperative hesitation, and (IV) the overall subjective success of the axis correction.

RESULTS

A total of 30 physical models were successfully printed and utilized for preoperative rehearsal. Analysis of the post-operative surgeon questionnaires revealed high approval ratings across all surveyed domains. The median Likert score for the model's contribution to planning the axis correction maneuver was 4.2 . Descriptive statistics and non-parametric evaluation demonstrated that practicing on the 3D models significantly improved the surgeons' intraoperative confidence and perceived accuracy of the operational maneuvers.

CONCLUSIONS

Integrating high-resolution 3D resin printing into preoperative planning offers a highly effective, tactile training modality for rhinoplasty. Based on surgeon-reported outcomes, preoperative practice on patient-specific models significantly enhances spatial understanding and maneuver precision. This accessible methodology bridges the gap between digital imaging and physical surgical execution, ultimately optimizing both surgical training and axis correction procedures.

OP-1411

Evaluation Of İncision Choice On Aesthetic And Functional Outcomes In Parotid Surgery

Muhammet Fatih Gokmen[1], **Furkan Gürsul**[1], **Çağdaş Elsürer**[1]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, Selçuk University Faculty of Medicine, Konya, Turkey*

BACKGROUND & AIM

This study aimed to evaluate and compare different skin incision techniques used in patients undergoing parotid surgery at our institution with respect to aesthetic outcomes assessed by both patients and physicians, functional outcomes, and early and late postoperative complication rates, in order to determine the clinical advantages and disadvantages of each incision type.

MATERIAL & METHODS

Ethical approval was obtained from the Selçuk University Faculty of Medicine Local Ethics Committee (Approval No: 2025/244). Patients who underwent parotid surgery for benign parotid masses were invited for follow-up by two study authors and completed a structured evaluation form. The form collected data on age, sex, date of surgery, follow-up duration, patient- and physician-rated cosmetic appearance and acceptability of the incision, presence of residual or recurrent disease, sensory loss, Frey's syndrome, and other complications. Patients operated on for malignant tumors, infection, trauma, or sialolithiasis were excluded. Data were recorded in Microsoft Excel and analyzed using SPSS version 29 (IBM Corp., Armonk, NY, USA). Parametric variables were analyzed with the independent samples t-test, non-parametric variables with the Mann–Whitney U test, and categorical variables with the chi-square test

RESULTS

A total of 40 patients were included (mean age: 50.03 years; 62.5% male), with a mean follow-up of 40.33 months. Twenty-five patients underwent Modified Blair incision (MBI) and 15 facelift incision (FLI). No residual or recurrent tumors were detected in either group. Patient satisfaction scores were 8.76/10 for MBI and 9.33/10 for FLI (p=0.256). Physician satisfaction was significantly higher in the FLI group (9.2 vs. 8.32; p=0.042). The overall complication rate was 8% in the MBI group (one marginal mandibular nerve palsy, one infection) and 13.4% in the FLI group (one facial palsy, one hematoma). Sensory loss was clinically less frequent in the MBI group; however, the difference was not statistically significant (p=0.30). Although Frey's syndrome was observed less frequently in the FLI group, this difference did not reach statistical significance (p=0.213).

CONCLUSIONS

Parotid surgery incision selection has traditionally prioritized surgical exposure and facial nerve safety. Advances in anatomical knowledge and intraoperative monitoring have reduced facial paralysis rates, shifting focus toward cosmetic and functional outcomes, particularly in benign cases. The Modified Blair incision (MBI) remains the standard approach, while the facelift incision (FLI) seeks improved cosmetic concealment. In our study, patient satisfaction was similar between techniques; however, physician-rated cosmetic scores were significantly higher with FLI. Complication rates, sensory loss, and Frey's syndrome did not differ significantly. Incision choice should therefore be individualized according to patient expectations and surgical considerations.

OP-1412

Analysis Of Serum Lipid Profiles In Patients With Head And Neck Cancer And Comparison With A Healthy Control Group

Buse Genc Saglam[1], **B. Baris Buyuk**[1]

[1]*Ankara Oncology Training and Research Hospital, Department of Otolaryngology–Head and Neck Surgery, Ankara, Turkey*

BACKGROUND & AIM

Tumor cells reprogram lipid metabolism to meet the high energy demands of uncontrolled proliferation and biomembrane synthesis. Lipoprotein(a), an independent cardiovascular risk factor, may also play a role in tumor biology. This study aims to evaluate Lipoprotein(a) levels alongside serum lipid profiles — Total Cholesterol, HDL, LDL, VLDL, and Triglycerides — in treatment-naive head and neck squamous cell carcinoma patients, and to compare these parameters with a healthy control group matched for age and sex, in order to assess their diagnostic and prognostic biomarker potential.

MATERIAL & METHODS

This observational case-control study will enroll 100 participants: 50 treatment-naive patients with histopathologically confirmed squamous cell carcinoma of the head and neck region and 50 healthy controls matched for age and sex. Exclusion criteria include use of lipid-altering medications, primary lipid disorders, uncontrolled endocrine diseases (diabetes, hypothyroidism), chronic renal or hepatic failure, active infection, chronic inflammatory conditions, and pregnancy or lactation. Following 8–12 hours of fasting, peripheral venous blood samples will be collected. Total Cholesterol, HDL, LDL, VLDL, Triglycerides, and Lipoprotein(a) concentrations will be measured using photometric and immunoturbidimetric methods on fully automated analyzers. Sample size was calculated via G*Power 3.1 (effect size d = 0.58, $\alpha = 0.05$, power = 80%), requiring a minimum of 48 participants per group. Statistical analyses will be performed using SPSS 31.0; Independent samples t-test or Mann-Whitney U test will be applied based on normality, with significance set at $p < 0.05$.

RESULTS

It is anticipated that serum Lipoprotein(a) levels will be significantly elevated in head and neck squamous cell carcinoma patients compared to healthy controls, reflecting tumor-driven alterations in lipid metabolism. Similarly, Total Cholesterol,

LDL, VLDL, and Triglyceride levels are expected to differ significantly between the two groups, while HDL levels may be comparatively reduced in the patient group. These differences are hypothesized to correlate with TNM staging and histopathological characteristics of the tumor. If confirmed, elevated Lipoprotein(a) alongside an unfavorable lipid profile may indicate a metabolic environment conducive to tumor progression. These findings would support the potential utility of Lipoprotein(a) and serum lipid parameters as accessible, cost-effective diagnostic and prognostic biomarkers in the clinical management of head and neck cancers.

CONCLUSIONS

This study will provide novel insights into the relationship between Lipoprotein(a), serum lipid parameters, and head and neck squamous cell carcinoma. By comparing lipid profiles of treatment-naive cancer patients with healthy controls, the diagnostic and prognostic biomarker potential of these parameters will be systematically evaluated. If significant differences are confirmed, Lipoprotein(a) and lipid panel measurements may offer a cost-effective and readily accessible tool in the clinical management of head and neck cancers, contributing original data to the growing body of literature on metabolic reprogramming in oncology.

Impact Of Blood Pressure On Platelet-Rich Fibrin (PRF) Production: A Quantitative And Qualitative Analysis

Abdullah ÖZDEM[1], **Yusuf Berk GÜÇLÜ**[1], **Simge KILIÇASLAN**[2], **Fatih ÖZÇELİK**[2], **Dilara AĞCA**[1], **Mehmet ECE**[1], **Suat TURGUT**[1]

[1]*Department of Otorhinolaryngology – Head and Neck Surgery, Şişli Hamidiye Etfal Training and Research Hospital, University of Health Sciences, Istanbul, Turkey;* [2]*Department of Medical Biochemistry, Şişli Hamidiye Etfal Training and Research Hospital, University of Health Sciences, Istanbul, Turkey*

BACKGROUND & AIM

Platelet-Rich Fibrin (PRF) is an autologous biomaterial widely utilized in otolaryngology to enhance tissue regeneration and wound healing. Despite its frequent clinical use, the impact of perioperative hemodynamic variations on its biological profile remains poorly understood. This prospective, single-blinded study aims to evaluate the quantitative mass and the growth factor content—specifically TGF-β and EGF—of PRF obtained during preoperative normotensive and intraoperative controlled hypotensive states in rhinoplasty patients. The objective is to determine whether systemic blood pressure values significantly influence the regenerative potential of PRF, ultimately aiming to optimize PRF preparation protocols.

MATERIAL & METHODS

This prospective, single-blind clinical study included patients aged 18–65 years without systemic disease undergoing elective operations. Exclusion criteria comprised chronic conditions, malignancies, history of chemoradiotherapy, or immunosuppression. Based on power analysis (α = 0.05, 80% power, effect size = 0.8), a minimum sample size of 34 patients was determined; however, 45 patients were enrolled to account for potential dropouts and data loss. Blood samples were collected at two perioperative stages: the preoperative normotensive state and the intraoperative controlled hypotensive state. PRF was prepared using a standardized double-tube centrifugation method without anticoagulants. Quantitative analysis involved measuring PRF mass and volume, while qualitative assessment included the determination of growth factor content (specifically TGF-β and EGF) using the ELISA method. The biochemistry team remained blinded to the hemodynamic origin of the samples. Statistical analysis was conducted to evaluate the impact of systemic blood pressure values on PRF characteristics.

RESULTS

The study included 45 patients (36% female) with a mean age of 33.0 ± 12.3 years. No significant difference was observed in PRF weight between normotensive (509 ± 99 mg) and hypotensive (526 ± 112 mg) states ($p = 0.4309$). While serum TGF-β and EGF levels remained stable across both conditions ($p > 0.05$), analysis of PRF supernatants revealed significantly higher growth factor concentrations under hypotensive conditions. Specifically, PRF-TGF-β (46.2 vs 37.5 pg/mg PRF, $p = 0.0005$) and PRF-EGF (1.19 vs 0.95 pg/mg PRF, $p = 0.0002$) levels were significantly increased during hypotension, with large effect sizes ($r = 0.52$ and 0.56, respectively). Correlation analysis demonstrated a positive association between PRF weight and PRF-TGF-β in both conditions (Spearman's $rs = 0.364$ and $rs = 0.408$). ROC analysis indicated limited discriminative capacity of PRF-derived growth factors in distinguishing hemodynamic states (AUC: 0.686 for TGF-β; 0.677 for EGF).

CONCLUSIONS

Controlled hypotension significantly increases TGF-β and EGF content within PRF without affecting systemic serum levels. The positive association between PRF weight and PRF-TGF-β—more pronounced under hypotensive conditions—suggests that intraoperative hemodynamic variations may modulate platelet activation and growth factor release dynamics. These findings indicate that the biological activity of PRF is sensitive to perioperative blood pressure states, potentially conferring a regenerative advantage during controlled hypotensive anesthesia. However, the limited discriminative performance observed in ROC analysis suggests that these growth factors are better suited as indicators of PRF bioactivity rather than reliable markers of hemodynamic status.

OP-1414

Can Brain Imaging Identify Tinnitus Subtypes That Clinical Tests Miss? A Machine Learning Study

Vinh Nguyen[1], **Ada W.S. Leung**[2], **Nahla A. Gomaa**[1]

[1]*Division of Otolaryngology–Head and Neck Surgery, Faculty of Medicine and Dentistry, University of Alberta;* [2]*Faculty of Rehabilitation Medicine, University of Alberta*

BACKGROUND & AIM
Tinnitus is diagnosed entirely by subjective self-report, with no validated objective test to confirm its presence or distinguish clinically relevant subtypes. Tinnitus without hearing loss (T) and tinnitus with hearing loss (THL) are clinically indistinguishable on standard instruments: Tinnitus Handicap Inventory (THI) scores do not differ between groups (p=0.369), nor does tinnitus duration (p=0.121). Yet accurate subtype differentiation directly influences treatment selection; sound-amplification strategies are prioritised in THL while cognitive-behavioural approaches are emphasised when peripheral hearing is preserved. We tested whether task-based functional MRI (fMRI) features could discriminate tinnitus subgroups at the individual level using machine learning.

MATERIAL & METHODS
Thirty-two adults (8 healthy controls [HC], 13 T, 11 THL) underwent an auditory oddball task-fMRI protocol. Brain activity patterns, specifically signal amplitude and variability, were measured across 48 cortical regions involved in auditory processing and self-referential cognition (yielding 96 features per participant). A machine learning classifier (random forest) was trained to distinguish the three groups, with rigorous cross-validation (50 repeats) and permutation testing (500 iterations) to confirm results exceeded chance. Age effects were controlled for within the analysis.

RESULTS
Despite clinical indistinguishability on THI (p=0.369) and tinnitus duration (p=0.121), brain imaging significantly distinguished all three groups (healthy controls, T, and THL) above chance levels (balanced accuracy 0.535, p=0.018), a result that held after controlling for age (0.553, p=0.018). Critically, distinguishing T from THL improved from near chance (0.563) to 0.636 after controlling for age. The most reproducibly discriminating brain regions were Heschl's gyrus (primary auditory cortex; 78% of models), insular cortex (71%), and posterior cingulate cortex (70%).

CONCLUSIONS
Brain imaging detected real differences between tinnitus subtypes that questionnaires and clinical history cannot capture. Three brain regions, Heschl's gyrus, insular cortex, and posterior cingulate cortex, consistently distinguished the groups and represent promising targets for an objective tinnitus test. With external validation in age-matched cohorts, this approach could support objective confirmation of tinnitus diagnosis and individual-level patient stratification to guide treatment selection.

Improved Usability Of An Active-Polarized 3D Display In Exoscopic Surgery Under Non-Optimal Viewing Conditions

Ryuhei Okada[1], **Keiji Honda**[2], **Koharu Nakayama**[3], **Takeshi Tsutsumi**[2], **Takahiro Asakage**[1]

[1]*Department of Head and Neck Surgery, Institute of Science Tokyo, Tokyo, Japan;* [2]*Department of Otorhinolaryngology, Institute of Science Tokyo, Tokyo, Japan;* [3]*Medical Solutions Business Div. Life Science & Technology Business Unit, Sony Corporation, Tokyo, Japan*

BACKGROUND & AIM
Three-dimensional (3D) exoscopes have increasingly been used in otolaryngology-head and neck surgery because they allow surgeons to operate in an ergonomic posture while sharing the surgical view with assistants and trainees. However, conventional passive-polarized 3D displays (PPDs) have limitations in vertical viewing angles, which may impair stereoscopic perception when the display is viewed from non-frontal positions. This can be problematic for assistants or surgeons working at different eye levels. We evaluated the usability and task performance of a prototype active-polarized display (APD), which is designed to maintain 3D visibility across a wider viewing range.

MATERIAL & METHODS
A 32-inch APD prototype was compared with a commercially available 32-inch PPD using the ORBEYE 4K 3D exoscope system. Twenty-four otorhinolaryngologists and head and neck surgeons participated. The viewing position was set 100 cm horizontally from the display, with the line of sight directed 20downward toward the screen center, a condition known to be unfavorable for PPD. Participants performed a procedural task simulating stapes surgery for 10 minutes. The number of successfully completed tasks was counted. Visual fatigue was evaluated using a target-tracking eye-movement test performed

before and after the task. Usability was assessed with a seven-item questionnaire. Data were analyzed using Wilcoxon signed-rank tests with Benjamini–Krieger–Yekutieli correction. This study was supported by the Cooperation Program between Tokyo Medical and Dental University (currently called Institute of Science Tokyo) and Sony Corporation.

RESULTS

Questionnaire scores favored APD across all items, with particularly large differences in 3D visibility and ease of procedure (both $q < 0.001$). The number of successfully completed procedural tasks was significantly higher with APD than with PPD (median 15.5 vs. 12 tasks; $p = 0.008$). Although objective oculomotor fatigue measured by the saccadic main-sequence slope ratio did not reach statistical significance ($p = 0.188$), a trend toward less fatigue was observed with APD.

CONCLUSIONS

Under non-optimal viewing conditions for PPDs, the APD demonstrated superior usability and task performance in a simulated surgical environment. APD may improve visualization for assistants or surgeons operating at different eye levels and could enhance performance in procedures requiring fine manipulation.

OP-1416

Simplifying BPPV Education: The C Method For Intuitive Prediction Of Nystagmus Patterns

Melikşah Çakır[1]

[1]*Kocaeli City Hospital*

BACKGROUND & AIM

Accurate interpretation of nystagmus patterns is essential for the diagnosis of benign paroxysmal positional vertigo (BPPV). However, understanding the three-dimensional relationship between otolith movement, semicircular canal orientation, and ocular motor responses is conceptually challenging for residents in training and often relies on rote memorization. To address this limitation, we developed the “C Method” a novel hand-motion–based educational technique designed to enable intuitive, logic-driven prediction of nystagmus direction. This pilot study aimed to evaluate the feasibility and educational effectiveness of the C Method in otolaryngology residency training.

MATERIAL & METHODS

Thirty-four otolaryngology residents with 0–43 months of clinical experience participated in this prospective educational intervention. Participants completed a structured 10-item multiple-choice test assessing their ability to predict expected nystagmus direction across a range of common and uncommon BPPV scenarios. Following a standardized 20-minute training session introducing the C Method, the same test was re-administered. Pre- and post-training scores were compared using paired-sample t-tests to assess learning outcomes.

RESULTS

The results showed that the mean number of correct responses increased significantly from 2.09 ± 2.11 before training to 5.50 ± 2.08 after training). The Wilcoxon signed-rank test revealed that this increase was statistically significant ($Z = 4.742$, $p < 0.001$), with a very large effect size ($r = 0.81$). Furthermore, the frequency of selecting the “I don’t know” option decreased markedly from 158 to 17 responses, reflecting improved conceptual understanding and increased diagnostic confidence. Performance improvements were observed across both typical and more complex BPPV scenarios, suggesting that the method may support conceptual understanding beyond simple pattern memorization.

CONCLUSIONS

The C Method appears to be a simple, cost-free, fast and practical educational tool that may assist residents in predicting BPPV-related nystagmus patterns more intuitively. By offering a visual and logic-based framework, this approach has the potential to reduce reliance on memorization and facilitate the learning process. The C Method may serve as a useful adjunct in vestibular education and otology training. Further studies incorporating clinical application, larger cohorts of residents and audiologists, and long-term follow-up are needed to more fully evaluate its educational value and clinical relevance.

Comparative Results Of Intraoperative Neurophysiological Parameters Using A Hand Assistant System Versus Manual Electrode Array Insertion In Children

Musaev Abdukhalil[1], **Abdukamilova Mukhlisa**[1], **Inoyatova Flora Ilyasovna**[1], **Abdukayumov Abdumannon**[1], **Nadjmutdinova Nazima**[1]

[1]*Republician Center of Pediatrics in Uzbekistan*

BACKGROUND & AIM

To evaluate the feasibility, safety, and intraoperative neurophysiological outcomes of electrode array insertion using a Hand Assistant System during cochlear implantation in children with normal inner ear anatomy and to compare these results with those obtained using the conventional manual insertion technique.

MATERIAL & METHODS

A retrospective analysis of clinical data from the Republican Specialized Scientific and Practical Medical Center of Pediatrics was conducted for the period 2024–2025. Cochlear implantation was performed in 60 children with normal inner ear anatomy. In 30 cases, the electrode array was inserted using the conventional manual technique, while in 30 cases insertion was performed with the Hand Assistant System (OtoDrive/OtoArm). Intraoperative monitoring included electrically evoked compound action potential telemetry (ART), ground path impedance measurements, the number of electrodes with recordable responses, and electrode insertion speed. A maximum stimulation charge of 30 qu was used in all cases.

RESULTS

In the Hand Assistant System group (n = 30), ground path impedance values ranged from 0.80 to 1.20. Complete ART responses from all 12 electrodes were recorded in 26 children (86.7%), while 4 patients (13.3%) demonstrated responses from 8–9 electrodes. The electrode insertion speed was 0.3 mm/s.In the manual insertion group (n = 30), ground path impedance values ranged from 0.87 to 1.50. Complete ART responses from all 12 electrodes were obtained in 23 children (76.7%), whereas 7 patients (23.3%) demonstrated responses from only 6–7 electrodes. The electrode insertion speed was 0.1 mm/s.

CONCLUSIONS

The use of a Hand Assistant System for electrode array insertion in children is associated with more stable intraoperative neurophysiological responses and more favorable impedance values compared with the conventional manual technique. Despite requiring additional insertion time, the robotic-assisted approach may potentially reduce the risk of cochlear structure trauma.

OP-1418

Patient-Reported Concerns, Emotional Status, And Satisfaction Following Tonsillectomy Performed As Day Surgery: A Prospective Questionnaire-Based Study

Austeja Kucinskiene[1], **Patricija Zenkiene**[1], **Eugenijus Lesinskas**[1]

[1]*Ear, Nose and Throat department, Vilnius University Hospital Santaros Klinikos, Vilnius, Lithuania*

BACKGROUND & AIM

Tonsillectomy is one of the most commonly performed procedures in otorhinolaryngology and is increasingly undertaken as day surgery. Although this surgical model is considered safe and efficient, patient concerns, emotional status, and perceptions of same-day discharge remain insufficiently explored. Patient-reported outcome measures are essential for evaluating perioperative care, postoperative pain management, and acceptance of day surgery pathways.

Aim.

To assess patient concerns, emotional state, expectations, and knowledge before tonsillectomy performed as day surgery, as well as postoperative pain, recovery, mood, and satisfaction with treatment and same-day discharge during the first two postoperative weeks.

MATERIAL & METHODS

This prospective questionnaire-based study included adult patients undergoing elective tonsillectomy. A structured questionnaire was administered preoperatively and repeated at 1 week and 2 weeks after surgery. The preoperative assessment focused on emotional status, concerns regarding pain, anesthesia and complications, level of knowledge, expectations for postoperative pain management, comorbidities, and attitudes toward same-day discharge. Postoperative assessments evaluated pain intensity using a numeric rating scale, analgesic use and effectiveness, complications, emotional well-being, functional recovery, return to daily activities, and overall satisfaction with surgical outcomes and discharge on the day of surgery. Data were collected prospectively and analyzed using descriptive statistical methods.

RESULTS

A total of 70 patients underwent tonsillectomy performed as day surgery. Preoperative anxiety was reported by 53.6% of patients, with a mean anxiety score of 5.4 ± 2.6 and a median score of 5 (range 1–10). The most common concerns were postoperative pain, bleeding, and anesthesia.

The median duration of postoperative pain was 13 days, with pain most frequently peaking within the first postoperative week rather than on the day of surgery. Same-day discharge was achieved in 42.9% of patients.

Overall satisfaction was high, with a mean score of 3.9 ± 1.3; approximately 75% of patients were satisfied or very satisfied, and 87.5% would recommend the procedure. A significant negative association was observed between postoperative pain duration

and satisfaction (Spearman's ρ = −0.49, p = 0.035). Preoperative anxiety showed a moderate, non-significant association with lower satisfaction (ρ = 0.37, p = 0.096).

CONCLUSIONS

Tonsillectomy performed as day surgery is well accepted by patients when supported by structured preoperative counseling and standardized postoperative pain management. The presented questionnaire is a practical tool for evaluating patient-reported outcomes and may contribute to further optimization of day surgery practice in otorhinolaryngology.

KEYWORDS

Tonsillectomy, Day surgery, emotional status, otorhinolaryngology.

OP-1419

H1 Receptor Gene Polymorphisms In Subjective Tinnitus: Susceptibility And Pharmacogenomic Implications

Gülçin Uysal[1], **Elif Kaya Çelik**[2], **Nihan Bozkurt**[3]

[1]Department of Otorhinolaryngology, Kağızman State Hospital, Kars, Türkiye; [2]Department of Otorhinolaryngology, Tokat Gaziosmanpaşa University Hospital, Tokat, Türkiye; [3]Department of Medical Biology, Faculty of Medicine, Tokat Gaziosmanpaşa University, Tokat, Türkiye

BACKGROUND & AIM

Tinnitus affects 10–17% of the adult population and severely impairs quality of life in 1–2% of individuals, yet its pathophysiology remains incompletely understood. Histamine 1 (H1) receptors are expressed in the stria vascularis, spiral ganglion, and vestibular neuroepithelium of the inner ear, regulating cochlear microcirculation via nitric oxide-mediated vasodilation. Betahistine dihydrochloride, a widely used tinnitus agent acting as a weak H1 agonist and potent Histamine 3 (H3) antagonist, produces variable treatment outcomes whose genetic basis remains unexplored. We aimed to evaluate whether H1 receptor gene 1068-A/G (rs2067468) and Leu449Ser (rs2067470) polymorphisms are associated with tinnitus susceptibility and betahistine treatment response.

MATERIAL & METHODS

This retrospective case-control study enrolled 75 patients with subjective tinnitus (42 female, 33 male; aged 18–65 years) and 74 age-matched controls. All tinnitus patients completed 90 days of betahistine 24 mg twice daily. Pure-tone audiometry, tinnitus loudness matching, and the Tinnitus Handicap Inventory (THI) were administered at baseline and day 90. Treatment response was defined as ≥7-point THI reduction or ≥15 dB decrease in loudness matching. Genotyping of the 1068-A/G and Leu449Ser polymorphisms was performed by polymerase chain reaction–restriction fragment length polymorphism (PCR-RFLP) using BseNI restriction endonuclease. Chi-square, Fisher's exact test, and independent-samples t-test were applied ($p<0.050$).

RESULTS

Neither polymorphism differed significantly between tinnitus and control groups in genotype or allele frequency (p=0.448 and p=0.511, respectively), indicating no association with tinnitus susceptibility. Betahistine significantly improved all THI subscales and loudness matching values (all $p<0.001$). When response was assessed by loudness matching, none of the five G-allele carriers (4 AG, 1 GG) responded to treatment; genotype distribution significantly differed between responders and non-responders (p=0.014). THI-based response did not differ by genotype (p=1.000). Leu449Ser was not associated with treatment response by either criterion (p=0.393 and p=0.172).

CONCLUSIONS

Although H1 receptor polymorphisms were not associated with tinnitus susceptibility in this cohort, the G allele of the 1068-A/G variant appears to negatively influence the psychoacoustic response to betahistine, likely through impaired cochlear H1-mediated vasodilation. The preserved THI response across genotypes implicates betahistine's central H3 antagonist mechanism as genotype-independent. These findings introduce H1 receptor pharmacogenomics as a novel framework for understanding variable tinnitus treatment outcomes. Larger prospective studies are warranted.

OP-1420

Global Warming, Prolonged Pollen Seasons And The Rising Prevalence Of Allergic Rhinitis: A Systematic Review Of Epidemiological Evidence

Reyhan Ozcan Bilgic[1], **Neslihan Kul Turhan**[2]

[1]Ankara Oncology Training and Research Hospital, Department of Otolaryngology–Head and Neck Surgery, Ankara, Turkey; [2]Ankara Sanatoryum Training and Research Hospital, Department of Otolaryngology–Head and Neck Surgery, Ankara, Turkey

BACKGROUND & AIM

Climate change is reshaping the biological environment in ways that directly affect human health. Rising temperatures and elevated atmospheric CO_2 have been shown to extend pollen seasons and enhance the allergenic potency of airborne pollen, contributing to a growing burden of allergic rhinitis worldwide. Although epidemiological data supporting this association are

accumulating, a comprehensive synthesis of the current evidence remains limited. This review aims to evaluate the relationship between global warming, prolonged pollen seasons, and the rising prevalence of allergic rhinitis through a PRISMA-compliant systematic review of the epidemiological literature, with particular attention to Northern Hemisphere and Mediterranean basin findings.

MATERIAL & METHODS

A systematic review was conducted in accordance with the PRISMA guidelines. A comprehensive literature search was performed across PubMed/MEDLINE, Web of Science, Embase, and environmental science databases including GreenFile, covering publications from 2000 to 2025. The following search terms were used in various combinations: "climate change," "global warming," "pollen season," "allergic rhinitis," "prevalence," "phenology," and "temperature." Studies were eligible for inclusion if they reported epidemiological data on pollen seasonality or allergic rhinitis prevalence in relation to climatic variables. Reviews, editorials, case reports, and studies focusing exclusively on non-allergic rhinitis were excluded. Supplementary data were obtained from publicly available databases of the World Health Organization (WHO) and the European Environment Agency (EEA).

RESULTS

The evidence consistently supports a biological cascade linking climate change to allergic rhinitis: rising temperatures and elevated atmospheric CO_2 have progressively extended pollen seasons and amplified pollen allergenicity across temperate and Mediterranean regions, with particularly well-documented changes in birch, grass, and olive species. Reviewed studies collectively suggest that climate change is not merely a background variable but an active driver of allergic rhinitis epidemiology. Parallel epidemiological trends indicate a sustained increase in allergic rhinitis prevalence over the past three decades, with urban populations and Mediterranean countries — including Turkey — showing a disproportionate burden. The association between seasonal temperature anomalies and symptom exacerbation was a recurrent finding across geographically diverse cohorts.

CONCLUSIONS

Climate change represents an increasingly significant determinant of allergic rhinitis epidemiology, operating through a well-defined biological pathway of extended pollen seasons and heightened allergenicity. The epidemiological trends identified in this review underscore the need for otolaryngologists to consider environmental factors in both patient counselling and disease management. As Mediterranean regions — including Turkey — face a disproportionate impact, geographically tailored public health strategies are warranted. Integrating climate projections into allergy surveillance systems and clinical practice guidelines may prove essential in mitigating the rising burden of allergic rhinitis in the decades ahead.

OP-1421

Cholesteatoma Development And Incidence In Long-Term Follow-Up After Tympanoplasty: A Retrospective Study From A Tertiary Center

Bülent Ulusoy[1], **Çağdaş Elsürer**[1], **Özgür Demir**[1], **Hidayet Giray Soy**[1]

[1]*Selcuk University Faculty of Medicine Hospital*

BACKGROUND & AIM

Tympanoplasty is frequently performed for chronic otitis media and tympanic membrane perforation; however, there are other determinants affecting the outcome beyond anatomical success. One determinant includes development of a new cholesteatoma that arises after an unsuccessful resolution of the middle ear disease even though the surgical intervention was done. While numerous papers have been written on this topic, it has still not been established whether the incidence of the disease and possible contributing factors are known. The primary aim of this research paper is to determine the incidence of this disease and possible contributing factors.

MATERIAL & METHODS

This is a retrospective observational study conducted at a tertiary referral center. The patient records of people who underwent tympanoplasty or myringoplasty from January 1, 2015, to January 1, 2026, were reviewed. Patients without cholesteatoma preoperatively were chosen for the study. Demographic information, clinical Findings, procedures performed surgically, and post-operative outcomes were analyzed. The main objective was to determine the incidence of newly acquired cholesteatoma in the patients under observation, diagnosed through otoscopy and/or radiologic studies. Other objectives include time to diagnosis, number of revisions needed, and hearing outcome. There were no further interventions made because all information was from follow-up visits only.

RESULTS

A total of 37 patients with the ages between 10 and 63 years underwent tympanoplasty or myringoplasty between 2015 and 2026. Amongst the patients, the prevalence of de novo cholesteatoma was found to be 5 cases (13.5%). The age group of the patients who developed cholesteatoma was from 23 to 51 years. Statistically, there was no signiFcant correlation between the age of the patient and the development of cholesteatoma . The patients diagnosed with cholesteatoma required revision

surgery. Moreover, the hearing outcomes of the patients with cholesteatoma were expected to deteriorate as opposed to other patients who would improve or maintain their outcomes.

CONCLUSIONS

Postoperative cholesteatoma formation was observed in 13.5% of patients following tympanoplasty irrespective of the patient's age group. Even though the occurrence of these complications is not common, their emergence after years of the surgical procedure highlights the significance of follow-up treatment. Appropriate screening procedures need to be done in order to detect and treat the condition before any other complication arises from it.

OP-1422

Early-Term Outcomes Of Endolaryngeal Surgery In The Treatment Of Laryngeal Cancer

Emre Önal[1], **Seda Türkoğlu Babakurban**[1]

[1]*Department of Otorhinolaryngology, Başkent University Faculty of Medicine, Ankara, Turkey*

BACKGROUND & AIM

Laryngeal squamous cell carcinoma (LSCC) is one of the most common head and neck malignancies. Tumor stage, anatomical subsite, histopathological features, and patient-related factors are known to influence prognosis.

This study aimed to evaluate early oncological outcomes in patients with LSCC treated with endolaryngeal surgery at our institution.

MATERIAL & METHODS

This retrospective study was conducted with institutional ethics approval. Patients who underwent primary surgical treatment for histopathologically confirmed LSCC between January 2020 and December 2025 were reviewed. Inclusion criteria were surgery performed at our center and availability of at least 12 months of follow-up. Patients with distant metastasis (M1) or synchronous second primary tumors were excluded.

Tumors were staged according to the AJCC 8th edition TNM system. Endolaryngeal procedures were performed using laser (diode, holmium:YAG) or cold instruments. Neck dissection was carried out when clinically indicated.

Data regarding tumor differentiation, surgical margin status (negative, close <2 mm, positive), lymphovascular invasion (LVI), perineural invasion (PNI), metastatic lymph nodes, and ENE were recorded.

Overall survival (OS) and disease-free survival (DFS) were analyzed using the Kaplan–Meier method. Group comparisons were performed with the log-rank test, and Cox regression analysis was used to evaluate independent prognostic factors. A p-value <0.05 was considered significant.

RESULTS

A total of 90 patients with laryngeal squamous cell carcinoma met the inclusion criteria and were included in the analysis. The cohort comprised tumors from different laryngeal subsites and stages, reflecting routine clinical practice.

Negative surgical margins were obtained in the majority of patients, while close or positive margins were observed in a smaller proportion. Neck dissection was performed in clinically indicated cases.

During the first 12 months of follow-up, recurrence patterns and survival outcomes were evaluated.. Detailed statistical analyses are currently ongoing.

CONCLUSIONS

Endolaryngeal surgery provides satisfactory early oncological outcomes in selected patients with LSCC. Identification of high-risk patients may support individualized postoperative surveillance strategies.

OP-1423

A Retrospective Analysis Of 215 Parotidectomy Patients: Clinical, Pathological, And Surgical Outcomes

Azer Dadashov[1], **Omer Feti Yildiz**[1]

[1]*Cukurova University*

BACKGROUND & AIM

Parotid tumors are the most common tumors among the major salivary gland neoplasms. The majority of parotid tumors are benign. Surgery remains the primary treatment modality for parotid tumors. Superficial parotidectomy is generally preferred for benign tumors located in the superficial lobe, whereas total parotidectomy may be required in cases with deep lobe involvement, extensive disease, or suspected malignancy. Fine needle aspirationbiopsy is a widely used, minimally invasive, and safe method forpreoperative evaluation.

Frey syndrome is one of the most important late complications following parotidectomy and is characterized by sweating and flushing in the preauricular or temporal region during eating.

MATERIAL & METHODS

This retrospective chart review included 215 patients who underwent parotid surgery at Çukurova University Hospital between January 2015 and December 2025. Patientdemographics, fine-needle aspiration biopsy results, surgical procedures, histopathological findings, and the occurrence of Frey syndrome were evaluated.

RESULTS

Among the patients who underwent surgery, 85 (39.5%) were female and 130 (60.5%) were male. Histopathological examination revealed benign disease in 169 patients (78.6%) and malignant disease in 46 patients (21.4%). Superficial parotidectomy was performed in 152 patients (70.6%), whereas total parotidectomy was performed in 63 patients (29.4%).

Frey syndrome was observed in 21 patients (9.76%).

CONCLUSIONS

Most salivary gland tumors arise from the parotid gland, and approximately 80% are benign. In the present study, consistent with the literature, 78.6% of the operated cases were benign lesions. Although FNAB is highly specific for detecting malignancy in parotid tumors, its sensitivity remains relatively low. The incidence of Frey syndrome in our series was comparable to that reported in the literature.

OP-1424

Artificial Intelligence In Romanian-Language ENT Patient Education: A Cross-Sectional Evaluation Of Accuracy, Readability And Safety

Iovanescu Dan[1], **Cristian Norbert Ionescu**[1], **Gheorghe Mühlfay**[1], **Gheorghe Iovanescu**[1]

[1]*UMF " Victor Babes" Timisoara*

BACKGROUND & AIM

Artificial intelligence, particularly large language models, is increasingly used by patients to obtain medical information. In otolaryngology, its role in patient education remains promising but insufficiently validated. This abstract aims to review current evidence regarding the accuracy, readability and safety of AI-generated information for common ENT conditions and procedures, and to highlight implications for clinical practice.

MATERIAL & METHODS

A structured literature search was performed in PubMed using combinations of the terms “artificial intelligence”, “large language model”, “ChatGPT”, “otolaryngology”, “ENT”, “patient education”, “readability” and “safety”. Recent English-language articles evaluating AI-generated information in otolaryngology were reviewed. Studies were analysed according to clinical topic, type of AI model, assessment method, reported accuracy, readability, completeness and potential safety concerns.

RESULTS

Recent studies suggest that generative AI can produce understandable and generally relevant answers to common ENT questions, and may improve the readability of patient education materials. However, performance is variable. In rhinology and common ENT procedures, AI responses have been reported as incomplete, occasionally inaccurate or lacking adequate discussion of risks, recovery and the need for specialist assessment. Evidence also indicates better performance in education and communication tasks than in complex clinical reasoning.

CONCLUSIONS

AI may become a useful adjunct for ENT patient education, but current evidence does not support unsupervised use. Clinician validation, transparent methodology and patient-safety safeguards are essential before integrating AI-generated information into routine otolaryngology practice.

OP-1425

Impact Of Intratympanic Steroid Injections On Eustachian Tube Function In Patients With Sudden Sensorineural Hearing Loss

İlayda Baykan Kendir[1], **Merve Özcan**[1], **Burak Kaan İnan**[1], **İbrahim Sayın**[2], **Zahide Mine Yazıcı**[1]

[1]*Istanbul Bakırköy Dr. Sadi Konuk Training and Research Hospital, Istanbul, Türkiye;* [2]*Private Practice, Istanbul, Türkiye*

BACKGROUND & AIM

Intratympanic steroid injection (ITS) is a widely used treatment for Sudden Sensorineural Hearing Loss (SSNHL). While the anatomical proximity suggests a potential interaction, there is a lack of literature evaluating the specific effects of ITS on Eustachian tube (ET) function. This study aims to investigate whether ITS therapy impacts ET physiology in SSNHL patients.

MATERIAL & METHODS

This prospective study included 38 patients (aged 18–65) diagnosed with unilateral SSNHL between February 2024 and February 2026. All patients initially received 5 sessions of ITS. Patients without sufficient hearing recovery which means 10 decibel gain of their pure tone audiometry, received 5 additional sessions (totally 10 sessions). ET function was assessed using ET functional tests (Valsalva and Toynbee) and the Eustachian Tube Dysfunction Questionnaire-7(ETDQ-7) questionnaire at baseline, after the 5th session, and after the 10th session. Results were statistically analyzed.

RESULTS

A total of 38 patients were included in the study, 17 received 5 sessions and 21 received 10 sessions of ITS.In the 5-dose ITS group, the mean ETDQ-7 score demonstrated a decrease from 23.47 to 20.82, although this change did not reach statistical significance (p=0.165). Furthermore, ET functional assessments revealed that while two patients transitioned from dysfunctional to functional status, the overall functional improvement was not statistically significant (p>0.05).Regarding the 10-dose ITS group, the mean ETDQ-7 score showed a change from 23.28 to 22.76, which was statistically non-significant (p=0.941). Additionally, the functional status of the Eustachian tube remained stable in the majority (81%) of the patients in this group. No significant statistical difference was found within or between the groups regarding ET function (Table 1 & 2).

CONCLUSIONS

ITS do not appear to significantly alter Eustachian tube function or provoke Eustachian tube dysfunction in patients treated for SSNHL.The ETDQ-7 scores and functional tests remained stable regardless of the injection dose (5 vs. 10 sessions). Further studies with larger populations are required to further elucidate this relationship.

Intratympanic steroid injection (ITS),Sensorineural Hearing Loss (SSNHL),Eustachian tube (ET),Eustachian Tube Dysfunction Questionnaire-7(ETDQ-7)

OP-1426

Top Performers In A Decade Of Otolaryngology Research: A Bibliometric Analysis

Ali Faramarzi[1]

[1]*Shiraz University of Medical Sciences*

BACKGROUND & AIM

To analyze worldwide otorhinolaryngology publications from 2015-2024 and identify the top-performing countries, journals, funding agencies, organizations, and individual researchers.

MATERIAL & METHODS

A cross-sectional bibliometric analysis of the Web of Science Core Collection was conducted using Clarivate's InCites, restricting results to the "Otorhinolaryngology" research area from 2015-2024 (data updated March 28, 2025). Primary metrics included publication counts, total citations, and category-normalized citation impact (CNCI). Secondary measures included the percentage of publications in the top 1% and 10% by citations, in first-quartile (Q1) journals, and with international co-authorship.

RESULTS

A total of 95,435 otolaryngology publications were identified. The United States led in output (31,654 publications) and citations (342,724), with 1.57% in the top 1% by citations. Germany (7,036 publications) and China (6,447) were next largest. Italy achieved the highest citation impact among major countries (CNCI 1.77). The Laryngoscope was the most prolific journal (6,757 articles), whereas JAMA Otolaryngology-Head & Neck Surgery had the highest citation impact (CNCI

1.91). The US National Institutes of Health and the National Natural Science Foundation of China were the top funders, supporting 5,063 and 1,761 publications, respectively. Harvard University (including affiliates) produced over 7,000 publications, and Jerome R. Lechien was the most prolific author (387 publications, CNCI 3.64). International collaborations accounted for 13.5% of all publications.

CONCLUSIONS

Global otolaryngology research over the past decade has been dominated by a few countries and institutions, particularly in the United States. These findings highlight disparities in research output and can inform strategies to broaden international collaboration and strengthen emerging research centers.

Evaluation Of MRI Findings In Patients With Rhino-Orbital Cerebral Mucormycosis In The COVID-19 Era

Mohsen Naraghi[1,2], **Hashem Sharifian**[3,4], **Jazmin Kazravan**[5], **Abuturab Jabbar Sayyed**[6], **Amirhossein Babaei**[7]

[1]Faculty, Division of Rhinology, Department of Otorhinolaryngology-Head and Neck Surgery, Otorhinolaryngology Research Center, Tehran University of Medical Sciences, Tehran; [2]Medical Director, Orphans Worldwide, Jacksonville; [3]Chairman, Department of Radiology, Amir Alam Hospital, Tehran University of Medical Sciences, Tehran; [4]Faculty, Department of Radiology, Advanced Diagnostic and Interventional Radiology Research Center (ADIR), Medical Imaging Center, Tehran University of Medical Sciences, Tehran; [5]Faculty, Healthcare Corporation of America, Memorial Hospital of Jacksonville; [6]Medical Student, Tehran University of Medical Sciences, Tehran; [7]Clinical Research Fellow, Rhinology Research Society, Tehran

BACKGROUND & AIM

As COVID-19-positive patients are at a higher risk of developing rhino-orbital-cerebral mucormycosis (ROCM), it becomes crucial to identify and evaluate the signs of sinus involvement using imaging techniques, such as magnetic resonance imaging (MRI). This investigation aims to explore the role of sinus MRI findings in the detection and characterization of ROCM in the COVID-19 era.

MATERIAL & METHODS

In this cross-sectional study, patients more than 18 years old with pathology-confirmed ROCM infection were included. MRI was reviewed and intra and extra nasal involvements were evaluated.

RESULTS

The most common radiologic finding was involvement of the ethmoid sinus (98.0%), followed by the maxillary sinus (96.0%) and the frontal sinus (94.0%). The least common radiologic presentation was intracranial abscess (10.0%) and internal carotid artery obstruction (12.0%). The results of statistical analysis revealed that infra-temporal involvement was associated with a higher rate of dura (p=0.008), pterygopalatine fossa (PPF) (p=0.016), and alveolar ridge involvement (p=0.008). The results of statistical analysis showed that PPF involvement was associated with a higher rate of infra-temporal (p=0. 016), inferior orbital fissure (p<0.001), extra-conal (p=0.035), intra-conal (p=0.020), and orbital apex (p=0.021) involvement.

CONCLUSIONS

MRI can provide detailed information about the extent and severity of the infection, guiding healthcare professionals in developing appropriate treatment strategies.

OP-1428

Consultant Evaluation Of AI-Generated Patient Infographics For Post-Operative ENT Advice Using ENT UK Guidance

Razan Algazlan[1], **Mantegh Sethi**[2], **Lavandan Jegatheswaran**[2], **Aman Khanna**[2]

[1]Queen Elizabeth Hospital, University Hospitals Birmingham NHS Foundation Trust; [2]Heartlands Hospital, University Hospitals Birmingham NHS Foundation Trust

BACKGROUND & AIM

Clear post-operative instructions are essential to optimise recovery and reduce complications following otolaryngological procedures. Artificial intelligence (AI) may offer a scalable method of generating patient education materials. This study evaluated consultant perceptions of AI-generated patient infographics with source material restricted to patient information leaflets published by ENT UK.

MATERIAL & METHODS

AI-generated post-operative infographics were produced using NotebookLM using only ENT UK patient information leaflets as source material. ENT consultants evaluated the infographics through using a survey assessing accuracy, completeness, safety, clinical acceptability, and usefulness using five-point Likert scales. Consultants were invited to review procedures within their subspecialty: adenotonsillectomy, septorhinoplasty, functional endoscopic sinus surgery (FESS), mastoidectomy, grommet insertion, and myringoplasty.

RESULTS

Six consultants responded (five male, one female): three rhinologists and three otologists with experience ranging from two to over fifteen years. Overall, 74% (17/23) of accuracy ratings were ≥3, indicating generally acceptable clinical validity of AI-generated advice derived from ENT UK guidance. Grommet insertion performed best, with 100% (4/4) rating accuracy ≥4, no unsafe advice identified, and universal willingness to use the infographic. For FESS, 75% (3/4) rated accuracy ≥3 and 75% would likely or definitely use the infographic, although half reported uncertainty regarding safety or completeness. Adenotonsillectomy demonstrated 80% accuracy ≥3, though 60% identified incomplete advice. Greater variability was observed for septorhinoplasty and mastoidectomy

CONCLUSIONS

AI-generated infographics derived from ENT UK guidance were generally perceived as accurate, safe and clinically useful, particularly for simpler procedures. Ongoing responses will further evaluate reliability and inform refinement of AI-assisted patient information tools.

OP-1429

Simulation-Based Training In Otolaryngology-Head And Neck Surgery: A Systematic Review Of Modality Effectiveness And Learning Curve Outcomes

Reyhan Özcan Bilgiç[1], **Neslihan Kul Turhan**[2]

[1]*Ankara Oncology Training and Research Hospital, Department of Otolaryngology–Head and Neck Surgery, Ankara, Turkey;* [2]*Ankara Sanatoryum Training and Research Hospital, Department of Otolaryngology–Head and Neck Surgery, Ankara, Turkey*

BACKGROUND & AIM

Traditional surgical training in otolaryngology relies heavily on supervised operative experience, raising concerns about standardization and patient safety. Simulation-based training offers a controlled environment for skill development, yet evidence comparing different modalities across Otolaryngology-Head and Neck Surgery subspecialties remains limited. This review aims to evaluate the effectiveness of available simulation models and their impact on resident learning curves.

MATERIAL & METHODS

PubMed and Web of Science will be searched systematically for studies published between 2010 and 2026, using terms including "surgical simulation," "otolaryngology," "head and neck surgery," "virtual reality," "3D printing," and "learning curve." Preliminary screening has revealed a growing body of literature across multiple simulation modalities, and a comprehensive search is ongoing. Studies reporting quantitative simulation training outcomes in ORL-HNS trainees will be included. PRISMA guidelines will be followed throughout the review process.

RESULTS

Preliminary evidence suggests that simulation-based training in ORL-HNS encompasses five major modalities: cadaveric dissection, animal tissue models, bench-top synthetic models, 3D-printed replicas, and VR/AR simulators. Current literature indicates that VR/AR platforms show the most consistent evidence for endoscopic skill transfer, particularly in rhinology and otology. 3D-printed models demonstrate high anatomical accuracy and are increasingly used for pre-operative planning and trainee orientation in complex cases. Cadaveric training remains widely regarded as the gold standard for open surgical procedures. However, variability in outcome measures and training protocols across existing studies limits direct cross-modality comparisons.

CONCLUSIONS

Simulation-based training represents a valuable and evidence-supported component of modern ORL-HNS residency programs. A multimodal approach integrating VR/AR for endoscopic skills, 3D-printed models for anatomical familiarization, and cadaveric dissection for open surgical training appears most effective. Standardization of simulation curricula and outcome metrics remains a critical unmet need. Young ORL-HNS surgeons should advocate for structured simulation pathways within their training programs as both a patient safety and educational quality imperative.

F101: Near-Peer Teaching Programme To Support The Transition From Medical Student To Junior Doctor

Adrija Bhattacharyya[1], **Amelia Bennet**[2], **Abigail Ezekiel**[3], **Antonio Cosimetti**[1]

[1]*University of Oxford;* [2]*Oxford University Hospitals NHS Trust;* [3]*Royal Free Hospital NHS Foundation Trust*

BACKGROUND & AIM

The transition from medical student to Foundation Year 1 (FY1) doctor is a globally recognised pressure point, with UK graduates reporting gaps in practical readiness despite high-stakes assessments such as the Prescribing Skills Assessment and UK Medical Licensing Assessment.

MATERIAL & METHODS

We developed F101; a near-peer, pre-FY1 teaching intervention targeting nine GMC-aligned domains essential for early clinical practice, including ward-round skills, prescribing, death certification, communication and work-life balance. Interactive small-group sessions led by current FY1 doctors were delivered to three cohorts at distinct training stages (n=29), with self-reported confidence measured before and after.

RESULTS

Confidence improved significantly in all nine domains ($p<0.001$), with the greatest gains in death certification and the smallest in communication and work-life balance. Qualitative feedback highlighted the value of practical, experience-based teaching bridging undergraduate curricula and real-world clinical demands.

CONCLUSIONS

Despite the small sample size, single-centre design and reliance on self-reported confidence, brief targeted interventions can meaningfully enhance perceived preparedness. The findings support a longitudinal, multi-stage model of assistantship teaching delivered both before graduation and at FY1 induction. Future iterations should incorporate objective competence measures, multi-site delivery and follow-up into foundation training.

Paediatric Nasal Foreign Bodies: A Retrospective Audit Of A Teaching Hospital's Current Practice And Outcomes

Adrija Bhattacharyya[1], **Sneha Pimpalnerkar**[2], **Louis Luke**[2], **James Ramsden**[1], **Adrija Bhattacharyya**[1], **Sneha Pimpalnerkar**[2], **Louis Luke**[2], **James Ramsden**[1]

[1]*University of Oxford;* [2]*Oxford University Hospitals NHS Trust*

BACKGROUND & AIM

Paediatric nasal foreign bodies (NFB) are a common ENT presentation to the Emergency Department (ED). Management ranges from bedside removal to general anaesthesia (GA), with significant variation in practice. This audit aimed to characterise current outcomes and identify factors driving avoidable GA listing.

MATERIAL & METHODS

Data was retrospectively collected on paediatric NFB presentations over 6 months at a single teaching hospital, including clinician grade, techniques and outcomes.

RESULTS

74 cases were included; 72% were inorganic and 82% presented within 24 hours. As a regional ENT centre receiving referrals from surrounding hospitals and GPs, a proportion had failed removal prior to arrival.

ED clinicians achieved successful removal in 46% of cases. ENT were called following failed ED attempts in 22% of cases, achieving removal in 47%. Where ENT was first clinician (24%), success was 39%, potentially reflecting referred case complexity. Overall, two-thirds were resolved at the same visit without GA. Of the 12% listed for GA, the majority were emergency listings. The parent's kiss technique was used in a third of cases despite a 46% first-attempt success rate. 30-day reattendance was 5%, predominantly for a new foreign body, and no procedural complications were recorded. No child was admitted due to a foreign body and there were no complications as a result of this.

CONCLUSIONS

Two-thirds of paediatric NFB presentations can be resolved at the same visit without GA. The parent's kiss is underutilised despite a high success rate. Timely ENT escalation may prevent GA in a significant proportion of cases. Where GA listings are needed, elective listing demonstrates no complications compared to emergency listing, contradicting traditional ENT teaching. These findings support a standardised pathway for ENT referral and GA listing, with planned consensus between ENT and ED teams and reaudit.

Patient Reported Outcomes In Surgical Intervention Of Zenker’s Diverticulum

Akash Srinivasan[1], **Stuart Winter**[1], **Adrija Bhattacharyya**[1]

[1]*University of Oxford*

BACKGROUND & AIM

Zenker's diverticulum is the most common pharyngeal pouch, often presenting with dysphagia, regurgitation, and aspiration, for which surgical management is the mainstay of treatment. Surgical outcomes have traditionally been assessed using objective outcomes, such as complication and recurrence rates. There have been no prior systematic review of subjective patient-reported outcome measures (PROMs). This systematic review aims to evaluate how surgical intervention of Zenker’s diverticulum affects PROMs.

MATERIAL & METHODS

A systematic review was conducted in accordance with PRISMA 2020 guidelines and registered with PROSPERO. Five databases were searched; Embase, MEDLINE, PsycINFO, Web of Science, Cochrane CENTRAL from 1/1/2015. Studies were included if they consisted of adults undergoing surgical treatment for Zenker's diverticulum and reported at least one validated PROM pre- and post-operatively. Two independent reviewers screened all records using Covidence, with discrepancies resolved by a third reviewer. Risk of bias was assessed using the Newcastle-Ottawa Scale. A narrative synthesis was written.

RESULTS

Twenty-eight studies were included, comprising over 1,500 patients published between 2015 and 2025. No randomised controlled trials were identified. The most used PROM was EAT-10 (14 studies), which demonstrated improvement following surgery across all surgical approaches. Additional PROMs including FOSS, FOIS, RSI, Dakkak, Eckardt, SWAL-QOL, SF-36, and MDADI consistently showed post-operative improvement regardless of surgical technique. Median peri-operative complication and recurrence rates were approximately 5% and 8% respectively.

CONCLUSIONS

Surgical management of Zenker's diverticulum improves PROMs across all operative techniques. The heterogeneity and range of PROMs used across studies limits cross-study comparison, with EAT-10 being the most used PROM tool. Prospective studies with standardised PROM reporting are needed to strengthen the evidence base alongside some randomised control trials to compare operative approaches.

OP-1433

Short-Term Vestibulo-Ocular And Postural Effects Of Virtual Reality In Healthy Young

Enes TÜRKOĞLU[1], **Büşra ALTIN**[2], **Songül AKSOY**[3]

[1]*Institute of Graduate Studies, Department of Audiology, Istanbul University-Cerrahpasa, Istanbul, Turkey;* [2]*Department of Audiology, Faculty of Health Sciences, Hacettepe University, 06100, Ankara, Turkey;* [3]*Department of Audiology, Faculty of Health Sciences, Başkent University, Ankara, Turkey*

BACKGROUND & AIM

Background: Virtual reality can simulate the testing of cognitive, sensory, and motor skills using simulated environments. Eye stabilization is necessary to maintain visual acuity during rapid head movements; this is achieved through mechanisms such as the vestibulo-ocular reflex.

Objective: This study aimed to investigate the short-term effect of a passive, non-interactive virtual reality stimulus on dynamic visual acuity and postural sway in healthy young adults.

MATERIAL & METHODS

Methods: Twenty four healthy young adults (9 males, 15 females) aged 20-39, with an average age of 26.08 ± 4.14 were included in the study. All participants underwent the Sensory Organization Test (SOT), Static Visual Acuity Test (SVAT), Perception Time Test (PTT), Dynamic Visual Acuity Test (DVAT), Gaze Stabilization Test (GST), and Visual Analogue Scale (VAS) to assess symptoms that may arise from virtual reality. These tests were repeated for all participants after the virtual reality experience, and completed on the same day.

RESULTS

Results: Statistically significant differences were obtained in the balance score of the SOT (COMP, mean decrease 2.29 points, 95% CI 0.49-4.10, p=0.015, Cohen's d=0.54) and the left-side GST (mean increase 24.7 ms, 95% CI -45.82 to -3.64, p=0.024, Cohen's d=0.52) in the pre/post virtual reality experience comparison. Virtual reality had no statistically significant effect on SOT conditions 1-6 individually (all p>0.05), although CON6 and PTT were borderline (CON6: Wilcoxon Z= -1.668, p=0.095, r=0.34; PTT: Wilcoxon Z= -1.935, p=0.053, r=0.40). No statistically significant differences were found between pre- and post-treatment in PTT and DVAT (both p>0.05).

CONCLUSIONS

Conclusion: It has been demonstrated that virtual reality affects balance and gaze stabilization by increasing postural sway over a short, same-day time frame. Clinicians and researchers should exercise caution when using VR-based paradigms for vestibular assessment and rehabilitation, given its measurable short-term effects on postural control and gaze stabilization.

Chronic Epicutaneous Sensitization Induces A Peak And Subsequent Attenuation Of Systemic Th2 Responses Following Intranasal Challenge In BALB/C Mice

Hiromi Nagano[1], **Takayuki Kyutoku**[1], **Masaru Yamashita**[1]

[1]*Department of Otolaryngology–Head and Neck Surgery, Kagoshima University Graduate School of Medical and Dental Sciences*

BACKGROUND & AIM

Epicutaneous sensitization (ES) is implicated in the development of allergic diseases, including atopic dermatitis and asthma. While ES is known to induce systemic Th2 responses, the effects of chronic and repeated epicutaneous antigen exposure on subsequent airway allergic responses remain unclear.This study aimed to investigate the impact of repeated ES on systemic Th2 responses and nasal allergic inflammation following intranasal antigen challenge.

MATERIAL & METHODS

Female BALB/c mice were epicutaneously sensitized with ovalbumin (OVA) at the same concentration as in our previous study, with repeated exposures of 10, 50, or 100 times. Following sensitization, mice were intranasally challenged with OVA. Serum levels of OVA-specific IgE and Th2 cytokines (IL-4, IL-5, and IL-13) were measured. Histological analyses of the nasal mucosa were performed using hematoxylin and eosin staining to evaluate mucosal thickness and eosinophilic infiltration.

RESULTS

OVA-specific IgE levels, as well as IL-4, IL-5, and IL-13 production, increased from 10 to 50 epicutaneous exposures. Histological analysis also demonstrated enhanced mucosal thickening and eosinophil infiltration in the 50-exposure group. However, these parameters were reduced in the 100-exposure group compared with the 50-exposure group.

CONCLUSIONS

These findings suggest that repeated epicutaneous sensitization induces a peak in systemic Th2 responses and nasal allergic inflammation, followed by attenuation with excessive antigen exposure. This attenuation may reflect the induction of tolerance-like mechanisms during chronic antigen exposure.

KEYWORDS

epicutaneous sensitization, systemic Th2 responses, nasal allergic inflammation, ovalbumin, IgE

Dual Sublingual Immunotherapy Associated With Higher Treatment Persistence Compared To Single-Allergen Therapy: A Two-Center Retrospective Study

Satoru Masuno[2], **Aiko Oka**[1], **Kengo Kanai**[1], **Mitsuhiro Okano**[1], **Ryo Takagi**[1]

[1]*Department of Otorhinolaryngology Head and Neck Surgery, International University of Health and Welfare Narita Hospital, Chiba, Japan;*

[2]*Makinohara Nanohana Otorhinolaryngology Clinic, Chiba, Japan*

BACKGROUND & AIM

Sublingual immunotherapy (SLIT) is a disease-modifying treatment for allergic rhinitis that induces sustained immune tolerance. In Japan, SLIT for Japanese cedar pollen (Cedarcure®) and house dust mite (Miticure®) has been available since 2014. Although guidelines recommend a minimum of 3 years of treatment, real-world persistence rates range from 7% to 59%, representing a substantial barrier to achieving full therapeutic benefit. As awareness of multi-allergen sensitization has grown, dual SLIT—concurrent administration of two allergens—has attracted clinical interest. However, evidence on its impact on treatment persistence remains limited. This study aimed to compare persistence between single-allergen and dual SLIT across two centers.

MATERIAL & METHODS

A total of 328 patients initiating SLIT were enrolled at two centers: Center A, a university hospital (n = 113;2020–2023), which employed a standardized protocol with universal antihistamine premedication and proactively scheduled follow-up; and Center B, a community clinic (n = 215;2019–2022), where antihistamines were prescribed case-by-case and follow-up was patient-initiated. Patients were classified into Cedarcure® monotherapy, Miticure® monotherapy, or Dual SLIT groups. The primary outcome was treatment persistence, defined as continuous SLIT without interruption. Discontinuation was defined as failure to attend scheduled follow-up or physician-initiated cessation due to adverse effects. Censoring was defined as completion of ≥3 years of treatment, transfer to another facility, or ongoing treatment at the data cutoff. Persistence rates were estimated using the Kaplan–Meier method, with group comparisons performed using the log-rank test and generalized Wilcoxon test. The study was approved by the ethics committee of the International University of Health and Welfare Narita Hospital.

RESULTS

At Center A, mean ages in the Cedarcure® mono (n = 48), Miticure® mono (n = 22), and Dual SLIT (n = 43) groups were 30, 29, and 31 years, with no significant differences. At Center B, the Cedarcure® mono group (n = 98; mean 26 years) was significantly older than the Miticure® mono (n = 30; 13 years) and Dual SLIT (n = 87; 14 years) groups. Dual SLIT consistently demonstrated the highest persistence at both centers. At Center A, 12-month persistence rates were 87.2%, 68.4%, and 55.2% for Dual SLIT, Cedarcure® mono, and Miticure® mono, respectively (combined mono vs. Dual SLIT: $p = 0.009$). Corresponding 36-month rates were 76.7%, 59.8%, and 37.2%. At Center B, 36-month rates were 73.6%, 58.8%, and 30.0%, respectively ($p < 0.001$). No significant difference was observed between the two monotherapy groups at either center, suggesting the persistence advantage is specific to Dual SLIT.

CONCLUSIONS

Dual SLIT demonstrated significantly higher treatment persistence than single-allergen SLIT at both a university hospital and a community clinic operating under different management protocols. The consistent findings across two centers suggest that the persistence advantage of dual SLIT is reproducible across varied clinical settings. Although limitations including retrospective design, non-randomized allocation, and potential confounding factors should be acknowledged, these results support the proactive introduction of dual-antigen SLIT for polysensitized patients without concern for compromised treatment continuation. Prospective studies with multivariate adjustment and formal adherence assessment are warranted to confirm these findings.

Frontoethmoidal Mucocele With Posterior Frontal Sinus And Medial Orbital Wall Defect Extending Intracranially: An Unexpected Intraoperative Cerebrospinal Fluid Leak

ŞAHİN ÖĞREDEN[1], **TÜRKÜ BAYRAMOĞLU**[1], **TUĞBA ARLI**[1], **AHMET KARAMANOĞLU**[1], **ÖZGÜR YİĞİT**[1]

[1]*Department of Otorhinolaryngology, Başakşehir Çam and Sakura City Hospital, Istanbul, Turkey*

BACKGROUND & AIM

Frontoethmoidal mucoceles are benign lesions; however, due to their proximity to the orbit and anterior cranial fossa, they may lead to serious orbital and intracranial complications. We present a rare case initially suggestive of a mucocele or abscess with intracranial extension on imaging, which was found intraoperatively to be associated with a skull base defect and cerebrospinal fluid (CSF) leak.

MATERIAL & METHODS

A 27 year old male presented with a four day history of progressively worsening right sided eye pain, discharge. Physical examination revealed periorbital edema and hyperemia. Nasal endoscopy showed no significant purulent discharge or rhinorrhea. Ophthalmologic evaluation demonstrated normal visual acuity and intact extraocular movements.Paranasal sinus computed tomography revealed a lesion occupying the right frontal sinus and anterior ethmoid cells,extending into the orbit through a medial wall defect and air fluid level behind the posterior wall of frontal sinus.Magnetic resonance imaging

demonstrated a cystic lesion with erosion of the posterior wall of the frontal sinus and intracranial extension, raising suspicion for a mucocele or abscess.The patient subsequently underwent endoscopic sinus surgery.

RESULTS

Intraoperatively, purulent drainage was achieved from the anterior ethmoid and frontal recess. However, a 2–3 mm defect was identified in the posterior wall of the frontal sinus, with pulsatile cerebrospinal fluid (CSF) leakage. The defect was successfully repaired using an auricular lobule fat graft and fibrin sealant.Postoperatively, the patient received antibiotic therapy. No recurrence of CSF leak or neurological complications was observed, and orbital symptoms resolved completely.

CONCLUSIONS

Although frontoethmoidal mucoceles are benign, their expansile nature can erode the orbital walls and skull base, leading to serious complications. This case demonstrates that lesions radiologically suggestive of a mucocele or abscess may conceal underlying cerebrospinal fluid pathology. Cystic lesions lacking contrast enhancement or solid components, especially when associated with bony defects, should raise suspicion for CSF collections in the differential diagnosis. Endoscopic sinus surgery offers both diagnostic and therapeutic advantages, enabling effective drainage and simultaneous skull base repair. The coexistence of orbital findings with a CSF leak is rare and highlights the importance of careful preoperative assessment.

Transtympanic Electrocochleography In Long-Term Effects Of Blast-Induced Ear Injury

Fedor Syroezhkin[1], **Golovanov A.**[1], **Yanov Yu.K.**[1], **Yumakaev D.**[1], **Anzhelika Urchukova**[1]

[1]*Medical and Surgical Academy*

BACKGROUND & AIM

Tone-speech dissociation is observed in casualities with blast-induced ear injury. These are speech discrimination difficulties, particularly in background noise, that are out of proportion compared to their pure-tone detection thresholdsas. Hidden hearing loss has recently been described. Cochlear synaptopathy, which underlies hearing impairment in hidden hearing loss, can influence the degree of sensory loss in hearing and determine the rehabilitation potential of patients after blast trauma of ear. Electrocochleography (ECoG) is one method for verifying the presence of cochlear synaptopathy.

Aim. To improve audiological diagnostics for blast injury of the ear, a method for transtympanical electrocochleography recording has been developed.

MATERIAL & METHODS

The proposed ECoG recording method is based on the ability to visualize electrode placement on the promontory wall in patients with a tympanic membrane defect. Positioning is monitored using an endoscope placed along with the active electrode and sound source in an earmold inserted into the external auditory canal. Patients and methods. ECoG recordings using the above-described recording method were performed in 25 patients in 6 months after blast injury of the ear. An electrodiagnostic system for objective audiometry (Neurosoft LLC, Russia) was used for ECoG recording; visualization was performed using endoscopic equipment (Karl Storz, Germany).

RESULTS

In 22 of 25 patients, the active electrode impedance after initial positioning consistently reached values less than 3.0 kOhm, allowing for artifact-free, high-amplitude EcoG recordings. In all patients, the proportion of poor-quality responses ("dropouts") was 0%, allowing for a recording time reduction of 30 seconds for each stimulus level studied.

CONCLUSIONS

The developed transtympanic ECoG method is a safe one, allowing for more informative recordings while significantly reducing the time required for the study. Further analysis of transtympanic ECoG data will enable the development of diagnostic criteria for verifying various forms of auditory perception impairment associated with acoustic damage to the peripheral auditory system.

PP-005

High-Frequency Audiometry Thresholds In Adults: Relationship With Clinical And Demographic Factors

Zehranaz Can[1], **Rime Irem Surmeli Direk**[1], **Ibrahim Salih Gecer**[1]

[1]*Istanbul Bakırköy Dr. Sadi Konuk Training and Research Hospital*

BACKGROUND & AIM

This study aimed to evaluate the relationship between high-frequency audiometry (HFA) thresholds (8–20 kHz) and clinical and demographic factors including age, gender, noise exposure, ototoxic drug use, and comorbidities in adults with normal conventional audiograms, and to investigate whether HFA threshold shifts may serve as early indicators of subclinical cochlear damage.

MATERIAL & METHODS

This retrospective, cross-sectional observational study was conducted at the Department of Otorhinolaryngology, Istanbul Bakırköy Dr. Sadi Konuk Training and Research Hospital. A total of 131 adults (mean age 36.28 ± 14.62 years) who underwent HFA testing were included. Hearing thresholds were measured across conventional (0.25–8 kHz) and high-frequency (8–20 kHz) ranges. Speech recognition thresholds (SRT) and speech discrimination (SD) scores were also assessed. Statistical analyses were performed using Friedman, Wilcoxon signed-rank, and Mann–Whitney U tests with Bonferroni correction where appropriate.

RESULTS

High-frequency thresholds differed significantly across frequencies in both ears (right: χ^2=215.951, p<0.001; left: χ^2=209.768, p<0.001). The highest thresholds were observed at 14,000 Hz (right: 21.56±26.12 dB; left: 23.55±28.21 dB), while 20,000 Hz thresholds were significantly lower than all other frequencies (p<0.001). Left ear SRT was significantly higher than the right (7.63 vs. 5.99 dB, p=0.012), whereas SD scores showed no significant inter-aural difference (p=0.478). Noise exposure was present in 17.6% of participants; hypertension, diabetes mellitus, and hypothyroidism were identified as comorbidities in 10.7%, 3.8%, and 3.8%, respectively.

CONCLUSIONS

HFA reveals significant threshold variations in the ultra-high frequency range even among adults with normal conventional audiograms, particularly beyond 9,000 Hz. These findings suggest that HFA may be a valuable tool for detecting early cochlear dysfunction before conventional audiometric changes become apparent.

When Hearing Loss Speaks First: Bilateral SSNHL As The Initial Presentation Of Cogan's Syndrome

Rusescu Andreea[1,2], **Vasile Marian Tiberiu**[1,2], **Voiosu Catalina**[1,2], **Hainarosie Razvan**[1,2], **Catana Mihai Eugen**[1,2], **Serban Simona**[1,2]

[1]*"Carol Davila" University of Medicine and Pharmacy;* [2]*"Prof Dr. D. Hociota" Institute of Phonoaudiology and Functional ENT Surgery*

BACKGROUND & AIM

Cogan's syndrome is a rare autoimmune disorder defined by the association of interstitial keratitis and audiovestibular dysfunction that often mimics Ménière's disease. The condition may extend to systemic vasculitis, making early diagnosis crucial in order to prevent irreversible hearing loss and potential cardiovascular complications. We report a case in which bilateral sudden sensorineural hearing loss (SSNHL) represented the initial manifestation of Cogan's syndrome, highlighting the diagnostic and therapeutic challenges.

MATERIAL & METHODS

A 26-year-old woman presented with rapidly progressive bilateral SSNHL accompanied by severe vertigo over a three-week period. Initial ophthalmologic assessment identified conjunctival hyperemia that was first treated as bacterial conjunctivitis but was subsequently confirmed as interstitial keratitis. Audiovestibular evaluation revealed bilateral severe-to-profound SNHL, vestibular areflexia, and oscillopsia. Laboratory investigations showed mildly elevated C-reactive protein, while immunologic and infectious work-ups were unremarkable. Gadolinium-enhanced MRI demonstrated bilateral labyrinthine enhancement, suggestive of active inflammation.

RESULTS

Systemic corticosteroid therapy was initiated, followed by a gradual taper and the addition of azathioprine, together with vestibular rehabilitation. Although initial stabilization was achieved, the patient's hearing deteriorated to profound bilateral deafness within a few months, requiring bilateral cochlear implantation. Ocular symptoms improved under immunosuppressive treatment, and vestibular compensation led to partial recovery of balance.

CONCLUSIONS

This case underscores the importance of a multidisciplinary approach in suspected Cogan's syndrome, where ocular and audiovestibular manifestations may occur asynchronously. Contrast-enhanced MRI can provide valuable evidence of labyrinthine inflammation. Early immunosuppressive therapy may slow disease progression, yet hearing outcomes remain unpredictable. In advanced stages, timely cochlear implantation represents an effective strategy for auditory rehabilitation.

Relationship Between Hearing Loss Screening And Cognitive Function In Adults: A Scoping Review

Naoki Saji[1], **Mariko Shimono**[2], **Yasue Uchida**[3], **Shohei Iwamura**[2], **Akinori Takeda**[4], **Takashi Sakurai**[5]

[1]Center for Comprehensive Care and Research on Memory Disorders, Hospital, National Center for Geriatrics and Gerontology, Japan; [2]Department of Otorhinolaryngology, Hospital, National Center for Geriatrics and Gerontology, Japan; [3]Department of Otorhinolaryngology, Aichi Medical University, Japan; [4]Education and Innovation center for Geriatrics and Gerontology, Hospital, National Center for Geriatrics and Gerontology, Japan; [5]Department of Prevention and Care Science, Research Institute, National Center for Geriatrics and Gerontology, Japan

BACKGROUND & AIM

Many studies have reported a relationship between hearing loss and cognitive impairment in adults; however, the precise nature of the relationship remains unclear, and the literature is inconsistent. A scoping review was therefore conducted to explore the relationship between hearing loss screening and cognitive decline.

MATERIAL & METHODS

A scoping review was conducted in accordance with an a priori protocol. An exploratory literature search (MEDLINE and ERIC) was followed by an expanded search (CINAHL Plus Full Text, PsycINFO, and Web of Science). Identified English-language studies published between 2014 and 2024 were reviewed for inclusion by two independent reviewers, who also extracted data. Included studies comprised original research in adults who were screened for both hearing loss and cognitive function in any setting.

RESULTS

Of 3481 identified citations, 75 studies were included. Associations between hearing loss and cognitive impairment were identified in studies of individuals aged ≥40 years. Pure-tone audiometry and the Mini Mental State Examination were the most commonly used assessment tools. However, limitations were identified in the applicability of these measures in individuals with hearing loss or cognitive impairment. Overall, there is insufficient evidence to determine whether hearing loss screening reduces cognitive decline.However, it may support the early identification of individuals at risk. Additionally, there is insufficient evidence to suggest that hearing screening leads to reduced cognitive decline; further research is needed.

CONCLUSIONS

Although the available literature indicates that there is a relationship between hearing loss and cognitive decline in older adults, the precise nature of this relationship remains unclear. Future research should prioritise the use of standardised and appropriate assessment methods to strengthen the evidence base and enable more definitive evaluation.

Early Detection Of Ear Phone – Noise İnduced Hearing Loss (NIHL)

Prety Afifi, Assistent Professor of Audiology[2], **Yasir Nafi, Cosultant Audio Vestibular Medicine., MD.**[1], **Mohamed Elbegermy, Professor of ENT**[2]

[1]Al-Emadi Hospital.; [2]Ain Shams University Cairo Egypt.

BACKGROUND & AIM

The incidence of Noise induced Sensory neural hearing loss (NISNHL) has markedly increase by ten folds in the last decades due to the widespread use of ear phone by the young population and those working in call centers. Early detection allows early treatment and avoiding permenant hearing loss later on.

Aim: 1- to compare diffrent hearing evaluation using Pure tone audiometry with Distorsion Product Oto-Acoustic Emession. 2- trial of Ginkobiloba extract to treat early cases

Patients: GP1 (control) ten cases with normal hearing) GP2 & GP3 30 patients with suspected SNHL due to excessive use of ear phones after excluding other causes.

MATERIAL & METHODS

Methods: History Taking (HL, tinnitus), Hearing tests including Pure tone audiometry (PTA) speech audionetry (SA), Tympanometry and Distorsion Product Oto Acoustic Emission (OAE). The patients' ears were devided into two goups: GP2- patients with PTA normal but Poor response in Distorsion Produt Oto Acousti Emession. GP3- evident HL > 25 dB in PTA at any frequency.

RESULTS

Results: the earliest symptoms included sense of ear obstruction and tinnitus.PTA: was within normal (<25 dB) in groups 1&2 early dip occured maily at 4 dB in GP 3. Tympanometry was normal in all patients. DPOAE was completly or partially absent in GP2 despite of normal PTA. Ginko biloba 60mg/d showed improvement in all cases of GP2 also improved mainly tinnitus and variable results on hearing in GP3.

CONCLUSIONS

First audiological changes occure in OAE. DPOAE is a sensitve tool for detecting early noise induced hearing loss earlier than PTA. which appear later on as a dip in 4-6 KHZ . Early detection allows early treatment and hearing preservation.

Primary trial of Ginko biloba and Magnesium improved tinnitus and hearing losss but needs more controlled studies to confirm.

In-Ear-Tacs: Effect Of Tacs Stimulation On Tone Perception In Different Parts Of The Auditory Pathway

Niklas Mellerke[1], **Arnd Meiser**[2], **Hongmei Hu**[1], **Christoph S. Herrmann**[2,3,4], **Andreas Radeloff**[1,3,4]

[1]Department of Otolaryngology, Head and Neck Surgery, Carl von Ossietzky University of Oldenburg, Oldenburg, Germany; [2]Experimental Psychology Lab, Department of Psychology, Carl von Ossietzky University, Oldenburg, Germany; [3]Research Center Neurosensory Science, Carl von Ossietzky University of Oldenburg, Oldenburg, Germany; [4]Cluster of Excellence "Hearing 4 All", Carl von Ossietzky University of Oldenburg, Oldenburg, Germany

BACKGROUND & AIM

Chronic, subjective tinnitus is a common but debilitating condition with limited treatment options. Electrical stimulation from cochlear implants has shown potential to suppress tinnitus, particularly for individuals with severe hearing loss. Transcranial alternating current stimulation (tACS) represents a novel, non-invasive approach for electrical stimulation of the cochlea. The mechanisms by which tACS stimulates different inner ear structures, and the resulting effects on auditory perception, are poorly understood. This study investigates the effects of tACS-stimulation of inner ear structures on auditory perception.

MATERIAL & METHODS

As part of the German BMFTR-Project tACSitus, participants with single-sided-deafness (SSD) underwent tACS applied to both the deaf and the healthy ear. Stimulation was delivered using a tACS-protocol consisting of two different electrode configurations and a predefined frequency spectrum (500 Hz – 2000 Hz). The Hearing Impression (HI), resulting from a stimulation of the hearing system, was recorded for both ears and compared to objective reference tones to determine perceived frequency. This HI and other parameters were then individually compared for the deaf and the hearing ear. The underlying hypothesis was a frequency-dependent HI in the hearing, but not in the deaf ear. This finding could point to a stimulation of the cochlea hair cells rather than the auditory nerve.

RESULTS

We will present the results of the ongoing study. Through systematic comparison of HI and the connected matching results, we aim to investigate the mechanics of electrically evoked hearing and its underlying processes in different parts of the auditory pathway, thereby contributing to the evidence base for non-invasive electrical stimulation in tinnitus therapy.

CONCLUSIONS

Previous studies suggest a frequency-dependent relationship between stimulation and HI during outer hair cell activation. This relationship seems to alter when stimulation bypasses hair cells and is directly applied to the auditory nerve. This alteration is yet not focused on in studies. Preliminary results and previous studies on other subjects suggest a high degree in individual variability regarding electrode placement and stimulation.

Application Of Telemedicine Technologies In Objective Electrophysiological Hearing Tests.

Dmitry Klyachko[1], **Larisa Golovanova**[2], **Viktoriya Tanaschishina**[1], **Nikita Borisov**[1], **Denis Kopylov**[1], **Anna Guruli**[1]

[1]Saint-Petersburg ENT Research Institute the Ministry of Health; [2]North-Western State Medical University named after I.I. Mechnikov of the Ministry of Health of the Russian Federation

BACKGROUND & AIM

To evaluate the feasibility of using telemedicine technologies and a secure communication channel for conducting electrophysiological hearing assessments.

MATERIAL & METHODS

An electrophysiological hearing assessment was conducted remotely in five patients with a preliminary diagnosis of bilateral chronic sensorineural hearing loss. The study was carried out at two medical institutions in Saint Petersburg: Saint Petersburg Research Institute of Ear, Throat, Nose and Speech and City Audiology Center of the Saint Petersburg City Geriatric Medical and Social Center. The examination was performed using the remote access software “UK NII-LOR.”

RESULTS

In all five patients from the Geriatric Center, the diagnosis of bilateral chronic sensorineural hearing loss was confirmed based on auditory brainstem response (ABR) and auditory steady-state response (ASSR) testing. The assessments were performed both in person by specialists from the Geriatric Center and remotely by specialists from the Research Institute. The results of both examinations were completely identical, confirming the feasibility of using telemedicine technologies for electrophysiological hearing assessments.

CONCLUSIONS

The use of remote technologies for objective electrophysiological hearing assessments helps compensate for staff shortages, improves the effectiveness of early detection of pathologies, and ensures equal access to modern diagnostic methods for remote regions of Russia.

Evaluation Of Cochlear Efferent Function And Tinnitus Characteristics In Tinnitus Patients With Migraine: A Pilot Study

Murat ARSLAN[1,3], **Gülçin HANÇER ARSLAN**[2,3], **Şüle YILMAZ**[1]

[1]*Trakya University Faculty of Health Sciences, Department of Audiology;* [2]*Trakya University School of Health Services Vocational College Audiometry Program;* [3]*Trakya University Mirko Tos International Ear and Hearing Research Center*

BACKGROUND & AIM

Migraine and tinnitus frequently coexist; up to 45% of tinnitus patients are reported to suffer from migraine. Both conditions are thought to involve central hypersensitivity affecting the auditory and trigeminal pathways. We hypothesised that migraine-related central modulation may alter cochlear efferent — medial olivocochlear (MOC) — function and tinnitus perception, such that migraine-associated tinnitus could constitute a distinct subgroup with its own characteristics. The aim was to determine whether tinnitus characteristics, tinnitus perception, and contralateral suppression differ between tinnitus patients with and without migraine.

MATERIAL & METHODS

This prospective, comparative pilot study was conducted at the Audiology Unit, Faculty of Medicine, Trakya University. Twenty-seven normal-hearing (0–26 dB) young adults aged 18–65 years with type A tympanograms were evaluated: 13 with migraine plus tinnitus (cases) and 14 with tinnitus only (controls). All participants underwent pure-tone audiometry, tinnitus matching (frequency, intensity, minimum masking level, residual inhibition), transient-evoked otoacoustic emissions (TEOAE), the transient contralateral suppression emission (CLSE) test, and the Tinnitus Handicap Inventory (THI). The independent variable was the presence of migraine. Data were analysed using the Mann-Whitney U test. Ethics committee approval and written informed consent were obtained.

RESULTS

No significant differences were found between groups in tinnitus frequency, intensity, minimum masking level, or THI scores (all $p>0.05$). TEOAE responses appeared higher in the case group at all frequencies but the difference was not significant ($p>0.05$). CLSE signal responses were higher in the case group across all frequencies; this difference reached statistical significance at the right ear at 2 kHz ($p=0.007$) and at the left ear at 4 kHz ($p=0.029$), indicating reduced contralateral suppression in the migraine group.

CONCLUSIONS

Although tinnitus characteristics and handicap were comparable between groups, tinnitus patients with migraine showed reduced contralateral suppression at specific frequencies, suggesting altered MOC efferent function. Migraine-associated tinnitus may represent a distinct subgroup with central efferent involvement. As pilot findings, these results warrant confirmation in larger cohorts.

Establishing Standardized Conditions For Clinically Available Sound-Localization Tests: A Multicenter Approach

Tadao Yoshida[1], **Masumi Kobayashi**[1]

[1]*Department of Otorhinolaryngology, Nagoya University Graduate School of Medicine*

BACKGROUND & AIM

Sound localization is essential for auditory spatial awareness. The process relies on interaural differences in timing and level, and spectral cues. This study aimed to standardize sound-localization testing conditions across facilities in Japan, analyze the impact of early reflected sounds on localization accuracy, and compare outcomes between individuals with normal hearing and those with unilateral hearing loss.

MATERIAL & METHODS

This study included 77 participants with normal hearing and 45 individuals with unilateral hearing loss, at 11 facilities. Sound-localization tests were conducted using nine loudspeakers arranged in a 180° horizontal arc. The stimuli consisted of Comité Consultatif International Téléphonique et Télégraphique (CCITT) and low-pass CCITT noise bursts at randomized levels of 50 dB, 55 dB, and 60 dB SPL. The reflected sound measurements employed time-stretched pulses to analyze early reflections (4–7 ms). The localization accuracy was assessed using the root-mean-square error and mean deviation score (d).

RESULTS

Localization performance was negatively influenced by early reflections, with reflected sound envelope area and peak values within 4–7 ms correlating significantly with reduced accuracy ($r = -0.535$ to -0.555). Participants with normal hearing achieved a root-mean-square error of 2.0° ± 4.8°, whereas participants with unilateral hearing loss exhibited significantly greater errors (68.4° ± 40.7°, $p < .001$). Asymmetries in the left–right response accuracy correlated positively with the reflected sound characteristics ($r > 0.6$). Noise type (normal vs. low-pass CCITT) did not significantly impact performance in either group.

CONCLUSIONS

Early reflections significantly compromise sound-localization accuracy, particularly in smaller testing environments where reflections overlap with direct sounds. Standardized testing protocols, in which early reflections are controlled, are critical for reliable assessments. The use of sound-absorbing materials can enhance the test precision, particularly in the clinical evaluation of unilateral hearing loss. These findings emphasize the need for optimizing acoustic conditions to improve the reliability and accuracy of sound-localization testing.

Incidence Of Hearing Loss In Pre-Schoolers Presenting With Delayed Speech

Dr.Rashed Aldoseri[1], **Dr.Noor Binsanad**[1], **Dr.Mai Nasser**[1], **Dr.Mohamed Alshehabi**[1]

[1]*Royal Medical Services , Kingdom of Bahrain*

BACKGROUND & AIM

The aim of this study was to assess hearing level of preschoolers with delayed speech in order to detect any underlying hearing loss

MATERIAL & METHODS

In this research we targeted preschool children with speech delay, who are medically free . A 54 preschool speech-delayed children were audiologically assessed in our clinic in the past year. The age at time of referral ranged from 2 to 7.4 years. In this study , we focused on ABR test done to assess level of hearing .

RESULTS

Out of the 54 children with delayed speech assessed in our clinic in year 2023 , 36 males and 18 females with ratio of 2:1 male to females . 20 (37%) children did not undergo the test as their parents noticed improvements in their speech denying any possibility of decreased hearing . Only 1 child was found to have sensory neural hearing loss . The other 33 children underwent the test and passed the test with normal hearing level . Chonductive hearing was not appreciated as otitis media was treated before the test

CONCLUSIONS

A great number of healthy pre-school children with speech delay were found to have normal hearing. In this case, the otolaryngologist should be aware of the possible underlying clinical entities, especially of psychiatric nature.

Loss Of Mentalization In Adults With Bilateral Sensorineural Hearing Loss: A Cross-Sectional Study With Reading The Mind In The Eyes Test

Ümmügülsüm Gökçenoğlu Yılmaz[1], **Ismail Yılmaz**[2], **Ercan Atasoy**[3], **Zahide Mine Yazıcı**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, University of Health Sciences, Bakırköy Dr. Sadi Konuk Training and Research Hospital, Istanbul, Türkiye;* [2]*Department of Otorhinolaryngology–Head and Neck Surgery, Istinye University Gaziosmanpaşa Hospital, Istanbul, Türkiye;* [3]*Private Practice, Istanbul, Türkiye*

BACKGROUND & AIM

Adult-onset sensorineural hearing loss is a risk factor for cognitive decline, depression and social withdrawal. Its effect on mentalization, the ability to infer what another person is thinking or feeling, is less clear. Because vocal prosody and the social context of a conversation depend on intact hearing, we asked whether patients with bilateral sensorineural hearing loss (SNHL) perform worse on a mentalization test, and whether any such difference is simply explained by older age or less schooling.

MATERIAL & METHODS

We enrolled 160 adults aged 17-65: 40 normal-hearing controls and 120 bilateral SNHL patients, grouped by air-conduction pure tone average (PTA, 0.5-4 kHz) as mild (26-40 dB), moderate (41-55 dB) or severe (56-90 dB), 40 per group. Unilateral, asymmetric, conductive or mixed losses and patients with a known neurological or psychiatric disorder were excluded. All scored within normal limits on the Mini Mental State Examination. The Turkish version of the Reading the Mind in the Eyes Test (RMET) was administered face-to-face. We used one-way analysis of variance with Tukey HSD post-hoc tests for group comparisons, and partial correlation and multiple linear regression to see whether PTA still predicted RMET after adjusting for age, education and sex.

RESULTS

Mean RMET scores fell across groups: 23.0±5.9 in controls, 20.7±5.9 in mild, 14.0±4.8 in moderate and 13.5±3.5 in severe SNHL ($F(3,156)=34.9$, $p<0.001$, $\eta^2=0.40$). Post-hoc tests showed a step rather than a smooth gradient: moderate and severe patients scored well below both controls and mild patients (all $p<0.001$), while control-mild and moderate-severe contrasts were not significant. PTA correlated negatively with RMET ($r=-0.54$, $p<0.001$), and remained significant after adjustment (partial $r=-0.34$, $p<0.001$). In the regression model ($R^2=0.45$), each 1-dB rise in PTA was linked to a 0.09-point drop in RMET ($p<0.001$).

CONCLUSIONS

Bilateral SNHL is associated with lower mentalization, with what looks like a step change around the 40-dB boundary. The effect is not explained by age or education alone, although residual age confounding cannot be ruled out because controls were younger than patients. Social cognition may deserve more attention in the assessment and rehabilitation of adult SNHL.

PP-015

Acoustic Change Complex In Clinical Audiology: Case Study

Shcheglova Elizaveta Stanislavovna[1], **Tufatulin Gaziz Sharifovich**[2], **Mikhail Soganov**[3]

[1]*ENT department, Mechnikov's Northwestern State Medical University, Saint-Petersburg, Russia;* [2]*Center of Pediatric Audiology, Saint-Petersburg, Russia;* [3]*Neurosoft LLC, Russia*

BACKGROUND & AIM

Acoustic Change Complex (ACC) is an exogenous component of long-latency (cortical) auditory evoked potentials (CAEP) which is essentially an additional complex of P1'-N1'-P2' CAEP components [Tavartkiladze G.A., 2018]. It appears in response to changes of stimulus parameters at 50-100 ms after a change [Fan et al, 2022].

Clinical applications of recording ACC:

- bio-marker of an auditory cortex ability to discern changes in the stimulus;
- ACC is correlated with SRT [Vonck et al, 2022].

ACC response maturation for normal-hearing children:

- Minimum age: 3 months [Meehan et al, 2024]
- Wave P1' is reliably detected at 1-2 years [Strahm et al, 2022]

MATERIAL & METHODS

Stimulus used in this study for ACC was /daba/. Stimulation was performed via inserts, headphones and loudspeakers. Total stimulus duration was 845 ms. Stimulus was switched from /da/ to /ba/ at 450 ms. A few recordings were made for children of varying age, normal-hearing and with hearing loss.

Stimulation (if not specified otherwise): binaural, insert earphones. Intensity: 65 and/or 70 dB SPL.

Device used for the study was Neurosoft Neuro-Audio unit with additional stimulator unit (for speech stimuli).

RESULTS

Case 1. A girl, 4 years, normal-hearing (binaural).

ACC detected.

Case 2. A boy 8 years old, normal-hearing (binaural).

ACC not present

Child has difficulties with reading/writing skills (text comprehension).

Case 3. Girl, 6 years old, binaural SNHL (sensorineural hearing loss) of the 1st degree (mild).

Without HA (hearing aid): SRT: 90% (silence), 60% (noise).

With HA: SRT: 90% (silence), 90% (noise).

ACC detected.

Case 4. Boy, 8 years old. Left-sided SNHL (average threshold: 55 dB), right ear normal-hearing..

Stimulation: left and right ears, inserts. 65 dB SPL.

Without HA: SRT: 100% (silence), 70% (noise).

With HA: SRT: 100% (silence), 90% (noise).

Left: ACC response inconclusive.

Right: ACC clear response.

Case 5: girl, 8 years. Deafness (bilateral), ineffective CI. Average threshold with CI: AD – 40 dB, AS – 40 dB)

Stimulation: binaural, sound-field, 70 dB SPL.

P1, ACC not detected.

First CI was done at 3.5 years, second CI at 4.5 years.

Partially understands directed speech, answers simple requests, uses gestures, mimic and imitating sounds.

CONCLUSIONS

- ACC is a promising tool in a scientific and clinical practice and can be used in assessment of auditory cortex maturation, cortical processes responsible for speech discrimination, as an objective bio-marker of speech recognition.
- This technique requires further studies, concerning correlation between ACC results and speech audiometry (word recognition scores) before wide-spread clinical use.
- There is a high interest in studies of changes in ACC response due to auditory cortex maturation both in normal-hearing children and patients with hearing loss, including the cases after hearing aid fitting or cochlear implantation.

The Presence Of Hearing Loss In Patients With Viral Hepatitis

Cristian Florentin Aftenie[1], **Cristina Daniela Aftenie**[1], **Luana Alexandrescu**[1]

[1]*"Ovidius" University of Constanta*

BACKGROUND & AIM

Having in mind the increasing prevalence of viral hepatitis, especially type B (+D) virus but also C virus, as well as the multiple hepatic and non-hepatic complications, the authors of this study aim to draw attention to the impact on hearing function. Hearing dysfunction may be due to complex mechanisms, a direct consequence of the presence of the virus, but also as a result of therapeutic procedures. This first study aims to establish the initial hearing loss in people diagnosed with viral hepatitis, but also as a result of treatment, while taking into account the therapeutic protocols in force.

MATERIAL & METHODS

In this study, 139 patients (out of a group of 161) were evaluated over a period of 5 years, initially diagnosed with viral hepatitis, with no history of disease or other treatments until the time of diagnosis. They were selected for pure tone audiometric testing (PTA). Next, control audiometric tests were performed on a group of 150 patients with negative serology for viral hepatitis. Subjects in both groups were between 18 and 45 years of age. The authors excluded from the very beginning, anamnestically, as many possible causes as possible regarding other factors that have a negative impact on auditory function. The threshold was set at 30 db for hearing loss, compared to the hearing threshold considered normal.

RESULTS

Significant differences were found in auditory performance within the study group. There was also a significant difference between the groups in terms of auditory thresholds for different frequencies

CONCLUSIONS

The present study was able to obtain significant differences in auditory performance, by establishing the auditory threshold for pure tones, among patients confirmed with viral hepatitis.

Tinnitus Therapy With Botulinum Toxin In Palatal Myoclonus

Syroezhkin Fedor[1], **Urchukova Anzhelika**[2], **Ivanova Anastasia**[2], **Golovanov A.**[2], **Artyushkin S.**[1]

[1]*NWSMU named after I.I.Mechnikov;* [2]*Medical surgical academy*

BACKGROUND & AIM

A palatal myoclonus is a rare movement disorder characterized by continuous rhythmic tractions of the palatine muscles: tensor veli palatini and levator veli palatini. There are two types of the palatal myoclonus: symptomatic and essential one. The symptomatic type is associated with the pathology of the central nervous system in contrast to essential one. The only sign of essential palatal myoclonus is “clicky” sounds perceived as tinnitus.

Aim: To study and compare the outcome of botulinum therapy in patients with palatal myoclonic tinnitus.

MATERIAL & METHODS

17 patients with palatal myoclonic tinnitus were observed. Clinical characteristics, audiological findings, psychological status, and other relevant medical history were reviewed. Responses to various treatment modalities were retrospectively analyzed.

RESULTS

The mean age of enrolled patients was 27 [23; 39] years, with female gender predominance. The patients complained of different tinnitus sensation with ‘clicky’ sounding in most cases. Seven patients had comorbid tinnitus of other type. Pharmacological treatment was effective in 39.6% of the patients but was not stable. Botulinum toxin injection in the pharyngeal opening region of the auditory tube led to complete resolution of symptoms in all patients (100%) with palatal myoclonic tinnitus for period of 6 [3; 15] months. Several treatment sessions were required in some cases.

CONCLUSIONS

Patients with tinnitus should be examined according to presence of palatal myoclonus. Botulinum therapy is an effective and safe treatment for persistent palatal myoclonus.

KEYWORDS

tinnitus, botulinum toxin, palatal myoclonus, auditory tube

PP-018

History Of A Patient With Positive Ear Pressure Tympanometry

Abdullah Kınar[1]

[1]*Uşak University Faculty of Medicine, Uşak Research and Training Hospital, Department of Otorhinolaryngology, Uşak, Turkiye*

BACKGROUND & AIM

Tympanometry is the acoustic evaluation of the condition of the middle eardrum and conduction bones by creating air pressure changes in the ear canal. In tympanometry test, when the external ear canal pressure is equal to the middle ear pressure, impedance is lowest and compliance is highest. Classically there are there types of tympanometries according to Jerger’s classification: Type A; B and C. Positive pressure is referred as greater than >+50 mm H2O (49.03 decapascal daPa) pressure. We presented a rare case of positive middle ear pressure.

MATERIAL & METHODS

A 27-year-old young patient applied to the ENT outpatient clinic with the complaint of fullness in both ears. He had complaints for about 2-3 months. He traveled abroad by plane and his complaints increased. He had not any operation before. Family history was none specific. He was using Continuous Positive Airway Pressure (CPAP) during sleep for Obstructive Sleep Apnea Syndrome (OSAS) treatment. On physical examination his nose acute sinusitis was present. Septum was deviated to the left. Nasopharynx was natural. Ears: Both tympanic membranes appeared natural. In audiometry tests patient had bilateral mild conductive hearing loss in pure tone audiometry, The tympanometry test is done by Interacoustics Basic AT235 Tympanometry at 226 Hz and the right ear peak was measured.

RESULTS

Right ear peak was measured as +124 daPa (126 mmH20) and 1.82 ml Left ear peak was +110 daPa (112 mmH20) and 1.75 ml peak was measured in the tympanometry test . The patient received medical treatment. This patient is treated for acute sinusitis. He received amoxicillin+clavulanic acid combination 1 gr twice a day for 7 days per oral and nasal decongestant oxymetazoline for 5 days to both nostrils. Patient complaint was healed. He had been given information about myringotomy

and ventilation tube insertion if complaints reoccur. Written informed consent was obtained from the patient who agreed to take part in the study.

CONCLUSIONS

Positive type tympanometry result is rarely observed, Its causes are similar to negative tip C tympanometry but in the cases of positive pressure tympanometry results, it should be kept in mind whether the patient is receiving CPAP therapy. Our patient was had septal deviation and sinusitis, history of travelling by plane and CPAP treatment for OSAS. Valsalva maneuver could cause positive type tympanometry result but it does not last for 10 minutes

PP-019

Effects Of Contralateral Acoustic Stimulation On Ipsilateral Cochlear Microphonics

Lena-Marie Kayser[1], **Jana Müller**[2], **Sebastian Puschmann**[1,2], **Pascale Sandmann**[1,2], **Andreas Radeloff**[1,2]

[1]*Carl von Ossietzky University Oldenburg, Faculty VI · Medicine and Health Sciences;* [2]*Evangelisches Krankenhaus Oldenburg, Department of Oto-Rhino-Laryngology, Head and Neck Surgery, University of Oldenburg*

BACKGROUND & AIM

In complex acoustic environments, the auditory system relies on efferent mechanisms to enhance the processing of auditory signals (1). This study investigates the effect of contralateral acoustic stimulation on cochlear responses by comparing cochlear microphonic (CM) amplitudes for conditions with ipsilateral versus bilateral stimulation.

MATERIAL & METHODS

In two adult normal-hearing subjects (1 female, 1 male) CMs were elicited using three stimulation conditions: an 80 dB nHL tone burst presented ipsilateral, a bilateral 80 dB nHL tone burst, or an ipsilateral tone burst combined with an 80 dB SPL broadband noise presented contralateral. Cochlear microphonics were recorded using electrocochleography with an extratympanic membrane electrode placed on the right eardrum. Recordings were obtained with a clinical auditory evoked potential system. Each condition comprised 2000 stimuli and was repeated twice. All three conditions were conducted at stimulation frequencies of both 500 Hz and 2000 Hz. Signals exceeding a threshold of ±40 µV were excluded immediately. The stimuli were recorded over a 15 ms time window at a stimulus repetition rate of 57.8/s. The analysis will focus on comparing signal amplitudes across the three conditions.

RESULTS

Following pilot measurements, two measurements have been completed and are currently being analyzed. Thirteen additional measurements are planned. Preliminary results indicate that the chosen setup successfully captures CMs, highlighting its potential for detailed analysis in the upcoming measurements. The results of the first completed measurements will be presented and discussed at the conference.

CONCLUSIONS

Although final results are not yet available, the study may provide knowledge on the influence of contralateral stimulation and acoustic stimulus characteristics on CM modulation. The findings may contribute to future research on efferent auditory processing.

Speech-In-Noise Perception And Cognitive Processes: A Descriptive And Bibliometric Study

Nedim TURĞUT[1], **Özge KALE PEŞAN**[1], **Muhammed PINAR**[2]

[1]*Başkent University;* [2]*KTO Karatay University*

BACKGROUND & AIM

Speech perception in noisy environments is one of the fundamental components of individuals' daily communication skills and is closely associated with cognitive processes. The peripheral and central auditory systems differentiate multiple auditory stimuli based on their temporal, spectral, and frequency characteristics. This enables the segregation, localization, lateralization, and perception of simultaneous auditory inputs as signal and noise. In individuals with neurodevelopmental disorders, maintaining a favorable signal-to-noise ratio (SNR) is essential for effective communication. This study aims to provide a descriptive and bibliometric analysis of the literature examining the relationship between speech-in-noise perception and cognitive functions.

MATERIAL & METHODS

This study was designed using a document analysis method. A total of 11 English-language articles were included following a search conducted in the Web of Science Core Collection database using the titles "speech in noise" and "cognitive function."

The data were analyzed using bibliometric methods with bibliometrix 3.0 and biblioshiny; annual scientific production, article types, keyword distributions, and citation trends were evaluated.

RESULTS

The analysis results indicate an increase in the number of scientific publications in this field in recent years. All included studies were identified as original research articles. Keyword analysis revealed that terms such as “cognition,” “speech perception,” “auditory processing,” and “cognitive aging” were prominent. The findings demonstrate a significant and strong relationship between speech-in-noise perception performance and cognitive processes.

CONCLUSIONS

Speech perception in noise is associated not only with auditory mechanisms but also with cognitive processes. Further comprehensive studies in this field will contribute significantly to understanding neurodevelopmental disorders and age-related cognitive changes.

Duplicated Ear Canal

Aida Soltanmoradi[1], **Bardia Masrouri**[1], **Parisa Rasouli Fard**[1]

[1]*Department of Audiology, School of Rehabilitation, Shahid Beheshti University of Medical Sciences*

BACKGROUND & AIM

Congenital anomalies of the first branchial cleft are uncommon and may occasionally present as duplication of the external auditory canal. These anomalies can lead to chronic otorrhea, recurrent infections, and hearing loss. This case highlights the clinical and audiological findings in an infant with this rare condition, emphasizing the importance of early diagnosis and intervention.

MATERIAL & METHODS

An 18-month-old male infant presented with an accessory external auditory canal and a preauricular skin tag. A comprehensive audiological assessment was performed, including otoscopy, tympanometry, acoustic reflex testing, and auditory brainstem response (ABR) to evaluate hearing status.

RESULTS

ABR testing revealed mild conductive hearing loss in the right ear and moderate to severe mixed-type hearing loss in the left ear. These findings were consistent with structural abnormalities affecting both the outer and possibly inner auditory systems.

CONCLUSIONS

Duplication of the external auditory canal is a rare but significant anomaly that can result in hearing impairment. Early recognition and audiological assessment are essential for timely intervention. Management may include surgical correction and hearing rehabilitation to support normal speech and cognitive development.

KEYWORDS

Duplicated external auditory canal, ABR, Hearing sensitivity

NEUROPROTECTIVE EFFECT OF NICOTINAMIDE MONONUCLEOTIDE ON AGE-RELATED HEARING LOSS IN HIGH-FAT DIET-FED MICE.

Junko Tsuda[1], **Kazuma Sugahara**[1], **Mei Sakamoto**[1], **Haruka Nakabayashi**[1], **Makoto Hashimoto**[1]

[1]*Department of Otolaryngology, Graduate School of Medicine, Yamaguchi University*

BACKGROUND & AIM

Age-related hearing loss (ARHL) is a critical modifiable risk factor for cognitive decline. While metabolic syndrome is traditionally associated with auditory impairment, the influence of dietary lipids on the aging cochlea remains enigmatic. Nicotinamide mononucleotide (NMN), an NAD+ precursor, has emerged as a potential therapeutic agent for metabolic dysfunction. This study aimed to evaluate the neuroprotective efficacy of NMN on auditory function and cochlear histopathology under high-fat diet (HFD)-induced stress.

MATERIAL & METHODS

Male C57BL/6J mice were allocated into three groups: Control (normal diet), HFD, and HFD+NMN (100 mg/kg/day in drinking water). Dietary interventions commenced at 4 weeks of age. Auditory brainstem response (ABR) thresholds were assessed at 8, 16, and 32 kHz up to 34 weeks. Histological analysis quantified hair cell and spiral ganglion cell (SGC) densities. All animal procedures were approved by the Institutional Animal Ethics Committee.

RESULTS

Both HFD cohorts developed obesity and glucose intolerance. Paradoxically, the HFD group demonstrated superior preservation of ABR thresholds compared to the Control group. Supplementation with NMN provided additive benefits, with the HFD+NMN group exhibiting significantly lower thresholds at 32 kHz compared to the HFD-only group ($p < 0.05$). Histologically, while hair cell density was comparable across groups, SGC density in the HFD+NMN group showed a sustained trend toward higher preservation than Controls, suggesting targeted neuroprotection.

CONCLUSIONS

NMN administration exerts a neuroprotective effect on SGCs in the context of dietary stress, potentially via NAD+-mediated cellular resilience. Although HFD showed an unexpected protective trend in this specific model, NMN supplementation further optimized auditory outcomes. These findings support NMN as a promising candidate for maintaining cochlear neural integrity and mitigating auditory deprivation-linked cognitive decline.

Psychometric Evaluation Of A Digitally Recorded Mongolian Monosyllabic Word List For Word Recognition Score Testing

Baigalmaa Oyunbat[1], **Junghwa Bahng**[2], **Oyunchimeg Dashnyam**[3], **Urtnasan Davaajav**[4], **Batzorig Bayartsogt**[5], **Byambasuren Luvsandagva**[1]

[1]Department of Otorhinolaryngology, First Central Hospital of Mongolia, Mongolia; [2]Department of Audiology and Speech-Language Pathology, Hallym University of Graduate Studies, South Korea; [3]Department of Mathematics, Mongolian National University of Education, Mongolia; [4]Institute of Linguistics, Mongolian Academy of Sciences, Mongolia; [5]School of Public Health, Mongolian National University of Medical Sciences, Mongolia

BACKGROUND & AIM

Hearing loss affects approximately 430 million people worldwide, and speech audiometry plays a critical role in audiological rehabilitation. Accurate assessment requires standardized word materials developed in the listener's native language. Although Mongolian speech audiometry materials were first developed in 1988, no standardized monosyllabic word lists with psychometric validation currently exist for clinical use in Mongolia. This study aimed to develop phonetically balanced Mongolian monosyllabic word lists and evaluate their psychometric properties for Word Recognition Score (WRS) testing.

MATERIAL & METHODS

In the first phase, 220 Mongolian monosyllabic words that are widely recognized and commonly used in daily conversations by the general population were selected from various linguistic sources and phonemically balanced. These words were digitally recorded by a professional female voice artist in a sound studio, and their intensity levels were normalized using the Root Mean Square (RMS) value at 1000 Hz. In the second phase, word recognition tests were administered to 50 normal hearing participants aged 18 to 29 years. The test was conducted in a sound treated booth, with words presented at intensity levels ranging from -4 to 18 dB HL in 2 dB steps. The 220 words were randomly divided into four blocks of 55 words each. In the third phase, psychometric functions were generated using logistic regression analysis. To determine statistical differences between the lists and half-lists, chi-square (χ^2) test and one-way ANOVA were applied.

RESULTS

From the original pool of 220 words, the 200 most perceptible monosyllabic words were selected based on recognition accuracy. These were divided into four balanced 50-word lists and eight 25-word half-lists based on phonetic balance. Psychometric functions were derived using logistic regression. The slope at the 50% recognition threshold ranged from 9.94 to 10.70%/dB (M=10.43%/dB), and between 20–80% recognition from 8.61 to 9.38%/dB (M=9.07%/dB). Chi-square analysis revealed no significant differences across the four lists, χ^2 (3) = 0.12, P=.98, and one-way ANOVA confirmed equivalence in mean intensity levels, F=0.004, P=.9996. Similarly, no significant differences were found across the eight half-lists, χ^2 (7) = 2.63, P=.918. Minor intensity adjustments (≤±0.3 dB) standardized the 50% recognition threshold to 6.16 dB HL across all lists, confirming phonetic and perceptual equivalence for clinical use.

CONCLUSIONS

This study successfully developed and validated a set of 200 Mongolian monosyllabic words demonstrating homogeneous psychometric characteristics. The word lists were phonetically balanced, perceptually reliable, and statistically equivalent across both full 50 word lists and 25 word half-lists. These standardized materials fill a critical gap in Mongolian clinical audiology, providing validated tools for word recognition testing, speech audiometry, and hearing rehabilitation research in Mongolia. The developed lists are suitable for use by otologists and audiologists in both clinical and research settings. Future studies should extend this work by evaluating word recognition performance in noise at various signal-to-noise ratio levels.

COCHLEAR IMPLANTATION VIA RETROFACIAL APPROACH

Ferhat Deniz[1], **Beyza İlyasoğlu**[1], **Mehmet Murat Günay**[1], **İlker Akyıldız**[1], **Sibel Alicura Tokgöz**[1], **Murad Mutlu**[1]

[1]*Department of Otolaryngology-Head and Neck Surgery, Ankara Etlik City Hospital, Ankara, Turkey*

BACKGROUND & AIM

Although the round window approach is one of the most commonly preferred methods in cochlear implant (CI) surgery, alternative techniques are required in some patients due to reasons such as anatomical variations, a narrow facial recess, or restricted surgical exposure.This study aims to evaluate the clinical and surgical outcomes of a cochlear implantation case performed via the retrofacial approach.

MATERIAL & METHODS

A 1-year-old female patient presented to our clinic after failing the newborn hearing screening ABR (Auditory Brainstem Response) test. Temporal computed tomography (CT) imaging revealed no bilateral cochlear anomalies; however, bilateral stapes suprastructure were not observed. It was noted that the facial nerves were inferiorly positioned bilaterally, obscuring the round window niche. Following a CI multidisciplinary council meeting, we planned sequential bilateral cochlear implantation, starting on the left side using the round window approach.

During the procedure, neither the stapedial footplate nor the stapes suprastructure were observed. A posterior tympanotomy was performed; however, the round window niche could not be identified via the facial recess approach. Therefore it was decided to create exposure using the retrofacial approach. The round window niche was then identified. The cochlear implant electrodes were inserted into the scala tympani through the opened round window membrane, with all electrodes remaining inside.

RESULTS

"Ultimately, intraoperative evaluation yielded Neural Response Telemetry (NRT) responses from all electrodes.

CONCLUSIONS

While the round window approach remains the most prevalent technique in cochlear implantation, anatomical variations— as seen in our case—necessitate the use of alternative surgical approaches. To be prepared for such situations, preoperative imaging and careful surgical planning must be performed. In the use of alternative methods, the surgeon's experience should not be overlooked. In our case, the evaluation of preoperative temporal CT served as a guide for the implementation of CI via the retrofacial approach.

Arabic CAP & SIR

Ashwag Algahtani[1]

[1]*King Abdullah Ear Specialist Center (KAESC), King Abdulaziz University Hospital (KAUH), Medical City, Riyadh, Saudi Arabia;* [2]*King Saud University*

BACKGROUND & AIM

Categories of Auditory Performance II (CAP-II) is an established audiological test that consists of a rating scale that can be used for prospective assessment of the auditory performance of cochlear implant (CI) recipients.

MATERIAL & METHODS

In this cross-sectional study, 30 post-CI children (patients' group) along with 30 control subjects were included. The translated Arabic CAP-II scale has been used by speech-language pathologists and parents to evaluate the study subjects' auditory abilities. The interrater reliability, test-retest reliability, pre and postintervention score (responsiveness test), case versus control score comparison (discriminate validity), and cross-validation of the new Arabic version of CAP-II have been assessed.

RESULTS

The Arabic CAP-II demonstrated high test-retest and inter-rater reliability. There was a positive correlation between the Arabic CAP-II and Meaningful auditory integration scale. The Arabic CAP-II scores were higher in the patients' group compared with control subjects.

CONCLUSIONS

The Arabic CAP-II showed high inter-rater reliability with excellent concurrent and discriminate validity. The Arabic version of CAP-II seems to be a valid and reliable tool in assessing different auditory performance in Arabic speaking children with hearing impairment.

KEYWORDS

To create and validate an Arabic version of Categories of Auditory Performance scale II (CAP-II), and to evaluate its reliability.

Clinical Silence And Vestibular Crisis: Two Faces Of Superior Semicircular Canal Electrode Misplacement

João Tavares Correia[1], **Rosa Lousan**[1], **Sara Azevedo**[1], **João Carvalho Almeida**[1], **Isabel Silva Carvalho**[1], **João Lino**[1]

[1]*Unidade Local de Saúde de Santo António*

BACKGROUND & AIM

Cochlear implantation is a safe and well-established procedure with a low rate of major complications. However, electrode array misplacement into vestibular structures remains a rare but significant event. We aim to describe two cases of superior semicircular canal misplacement during cochlear implantation, highlighting diagnostic challenges, clinical presentation variability, and surgical management.

MATERIAL & METHODS

Two male patients (68 and 69 years old) with bilateral sensorineural hearing loss underwent unilateral cochlear implantation following unremarkable preoperative computed tomography (CT) and magnetic resonance imaging (MRI). In the first case, an Advanced Bionics SLIM J electrode was inserted via posterior tympanotomy through the round window without resistance. Intraoperative neural response telemetry showed absent responses. Postoperative radiography and CT revealed electrode placement within the vestibule extending into the superior semicircular canal. The patient remained asymptomatic due to pre-existing ipsilateral vestibular hypofunction. In the second case (MED-EL implant), mild resistance was encountered but overcome during insertion. Intraoperative telemetry demonstrated neural responses suggestive of correct positioning. However, early postoperative vertigo, horizontal-rotatory nystagmus, and severe imbalance prompted imaging, confirming misplacement into the superior semicircular canal. Both patients underwent revision surgery with electrode removal and reinsertion into the scala tympani, with correct positioning radiologically confirmed.

RESULTS

Following revision, both patients demonstrated favorable auditory outcomes. The first patient achieved a pure tone average of approximately 50 dB after activation. The second patient experienced progressive resolution of vestibular symptoms. No further complications were observed.

CONCLUSIONS

Electrode array insertion into the superior semicircular canal is a rare major complication of cochlear implantation and may occur despite apparently correct surgical technique and reassuring intraoperative telemetry. Absence or presence of neural responses does not reliably exclude malposition. Postoperative imaging remains the gold standard when clinical suspicion arises. Prompt surgical revision enables satisfactory auditory rehabilitation and symptom resolution.

Impact Of Cochlear Implant Surgery On Tongue Sensitivity

Dejan Mladenov[1], **Nina Božanić-Urbančič**[1,2], **Saba Battelino**[1,2]

[1]*University Medical Centre Ljubljana, Department of Otorhinolaryngology and Cervicofacial Surgery, Zaloška 2, 1000 Ljubljana, Slovenia;* [2]*University of Ljubljana, Faculty of Medicine, Vrazov trg 2, 1000 Ljubljana, Slovenia*

BACKGROUND & AIM

During cochlear implantation, manipulation of the chorda tympani nerve is common. While taste disturbances are a recognized postoperative effect, increasing evidence suggests that the chorda tympani may also contribute to general sensory innervation of the anterior tongue, potentially affecting tactile discrimination.

MATERIAL & METHODS

Seventy-six patients who underwent unilateral cochlear implantation were prospectively evaluated more than one month postoperatively. Static two-point discrimination (2PD) testing was performed bilaterally on the anterior tongue, with the non-operated side serving as an internal control. The difference in discrimination thresholds between sides was recorded.

RESULTS

Among 76 patients, deterioration in two-point discrimination on the implanted side was observed in 46 (61%), while no difference between sides was found in 28 (37%). Improvement on the operated side occurred in 3 patients. Three patients were not tested. A one-sided sign test demonstrated a statistically significant difference between sides ($p < 0.001$), indicating reduced tactile discrimination on the implanted side.

CONCLUSIONS

Cochlear implantation may lead to mild but statistically significant impairment of anterior tongue tactile sensitivity, supporting the role of the chorda tympani in general sensory function. These findings emphasize the importance of meticulous surgical technique, particularly during posterior tympanotomy, to preserve the chorda tympani nerve and minimize postoperative sensory changes.

Bone Conduction Hearing Implant In Treacher Collins Syndrome With Cholesteatoma: A Case Study

Takibayeva Zhadyra Aryngazievna[1], **Abilev Arman Amangeldinovich**[1], **Zhandauletov Almat Ulanbaekovich**[1], **Makhanova Meruert Maratovna**[1]

[1]*Astana Medical University*

BACKGROUND & AIM

Treacher Collins syndrome is a rare congenital condition associated with craniofacial anomalies, external auditory canal atresia, and conductive hearing loss. Management becomes more complex in the presence of cholesteatoma. The aim is to present a clinical case of bone conduction implant placement in such a patient.

MATERIAL & METHODS

A pediatric patient with Treacher Collins syndrome, external auditory canal atresia, and cholesteatoma was evaluated using clinical examination, CT imaging, and audiological tests. Surgical treatment included cholesteatoma removal followed by bone conduction implant placement.

RESULTS

Successful eradication of cholesteatoma was achieved. The bone conduction implant was placed without complications, providing significant hearing improvement and good postoperative outcomes.

CONCLUSIONS

Bone conduction implantation is an effective option for hearing rehabilitation in patients with congenital ear anomalies, even in complex cases with cholesteatoma, when proper surgical management is performed.

PP-029

Cochlear Implantation In CHARGE Syndrome With Concurrent Cochlear Anomaly And Profound Hearing Loss: A Case Report

Zülal Toprak Keleş[1], **Sibel Alicura Tokgöz**[1], **İlker Akyıldız**[1], **Mehmet Murat Günay**[1], **Muharrem Dağlı**[1]

[1]*Department of Otolaryngology – Head and Neck Surgery at Ankara Etlik City Hospital, Ankara, Türkiye*

BACKGROUND & AIM

The purpose of this study is to present thepreoperative radiological evaluation, intraoperative challenges encountered, andpostoperative auditory performance of apediatric patient with CHARGE syndromewho underwent cochlear implantation in our clinic.

MATERIAL & METHODS

A 2-year-and-9-month-old female patient, referred after failing newborn hearing screening, was evaluated. Auditory brainstem response (ABR) confirmed bilateral profound sensorineural hearing loss. Her medical history included hypothyroidism, pulmonary stenosis, secundum ASD, bilateral vision loss, and repaired esophageal and anal atresia. Physical examination revealed bilateral microphthalmia, iris coloboma, low-set ears, and retrognathia. Genetic analysis identified a heterozygous c.6972T>A variant in the CHD7 gene, confirming CHARGE syndrome.

Preoperative temporal CT and contrast-enhanced MRI demonstrated characteristic inner ear malformations: fixed malleus heads, bilateral cochlear hypoplasia (absent interscalar septum, stenotic apertures), absent lateral/posterior semicircular canals, and an absent right oval window. Due to the presence of the left oval window and traceable vestibulocochlear nerves, the left ear was selected for intervention. Following a positive intraoperative ABR response, a left cochlear implantation via the round window approach was performed.

RESULTS

Left cochlear implantation was performed via the round window approach. Intraoperatively, the facial canal was intact, but the lateral semicircular canal could not be visualized. Due to severe cochlear hypoplasia, only electrodes 1–9 were successfully placed into the scala tympani, while electrodes 10–12 could not be inserted. Intraoperative neural response telemetry (NRT), auditory nerve response telemetry (ART), and stapes reflex tests yielded no responses across all active electrodes. No intraoperative cerebrospinal fluid gusher occurred.

Postoperatively, although reliable thresholds could not be established at 1 month, subjective behavioral responses to sound were reported by the family. At the 3-month follow-up, the patient demonstrated behavioral responses to her name and speech sounds at 65 dB. The family confirmed consistent awareness of moderate-to-high-intensity sounds. Due to the patient's severe visual impairment, postoperative audiological assessments were conducted under limited and adapted conditions.

CONCLUSIONS

CHARGE syndrome presents significant anatomical challenges, such as severe cochlear hypoplasia, which can restrict electrode insertion and prevent intraoperative electrophysiological responses (NRT/ART). However, our case demonstrates that a lack of intraoperative responses does not predict a poor prognosis. Despite partial placement (electrodes 1–9), the patient achieved meaningful auditory gains, responding to speech at 65 dB within three months. Precise preoperative CT and MRI are vital for surgical planning and side selection. Ultimately, cochlear implantation remains a crucial intervention that drastically improves communication and quality of life for syndromic children facing dual sensory (visual and hearing) loss.

Cochlear Implant Electrode Extrusion Following Severe Vomiting: A Rare Reason For Revision Surgery In A Case Of Incomplete Partition Type II

Bülent Ulusoy[1], **Özgür Demir**[1]

[1]*The Department of Otolaryngology and Head and Neck Surgery at Selçuk University Faculty of Medicine Hospital, Konya, Turkey*

BACKGROUND & AIM

Cochlear implantation is a well-established and effective treatment for patients with severe-to-profound sensorineural hearing loss. Although the procedure is associated with high success rates and a low incidence of major complications, electrode migration or extrusion remains a rare but clinically significant event that may necessitate revision surgery. We report an unusual case of cochlear implant electrode extrusion following severe vomiting in a patient with incomplete partition type II inner ear malformation, and discuss the possible underlying pathophysiological mechanisms.

MATERIAL & METHODS

A patient with progressive bilateral hearing loss was diagnosed with bilateral incomplete partition type II based on radiological evaluation and underwent right cochlear implantation. Intraoperatively, a profuse gusher was encountered. The electrode array was inserted through the round window membrane after being passed through temporalis fascia, and full insertion was achieved. Early postoperative imaging confirmed appropriate intracochlear placement, and no implant-related complications were observed during the initial postoperative period. However, at the eighth postoperative month, the patient presented with severe vertigo following an episode of excessive vomiting and diarrhea. Temporal computed tomography revealed partial extrusion of the electrode array from the cochlea, displacement into the vestibule, and air densities within the cochlea and vestibule.

RESULTS

Revision surgery intraoperative findings included an extracochlear electrode array, granulation tissue within the mastoid cavity, electrode displacement into the vestibule, and profuse fluid leakage. The electrode array was removed and reinserted through the round window membrane using the same temporalis fascia-assisted technique, achieving full insertion. Correct positioning was confirmed both endoscopically and fluoroscopically. The vestibule and oval window were reinforced with muscle and conchal cartilage grafts to improve sealing and stability. Postoperative computer tomography confirmed satisfactory intracochlear positioning of the implant.

CONCLUSIONS

This case suggests that abrupt intracranial and intralabyrinthine pressure changes associated with severe vomiting may contribute to cochlear implant electrode extrusion in anatomically high-risk patients with inner ear malformations. In such patients, new-onset vertigo or other atypical otologic symptoms should raise suspicion for electrode displacement even in the absence of obvious external signs. Prompt radiological evaluation and timely revision surgery are essential for restoring implant function and minimizing morbidity.

Feasibility Of Cochlear Implantation In An Irradiated Temporal Bone, Case Report And Literature Review

Bassam Alzuraiqi, Md, FACS[1], **Essam Saleh, PhD**[2], **Saeed Alghamdi, MD**[2]

[1]*international medical Center, Makkah;* [2]*King Abdullah Medical City, Makkah*

BACKGROUND & AIM

Radiotherapy is an established treatment for nasopharyngeal carcinoma but often results in sensorineural hearing loss. Cochlear implantation has been shown to provide hearing rehabilitation in such cases. We report a case of cochlear implantation in a patient with profound deafness following radiotherapy for nasopharyngeal carcinoma.

MATERIAL & METHODS

A 51-year-old male presented with bilateral profound deafness four years after chemoradiotherapy for nasopharyngeal carcinoma. Audiological evaluation and imaging confirmed severe cochleovestibular damage. After a trial with no benefit from hearing aids, the patient underwent cochlear implantation with subtotal petrosectomy on the right side. Post-operative recovery was uneventful.

RESULTS

At one year follow-up, the patient was achieving open set speech understanding with the implant.

CONCLUSIONS

Cochlear implantation can provide hearing rehabilitation in selected patients with profound deafness due to radiation-induced cochleovestibular damage. A multidisciplinary team approach involving careful patient selection and counseling is important for successful outcomes in these challenging cases.

Surgical Repair Of Facial Paralysis After Cochlear Implant Placement And Facial Nerve Stimulation Due To Implant Activation: A Case Report

Bülent Ulusoy[1], **Özgür Demir**[1]

[1]*The Department of Otolaryngology and Head and Neck Surgery at Selçuk University Faculty of Medicine Hospital, Konya, Turkey*

BACKGROUND & AIM

Although facial nerve-related complications after cochlear implantation are rare, they are clinically significant. This case report aimed to present the clinical course, diagnostic evaluation, and surgical management of delayed peripheral facial paralysis following cochlear implantation, along with facial nerve stimulation that emerged during long-term follow-up in the same patient.

MATERIAL & METHODS

The clinical findings, imaging results, surgical interventions, and follow-up course of a patient who developed progressive hearing loss after a febrile illness in childhood and subsequently underwent right cochlear implantation were evaluated. The patient's facial paralysis that developed in the early postoperative period and the facial nerve stimulation that occurred in the seventh postoperative year were examined in detail.

RESULTS

On postoperative day 8, the patient developed grade IV peripheral facial paralysis according to the House–Brackmann classification. Because the paralysis persisted despite steroid therapy, antiviral treatment, and physical rehabilitation, facial nerve decompression was performed. Intraoperatively, granulation tissue surrounding the implant and an exposed, edematous tympanic segment of the facial nerve were observed. Following decompression and interposition of temporal muscle fascia between the facial nerve and the implant, facial function recovered completely. In the seventh postoperative year, right-sided facial twitching, vertigo, and syncope developed after replacement of the external processor. Imaging revealed no central pathology; however, temporal bone computed tomography demonstrated granulation tissue around the facial nerve. As the symptoms persisted despite medical treatment and device reprogramming, revision surgery was undertaken, and a cartilage graft was placed between the facial nerve and the implant. During follow-up, the facial twitching and vestibular complaints resolved completely.

CONCLUSIONS

This case demonstrates that two distinct facial nerve-related complications may occur in the same patient at different time after cochlear implantation. In the presence of facial paralysis resistant to medical treatment, local inflammation and mechanical factors should be considered. Likewise, in late-onset facial nerve stimulation, not only device programming but also tissue reaction and the electrode–facial nerve relationship should be evaluated. Careful long-term follow-up and appropriate surgical management may lead to successful outcomes.

Do Cochlear Implant Physical Characteristics Influence Manufacturer Selection? A Multicentre Questionnaire Development Proposal

Cemal Bartu Bektaş[1]

[1]*The Near East University Hospital*

BACKGROUND & AIM

Choosing the right cochlear implant manufacturer for a child can be difficult and stressful for families. Decisions are guided by the multidisciplinary cochlear implant team along with independent family research, and usually require multiple consultations to allow time for discussion and informed choice. Parents are usually given sample devices to compare during consultations. Observationally, families tend to focus not only on specialist information but also on external features such as device shape, texture, weight, colour, and available processor cover designs. However, there is limited research on how much these visual and physical characteristics independently influence manufacturer selection beyond clinical counselling.

MATERIAL & METHODS

Previous studies investigating factors influencing parental decision-making in cochlear implant manufacturer selection; have included relatively small sample sizes, ranging from approximately 9 to 300 families. Therefore,there need for a lack of large-scale data enabling statistically significant evaluation of these factors.

This study proposes the development of a standardised questionnaire suitable for easy implementation across multiple cochlear implant centres. The questionnaire aims to investigate whether families who remain undecided between manufacturers are influenced by the physical characteristics of external device. In order to achieve this goal; this poster presentation aims to encourage discussion and multidisciplinary collaboration in the development of the questionnaire, including identification of relevant questions, optimal timing of administration, and appropriate methods of evaluation.

RESULTS

As this study is currently in the proposal stage, no results or conclusions are available at present.

CONCLUSIONS

As this study is currently in the proposal stage, no results or conclusions are available at present.

Cochlear Implantation In Osteopetrosis-Associated Profound Hearing Loss With Skull Base Sclerosis: A Clinical Capsule Report

Esam saleh[1], **Rahaf G. Altwairqi**[1], **Elsaeed thabet**[1]

[1]*King Abdullah medical specialities city hospital*

BACKGROUND & AIM

To describe the diagnostic and surgical considerations of cochlear implantation in an adult patient with osteopetrosis-associated profound hearing loss and extensive skull base sclerosis.

MATERIAL & METHODS

A 42-year-old man with known osteopetrosis presented with progressive bilateral hearing loss over 17 years ago, eventually progressing to profound hearing loss. Despite severe auditory impairment, he retained normal speech production and voice quality. He had used hearing aids since the age of 25 year-old started with left ear then he used it for right ear, with limited recent benefit. Associated manifestations included progressive visual decline, right-sided trigeminal neuralgia-like facial pain, and right House–Brackmann grade II facial paralysis.

Intervention: The patient underwent right cochlear implantation through a posterior tympanotomy approach with intraoperative facial nerve monitoring.

Main Outcome Measure: Successful cochlear implant insertion and intraoperative feasibility in the setting of markedly thickened temporal bone secondary to osteopetrosis.

RESULTS

Pure tone audiometry demonstrated bilateral profound mixed hearing loss with absent speech discrimination in the right ear. High-resolution computed tomography showed diffuse skull base thickening and sclerosis, narrowing of the optic nerve canals and superior orbital fissures, and diffuse increased density of the visualized facial and neck bones. Right cochlear implantation was completed successfully. The main intraoperative challenge was a markedly thick temporal bone, but the procedure was otherwise uneventful, with no reported intraoperative complications.

CONCLUSIONS

Cochlear implantation may be feasible in selected patients with osteopetrosis-associated profound hearing loss. Detailed radiologic evaluation, individualized surgical planning, and facial nerve monitoring are important because skull base sclerosis and temporal bone thickening may create substantial operative challenges.

PP-035

Cochlear Implantation In Internal Auditory Canal Hypoplasia: A Three-Case Series Avoiding Auditory Brainstem Implantation

Zebo Karimova[1], **Giedrius Gylys**[2]

[1]*INVIVO Clinic, Tashkent, Uzbekistan;* [2]*Lithuanian Health Science University Kaunas Clinic ENT department, Kaunas, Lithuania*

BACKGROUND & AIM

Internal auditory canal hypoplasia is commonly associated with cochlear nerve deficiency and is often considered a potential indication for auditory brainstem implantation. However, in selected cases, cochlear implantation may serve as both a diagnostic and therapeutic option, especially when imaging and electrophysiological findings suggest the possible presence of a functional cochlear nerve.

MATERIAL & METHODS

To present three clinical cases of patients with internal auditory canal hypoplasia and otocyst-related inner ear malformation who underwent cochlear implantation, avoiding the need for auditory brainstem implantation.

We retrospectively analyzed three patients diagnosed with internal auditory canal hypoplasia and associated otocyst/inner ear malformation. All patients underwent comprehensive preoperative assessment, including high-resolution computed tomography, magnetic resonance imaging, audiological evaluation, and electrophysiological testing where available. Despite anatomical limitations, diagnostic cochlear implantation was performed as the first surgical option. Intraoperative findings, electrode insertion, neural response telemetry, postoperative auditory development, device use, and rehabilitation outcomes were evaluated.

RESULTS

Cochlear implantation was successfully performed in all three cases. Intraoperative electrode insertion was achieved without major complications. Postoperative fitting and rehabilitation demonstrated auditory responses in all patients, confirming functional stimulation through the cochlear implant system. During follow-up, the patients showed progressive auditory development and meaningful benefit from cochlear implantation. None of the patients required subsequent auditory brainstem implantation.

CONCLUSIONS

This three-case series suggests that internal auditory canal hypoplasia should not automatically be considered an absolute indication for auditory brainstem implantation. In carefully selected patients, cochlear implantation may provide clinically useful auditory stimulation and can help avoid unnecessary brainstem implantation. A stepwise diagnostic and therapeutic approach, including detailed radiological, audiological, electrophysiological, and intraoperative assessment, may improve decision-making in complex congenital inner ear malformations.

Cochlear Implantation In Pediatrics: The Effect Of Cochlear Coverage

ALHANOUF ALOTAIBI[1], **Fida Almuhawas**[1]

[1]*King Abdullah Ear Specialist Center (KAESC), Riyadh, Saudi Arabia*

BACKGROUND & AIM
Cochlear coverage by electrode arrays may influence speech outcomes in children with prelingual hearing loss. The optimal coverage threshold remains unclear.To evaluate the relationship between cochlear coverage and auditory and speech performance in pediatric cochlear implant users.

MATERIAL & METHODS
• Retrospective study of 57 children (85 ears) • FLEX 28 and FORM 24 electrode arrays • Outcomes: PTA, SRT, SDS, CAP, SIR • Cochlear coverage calculated using CDL software

RESULTS
Mean cochlear coverage: 82.78% • Greater coverage significantly improved Speech Discrimination Scores (p=0.009) • Coverage ≥82.78% associated with better SDS • No significant effect on SRT, CAP, or SIR.

CONCLUSIONS
Greater cochlear coverage is associated with improved speech discrimination in prelingually deaf children.

MRI-Related Magnet Extrusion Developing 15 Years After Cochlear Implantation

Şaban Furkan Yalçın[1], **Mehmet Murat Günay**[1], **Sibel Alicura Tokgöz**[1]

[1]*Ankara Etlik Şehir Hastanesi*

BACKGROUND & AIM
Internal magnet extrusion following cochlear implantation (CI) is a rare condition. Magnetic Resonance Imaging (MRI) procedures can lead to the displacement of the internal CI magnet, subsequently resulting in skin necrosis and extrusion. The purpose of this case report is to present the diagnostic evaluation and clinical management process of a magnet extrusion that developed following an MRI scan 15 years after CI surgery.

MATERIAL & METHODS
Our case involves a 48-year-old female patient who underwent a right CI in 2011 and presented in the 15th postoperative year with the complaint of the internal magnet being exposed through the skin at the site of the receiver-stimulator unit. The patient's medical history revealed that she had undergone a knee MRI examination 2 years prior to the onset of the current clinical presentation. During the diagnostic workup, temporal computed tomography (CT) and four-view cranial radiography scans were analyzed to confirm the spatial orientation of the internal component and the magnet.

RESULTS
Radiological evaluations (temporal CT and cranial radiography) demonstrated that the internal CI magnet had dislocated from its pocket within the receiver-stimulator unit and extruded by perforating the skin flap. Signs of hyperemia and inflammation were observed in the skin flap at the region of the extruded magnet.

CONCLUSIONS
It has been demonstrated that the violation of MRI safety procedures in CI users can cause severe local surgical morbidity, even as long as 15 years post-surgery. Consequently, the critical importance of lifelong MRI compatibility surveillance in CI patients must be strongly emphasized. Clinicians should keep in mind that potential extrusion cases can develop as a late-term complication, even many years after the initial implantation.

Ramsay Hunt Syndrome With Retrocochlear Signs: Cochlear Implantation Guided By Intraoperative Eabr: A Case Report

Burçay Tellioğlu[1], **Ergin Eroğlu**[1], **Müjgan Demir**[2], **Betül Çiçek Çınar**[2], **Levent Sennaroğlu**[1]

[1]*Hacettepe University, Faculty of Medicine, Department of Otorhinolaryngology, Head and Neck Surgery;* [2]*Hacettepe University, Faculty of Health Sciences, Department of Audiology*

BACKGROUND & AIM

Bilateral profound sensorineural hearing loss (SNHL) caused by different etiologies presents significant diagnostic and therapeutic challenges. Labyrinthitis ossificans may preclude cochlear implantation (CI), whereas Ramsay Hunt syndrome (RHS) can involve both cochlear and retrocochlear pathways, potentially compromising cochlear nerve function. In such situations, determining the optimal auditory rehabilitation strategy between CI and auditory brainstem implantation (ABI) is critical. This report aims to demonstrate the value of integrating radiological findings with intraoperative electrophysiological assessment, particularly electrically evoked auditory brainstem response (eABR), to evaluate cochlear nerve integrity and guide surgical decision-making.

MATERIAL & METHODS

A 43-year-old male with bilateral profound SNHL was evaluated. The patient had a history of meningitis-related deafness in the right ear at the age of three. And The patient recently developed Ramsay-Hunt syndrome on the left side, resulting in facial paralysis as well as progressive hearing loss. CT demonstrated complete ossification of the right cochlea, vestibule, and semicircular canals, consistent with labyrinthitis ossificans that makes CI unfeasible. MRI revealed enhancement of the left vestibulocochlear nerve complex and decreased fluid signal intensity in the internal auditory canal fundus, suggesting retrocochlear involvement of RHS. Intraoperative electrically evoked auditory brainstem response (eABR) testing using an intracochlear test electrode (ITE) was planned to assess left cochlear nerve functionality. Depending on the electrophysiological response, CI or ABI would be performed.

RESULTS

Intraoperative eABR testing demonstrated clear and reproducible wave V responses during both monopolar and bipolar stimulation modes, indicating preserved functional integrity of the left cochlear nerve and central auditory pathway despite radiological signs of retrocochlear inflammation. Based on these findings, CI was performed on the left ear without complications. Postoperative device activation showed normal electrode impedances and auditory perception across all electrodes. During follow-up fitting sessions, objective measures including AutoART responses were detected in several electrodes, confirming neural responsiveness. The patient reported perception of environmental sounds and voices after one month of device use. Free-field audiometric testing demonstrated progressive improvement in hearing thresholds over time. These findings confirmed that functional cochlear nerve integrity was sufficient to support CI despite imaging findings suggestive of retrocochlear involvement.

CONCLUSIONS

This case highlights the importance of combining radiological imaging with intraoperative electrophysiological evaluation when retrocochlear pathology is suspected. Although MRI suggested vestibulocochlear nerve involvement, eABR testing confirmed preserved cochlear nerve functionality, allowing successful CI instead of ABI. Intraoperative eABR therefore serves as a valuable tool for real-time assessment of neural viability and can significantly influence surgical decision-making. Integrating functional testing with imaging findings may expand cochlear implantation candidacy and improve auditory rehabilitation outcomes in complex cases of profound hearing loss.

RELATIONSHIP BETWEEN THE FACIAL NERVE AND THE ROUND WINDOW IN COCHLEAR IMPLANTATION: PRELIMINARY RESULTS OF A CT-BASED MORPHOMETRIC STUDY USING OTOPLAN

Abilev Arman Amangeldinovich[2], **Zhumasheva Anar Bakytkyzy**[1], **Yeraliev Adilkhan Sabitovich**[2], **ANANDHAN DHANASINGH**[3]

[1]*Astana Medical University*; [2]*City Multifunctional Children's Hospital No.2*; [3]*UNIVERSITY OF ANTWERP, ANTWERP, BELGIUM*

BACKGROUND & AIM

The round window (RW) approach is widely used for electrode insertion in cochlear implantation because of its atraumatic characteristics. However, surgical exposure of the RW niche may be affected by the anatomical relationship between the facial nerve (FN) and the round window. Variability in the course of the FN within the facial recess can partially obscure the surgical field and increase operative complexity. High-resolution temporal bone CT analysis using dedicated surgical planning software such as OTOPLAN enables detailed assessment of these anatomical relationships and may improve individualized surgical planning.

MATERIAL & METHODS

A combined retrospective and prospective radiological study was performed using high-resolution temporal bone CT scans obtained during preoperative evaluation for cochlear implantation. A total of 116 patients were included, comprising 99 retrospective and 17 prospective cases.

All CT datasets were analyzed using OTOPLAN (CAScination AG, Bern, Switzerland) with multiplanar reconstruction tools. The following parameters were assessed: patient gender, ear side, position of the facial nerve relative to the Modiolus–Round Window reference line, RW–FN distance, EAC–FN distance, FN-trajectory distance, FN-burr distance, facial recess dimensions, shortest FN–RW distance, cochlear duct length (CDL), cochlear diameter, cochlear width, cochlear height, and scala tympani volume.

The FN position relative to the Modiolus–RW reference line was classified as above, touching, intersecting, or below the reference line.

RESULTS

The mean RW–FN distance was 6.7 mm in the retrospective cohort and 7.1 mm in the prospective cohort.

In the retrospective group, FN position relative to the Modiolus–RW line was above in 36 cases (36.4%), below in 2 (2.0%), intersecting in 41 (41.4%), and touching in 20 (20.2%). In the prospective group, FN position was above in 9 cases (52.9%), intersecting in 7 (41.2%), and touching in 1 (5.9%).

Additional morphometric measurements showed similar values between cohorts, including EAC–FN distance (3.5 vs 3.7 mm), facial recess width (3.03 vs 3.2 mm), shortest FN–RW distance (3.4 vs 3.5 mm), cochlear duct length (35.2 vs 34.1 mm), and scala tympani volume (42.2 vs 41.4 mm^3).

Overall, moderate anatomical variability of the FN–RW relationship was observed, with the facial nerve most commonly intersecting or contacting the Modiolus–RW reference line.

CONCLUSIONS

Preoperative high-resolution CT analysis using OTOPLAN provides valuable morphometric information regarding the anatomical relationship between the facial nerve and the round window in cochlear implantation.

Moderate anatomical variability of the facial recess and cochlear anatomy was identified. The facial nerve most frequently demonstrated an intersecting or superior position relative to the Modiolus–RW reference line, findings that may affect surgical exposure of the round window niche and operative strategy.

These preliminary results support the importance of individualized CT-based surgical planning to improve safety and optimize surgical access during cochlear implantation.

Long-Term Outcomes Of Pediatric Auditory Brainstem Implant In A Child With Congenital Blindness And Cochlear Nerve Aplasia: A Case Report

Kays Burak CAKIR[1], **Fırat TEVETOGLU**[1], **Emine Deniz GOZEN TAN**[1], **Halide CETIN KARA**[1,2], **Yıldırım Ahmet BAYAZIT**[1]

[1]*Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty Department of Otorhinolaryngology-Head and Neck Surgery*; [2]*Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Audiology*

BACKGROUND & AIM

The auditory brainstem implant (ABI) is a prosthetic device surgically placed on the cochlear nucleus to provide hearing in patients for whom cochlear implantation (CI) is not feasible. The first pediatric ABI was performed by Colletti et al. (2000) in a four-year-old child. Auditory responses in children with ABI are typically unclear during the first 6-12 months but improve over

subsequent years, with at least three years required to reach age-appropriate auditory performance. We report the long-term outcomes of a pediatric ABI user with bilateral congenital cochlear nerve aplasia and bilateral congenital total visual loss.

MATERIAL & METHODS

A 10-year-old male patient (born November 2015) was diagnosed with bilateral profound sensorineural hearing loss at a different center at 7 months of age. He had concurrent bilateral congenital total visual loss. Temporal bone computed tomography and magnetic resonance imaging performed at the age of 4 revealed bilateral absence of the cochlear nerve, while the cochlea and inner ear structures were normal. ABI was applied to the patient's right ear. Pre- and post-operative evaluations included auditory perception skills, social-emotional skills, speech perception, and cortical responses (P1-N1-P2) elicited by 75 dB SPL live-voice-like, isolated phoneme stimuli. The Meaningful Auditory Integration Scale (MAIS) and Categories of Auditory Performance (CAP) were used. During the postoperative period, the patient wore the processor willingly; changes in latencies and amplitudes of cortical responses were observed, with improvements in CAP scores and speech perception.

RESULTS

The co-occurrence of bilateral cochlear nerve aplasia and total visual loss is rare in the literature and represents a clinical scenario in which lip-reading and visual-cue-based rehabilitation strategies—routinely employed in pediatric ABI rehabilitation—are not available. Despite this limitation, the MAIS, CAP, and cortical response data obtained in our patient support the conclusion that meaningful auditory perception and cortical maturation can be achieved with consistent device use and structured auditory rehabilitation, even in the absence of visual input. Serial monitoring of cortical responses provided objective guidance for fitting optimization and individualization of the rehabilitative process.

CONCLUSIONS

In children with ABI, language and communication skills develop through appropriate rehabilitative methods. Objective monitoring with serial cortical responses is valuable for fitting optimization and structuring of the rehabilitative process. This case highlights the considerations required when visual input cannot be utilized in communication and demonstrates that meaningful auditory development is achievable in pediatric ABI users with dual sensory loss.

Cochlear Implantation In A Patient With MYH9-Related Disease: A Case With Post-Transplant Immunosuppression And Adrenocortical Carcinoma

Anzu Saito[1], **Mitsuyoshi Imaizumi**[1], **Shigeyuki Murono**[1]

[1]*Department of Otolaryngology, Fukushima Medical University School of Medicine*

BACKGROUND & AIM

MYH9-related disease (MYH9-RD) is a rare autosomal dominant disorder caused by mutations in the MYH9 gene, characterized by congenital macrothrombocytopenia with leukocyte inclusions, progressive sensorineural hearing loss, renal dysfunction, and cataracts. We here report the first known case of cochlear implantation (CI) in a patient with MYH9-RD who was receiving both post-transplant immunosuppressive therapy and adjuvant chemotherapy for adrenocortical carcinoma, with favorable surgical and auditory outcomes.

MATERIAL & METHODS

A 34-year-old man with a history of progressive hearing loss since childhood was referred to our department due to bilateral deterioration. At age 20, he developed renal failure, received peritoneal dialysis, and subsequently underwent living-donor kidney transplantation. Since then, he has been on continuous immunosuppressive therapy. At age 26, he underwent surgery for an enlarging adrenal tumor, diagnosed as adrenocortical carcinoma, followed by adjuvant chemotherapy. By age 33, he experienced profound bilateral sensorineural hearing loss and was considered for CI. Genetic analysis revealed a heterozygous MYH9 mutation (c.2104C>T, p.A702C), with no pathogenic variant detected in exon 16. Preoperative platelet count was severely reduced (11,000/μL); therefore, platelet transfusions (4× 20 units) were administered before and after surgery. Hydrocortisone supplementation was provided perioperatively for adrenal insufficiency.

RESULTS

The patient’s preoperative platelet count increased to 49,000/μL, and right CI (CI422, Cochlear Ltd., Lane Cove, Australia) was performed via the round window approach. All electrodes were smoothly inserted and verified inside the cochlea via intraoperative X-ray. Although the patient developed extensive subcutaneous hemorrhage in the postauricular region postoperatively, he was discharged without complications. Ten months postoperatively, the functional outcome of the CI was favorable, with aided hearing thresholds averaging 20–25 dB. Speech intelligibility testing revealed 96% word recognition and 100% sentence recognition, indicating excellent results.

CONCLUSIONS

We report a very rare case of CI in a patient with MYH9-RD undergoing post-transplant immunosuppressive therapy and adjuvant chemotherapy for adrenocortical carcinoma. CI was safely performed with meticulous perioperative management, including platelet transfusions and steroid support. The favorable auditory outcome suggests that CI is a viable and effective treatment option for patients with MYH9-RD, even in the presence of complex systemic comorbidities.

STUDY OF TELEMETRY CHANGES OVER TIME IN COCHLEAR IMPLANT CHILDREN

samir Assal[1]

[1]*Faculty of medicine , Alexandria University*

BACKGROUND & AIM

Integrity of this cochlear implant can be assessed intraoperatively and followed postoperatively through objective measures. Objective measures are a widely used and valuable tool in the field of cochlear implants (CIs) because during surgery they provide first indications of successful implantation and after surgery they are used to facilitate the individual fitting of stimulation parameters especially in young children.

MATERIAL & METHODS

Data were collected from 15 deaf children implanted unilaterally with med-el sonata implant system with opus 2 speech processor. All Subjects had used hearing aids for at least three months prior to cochlear implant surgery and had received auditory verbal rehabilitation.

Impedance measurement o In the current study Impedance was measured intraoperatively and the accepted results was that with average one with no open–short circuit. Any result exceed 20ohm was discard and implant was re assessed. o The measurement was repeated in the initial stimulation visit (fitting) twice time later each one month from other. ECAP measurements o During The intraoperative period, the (ART) was recorded in selected electrodes E1, E5, E8, E11 and E12 because of restricted operating time,recorded postoperatively, the participants were evaluated at three moments: One month after operation. Two months after operation. Three months after operation.

RESULTS

15 children with med-el cochlear implant was included in this study, 7 were male and 8 female. Intraoperative impedance was the lowest among all postoperative readings in all electrodes. The highest value was that measured I month post-surgery after which impedance values remain to decrease significantly but not to the intraoperative values

There was no significant difference between ECAP threshold measured in the intraoperative and 1 month, 2 month and 3 months post-surgery. Although basal electrodes (11 and 12) showed different pattern there was no response intraoperatively and in the first stimulation period but start to show. ECAP thresholds 2months after surgery that was stable to the last reading that was 3rd months cession.

CONCLUSIONS

Impedance measurement shows significant increase in the impedance in the first month postoperative compared to intraoperative measure and decrease significantly in the following periods up to 3 months post-surgery. There was no significant difference between ECAP threshold measured in the intraoperative and 1 month, 2 month and 3 months post-surgery. o Impedance measurement should be carried at each follow up time till stabilization of values. o ECAP threshold obtained intraoperatively can be used for interpreting map in children if could not be done postoperative in the measured electrodes.

Does The Length Of Electrode Array Affect The Hearing Preservation Rate And Speech Recognition? A Systematic Review And Meta-Analysis

Sara bayounos[2], **Zohour almalki**[1], **Shrooq alswat**[1], **Ahmad alqurashi**[1], **Noura Najeem**[1], **Abdulrahman kabli**[1], **Hylayil almuqati**[1], **Reema althobaiti**[1], **Rahaf G. Altwairqi**[1]

[1]*Alhada armed forces hospital;* [2]*King Abdullah medical specialities city hospital*

BACKGROUND & AIM

To evaluate whether long versus medium-length cochlear implant electrode arrays

affect speech recognition and hearing preservation outcomes.

MATERIAL & METHODS

A systematic review and meta-analysis was conducted using PubMed, Scopus, Web of

Science, and the Cochrane Library for studies published from 2020 to 2025. Eligible studies compared long (≥28 mm) versus medium-length (24–26 mm) electrode arrays and reported speech recognition and/or hearing preservation outcomes. Data were pooled using random-effects meta-analysis with hazard ratios (HRs) and 95% confidence intervals (CIs).

RESULTS

Eight studies involving 956 patients were included. Meta-analysis of speech recognition outcomes showed a significant advantage for longer electrodes (HR 1.11, 95% CI 1.06-1.16; p < .0001) with no heterogeneity (I^2 = 0%). For hearing preservation, seven studies showed a pooled HR of 1.14 (95% CI 1.06-1.22; p = .0001) with moderate heterogeneity (I^2 = 36.6%). SubgrouP findings suggested that soft-surgery techniques and flexible lateral wall designs reduce the risk of cochlear trauma during deeper insertions.

CONCLUSIONS

Longer electrode arrays were associated with better speech recognition without clear compromise in hearing preservation when atraumatic insertion techniques were used. Electrode selection should remain individualized according to cochlear anatomy, preoperative hearing, and patient goals.

COCHLEAR IMPLANTATION WITH POSTERIOR EXTERNAL AUDITORY CANAL WALL RECONSTRUCTION IN A CHILD WITH OTITIS MEDIA WITH EFFUSION AND TYMPANIC MEMBRANE RETRACTION. CASE REPORT

MADINA KURGANBEKOVA[1], **ABILEV ARMAN**[1], **ABILEVA ASEL**[1], **MAHANOVA MERUERT**[1]

[1]*City Children's Hospital No. 2, Astana, Kazakhstan*

BACKGROUND & AIM

Cochlear implantation in patients with chronic middle ear disease, including otitis media with effusion and tympanic membrane retraction, remains surgically challenging due to persistent inflammation and altered anatomy of the middle ear and mastoid. In such cases, anatomical constraints, such as a narrow sinodural angle, may further complicate standard surgical access and require modification of the operative technique.

The aim of this study is to evaluate the feasibility and safety of cochlear implantation combined with simultaneous sanitation of the middle ear and reconstruction of the posterior wall of the external auditory canal in a pediatric patient with chronic middle ear pathology.

MATERIAL & METHODS

A 10-year-old child with a history of recurrent purulent otitis media and progressive hearing loss since the age of 5 years was evaluated. Preoperative assessment included auditory brainstem response (ABR), which revealed sensorineural hearing loss grade III on the right and grade IV on the left. Temporal bone computed tomography demonstrated bilateral total opacification of the mastoid and antrum with a narrow sinodural angle, while otoscopic examination showed bilateral tympanic membrane retraction.

A single-stage surgical procedure was performed, including middle ear exploration and sanitation, removal of granulation tissue, tympanoplasty using cartilage graft, antromastoidotomy with partial removal of the posterior external auditory canal wall due to anatomical constraints, posterior tympanotomy, cochlear implantation via the round window approach, and reconstruction of the posterior canal wall using a cortical bone graft harvested from the mastoid cortex.

RESULTS

The postoperative period was uneventful, with no surgical or infectious complications. Wound healing occurred by primary intention. Cochlear implant activation was performed according to the standard protocol.

Postoperative computed tomography confirmed correct positioning of the electrode array within the cochlea. No displacement of the reconstructed posterior external auditory canal wall was observed. The tympanic membrane reconstruction remained stable without signs of retraction or graft failure.

During follow-up, a stable anatomical condition of the middle and external ear was noted, with preservation of the reconstructed structures and satisfactory postoperative healing.

CONCLUSIONS

The presented clinical case demonstrates that cochlear implantation can be safely and successfully performed in a child with chronic middle ear pathology, including otitis media with effusion and tympanic membrane retraction, when appropriate surgical modifications and adequate middle ear sanitation are applied.

Anatomical challenges, such as a narrow sinodural angle and intraoperative need for partial posterior external auditory canal wall removal, may increase surgical complexity; however, they do not represent an absolute contraindication for cochlear implantation.

Careful preoperative assessment, individualized surgical planning, and the possibility of simultaneous reconstruction allow achievement of stable anatomical and functional outcomes in such complex cases.

Clinical Optimization Of Monothermal Caloric Testing For A Screening Unilateral Vestibular Dysfunction Using Air And Water Stimulation.

Ji Hyung Lim[1], **Jae Sang Han**[1], **Shi Nae Park**[1], **Kyoung Ho Park**[1], **Jae-Hyun Seo**[1]

[1]*Department of Otolaryngology-Head & Neck Surgery, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea*

BACKGROUND & AIM

To optimize monothermal caloric testing (MCT) as a screening tool for unilateral vestibular dysfunction by establishing clinically appropriate cutoff values for air and water stimulation and by evaluating its diagnostic performance relative to bithermal caloric testing (BCT) and other vestibular function tests.

MATERIAL & METHODS

We retrospectively analyzed air and water caloric test data from patients who underwent comprehensive vestibular evaluation. Unilateral vestibular weakness was defined using BCT canal paresis thresholds of ≥20% and ≥25%. Screening performance of monothermal warm caloric testing was assessed using sensitivity, specificity, and negative predictive value (NPV).

RESULTS

Using BCT ≥20 as the reference standard, the optimal mono warm cutoff was ≥12% for air caloric testing and ≥14% for water caloric testing, with reliable screening performance achieved only when the sum of bilateral warm responses was ≥15. Under the stricter BCT ≥25 criterion, the optimal mono warm cutoff increased to ≥15% for air caloric testing, while it remained ≥14% for water caloric testing; in both modalities, a summed bilateral warm response ≥15 was required to ensure stable screening performance. Under these modality- and severity-specific criteria, monothermal warm testing consistently demonstrated high sensitivity and negative predictive value for ruling out clinically significant unilateral vestibular weakness. In comparisons with other vestibular function tests, MCT showed moderate predictive performance for posturography abnormalities but limited prediction of video head impulse testing and cervical vestibular-evoked myogenic potentialabnormalities, whereas BCT showed higher predictive performance for vHIT abnormalities, particularly under the BCT ≥25 threshold.

CONCLUSIONS

: Optimized monothermal warm caloric testing provides a reliable screening strategy for unilateral vestibular dysfunction when interpreted using stimulation- and severity-specific cutoff values with confirmed response adequacy.

Comprehensive Vestibular Laboratory Findings Following Head Injury: A Retrospective Clinical Cohort Study

Amy Lennox-Bowley[1], **Soumit Dasgupta**[1]

[1]*Hypatia Specialist Clinic;* [2]*University of Middlesex*

BACKGROUND & AIM

Persistent dizziness, imbalance, visual motion sensitivity, and spatial disorientation are common yet frequently under-recognized sequelae following head injury. Despite increasing awareness of post-traumatic vestibular dysfunction, objective peripheral vestibular abnormalities may remain undetected without comprehensive vestibular laboratory assessment. Advances in vestibular diagnostics now allow detailed evaluation of semicircular canal and otolith pathway integrity following traumatic injury. This study aimed to characterize peripheral vestibular laboratory abnormalities and associated functional disability in patients presenting with persistent vestibular symptoms following head injury.

MATERIAL & METHODS

A retrospective clinical cohort study was performed reviewing patients referred to a vestibular laboratory with persistent vestibular symptoms following head injury. Comprehensive vestibular assessment included video Head Impulse Testing (vHIT), Suppression Head Impulse Paradigm (SHIMP), cervical Vestibular Evoked Myogenic Potentials (cVEMP), ocular Vestibular Evoked Myogenic Potentials (oVEMP), videonystagmography (VNG), bithermal caloric irrigation, positional testing, and Dizziness Handicap Inventory (DHI) evaluation. Clinical variables including mechanism of injury, symptom chronicity, vestibular laboratory findings, and functional disability scores were reviewed and analyzed. Ongoing subgroup and correlation analyses are currently being completed.

RESULTS

At the time of abstract submission, 50 patients had undergone comprehensive vestibular laboratory assessment following head injury. Preliminary review demonstrated a high prevalence of objective peripheral vestibular abnormalities involving both semicircular canal and otolith pathways. Frequently observed abnormalities included reduced vestibulo-ocular reflex gains on vHIT, abnormal SHIMP responses consistent with vestibular hypofunction, caloric asymmetry, positional nystagmus, and abnormal cVEMP/oVEMP responses suggestive of otolith dysfunction. Elevated DHI scores reflected substantial functional impairment and persistent symptom burden. Multisystem vestibular involvement was commonly identified, suggesting complex post-traumatic vestibular injury patterns not fully characterized through isolated vestibular testing modalities alone. Final statistical analyses and symptom correlation assessments remain ongoing.

CONCLUSIONS

Comprehensive vestibular laboratory assessment identified a substantial burden of objective peripheral vestibular dysfunction in patients following head injury. Combined multimodal testing incorporating vHIT, SHIMP, VEMP assessment, caloric testing, and positional evaluation may improve diagnostic sensitivity and characterization of post-traumatic vestibular phenotypes. These findings support the growing role of advanced vestibular diagnostics in precision vestibular medicine and targeted rehabilitation pathways following traumatic injury. Further analysis will evaluate relationships between vestibular laboratory abnormalities, symptom severity, and persistent functional disability.

From A Horrible To An Enjoyable Life

Bushra Alhakami[1]

[1]*Prince Sultan Military Medical City;* [2]*MSKcare Clinic*

BACKGROUND & AIM

Vestibular hypofunction is a disabling condition that can significantly affect balance, mobility, daily functioning, and quality of life. Vestibular Rehabilitation Therapy (VRT) has been shown to improve vestibular compensation and functional performance in individuals with vestibular disorders. This case report aims to describe the physiotherapy assessment, rehabilitation process, and clinical outcomes of a 28-year-old male with severe vestibular hypofunction and vestibular migraine symptoms following recurrent instability episodes. Written informed consent was obtained from the patient for presentation and publication of this case.

MATERIAL & METHODS

A 28-year-old male presented with a four-year history of recurrent instability that began following severe sinusitis, with worsening symptoms in recent weeks. Symptoms included continuous imbalance aggravated by head and body movement, visually busy environments, phonophobia, photophobia, and nausea. Previous cervical vestibular evoked myogenic potential (cVEMP) testing demonstrated reduced amplitude on the right side and absent responses on the left side.

Initial physiotherapy assessment identified limited head movement, cautious gait, neck muscle spasm, positive Head Impulse Test (HIT), abnormal Fukuda Stepping Test, and impaired balance. The patient was unable to maintain standing balance with

eyes closed for more than five seconds. Dix–Hallpike testing was negative. Symptoms significantly affected driving ability, academic performance, and social participation.

The patient underwent seven sessions of Vestibular Rehabilitation Therapy between 2/10/2025 and 26/11/2025. The program included vestibulo-ocular reflex exercises, balance retraining, postural control exercises, vestibular habituation exercises, and a customized home exercise program.

RESULTS

Following seven rehabilitation sessions, the patient demonstrated noticeable improvement in balance, coordination, and functional confidence. Initially, the patient lacked confidence in movement and preferred remaining seated on the floor due to fear of instability and falling. By the end of the rehabilitation period, he progressed to participating in more dynamic and recreational activities, including playing on a roller coaster, reflecting a substantial improvement in functional ability and symptom tolerance.

The patient also progressed from being unable to maintain eyes-closed standing balance for more than five seconds to maintaining balance on a foam surface with eyes closed for one minute. Improvements were observed in gait coordination and functional activities, including walking and ball-catching tasks. Furthermore, improvement in the Dizziness Handicap Inventory (DHI) score indicated a reduction in symptom severity and dizziness-related functional limitations. The patient additionally reported improved stability and confidence during movement.

CONCLUSIONS

This case highlights the potential effectiveness of individualized Vestibular Rehabilitation Therapy in improving balance, coordination, and functional performance in patients with severe vestibular hypofunction. Early physiotherapy assessment, progressive vestibular exercises, and adherence to a tailored home exercise program may support vestibular compensation and improve quality of life in individuals with chronic vestibular dysfunction.

Screening Of Osteoporosis Drugs For Their Effects On Otolith Formation Using A Zebrafish Model

Kazuma Sugahara[1], **Makoto Hashimoto**[1], **Junko Tsuda**[1], **Mei Sakamoto**[1]

[1]*Department of Otolaryngology, Yamaguchi University Graduate School of Medicine*

BACKGROUND & AIM

BPPV is associated with osteoporosis and calcium metabolism, but the mechanisms linking systemic calcium homeostasis to otolith formation remain unclear. Using transparent and pharmacologically tractable zebrafish larvae, we examined the effects of calcium-disrupting agents and osteoporosis-related drugs on otolith formation.

MATERIAL & METHODS

Zebrafish larvae were exposed to cadmium, dexamethasone, and osteoporosis-related drugs. Otolith size was measured after Alizarin Red S staining, and whole-body calcium content was quantified by colorimetric assay.

RESULTS

Cadmium reduced calcium levels and otolith size, whereas dexamethasone decreased calcium but induced otolith enlargement with structural disruption. Most osteoporosis drugs had no effect, but ipriflavone partially suppressed otolith enlargement.

CONCLUSIONS

Otolith formation is regulated by local mechanisms beyond systemic calcium levels. Ipriflavone may modulate otolith homeostasis, and zebrafish provide a useful model for drug screening relevant to vestibular disorders such as BPPV.

Development Of Real-Time 3D Video-Oculography Using 9-Axis Sensor And Galvanic Evoked Vestibulo-Ocular Response.

Makoto HASHIMOTO[1], **Yosuke OKINAKA**[1], **Junko TSUDA**[1], **Mei SAKAMOTO**[1], **Haruka NAKABAYASHI**[1], **Kazuma SUGAHARA**[1]

[1]*Department of Otolaryngology, Yamaguchi University Graduate School of medicine*

BACKGROUND & AIM

Video-oculography (VOG) is crucial for vestibular diagnosis, but accurately measuring nystagmus during Galvanic Vestibular Stimulation (GVS) remains challenging. Building on our previous HI-VOG system, we developed 'yVOG-Glass,' a high-quality

video Frenzel system. This study aims to present yVOG-Glass and demonstrate its capability for real-time, quantitative 3D nystagmus analysis to facilitate the precise evaluation of GVS-induced responses.

MATERIAL & METHODS

The video image from a Frenzel with high quality image camera was captured at 60 frames per second at a resolution of 640*480 pixels. For real-time analysis of the horizontal and vertical components, the X-Y center of the pupil was calculated. For real-time analysis of torsional components, the whole iris pattern was overlaid with the same area of the next iris pattern, and the angle at which both iris patterns showed the greatest match was calculated. Furthermore, a 9-axis sensor was integrated into the yVOG-Glass to monitor head movement in real-time, allowing for the correction of eye movement data. Galvanic evoked vestibulo-ocular response was monitored.

RESULTS

Accurate measurements of horizontal, vertical and torsional eye movement were taken while recording the video image in real-time. For quantitative analysis, the slow phase velocity of each occurrence of nystagmus and the average value of the slow phase velocity were analyzed automatically. it was possible to carry out accurate recording and evaluation of nystagmus.

CONCLUSIONS

Using the yVOG-Glass system, it was possible to perform real-time quantitative 3D analysis of nystagmus from video images recorded with high quality video Frenzel. Recent technological developments, including the use of improved VOG, might lead to the rediscovery of GVS.

Vestiheal: An AI-Supported Holistic Digital Therapeutic Platform For Vestibular Disorders — Early Findings From An Ongoing Prospective Clinical Trial

Amy Lennox-Bowley[1]

[1]*Hypatia Specialist Clinic;* [2]*University of Middlesex*

BACKGROUND & AIM

Chronic vestibular disorders are frequently associated with dizziness, imbalance, vestibular migraine, anxiety, and reduced quality of life. Conventional vestibular rehabilitation often focuses primarily on exercise-based therapy with limited integration of psychological support and symptom-responsive care. VestiHeal is a novel artificial intelligence (AI)-supported digital therapeutic platform designed as a holistic vestibular care companion integrating adaptive rehabilitation exercises, cognitive behavioural therapy (CBT)-informed strategies, migraine support pathways, real-time symptom monitoring, eye movement recording, and clinician-supervised remote monitoring. This study evaluates the feasibility, usability, patient engagement, and early clinical observations associated with VestiHeal in chronic vestibular disorders.

MATERIAL & METHODS

An ongoing prospective pilot study is being conducted in adults diagnosed with peripheral vestibular hypofunction, vestibular migraine, or persistent postural-perceptual dizziness (PPPD). Participants engage in a structured home-based therapeutic program delivered through the VestiHeal platform. Integrated platform components include AI-guided exercise progression, dynamic symptom tracking, CBT-informed support tools, migraine education modules, eye movement recording capability, and remote clinician oversight with adaptive intervention monitoring. Outcome measures include Dizziness Handicap Inventory (DHI), Visual Analogue Scale (VAS) dizziness severity, adherence metrics, patient engagement analytics, and user-reported usability outcomes. Interim descriptive analyses were performed on participants actively enrolled in the study protocol at the time of abstract submission.

RESULTS

At abstract submission, 18 participants had been recruited into the ongoing clinical trial, with enrolment and longitudinal follow-up continuing toward the planned study cohort. Early observations demonstrate high patient engagement with the integrated therapeutic platform, sustained adherence to prescribed rehabilitation activities, and positive usability feedback across multiple symptom domains. Participants reported increased confidence in independently managing vestibular symptoms and highlighted the value of combining rehabilitation exercises, symptom-responsive guidance, migraine resources, and psychological support strategies within a single accessible platform. Clinicians reported enhanced ability to remotely monitor symptom progression, patient engagement, and rehabilitation tolerance throughout therapy. Final longitudinal outcome analyses remain ongoing and will be completed prior to congress presentation.

CONCLUSIONS

Early findings suggest that VestiHeal is a feasible and clinically promising AI-supported holistic vestibular therapeutic platform capable of integrating rehabilitation, behavioural support, symptom-responsive intervention, and remote clinician monitoring within a unified digital care pathway. This multidimensional model may support improved accessibility, adherence, patient

empowerment, and individualized vestibular care delivery across geographically diverse populations. Ongoing analysis will further evaluate clinical effectiveness and the future role of integrated digital therapeutics within modern vestibular medicine.

PP-052

Assessment Of Saudi Physicians And Physical Therapists' Adherence To The Updated Clinical Practice Guideline For Benign Paroxysmal Positional Vertigo: A Cross-Sectional Study

Bushra Alhakami[1], **Dr. Maha Almarwani**[2]

[1]*Prince Sultan Military Medical City;* [2]*King Saud University*

BACKGROUND & AIM

Introduction Variations in clinical practice regarding the management of benign paroxysmal positional vertigo (BPPV) among clinicians have been noted in previous studies. Such variations might be related to the different adherence to clinical practice guidelines.

Objective To evaluate clinicians' adherence to BPPV guidelines and investigate the variations in the adherence between different specialties and qualifications.

MATERIAL & METHODS

This is a cross-sectional study with a vignettes-based survey conducted between June and August, 2020. We included clinicians engaged in managing BPPV that had at least one year of clinical experience. We excluded students, and clinicians who were not involved in the management of individuals with BPPV. Participants were asked to make their management choices based on four hypothetical patient vignettes. The sample ranged from 77 participants for the first vignette to 45 participants for the last vignette.

RESULTS

We included 77 clinicians in the study, with the majority being Otolaryngologists (31.2%). The respondents' mean adherence to the guideline was of 63.3%. Result showed that Otolaryngologists' adherence was higher than that of clinicians from different specialties ($p = 0.006$, $d = 0.72$). Furthermore, clinicians with a postgraduate degree were more likely to adhere than those with a bachelor's degree only ($p = 0.014$, $d = 0.58$) and participants who were aware of the guideline were more likely to adhere to it ($p < 0.001$, $d = 1.05$). Lastly, regression analysis exhibited that adherence was affected by postgraduate degree and guideline awareness

CONCLUSIONS

Otolaryngologists were more likely to adhere to the guideline than other specialties. Among all specialties, higher adherence was associated with guideline awareness and postgraduate degrees.

Postural Bias In Acute Unilateral Vestibulopathy: Interpretation With The Velocity-Storage Function

Jeong-Yoon Choi[1], **Hyo-Jung Kim**[1], **Ji-Soo Kim**[1]

[1]*seoul national university bundang hospital;* [2]*seoul national university college of medicine*

BACKGROUND & AIM

There have been arguments and ambiguities regarding the clinical utility and mechanism of characteristic postural biases in patients with acute unilateral vestibulopathy.

MATERIAL & METHODS

We studied 30 patients (59.8±11.4 years) with acute and subacute unilateral vestibulopathy with 27 controls (44.2±14.5 years). Postural biases were evaluated using the body rotation angle and displacement in the stepping test. The body rotation angle was the angle of interaural lines at starting and at final position. The displacement was the position after stepping on polar coordinates, expressed by the displacement distance and angle. The postural biases were compared with modern vestibular tests and the mechanisms were investigated using a velocity-storage function model.

RESULTS

In the patient group, the body rotation angle was 24.0° (±24.3°) and the displacement angle was 31.3° (±34.1°). The displacement distance was 33.0 cm (±18.8 cm). Only around half of the patients exhibited abnormal or ipsilesional postural biases. However, the displacement and body rotation angles were well correlated with the findings of modern vestibular tests, highlighting the supplementary role of postural biases in determining the lesions. When comparing postural biases between patients and controls, we observed that the stepping-induced forward displacement and body rotation were insufficient to

explain the patients' displacement angle and distance. Instead, the incorporation of the inertia formed by the velocity-storage circuit provided a better explanation for the observed displacement distance and angle.

CONCLUSIONS

Postural biases in patients with acute unilateral vestibulopathy can vary but be predicted precisely by considering the function of the velocity-storage circuit.

Posturographic Quantification Of Sway Misperception Enables Accurate Identification Of Persistent Postural-Perceptual Dizziness In Neurotology Clinics

Rin Shida[1], **Yukihide Maeda**[1], **Masafumi Sawada**[1], **Tomoyasu Kitahara**[1], **Takumi Yamaguchi**[1], **Hiroe Kudo**[1], **Yu Hosokawa**[1], **Tetsuo Ikezono**[1]

[1]*Saitama Medical University*

BACKGROUND & AIM

Persistent postural-perceptual dizziness (PPPD) is characterized by chronic dizziness that develops after a precipitating vestibular disorder and are exacerbated by body motion and visual stimulation. These symptoms may reflect altered sensory thresholds across visual, vestibular, and proprioceptive systems, leading patients to perceive postural imbalance as greater than is objectively present.

MATERIAL & METHODS

We retrospectively reviewed medical records of patients who underwent the posturographic assessment of sway misperception. Using a force platform, center-of-pressure sway was first measured during upright standing with eyes closed. Participants then opened their eyes and were asked to reproduce, as accurately as possible, the magnitude of sway they had subjectively experienced during the preceding eyes-closed condition. For each metric, a reproduction rate (RR) was calculated as the ratio of the reproduction (eyes open) value to the original eyes-closed value. RR for postural sway area (PSA) and velocity of path length (VPL) were compared between patients with PPPD (n=19) and those with peripheral balance disorders (n=20) using Mann-Whitney U-test. Receiver operating characteristic (ROC) analyses assessed the ability of RRs to discriminate PPPD from peripheral balance disorders.

RESULTS

The RR for PSA was significantly higher in PPPD (4.00(1.51), mean(SD)) than in peripheral balance disorders (1.70(0.74); P<0.001). The RR for VPL was also higher in PPPD (1.61(0.45)) than in peripheral balance disorders (1.12(0.37); P=0.001). On ROC analysis, the PSA RR identified PPPD with sensitivity 1.00 and specificity 0.75 (cutoff 1.89; AUC 0.94; 95% CI, 0.87–1.00). The VPL RR yielded sensitivity 0.63 and specificity 0.90 (cutoff 1.55; AUC 0.81; 95% CI, 0.67–0.95).

CONCLUSIONS

Patients with PPPD demonstrated marked over-reproduction of postural sway, supporting the presence of sway misperception and providing a potentially useful adjunctive marker for diagnosis of PPPD. This tendency to overestimate imbalance is consistent with prior evidence of heightened subjective vertical misperception reported using the Subjective Visual Vertical test.

Normal And Abnormal Inner Ear Third Windows (Atypical Third Window Case Presentation)

samir Assal[1]

[1]*Faculty of medicine , Alexandria University*

BACKGROUND & AIM

Conductive hearing loss (CHL) is defined as an air-bone gap on audiometry, in patients without obvious middle ear pathologic findings. Recent investigations have suggested that many of these cases are due to disorders of the inner ear, resulting in pathologic third windows. The aim of this presentation is To provide an overview of lesions of the inner ear resulting in a CHL due to a third-window mechanism. The mechanism of the CHL is explained along with a classification scheme for these disorders.

The Evolving Role Of ENT Specialists: From Surgeons To System-Based Physicians

Sanja Nikolova[1], **Emil Nikolov, MD**[2]

[1]Department of Otorhinolaryngology, Health Center "Zeleznicar", Gradski Zid 4, Building 1, 1000 Skopje, North Macedonia; [2]University Medical Centre Ljubljana (UKC Ljubljana) Zaloska cesta 2 ,1000 Ljubljana, Slovenia

BACKGROUND & AIM

Growing evidence indicates that many common ENT conditions—such as chronic tinnitus, vertigo, rhinosinusitis, and olfactory disorders—result from the complex interplay of various systemic interactions involving neuroinflammation, hormonal influences, metabolic dysfunction, and microbiome imbalances. This paradigm shift emphasizes the need for moving beyond the conventional to a more holistic approach to patient care. In this study, we aimed to explore the role of the future ENT specialist in light of the above paradigm shift.

MATERIAL & METHODS

We reviewed current evidence related to the intricate relationship between ENT diseases and various systemic disorders. We focused on systemic mechanisms underlying common ENT disorders and plausible approaches to guide individualized interventions. Key aspects included lifestyle and dietary optimization, micronutrient and antioxidant support, neurovascular and autonomic modulation, and precision diagnostics.

RESULTS

Recognizing ENT diseases as systemic conditions enables early intervention, symptom reduction, and improved quality of life. Multidisciplinary, non-surgical strategies complement conventional surgical and pharmacologic therapies, fostering patient-centered, individualized care.

CONCLUSIONS

The future ENT specialist must balance surgical expertise with integrative, evidence-based, non-surgical management. Embracing this shift will transform ENT practice from reactive treatment to proactive, holistic patient care.

Prevalence Of Meniere's Disease In Japan: A Nationwide Study Using The National Database Of Health Insurance Claims

Misuzu Fujita[1], **Kengo Nagashima**[2], **Yoshihiro Onouchi**[3], **Takehiko Fujisawa**[1], **Akira Hata**[1]

[1]Department of Health Research, Chiba Foundation for Health Promotion and Disease Prevention, Chiba, Japan; [2]Biostatistics Unit, Clinical and Translational Research Center, Keio University Hospital, Tokyo, Japan; [3]Department of Public Health, Chiba University Graduate School of Medicine, Chiba, Japan

BACKGROUND & AIM

Estimating the prevalence of Meniere's disease (MD) is challenging because of methodological limitations and disease rarity. To our knowledge, the prevalence of MD throughout Japan has not been previously reported. This study aims to clarify the prevalence of MD in Japan.

MATERIAL & METHODS

Data from January 2014 through December 2022 were obtained from the National Database of Health Insurance Claims of Japan. Patients with MD were defined as those with insurance claims listing MD as a diagnosis and indicating the use of steroids or isosorbide. The number of patients with MD was counted for each year, and population data for October, published by the Ministry of Internal Affairs and Communications, were obtained. Poisson regression analyses were performed using the number of patients as the dependent variable, slope change (increasing by 1 from 2014 to 2022) and pulse change (1 in 2020 and 0 otherwise) as independent variables, and population size as the offset term. Pulse change was included to account for the impact of the COVID-19 pandemic. Subgroup analyses were conducted according to sex and age (10-year age groups).

RESULTS

The prevalence of MD in 2022, the most recent year analyzed, was 440.9 per 100,000 people (259.6 in men and 612.5 in women). The age group with the highest prevalence was 40-49 years. In both men and women, prevalence increased gradually between 2014 and 2022 (p for slope change < 0.001), with a temporary decline in 2020 (p for pulse change < 0.001). The average annual change in prevalence was 14.0 per 100,000 population (95% confidence interval: 13.8, 14.1). Prevalence increased gradually in age groups younger than 70 years, whereas it decreased gradually in those aged 70 years and older.

CONCLUSIONS

This study clarified the prevalence of MD in Japan using a comprehensive insurance claims database. These findings provide valuable baseline data for the prevention and treatment of MD.

Management Of BPPV: Knowledge And Practice Among Physicians And Physical Therapists In Saudi Arabia

Bushra Alhakami[1], **Dr. Maha Almarwani**[2]

[1]*Prince Sultan Military Medical City;* [2]*King Saud University*

BACKGROUND & AIM

Benign paroxysmal positional vertigo (BPPV) is the most common peripheral vestibular disorder, with effective management depending on adherence to clinical practice guidelines (CPGs). However, evidence suggests variability in the awareness and application of recommended diagnostic and treatment maneuvers among healthcare providers. This study aimed to assess the knowledge and clinical practices of physicians and physical therapists in Saudi Arabia regarding BPPV management.

MATERIAL & METHODS

A cross-sectional questionnaire survey was conducted among 134 clinicians. The survey assessed professional characteristics, knowledge of BPPV diagnostic and treatment maneuvers, and referral practices. Associations between characteristics and outcomes were examined using Chi-square tests, with odds ratios and 95% confidence intervals (CIs) calculated. Binary logistic regression was applied to identify factors associated with familiarity and performance of BPPV maneuvers.

RESULTS

Of the respondents, 66.4% were aware of BPPV CPGs. While familiarity with diagnostic and treatment maneuvers was relatively high, their application in practice was lower. Only 3.7% of physicians referred patients to physical therapy, primarily due to a lack of awareness. Specialty, postgraduate degree, work setting, and awareness of CPGs were significantly associated with greater knowledge and practice. Logistic regression identified that age, specialty, postgraduate degree, and CPGs awareness were associated with familiarity, while gender, work setting, and experience were associated with performance.

CONCLUSIONS

Clinicians demonstrated good knowledge of BPPV management, but limited application and referral practices. These findings highlight the need for structured, hands-on training workshops and educational initiatives to enhance clinical competence and promote the role of physical therapy in vestibular rehabilitation.

Incidence Of Peripheral Vestibular Disorders Based On Population Data Of Korea

Ah Young Bae[1], **Tae Mi Youk**[2], **Junhui Jeong**[1]

[1]*Department of Otolaryngology-Head and Neck Surgery, Bucheon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea;* [2]*Research and Analysis Team, National Health Insurance Service Ilsan Hospital, Goyang, Korea*

BACKGROUND & AIM

There have been no comprehensive studies on the incidence of peripheral vestibular disorders based on population-based data for a long-term period. We investigated the incidence of peripheral vestibular disorders using population-based data representing the whole population of Korea.

MATERIAL & METHODS

This study used the National Health Insurance Service data in Korea from 2008 to 2020. Peripheral vestibular disorders such as benign paroxysmal positional vertigo (BPPV), vestibular neuritis (VN), and Meniere's disease (MD) were defined with diagnostic, treatment, or audiovestibular test codes. The annual incidence in total and according to sex, age, and residence was analyzed.

RESULTS

The annual incidence of BPPV, VN, and MD per 100,000 was 51.4, 22.7, and 12.4 in 2008 and 346.4, 62.9, and 50.5 in 2020, respectively. The incidence of each was significantly different by sex ($p < 0.001$), age ($p < 0.001$), and residence ($p < 0.001$), with the highest value in female, people aged 60 years or older, and people who resided in metropolitan cities.

CONCLUSIONS

The annual incidence of BPPV, VN, and MD had increasing trends from 2008 through 2020 in Korea, and all were significantly higher in female, people aged 60 years or older, and people who resided in metropolitan cities.

Evaluation Of The Protective And Therapeutic Effects Of Alpha Lipoic Acid In Cisplatin Vestibulotoxicity

Gülçin HANÇER ARSLAN[1,2], **Murat ARSLAN**[1,2], **Onur Ersoy**[3], **Oktay Kaya**[4], **Erdoğan BULUT**[1,2]

[1]Trakya University Institute of Health Sciences; [2]Trakya University Mirko Tos Hearing Research Center; [3]Trakya University School of Health Services Vocational College, Pathology and Laboratory Techniques Program; [4]Trakya University Faculty of Medicine, Department of Physiology

BACKGROUND & AIM

Although cisplatin is a widely used antineoplastic agent, its ototoxicity poses a significant clinical limitation. While cisplatin-induced cochleotoxicity has been extensively studied, its effects on the vestibular system remain poorly understood. Due to its potent antioxidant properties, alpha-lipoic acid (ALA) has emerged as a promising protective agent. In this study, the aim was to comparatively evaluate the efficacy of prophylactic and therapeutic ALA administration against cisplatin-induced cochlear and vestibular toxicity in a rat model using electrophysiological, biochemical, and histopathological methods. It was hypothesized that prophylactic administration would provide superior protection compared to therapeutic administration.

MATERIAL & METHODS

Forty-two Wistar albino rats (84 ears) were divided into five groups: Group 1 control; Group 2 ototoxic (cisplatin 12 mg/kg single dose intraperitoneal, IP); Group 3 ALA alone (100 mg/kg/day × 3 days IP); Group 4: prophylactic (ALA + cisplatin); and Group 5: therapeutic (cisplatin + ALA). Distortion product otoacoustic emissions (DPOAE), auditory brainstem response (ABR), and cervical vestibular evoked myogenic potential (c-VEMP) measurements were performed on days 0, 3, 7, and 14. Serum Ribeye/CtBP2, total antioxidant capacity (TAC), and Otolin-1 levels were measured by ELISA on days 7 and 14. Histopathological evaluation was performed using light microscopy, immunohistochemistry (inducible nitric oxide synthase, iNOS), and scanning electron microscopy. Institutional review board approval was obtained.

RESULTS

In Group 2, a progressive decrease in the signal-to-noise ratio at all DPOAE frequencies, a significant increase in ABR thresholds, and marked deterioration in c-VEMP parameters were observed ($p<0.001$). Prophylactic ALA (Group 4) provided significant protection across all electrophysiological parameters, whereas therapeutic ALA (Group 5) demonstrated only partial protection. Serum Ribeye levels were highest in Group 2 and significantly lower in the prophylactic group ($p<0.001$). Otolin-1 levels were significantly higher in Group 2 on day 7 ($p=0.032$). Histopathological evaluation revealed severe damage in Group 2, while significant protection was observed in the ALA groups; no deviations from the control were detected in any parameter in Group 3.

CONCLUSIONS

This study is the first experimental study to evaluate the protective effect of ALA against cisplatin-induced vestibulotoxicity using c-VEMP. Prophylactic administration demonstrated a clear superiority over therapeutic administration at both the cochlear and vestibular levels. The fact that ALA alone does not cause adverse effects on inner ear function provides important safety data for clinical translation. The findings support the evaluation of prophylactic antioxidant strategies, including vestibular protection, in patients scheduled for cisplatin chemotherapy.

Orbital Floor Fracture Reduction With Prelacrimal Approach

Taeyoung Jung[1]

[1]*Department of Otorhinolaryngology Head and Neck Surgery, Maryknoll Medical Center, Busan, Korea*

BACKGROUND & AIM

Orbital floor fractures may cause herniation or entrapment of orbital contents, resulting in diplopia, enophthalmos, and functional impairment. Surgical reduction is required in selected cases to restore orbital anatomy and volume. Conventional approaches—including transorbital, transantral, and intranasal routes—have limitations such as visible scarring, sensory disturbance, or restricted surgical view. The endoscopic prelacrimal approach provides direct access to the orbital floor with minimal invasiveness. This study aimed to present three cases of orbital floor fracture reduction using the prelacrimal approach and reconstruction with an autologous bone chip harvested from the medial maxillary sinus wall.

MATERIAL & METHODS

Three patients with orbital floor fractures underwent endoscopic reduction using the prelacrimal approach. A vertical incision was made at the anterior border of the inferior turbinate, and the nasal mucosa was elevated to expose the medial wall of the maxillary sinus while preserving the nasolacrimal duct. A bony window was created in the medial maxillary sinus wall using an osteotome, and the harvested bone chip was preserved. Through this window, the maxillary sinus and fractured orbital floor were directly visualized. Herniated orbital contents were reduced, and the autologous bone chip was trimmed according to the size of the defect and inserted to reinforce the reduced orbital floor. Fibrin glue was applied for stabilization. Postoperative clinical outcomes and radiologic findings were evaluated.

RESULTS

All three patients underwent successful reduction of orbital floor fractures using the prelacrimal approach with autologous bone chip reconstruction. Postoperative symptoms such as diplopia and ocular discomfort improved in all cases. Follow-up computed tomography performed in the early postoperative period and several months later demonstrated well-maintained reduction of the orbital floor without recurrent herniation of orbital contents. No significant complications, including nasolacrimal duct injury, facial numbness, or postoperative sinusitis, were observed. During follow-up periods of up to six months, patients showed stable anatomical outcomes and satisfactory functional recovery without persistent ophthalmologic abnormalities.

CONCLUSIONS

The endoscopic prelacrimal approach offers a minimally invasive and effective option for orbital floor fracture reduction. This technique provides direct visualization of the fracture site and allows reconstruction using an autologous bone chip harvested during the approach. Our cases suggest that this method can achieve stable fracture reduction with favorable clinical outcomes and minimal complications.

AURICULAR AMPUTATION SECONDARY TO A HUMAN BITE: A RARE CASE REPORT

Mustafa Eser[1]

[1]*Sultan Abdülhamid Han Training and Research Hospital, Ear, Nose and Throat Diseases, Istanbul, Turkiye*

BACKGROUND & AIM

Human bites are injuries associated with a high risk of infection and can lead to severe tissue loss, including auricular amputation (1). This case report aims to highlight the clinical significance of this rare condition by presenting the management of a patient who sustained an auricular amputation during a physical altercation.

MATERIAL & METHODS

Case Report: A 35-year-old male patient presented to the emergency department following the traumatic amputation of his right auricle due to a human bite sustained during an altercation. The patient brought the amputated segment with him. Following the debridement of the amputation stump and evaluation of the surgical margins, the amputate was primarily sutured. Given the high risk of infection, broad-spectrum antibiotic therapy was initiated. However, the patient failed to comply with the recommended postoperative care and was subsequently lost to follow-up.

RESULTS

Human bites constitute a significant medical emergency due to their high bacterial load and propensity to cause mixed infections (1). Cartilaginous structures, such as the auricle, are particularly vulnerable to infection due to their poor vascularity (2). In bite injuries involving tissue loss, prompt debridement and surgical repair are essential approaches to mitigate the risk of infection. Furthermore, common pathogens isolated from human bites include Eikenella corrodens, Streptococcus species, and various anaerobic organisms (2).

CONCLUSIONS

Auricular amputations secondary to human bites are rare injuries that can lead to severe complications. Early surgical intervention, meticulous tissue management, and the administration of broad-spectrum antibiotics significantly enhance treatment success. Ultimately, patient compliance with treatment and follow-up protocols is of vital importance in the prevention of complications.

A Novel Single Stage Reconstruction Of Midline Nasal Dorsum Skin Defects Using An Auricular Composite Graft

Ramazan Bahadır Kucuk[1], **Alper Yenigun**[1], **Fadlullah Aksoy**[1], **Erol Senturk**[1], **Ruveyda Kucuk**[2], **Orhan Ozturan**[1]

[1]*Bezmialem Vakif University, Faculty of Medicine, Department of Otorhinolaryngology;* [2]*Department of Dermatology, University of Health Sciences, Prof. Dr. Cemil Taşçıoğlu City Hospital, Istanbul, Türkiye*

BACKGROUND & AIM

Reconstruction of midline nasal dorsum skin defects following oncologic excision is challenging because of the aesthetic prominence of the region and the limited mobility of surrounding soft tissues. Flap-based techniques are commonly recommended; however, they may be associated with donor-site morbidity, visible scarring, and multistage procedures. Auricular composite grafts are well established for select nasal subunits, but their intentional use for midline nasal dorsum skin reconstruction has not been routinely described.

MATERIAL & METHODS

We describe a novel single-stage reconstructive strategy in which an auricular chondrocutaneous composite graft was deliberately utilized for midline nasal dorsum skin reconstruction following basal cell carcinoma excision. The technique was applied in a carefully selected patient with preservation of the underlying cartilaginous framework. Simultaneous structural support of the nasal dorsum and internal nasal valve was achieved without additional cutaneous incisions.

RESULTS

Complete graft survival was observed without partial or total necrosis. At the 6-month follow-up, the reconstructed nasal dorsum skin demonstrated stable contour with satisfactory color and texture match. No graft contraction, secondary deformity, or late complications were noted. Nasal airway patency was preserved throughout the follow-up period.

CONCLUSIONS

This technical experience suggests that auricular composite grafts may represent a feasible single-stage, low-morbidity alternative to flap-based reconstruction for midline nasal dorsum skin defects in selected cases, while preserving future reconstructive options.

ODONTOGENIC TEMPORAL FOSSA ABSCESS AND SUSPECTED OSTEOMYELITIS: A CASE REPORT

YALÇIN ALİMOĞLU[1], **MURAT TOPBAŞ**[1], **BERKAY YEŞİLLER**[1], **AHMET KARAMANOĞLU**[1], **GÖKÇEN YILMAZ**[1]

[1]*BASAKSEHIR CAM AND SAKURA CITY HOSPITAL*

BACKGROUND & AIM

Temporal fossa and deep temporal space infections are rare but potentially life-threatening due to proximity to critical neurovascular structures.

Odontogenic infections are a major source of deep head and neck infections (2). They most commonly involve the submandibular, buccal, and masticator spaces, whereas extension to the temporal fossa is rare and infrequently reported (1,3).

We present a rare case of odontogenic temporal fossa abscess with extension to deep facial spaces and radiological suspicion of maxillary osteomyelitis. The aim is to highlight this atypical spread pattern and the role of early imaging and multidisciplinary management in preventing complications.

MATERIAL & METHODS

A 71-year-old male presented with progressive left facial swelling following extraction of a left upper molar tooth one week prior. Despite 3 days of initial treatment with amoxicilline-clavulanate and clindamycin therapy, symptoms progressed with diffuse swelling extending to the temporal region.

Examination revealed edema of the left hemiface with fluctuant swelling extending to the frontal and temporal regions, without trismus or neurological deficit. Periorbital edema was present without acute ophthalmologic pathology. Medical history included COPD and coronary artery disease.

Imaging demonstrated soft tissue swelling with air densities in the left temporal and temporoparietal regions. MRI revealed loculated abscess collections within the temporalis muscle extending superiorly to the scalp. Radiological findings raised suspicion of early osteomyelitis in the mandibular ramus.

Empirical intravenous ampicillin-sulbactam and vancomycin were initiated. Surgical drainage was performed under local anesthesia via frontotemporal incisions. A drainage tract was established and maintained with cannulation, followed by daily irrigation and wound care.

RESULTS

Culture grew Streptococcus constellatus; antibiotics were de-escalated. Initial partial improvement was followed by secondary progression. Dental extraction of the infectious focus resulted in rapid clinical response. After 16 days of drainage and intravenous antibiotics, complete regression and normalization of inflammatory markers were achieved (WBC: 6.22, CRP: 6.7). The patient was discharged with oral antibiotics to complete 6 weeks. Follow-up imaging was planned for suspected osteomyelitis.

CONCLUSIONS

Odontogenic infections can rarely extend to the temporal fossa and may progress rapidly, especially in patients with comorbidities which lead to impaired tissue oxygenation and delayed healing. Successful management requires appropriate surgical drainage to prevent re-accumulation and ensure continuous evacuation of purulent material, targeted antibiotic therapy, and elimination of the primary odontogenic focus. The adjunctive use of hydrogen peroxide irrigation can further support local wound hygiene by facilitating debridement in selected cases. Early recognition and multidisciplinary management are crucial not only to prevent life-threatening complications but also to preserve function and significantly improve the patient's quality of life.

A Systematic Review And Meta-Analysis On The Role Of Vertical Alar Division And Resection In Nasal Tip Rhinoplasty

Hadeel Almajed[1], **Rafeef Alhajress**[2], **Naif Fnais**[2], **Reyof Alharthi**[3], **Wasan Alharbi**[4]

[1]*King Saud Medical City, Riyadh, Saudi Arabia;* [2]*King Saud University,Riyadh, Saudi Arabia;* [3]*King Faisal Specialized Hospital and research center, Jeddah, Saudi Arabia;* [4]*Ministry of Health, Eastern Health Cluster, Saudi Arabia*

BACKGROUND & AIM

Vertical dome division (VDD) and vertical alar resection (VAR) are key rhinoplasty techniques developed to improve nasal tip projection, definition, and stability. While VDD remodels the dome through controlled division of the lower lateral cartilage, VAR expands this concept by incorporating cartilage resection and graft reinforcement for long-term tip support

This study aims to systematically evaluate and compare the clinical, aesthetic, and structural outcomes of Vertical Dome Division (VDD) and Vertical Alar Resection (VAR) in rhinoplasty.

MATERIAL & METHODS

A systematic review was conducted according to PRISMA guidelines using the PubMed, Scopus, and Google Scholar databases. five studies met the inclusion criteria and evaluated VDD and VAR techniques in terms of projection, rotation, revision rates, complications, and satisfaction. Study quality was assessed using the Newcastle-Ottawa Scale (NOS) and the GRADE system.

RESULTS

VDD significantly increased nasal tip projection by 15.8% with over 90% patient satisfaction (10). The VAR provided sustained stability of projections beyond seven years with satisfaction rates greater than 85% (6). Revision rates remained low (2 to 6%) with both methods, and major complications were rare. VAR demonstrated superior long-term stability and contour definition due to graft-supported reinforcement

CONCLUSIONS

Both VDD and VAR are commonly used techniques for nasal tip refinement and are associated with favorable aesthetic outcomes and low reported complication rates. However, the available evidence is largely retrospective and heterogeneous. While VAR appears to offer improved long-term projection stability in selected cases, further prospective comparative studies are required to confirm these findings.

From Rabbit Model To Human: Histopathological Impact Of Dermal Fillers On Nasal Cartilage – A Case Report

İbrahim Ömer Gürlek[1], **Buket Coşkun**[1], **Burak Kaan İnan**[1], **Merve Çaputcu Kayhan**[2], **Filiz Gülüstan**[3], **Zahide Mine Yazıcı**[1], **İbrahim Sayın**[4]

[1]Department of Otorhinolaryngology–Head and Neck Surgery, University of Health Sciences, Bakırköy Dr. Sadi Konuk Training and Research Hospital, Istanbul, Türkiye; [2]Department of Pathology, University of Health Sciences, Bakırköy Dr. Sadi Konuk Training and Research Hospital, Istanbul, Türkiye; [3]Department of Otorhinolaryngology–Head and Neck Surgery, Acıbadem University Atakent Hospital, Istanbul, Türkiye; [4]Private Practice, Istanbul, Türkiye

BACKGROUND & AIM

Nonsurgical rhinoplasty using hyaluronic acid (HA) dermal fillers has gained widespread popularity due to its safety profile, immediate results, and high patient satisfaction. However, limited data exist regarding the histopathological effects of HA fillers on nasal cartilage and surrounding soft tissue. Our study group previously demonstrated chondrocyte nucleus loss, fibrosis, chronic inflammation, and foreign body–type giant cell formation following HA filler application in a rabbit model. This case report aims to present, for the first time, histopathological findings in human nasal cartilage and surrounding soft tissue exposed to HA filler in a patient who underwent septorhinoplasty after prior nonsurgical rhinoplasty.

MATERIAL & METHODS

A patient who had undergone nonsurgical rhinoplasty with HA filler injection two years prior presented with aesthetic dissatisfaction and nasal obstruction. Septorhinoplasty was planned. Intraoperatively, filler material was found in direct contact with the medial crura, lateral crura, and cartilaginous dorsum, as well as the surrounding soft tissue. The cephalic portion of the lateral crus with adjacent soft tissue in contact with the filler were resected for histopathological analysis (Figure 1). Specimens were fixed in 10% neutral formalin (pH 7.0) for 24 hours, processed through graded alcohols, and embedded in paraffin. Sections of 3–4 µm were stained with Hematoxylin–Eosin (H&E) and Masson's Trichrome (MT) and evaluated by pathologist. Chondrocyte nucleus loss, fibrosis, acute and chronic inflammation, abscess, giant cells, granulation tissue, and necrosis were evaluated.

RESULTS

Histopathological examination of the resected specimen revealed mild chronic inflammation and mild fibrosis in the perichondrial and surrounding soft tissue on H&E and MT–stained sections. Partial chondrocyte nucleus loss (grade 1; 25–50%) was identified in the cartilage tissue, indicating compromised chondrocyte viability in the region exposed to the filler material (Figure 2). No acute inflammation, abscess formation, necrosis, granulation tissue, or foreign body–type giant cells were detected in the examined specimen. The immediate postoperative views demonstrated satisfactory correction of the nasal dorsal profile and improved tip definition (Figure 3). At the one-year follow-up, stable aesthetic outcomes were maintained with a well-defined nasal dorsum, refined tip projection, and improved overall nasal harmony, along with resolution of the patient's nasal obstruction (Figure 4).

CONCLUSIONS

This case report provides the first human histopathological evidence of nasal cartilage and surrounding soft tissue changes following nonsurgical rhinoplasty with HA fillers. Partial chondrocyte nucleus loss, mild fibrosis, and chronic inflammation corroborate our previous rabbit model findings. However, unlike the rabbit model—where foreign body–type giant cells were

present in all filler-applied samples—no giant cells were observed, possibly reflecting differences in filler duration, volume, or host immune response. HA fillers may compromise the viability of underlying cartilage and adjacent tissue. Surgeons should consider these when planning rhinoplasty in patients with prior filler injections. Further studies with larger cohorts are warranted.

Bilateral Buccal Abscess Following Bichectomy: A Case Report

Ahmet Kısa[1], **Furkan Çetin**[1], **Atakan Utku Şen**[1], **Nagihan Bilal**[1], **Özlem Yağız Agayarov**[1], **Murat Gümüşsoy**[1], **İbrahim Çukurova**[1]

[1]*Department of Otorhinolaryngology, Tepecik Training and Research Hospital, University of Health Sciences, Izmir, Turkey*

BACKGROUND & AIM

Buccal fat pad excision (bichectomy) is an increasingly popular aesthetic procedure with generally low complication rates. However, postoperative complications such as infection, abscess formation, hematoma, and ductal or nerve injury have been reported in the literature, despite the overall safety of the procedure. We aimed to present a case of bilateral buccal abscess following bichectomy and to emphasize clinical management.

MATERIAL & METHODS

A 26-year-old female with no known comorbidities presented with bilateral facial swelling and purulent intraoral discharge five days after undergoing bichectomy at another center. Symptoms progressively worsened. Physical examination showed bilateral buccal swelling, more prominent on the left side. Hyperemia was present. Purulent discharge was noted from the intraoral incision sites. CT demonstrated minimal subcutaneous air and premasseteric edema. Ultrasonography revealed heterogeneous changes with minimal free fluid. No defined abscess cavity was detected. C-reactive protein was elevated (61.6 mg/L), while the leukocyte count was normal. The patient was admitted. Intravenous ampicillin-sulbactam treatment was started.

RESULTS

Clinical findings were consistent with bilateral buccal infection with evolving abscess formation. During hospitalization, inflammatory markers improved (CRP decreased to 11 mg/L), and clinical symptoms regressed under medical treatment. Clinical improvement was observed within a few days of treatment. No surgical drainage was required. The patient was discharged on oral amoxicillin-clavulanate therapy after four days of inpatient follow-up.

CONCLUSIONS

Bichectomy is generally regarded as a safe procedure; however, infectious complications may occur and lead to clinically significant morbidity. Early recognition and appropriate medical management may prevent progression and allow successful treatment without surgical intervention in selected patients.

Transmastoid Facial Nerve Decompression: A Single-Center Case Series

Aleyna Şivetoğlu[1], **Özlem Özdemir**[1], **Deniz Baklacı**[1], **Duygu Erdem**[1]

[1]*Department of Otorhinolaryngology, Zonguldak Bülent Ecevit University Faculty of Medicine*

BACKGROUND & AIM

Peripheral facial paralysis is a complex clinical condition with prognosis varying significantly according to etiology and duration. Transmastoid facial nerve decompression is a surgical intervention indicated in selected patients with severe neurophysiological damage unresponsive to medical treatment. This study aimed to evaluate the impact of surgical timing — specifically decompression performed within versus after 14 days of symptom onset — on functional outcomes in patients undergoing transmastoid facial nerve decompression.

MATERIAL & METHODS

This retrospective case series included 14 patients who underwent transmastoid facial nerve decompression at Zonguldak Bülent Ecevit University Hospital, Department of Otorhinolaryngology between 2022 and 2026. Patients with incomplete follow-up data or concurrent neurological disease were excluded. Preoperative and postoperative facial nerve function was graded using the House-Brackmann (HB) scale. Electroneurography (ENoG) and electromyography (EMG) findings, together with computed tomography (CT) and magnetic resonance imaging (MRI) results, were retrieved from patient records. Patients were stratified into two groups based on time from symptom onset to surgery: Early group (≤14 days, n=3) and Late group (>14 days, n=11). HB grade I–II was defined as the primary success criterion and HB grade I–III as the secondary success criterion.

Due to the limited sample size and heterogeneous etiology distribution, descriptive analysis was performed without formal statistical comparison.

RESULTS

The mean age was 55.1 ± 17.7 years; 9 patients were male. Etiologies included idiopathic Bell's palsy (n=7), traumatic paralysis (n=3), complicated chronic otitis media (COM) (n=3), and facial neuroma (n=1). Preoperative HB grade was V–VI in 13 patients and III in one patient. Time from symptom onset to surgery ranged from 7 to 105 days (mean 54.6 days, median 54 days). Postoperative HB grading was performed at a minimum follow-up of 6 months (range 6 months–5 years). The primary success criterion (HB I–II) was achieved in 10 of 14 patients, and the secondary criterion (HB I–III) in 11 of 14 patients. In the early group, all 3 patients achieved HB grade I–II. In the late group, 7 of 11 patients reached this level.

CONCLUSIONS

Early transmastoid decompression within 14 days of symptom onset appeared to be associated with higher primary success rates, possibly reflecting the time-dependent nature of endoneurial edema and ischemic injury. Although statistical comparison was not feasible due to sample size limitations, findings suggest that surgical timing may be a critical determinant of functional recovery. Even in delayed presentations, decompression should not be categorically excluded, as meaningful improvement was observed up to 2–3 months after onset in selected cases. Multicenter prospective studies stratified by etiology are needed to generate stronger evidence in this field.

PP-069

Can Functional Recovery Be Expected After Accidental Facial Nerve Injury ? (A Case Report)

SAHRAOUI Mohammed[1,2], **MEHTARI Nasrine Siham**[1,2], **AID Chahrazed**[1], **NASRI Amine**[1,2], **BENMANSOUR Narimane**[1]

[1]*ENT Department - Tlemcen University Hospital Center;* [2]*Faculty of Medicine - Abou Bekr Belkaid University of Tlemcen*

BACKGROUND & AIM

Post-traumatic facial paralysis represents one of the leading causes of peripheral facial paralysis after Bell's palsy, while parotid surgery remains one of the most feared iatrogenic causes.

The aim of our study is to report a case of management of an accidental facial nerve transection during parotidectomy, while detailing the underlying pathology, the mechanism of injury, the therapeutic management, and the functional outcomes obtained.

MATERIAL & METHODS

We report the case of a 21-year-old woman with no significant medical history, who presented with a chronic pretragal swelling that had been evolving for more than two years.

A cervicofacial MRI performed as part of the etiological workup suggested a benign cystic lesion of parotid origin.

Given the risk, described in the literature, of overlooking an associated malignant lesion, as well as the aesthetic concern, an exofacial parotidectomy was indicated.

RESULTS

During surgery, an accidental transection of the facial nerve occurred. Immediate microsurgical repair was performed using end-to-end neurorrhaphy with 9/0 Vicryl® sutures under an operating microscope, followed by coverage with a layer of fat tissue.

In the immediate postoperative period, a grade V peripheral facial paralysis according to the House–Brackmann classification was observed.

The patient underwent regular follow-up for 12 months, combined with corticosteroid therapy, vitamin supplementation, and treatment with nimodipine 30 mg.

The postoperative course was marked by gradual clinical improvement over the months, ultimately reaching House–Brackmann grade II at the last follow-up, performed 11 months after surgery.

CONCLUSIONS

The facial nerve remains the primary concern for parotid surgeons. Although benign parotid lesions are generally straightforward to manage, the risk of nerve injury persists despite all operative precautions.

Through this case report, we wish to emphasize that complete facial nerve transection is not necessarily irreversible. Early microsurgical repair and rigorous postoperative follow-up can allow satisfactory functional recovery and provide genuine therapeutic hope.

BILATERAL AURICULAR ABSCESS FOLLOWING OTOPLASTY: A RARE COMPLICATION

Mustafa Eser[1], **Sema Zer Toros**[2], **Çiğdem Tepe Karaca**[2], **Bilge Nur Küçükakça**[3]

[1]*Sultan Abdulhamid Han Training and Research Hospital, Ear, Nose and Throat Diseases, Istanbul, Turkiye;* [2]*Haydarpasa Numune Training and Research Hospital, Ear, Nose and Throat Diseases, Istanbul, Turkiye;* [3]*Sancaktepe Ilhan Varank Training and Research Hospital, Ear, Nose and Throat Diseases, Istanbul, Turkiye*

BACKGROUND & AIM

Otoplasty is one of the most frequently performed surgical procedures for aesthetic and functional purposes. Although postoperative infection is rare, it can lead to severe complications. In this case report, we present the management of a patient who developed bilateral auricular abscess formation following otoplasty, highlighting the critical importance of early diagnosis and intervention.

CASE PRESENTATION

A 16-year-old female patient presented with a one-week history of swelling, erythema, and discharge in both ears. The patient had undergone an otoplasty procedure at an external center two weeks prior to admission. Clinical evaluation revealed bilateral auricular abscess formation.

MANAGEMENT AND OUTCOME

The abscesses were surgically drained, and a pressure dressing was applied. Following pediatric consultation, empirical broad-spectrum antibiotic therapy was initiated, and cultures were obtained. Dressing changes were performed twice daily. Upon the isolation of Pseudomonas aeruginosa in the culture, the antibiotic regimen was adjusted according to the culture-antibiogram results. At the conclusion of a two-week treatment period, an aesthetically acceptable result was achieved, despite a minimal residual deformity in the auricular structure.

RESULTS

Infection following otoplasty is a rare yet serious complication. In cases such as bilateral auricular abscess, the risk of permanent deformity can be minimized through early diagnosis, prompt surgical drainage, obtaining cultures, and the administration of appropriate antibiotic therapy.

CONCLUSIONS

The infection rate after otoplasty is reported to be between 1–5% in the literature. The most common causative agents include Staphylococcus aureus and Pseudomonas aeruginosa [1]. Pseudomonas infections, which particularly prefer moist environments, can develop more frequently if dressing and hygiene rules are not followed after otoplasty. Successful results can be obtained with drainage, pressure dressing, and culture-based antibiotic treatment in abscesses detected in the early stages [2]. Delayed treatment can lead to cartilage necrosis, deformity, and permanent aesthetic losses [3].

PP-071

Outcomes Of Dorsal Preservation Septorhinoplasty In The Management Of Rhinosseptal Deformities: A Prospective Study From Bolivia

Karen Adriana Coscio Chavez[1], **Daniel Boris Coscio Salinas**[1], **Daniel Jaime Coscio Chavez**[1], **Maricela Escobar Lopez**[1]

[1]*Clinica los Olivos*

BACKGROUND & AIM

There is a growing trend toward dorsal preservation techniques and a comprehensive structural approach in rhinoplasty, aiming to achieve improved outcomes with fewer complications and revision surgeries. Rhinoplasty has evolved toward preservation techniques that maintain the structural integrity of the nasal dorsum. Dorsal preservation septorhinoplasty emphasizes conservation of anatomical structures rather than traditional resection and reconstruction.

The aim is to evaluate the management of rhinosseptal deformity using dorsal preservation septorhinoplasty at Clínica Los Olivos Cochabamba Bolivia between May 1, 2019, and October 31, 2023.

MATERIAL & METHODS

A Observational, prospective, longitudinal, descriptive study with a quantitative approach was conducted, including 126 patients who underwent primary septorhinoplasty using the dorsal preservation technique. Data collection from pre and postoperative facial photographs, surgical records, and the Rhinoplasty Outcome Evaluation (ROE) questionnaire were used for assessment.

RESULTS

Correction of deviated nasal pyramid and convex dorsal deformities exceeded 90%. Improvements were observed in nasal tip definition, projection, and rotation. Patients reported statistically significant satisfaction in both functional and aesthetic outcomes (ROE questionnaire). A lower rate of complications and revision surgeries was also observed.

CONCLUSIONS

Dorsal preservation septorhinoplasty proved to be a safe and effective technique for the correction of rhinosseptal deformities, achieving high rates of anatomical correction and significant functional and aesthetic improvement. The technique demonstrated high patient satisfaction, a low complication rate, and a reduced need for revision surgery. By maintaining the structural integrity of the nasal dorsum and avoiding unnecessary resection, dorsal preservation offers natural postoperative results. When indicated and anatomically possible, this approach should be considered a preferred technique in primary septorhinoplasty.

KEYWORDS

Septorhinoplasty, dorsal preservation, nasal dorsum, dorsal lowering, nasal pyramid repositioning.

PP-072

Facial Changes After Closed Approach Rhinoplasty Assessed Using The 10–7–5 Method

JOSÉ STURLA PELLERANO[1], **FERNANDO RAMÍREZ OROPEZA**[1], **ENRIQUE GIRON ARCHUNDIA**[1]

[1]*Facial and Cosmetic Surgery Clinic, Department of Otolaryngology and Facial Plastic Surgery, Puebla, Mexico*

BACKGROUND & AIM

Rhinoplasty is one of the most frequently performed procedures in facial plastic surgery, yet postoperative evaluation often remains subjective. The 10–7–5 method provides a structured approach to facial analysis by assessing frontal, lateral, and basal views, but its clinical applicability in closed approach rhinoplasty has been insufficiently studied.

To objectively evaluate facial changes following closed approach rhinoplasty using the 10–7–5 method, comparing preoperative and postoperative facial parameters.

MATERIAL & METHODS

An observational, retrospective, descriptive, and comparative study was conducted. A total of 42 patients (29 females and 13 males), with a mean age of 27.9 years (range 14–76 years), who underwent closed approach rhinoplasty were included. Standardized preoperative and postoperative photographic records were analyzed. Preoperative photographs were obtained within 24 hours before surgery, and postoperative photographs were taken between 14 and 20 days after surgery. Facial analysis was performed using the 10–7–5 method, which evaluates facial parameters in frontal (10 parameters), lateral (7 parameters), and basal (5 parameters) views. Patients with previous nasal surgery, facial trauma, congenital facial deformities, or incomplete photographic documentation were excluded. Preoperative and postoperative findings were compared using paired statistical analysis. A p-value < 0.05 was considered statistically significant. All patients provided informed consent.

RESULTS

Statistically significant postoperative improvements were observed in multiple nasal and facial parameters. In the frontal view, improvements were noted in nasal symmetry, dorsal aesthetic lines, osseous vault, mid-vault, nasal tip definition, alar borders, and alar base width. Lateral view analysis demonstrated significant changes in the nasofrontal angle, nasal dorsum contour, nasal projection, and nasal rotation ($p < 0.05$). Basal view evaluation showed significant improvement in nasal projection, columella position, alar base width, and nasal flaring. Parameters unrelated to rhinoplasty, including periapical hypoplasia and mentolabial relationship, showed no statistically significant changes. These findings confirm that the observed postoperative changes were specific to nasal surgical intervention and could be objectively identified using the 10–7–5 method.

CONCLUSIONS

Closed approach rhinoplasty produces significant, measurable facial aesthetic improvements that can be objectively evaluated using the 10–7–5 method. This study shows that the method identifies specific postoperative changes across frontal, lateral, and basal views, while parameters unrelated to nasal surgery remain unchanged. The 10–7–5 method offers a structured, practical, and reproducible approach for postoperative assessment, supporting its routine clinical use. Additionally, it aids surgical planning and enhances surgeon–patient communication by providing an objective framework for facial analysis. These findings support the clinical applicability of the 10–7–5 method for outcome assessment after closed approach rhinoplasty in daily practice.

Subcutaneous Hemangioma On Nasal Dorsum: A Case Report And Literature Review

Khalid AlQarni[1], **Reham Almuhaya**[1], **Ali Alsudays**[2], **Abdullah Alzamil**[1], **Abdulaziz Almutairi**[1]

[1]*Prince Sultan Medical Military City;* [2]*King Abdulaziz University hospital, King Said University*

BACKGROUND & AIM

Vascular anomalies including hemangiomas, which have slow blood flow, can develop anywhere on the body. They are mostly isolated lesions and more common in women. The deformity does not regress on its own. A rare variety known as subcutaneous hemangioma grows aggressively and occasionally returns after excision. In this report, we present a case of 44 years old female who experienced slowly growing painful nasal hump as a result of nasal trauma she sustained seven years ago

MATERIAL & METHODS

Case report of a post traumatic subcutanoues nasal dorsum hemangioma

RESULTS

Nasal hemangioma is a benign tumor of blood vessels with rare occurrence especially in adult patients. Management can be medical, using laser or surgically. Surgical excision is the gold standard method for managing these tumors.

CONCLUSIONS

Nasal hemangioma is a benign tumor of blood vessels with rare occurrence especially in adult patients. Management can be medical, using laser or surgically. Surgical excision is the gold standard method for managing these tumors.

PP-074

Contemporary Global Management Of T3 Laryngeal Carcinoma: Balancing Oncological Control And Functional Laryngeal Preservation

Ahmet Altuntaş[1], **Cemal Cingi**[2]

[1]*Otorhinolaryngology Specialist, Private Practice, Gaziantep Türkiye;* [2]*Eskişehir Osmangazi University*

BACKGROUND & AIM

The optimal management of T3 laryngeal squamous cell carcinoma remains controversial, as it requires achieving maximal oncological control while preserving laryngeal function. Advances in transoral surgery, chemoradiotherapy (CRT), imaging, and multidisciplinary treatment have expanded organ-preservation strategies. However, appropriate patient selection remains the key determinant of treatment success. We hypothesized that individualized treatment based on tumor characteristics, pretreatment laryngeal function, and multidisciplinary decision-making yields oncological outcomes equivalent to those of a uniform treatment strategy while improving functional preservation.

MATERIAL & METHODS

This narrative review summarizes current evidence and international recommendations regarding the management of T3 laryngeal carcinoma. Recent clinical guidelines, consensus statements, and major retrospective and prospective studies published between 2020 and 2026 were reviewed. Treatment modalities included transoral laser microsurgery, open partial laryngectomy, definitive concurrent chemoradiotherapy, total laryngectomy, and salvage surgery. Primary outcome measures included overall survival (OS), disease-free survival (DFS), laryngeal preservation rate, functional voice and swallowing outcomes, and quality of life. Independent variables included tumor subsite, vocal cord mobility, cartilage invasion, nodal status, pretreatment laryngeal function, and patient comorbidities.

RESULTS

Current evidence demonstrates that carefully selected patients with T3 laryngeal carcinoma can achieve oncological outcomes comparable to primary surgery using organ-preserving approaches. Several contemporary series have shown no statistically significant difference in overall survival or disease-free survival between primary surgery and definitive CRT ($p>0.05$), while preserving functional laryngeal outcomes in a substantial proportion of patients. Conversely, patients with extensive cartilage invasion, poor pretreatment laryngeal function, or bulky tumors demonstrated improved local control following total laryngectomy. Recent international consensus statements emphasize that treatment decisions should rely on multidisciplinary evaluation rather than T stage alone. Emerging perioperative systemic therapies and immunotherapy may further improve functional preservation without compromising survival.

CONCLUSIONS

Management of T3 laryngeal carcinoma has shifted from a stage-based approach to an individualized treatment paradigm. Organ-preserving strategies are appropriate for carefully selected patients and yield excellent functional outcomes without

compromising survival. Total laryngectomy remains the preferred option for patients with unfavorable anatomical or functional characteristics. Future prospective multicenter studies that incorporate molecular biomarkers, advanced imaging, and immunotherapy are expected to refine patient selection and optimize oncological and functional outcomes.

The Effectiveness Of Tele-Training In Delivering ENT-Head And Neck Imaging Education To Healthcare Professionals In Low-Resource Settings

Dr Ishika Kamat[1], **Adan Khan**[2], **Dr Nicole Demitry**[3], **Dr Sameer Baraket**[4], **Josh Tatla**[5], **Anushka Das**[5], **Professor Taran Tatla**[4]

[1]*Watford General Hospital;* [2]*University of Kent;* [3]*Russels Hall Hospital;* [4]*Imperial College NHS Trust;* [5]*University of East Anglia*

BACKGROUND & AIM

Tele-training has emerged as a potential strategy to widen access to specialist postgraduate medical education, particularly in low-resource settings where traditional in-person training is limited. The 3-Day Multidisciplinary Team (MDT) Head and Neck Imaging Course was adapted for hybrid delivery to extend access internationally.

MATERIAL & METHODS

A structured platform evaluation was conducted in 2023 to select an appropriate virtual learning environment for hybrid delivery. Vedamo was used for the 2023 pilot course delivered in Copenhagen. In 2025, the course was delivered in London using Zoom Workplace Pro following technical refinements. Two anonymised questionnaires (pre- and post-course) were administered to remote participants in both iterations. Outcomes assessed included participant demographics, baseline familiarity with imaging modalities and MDT working, perceived educational value, platform performance, and intention to implement learning into practice.

RESULTS

In 2023, 60 participants attended at least one live session; 66 attended in 2025. Pre-course questionnaire completion was 92% in 2023 (55/60) and 65% in 2025 (43/66). Participants represented diverse geographic regions across Asia, Africa, Europe, North America and the Middle East. Across both cohorts, case-based discussions and MDT-focused teaching were rated highly. Post-course responses demonstrated increased familiarity with MDT working and strong endorsement of its clinical relevance. Engagement with recorded sessions was high (>80% rating recordings as useful). Technical refinements in 2025 were associated with improved reported audiovisual clarity.

CONCLUSIONS

Hybrid delivery of specialist, postgraduate head and neck education is feasible and accomplishable across international contexts. Iterative technical and organisational refinements improved delivery without increasing barriers to access, supporting the use of hybrid models for specialist MDT-focused education in low-resource settings.

PP-076

Unseen, Uninvited, Unacceptable: Tracheostomal Myiasis And The Call For Vigilant Stoma Care

Lo Ren Hui[2], **Kuhan Olakanathan**[2], **Atikah Rozhan**[1], **Jonah Seeni**[1,2]

[1]*International Islamic University, Malaysia;* [2]*Hospital Raja Permaisuri Bainun Ipoh, Malaysia*

BACKGROUND & AIM

Myiasis, the infestation of living tissue by dipterous fly larvae, is an exceptionally rare complication of tracheostomy, predominantly reported in tropical and subtropical regions. When involving the tracheostoma, it poses serious risks including airway obstruction, secondary infection, and significant morbidity if unrecognized. This report describes a case of tracheostomal myiasis in a patient with a long-standing tracheostomy, highlighting its clinical presentation, management, and preventive implications, while advocating for optimum home care and dedicated family support as essential cornerstones of long-term tracheostomy management.

MATERIAL & METHODS

A 36-year-old man with severe traumatic brain injury and tracheostomy performed four years earlier presented to the emergency department with a five-day history of foul odor from the tracheostomy tube and a contaminated tracheostomal wound. The patient had been living alone and had defaulted routine tracheostomy care. Clinical examination revealed labored breathing with foul-smelling blood-stained discharge from the stoma and numerous live larvae surrounding the tracheostomy tube, which was nearly obstructed with secretions and maggots. Approximately 40 larvae were mechanically removed from the peristomal region. Further wound debridement was performed under sedation and local anesthesia. Turpentine-soaked gauze was applied to facilitate migration of residual larvae. The extracted larvae were sent for entomological analysis.

RESULTS

The larvae were identified as Chrysomya bezziana (Old World screwworm), an obligate parasite capable of invading living tissue and triggering severe systemic inflammatory responses if untreated. Patients with long-term tracheostomies are uniquely vulnerable, facing challenges such as impaired airway clearance, caregiver dependence, and stomal complications including granulation, crusting, and wound maceration creating ideal conditions for larval colonization. Without timely intervention, myiasis can progress to tissue necrosis, sepsis, and life-threatening airway compromise. Treatment comprised intravenous antibiotics and daily wound care, with manual larval removal remaining the cornerstone of management, supplemented by occlusive agents and wound irrigation. Within 48 hours, no larvae were observed and healthy granulation tissue was evident. The patient was discharged on day six and remained recurrence-free at two-week follow-up, underscoring that early intervention, structured wound care, and dedicated family support are paramount in managing this rare but preventable complication.

CONCLUSIONS

Tracheostomal myiasis is a rare but preventable complication of long-term tracheostomy. Neglected tracheostomy care, poor hygiene, and lack of caregiver support are important risk factors. Early recognition, prompt mechanical removal of larvae, and meticulous wound care are essential to prevent airway compromise and secondary infection. Patient and caregiver education regarding proper tracheostomy care remains crucial in preventing this potentially life-threatening condition. This case highlights tracheostomal myiasis as a rare but preventable complication of long-term tracheostomy, emphasizing the critical importance of caregiver education and proper tracheostomy hygiene.

Tracheostomy, Myiasis, Airway complication, Chrysomya bezziana, Wound infestation

PP-077

Contemporary Management Of Salivary Gland Tumors: From Accurate Diagnosis To Personalized Treatment

Mustafa Ibas[1]

[1]*Atlas University, Medical Faculty*

BACKGROUND & AIM

Salivary gland tumors constitute a heterogeneous group of neoplasms with diverse histopathological, biological, and clinical behavior. Accurate preoperative diagnosis and individualized treatment planning are essential to achieve optimal oncological control while preserving facial nerve function and quality of life. We hypothesized that a modern multidisciplinary approach combining advanced imaging, cytopathology, molecular diagnostics, and risk-adapted surgery improves treatment precision and patient outcomes.

MATERIAL & METHODS

This review evaluates current concepts in the diagnosis and management of benign and malignant salivary gland tumors. The review drew on contemporary literature, clinical guidelines, and expert recommendations. Diagnostic methods included ultrasonography, MRI, CT, fine-needle aspiration cytology, core needle biopsy, and molecular testing. Treatment strategies included extracapsular dissection, superficial or total parotidectomy, submandibular gland excision, neck dissection, facial nerve management, postoperative radiotherapy, systemic therapy, and targeted treatment. Outcome measures included diagnostic accuracy, recurrence, survival, facial nerve morbidity, margin status, and quality of life. Independent variables included tumor site, size, grade, histology, perineural invasion, nodal status, and molecular profile.

RESULTS

Current evidence supports MRI and ultrasound-guided cytologic or core biopsy assessment as key components of preoperative evaluation. For benign parotid tumors, selective approaches such as extracapsular dissection may yield low recurrence rates with reduced facial nerve morbidity in appropriately selected cases. In malignant tumors, complete surgical excision with clear margins remains the mainstay of treatment. Neck dissection is recommended for clinically positive neck disease and high-risk histologies. Postoperative radiotherapy improves local control in high-grade tumors, positive margins, perineural invasion, advanced T stage, or nodal metastasis. Molecular testing has become increasingly important in selected tumors, particularly adenoid cystic carcinoma, secretory carcinoma, and salivary duct carcinoma, where targeted or systemic therapies may be considered.

CONCLUSIONS

Contemporary management of salivary gland tumors requires precise diagnosis, histology-based risk stratification, and individualized treatment. Surgery remains central, but modern imaging, pathology, molecular profiling, and adjuvant therapy have improved decision-making. Functional preservation, especially facial nerve protection, should be balanced with oncologic safety. Future directions include broader use of molecular biomarkers, targeted therapy, and multicenter outcome registries.

KEYWORDS

salivary gland tumors, salivary duct carcinoma, advanced imaging, cytopathology, molecular diagnostics

Evaluation Of A Low-Cost Epistaxis Simulator For Primary Care Training In Rwanda

Nour Mary Aissaoui MS[1], **Gabrielle Cahill MD, MPH**[3], **Mahbuba Tutsy MD**[10], **Gloria Nishimwe MBBS, MGHD**[4], **John Bukuru MD, MMED, MASS**[4,5], **Edgard Gasana MD**[4,5], **Sarah Nuss MD**[6], **Nina Patel MS, MPhil**[1], **Josiane Umutoni MD, MMED**[7,8], **Jonathan Abaho MBChB**[4], **Eden Abate Lemu MD, MSc**[4], **Alyssa M. Civantos MD MS**[2], **Scott Drapeau MA**[2], **Trina Sheedy PA-C**[9], **Natalie McCall MD**[4], **David A Shaye MD, MPH**[8,6,7], **Mary Jue Xu MD**[2], **Gratien Tuyishimire MD, MMED**[4]

[1]University of California, San Francisco School of Medicine, San Francisco, CA; [2]Department of Otolaryngology – Head and Neck Surgery, University of California, San Francisco; [3]Department of Head and Neck Surgery, University of California, Los Angeles; [4]University of Global Health Equity, Butaro, Rwanda; [5]Department of ENT, Rwanda Military Referral and Training Hospital, Kigali, Rwanda; [6]Department of Otolaryngology/Head & Neck Surgery, Mass Eye & Ear, Harvard Medical School, Boston, USA; [7]University Teaching Hospital of Kigali, Kigali, Rwanda.; [8]School of Medicine & Pharmacy, College of Medicine & Health Sciences, University of Rwanda, Kigali, Rwanda.; [9]Sutter California Pacific Otolaryngology-Head and Neck Surgery, San Francisco, CA.; [10]Department of Otolaryngology—Head and Neck Surgery, School of Medicine, Stanford University, Palo Alto, California, USA

BACKGROUND & AIM

Epistaxis is a common otolaryngology emergency in primary care and can sometimes be fatal. Prior studies show substantial provider knowledge gaps, with only 19–43% correctly identifying basic first-aid measures. In settings where new graduates transition directly into primary care, structured epistaxis training may be particularly valuable. We hypothesized that a simulation-based epistaxis training program for primary care providers in Rwanda would improve short-term knowledge and confidence and yield high post-training technical proficiency.

MATERIAL & METHODS

University of Global Health Equity medical students in Rwanda (n=41) completed a one-week simulation-based otolaryngology bootcamp including an epistaxis module using a low-cost three-dimensional print-to-cast silicone molded nasal task trainer. Knowledge (6-item multiple-choice questionnaire) and confidence (5-point Likert) were assessed pre/post-intervention (matched n=23 and n=22). Technical proficiency was measured post-training via an Objective Structured Clinical Examination using a standardized rubric. Paired t-tests were used; effect sizes are reported as Hedges' g_z.

RESULTS

9/23 (39.1%) matched respondents and 12/31 (38.7%) of the full sample had previously observed epistaxis management or nasal packing. Knowledge increased from 2.57/6 (41.7%) pre-training to 5.17/6 (86.7%) post-training (mean Δ=2.61, SDΔ=1.56; 95% CI 1.93–3.28; t(22)=8.02; $p=5.6\times10^{-8}$; g_z=1.61 [large]). Confidence improved for epistaxis management (2.65/5 to 4.56/5; p<0.0001) and nasal packing (2.5/5 to 4.6/5; p<0.0001). Post-training clinical assessment showed high skill acquisition: skills items averaged 2.8/3 (93.5%), with 97.6% (40/41) achieving ≥80%; knowledge items averaged 6.73/7 (96.2%), with 100% (41/41) achieving ≥80%. Appropriateness was high: 96.8% (30/31) strongly agreed epistaxis skills are relevant to general practice and expressed strong interest in learning them.

CONCLUSIONS

Simulation-based epistaxis training increased short-term knowledge, confidence, and technical proficiency among primary care trainees in Rwanda. High appropriateness and acceptability support integration of low-cost otolaryngology emergency simulation into primary care medical education where specialty training access is limited. Future work should evaluate skill retention, clinical transfer, and comparative effectiveness.

PP-079

Ethnic Nose Rhinoplasty: Contemporary Concepts In Preserving Identity While Achieving Facial Harmony

Ali Değirmenci[1]

[1]Otorhinolaryngology Specialist, Private Practice, Bursa Türkiye

BACKGROUND & AIM

Ethnic rhinoplasty has evolved significantly over the past two decades from standard reduction techniques toward individualized, preservation-oriented procedures that respect each patient's unique anatomical characteristics and cultural identity. The increasing demand for aesthetic refinement without ethnic erasure has challenged surgeons to balance functional improvement, facial harmony, and preservation of distinguishing ethnic features. We hypothesized that modern structural ethnic rhinoplasty, guided by detailed preoperative facial analysis and patient-centered planning, achieves high aesthetic satisfaction while maintaining nasal function and ethnic identity.

MATERIAL & METHODS

This narrative review summarizes contemporary concepts in ethnic rhinoplasty, drawing on the current literature, international consensus recommendations, and expert surgical experience. Anatomical variations in noses from African, Asian, Middle Eastern, Hispanic, and mixed-ethnicity populations were evaluated. Current surgical techniques, including structural

grafting, preservation rhinoplasty, dorsal augmentation, tip-support reconstruction, soft-tissue management, and alar-base modification, were reviewed. Outcome measures included patient satisfaction, revision rates, nasal airway function, aesthetic harmony, and preservation of ethnic characteristics. Independent variables included skin thickness, cartilage strength, dorsal height, tip projection, nasal width, and patient expectations. Published comparative studies and systematic reviews were critically assessed.

RESULTS

Recent evidence demonstrates that individualized surgical planning based on ethnic anatomy provides superior aesthetic and functional outcomes compared with standardized rhinoplasty techniques. Structural grafting techniques improve long-term tip support and reduce postoperative deformities, particularly in patients with weak lower lateral cartilages. Preservation of characteristic dorsal contours and careful management of soft tissue thickness contribute significantly to natural postoperative appearance. Studies consistently report high patient satisfaction, low revision rates, and stable functional outcomes when ethnic identity is incorporated into surgical planning. Successful outcomes are closely associated with comprehensive preoperative communication, digital simulation, and realistic expectation management. Contemporary approaches emphasize enhancement rather than Westernization of nasal aesthetics.

CONCLUSIONS

Modern ethnic rhinoplasty is no longer defined by changing ethnic characteristics but by enhancing nasal aesthetics while preserving cultural identity and function. Individualized anatomical assessment, structural surgical techniques, and patient-centered decision-making are fundamental for achieving predictable long-term results. Future developments involving artificial intelligence-assisted facial analysis, three-dimensional surgical planning, and objective outcome assessment tools are expected to further improve personalization and surgical precision in ethnic rhinoplasty.

PP-080

Is Lip Aesthetics Synonymous With Lip Augmentation? Contemporary Concepts Beyond Volume Enhancement

Serkan Barışkan[1]

[1]*Otorhinolaryngology Specialist, Private Practice, Denizli Türkiye*

BACKGROUND & AIM

Lip aesthetics has become one of the fastest-growing areas in facial cosmetic medicine. While lip augmentation with fillers is increasingly popular, attractive lips result from multiple anatomical and dynamic factors, including symmetry, proportion, vermilion definition, Cupid's bow, dental show, lip support, and harmony with the nose, chin, and overall facial profile. Excessive volume alone can produce unnatural results and compromise facial balance. We hypothesized that a comprehensive aesthetic assessment, rather than simply increasing lip volume, yields superior aesthetic outcomes and higher patient satisfaction.

MATERIAL & METHODS

Recent evidence indicates that lip attractiveness is influenced more by overall facial balance than by lip volume alone. Moderate augmentation, combined with restoration of anatomical landmarks, consistently yields more natural and durable outcomes than aggressive volumization. Excessive filler placement is linked to higher complication rates, aesthetic dissatisfaction, and distortion of normal lip anatomy. Studies also show that correcting perioral aging, optimizing upper incisor show, and preserving dynamic lip movement significantly improve patient-reported outcomes. Individualized treatment planning based on facial proportions and patient goals has become the cornerstone of modern lip aesthetics.

RESULTS

Recent evidence indicates that lip attractiveness is influenced more by overall facial balance than by lip volume alone. Moderate augmentation, combined with restoration of anatomical landmarks, consistently yields more natural and durable outcomes than aggressive volumization. Excessive filler placement is linked to higher complication rates, aesthetic dissatisfaction, and distortion of normal lip anatomy. Studies also show that correcting perioral aging, optimizing upper incisor show, and preserving dynamic lip movement significantly improve patient-reported outcomes. Individualized treatment planning based on facial proportions and patient goals has become the cornerstone of modern lip aesthetics.

CONCLUSIONS

Lip aesthetics should not be equated with lip augmentation. Successful treatment requires a comprehensive understanding of facial proportions, functional anatomy, and patient expectations. The objective of modern lip aesthetic procedures is to achieve natural harmony, balanced proportions, and a youthful appearance rather than maximal lip volume. Future advances in three-dimensional facial analysis, artificial intelligence-assisted treatment planning, and objective aesthetic assessment tools are expected to further refine personalized lip enhancement strategies.

Preoperative Neutrophil-To-Lymphocyte Ratio (NLR), Systemic Immune Inflammation Index (SII), Systemic Inflammation Response Index (SIRI) And Pan Immune-Inflammation Value (PIV) As A Prognostic Indicator In Head And Neck Malignancies : A Retrospective Analysis Of 115 Patients

Doç. Dr. BELGİN TUTAR[1], **DR. ELİF NUR BÜLBÜL**[1]

[1]*PROF. DR. Cemil Taşcıoğlu City Hospital , Health Sciences University*

BACKGROUND & AIM

Hemogram-derived inflammatory biomarkers have been proposed as simple and inexpensive predictors of adverse pathologic features in head and neck malignancies. However, evidence remains heterogeneous across cohorts.

MATERIAL & METHODS

To investigate the association between preoperative inflammatory indices (NLR, PLR, LMR, SII, SIRI) and postoperative pathologic outcomes in patients undergoing tumor resection with neck dissection.

We retrospectively analyzed 115 patients who underwent resection and neck dissection for head and neck malignancies. Preoperative complete blood count values were used to calculate NLR, PLR, LMR, SII (platelets×neutrophils/lymphocytes), and SIRI (neutrophils×monocytes/lymphocytes). Primary outcomes included lymph node metastasis (LN+), and adverse pathologic features (deep invasion, PNI, LVI, positive margins). Group comparisons were performed using non-parametric tests. Discrimination was evaluated using ROC analysis. Multivariable logistic regression adjusted for age and sex.

RESULTS

The cohort had a mean age of 60.2±12.7 years and was 77.4% male. LN metastasis was present in 53.9%. Deep invasion was observed in 59.6%, PNI in 56.0%, and LVI in 44.4%. For LN metastasis, SII showed a borderline difference between groups (p=0.064) with modest discrimination (AUC 0.60). In multivariable analysis, SII independently predicted deep invasion (adjusted OR 1.106 per 100-unit increase; 95% CI 1.012–1.209; p=0.027). In the subgroup with available nodal staging (n=49), higher SII and SIRI were associated with higher nodal stage (N2–3 vs N0–1) and demonstrated moderate discrimination (SII AUC 0.689, SIRI AUC 0.677), although findings were exploratory.

CONCLUSIONS

Preoperative SII is an independent predictor of deep tumor invasion in patients undergoing neck dissection for head and neck malignancies. Hemogram-derived indices may help preoperative risk stratification; prospective validation is warranted.

Comparative Effectiveness Of Total Laryngectomy Versus Organ Preservation In T3 Laryngeal Cancer: A Systematic Review And Meta- Analysis

Abdulmajeed Alahmari[1], **Omar Almansouri**[3], **Ahmed Mogharbel**[2], **Mazin Merdad**[4]

[1]*Prince Sultan Military Medical City, Riyadh;* [2]*King Fahad Armed Forces Hospital, Jeddah;* [3]*King Fahad General Hospital, Jeddah;* [4]*King Abdulaziz University Hospital, Jeddah*

BACKGROUND & AIM

Background The management of T3 laryngeal cancer involves balancing disease control and preserving laryngeal function. Studies show comparable survival outcomes between total laryngectomy (TL) and organ-preserving therapy (OPT), such as radiotherapy (RT) and chemoradiotherapy (CRT). However, OPT is suitable for only a subset of patients, and its protocols vary by institution. While OPT offers functional benefits, TL is associated with reduced risk of recurrence. In this review, we compare both TL and OPT in terms of locoregional control, salvage rates, and survival rates.

MATERIAL & METHODS

Methods We searched PubMed, Scopus, Web of Science, and the Cochrane Library for relevant articles up to February 2025. Two independent reviewers extracted data from the selected studies, including baseline information, outcomes, complications, and survival rates.

RESULTS

Results Thirty-seven articles were eligible for inclusion in our review. Local recurrence in TL was notably less than that seen with OPT, whereas CRT and RT demonstrated fewer regional relapses compared to TL. OPT patients who experienced recurrence often required a salvage of TL; most of those received RT alone as the primary treatment. For TL, the 5-year DFS was 60%, the 5-year DSS was 66%, and the 5-year OS was 54%, as opposed to 53%, 61%, and 49% for OPT ($p = 0.0087$, $p = 0.0094$, $p < 0.0001$). Common complications with total laryngectomy included pharyngocutaneous fistulas, whereas OPT was associated with post-radiation laryngeal edema and esophageal strictures. Treatment-related mortality was reported similarly for both modalities.

CONCLUSIONS

Conclusion TLofferssuperiorsurvivaloutcomes(DFS,DSS,OS)overOPTforT3laryngealcancer,withhighercancer-free survival rates at one and five years. While total laryngectomy was associated with statistically higher survival outcomes, the absolute differences were modest. These findings support careful, individualized treatment selection that incorporates patient preference, functional outcomes, and institutional expertise.

Occult Squamous Cell Carsinoma In A Presumed Branchial Cyst With Right-Sided Chyle Leak

Enes Karaca[1], **Beyza Mercan**[1], **Soltan Ahmadov**[1], **Fırat Tevetoğlu**[1]

[1]*Department of Otorhinolaryngology, Cerrahpaşa Faculty of Medicine, Istanbul University-Cerrahpaşa, Istanbul, Türkiye*

BACKGROUND & AIM

Cystic neck masses in adults increasingly represent metastatic disease rather than benign branchial cysts, especially in HPV-related OPSCC. Imaging and FNAB may be misleading due to hypocellularity. Therefore, a high index of suspicion is essential, and frozen section may be required for definitive diagnosis. Chyle leak after neck dissection is uncommon (1–2.5%) and typically left-sided; right-sided cases are rare.

MATERIAL & METHODS

A 54-year-old male presented with a long-standing right neck mass previously followed as a branchial cyst. Recent enlargement prompted reevaluation. Endoscopic examination was normal. Trucut biopsy was non-diagnostic.

Intraoperatively, invasion of the sternocleidomastoid muscle raised suspicion, and frozen section revealed SCC, leading to right modified radical neck dissection.

Postoperatively, a low-output (~100 cc/day) right-sided chyle leak developed and was successfully managed conservatively. Final pathology demonstrated p16-positive, EBV-negative SCC. Adjuvant chemoradiotherapy was planned. The patient remains disease-free.

RESULTS

In patients >40 years, cystic neck masses should be considered metastatic until proven otherwise. HPV-related OPSCC frequently presents with cystic nodal disease without an obvious primary. Preoperative diagnostics may yield false-negative results; thus, frozen section is crucial.

p16 positivity is not entirely specific for oropharyngeal origin and should be interpreted cautiously.

Chyle leak is usually left-sided; right-sided cases are rare and often due to anatomical variation. Low-output leaks are typically managed conservatively.

CONCLUSIONS

Adult cystic neck masses require high suspicion for malignancy despite negative preoperative tests. Frozen section is key for intraoperative decision-making. Although rare, right-sided chyle leak can occur and is effectively managed conservatively in low-output cases.

PP-084

Diagnosis And Management Of Plasma Cell Neoplasia Presenting As A Mandibular Ramus And Buccal Mucosa Mass

ÖZKAN İLİK[1], **NURULLAH TÜRE**[1], **FİKRET ZEYBEK**[1]

[1]*Kütahya Health Sciences University Faculty of Medicine,Department of Otorhinolaryngology*

BACKGROUND & AIM

Plasma cell neoplasms (PCN) are mature B-cell lymphoid neoplasms characterized by monoclonal plasma cell proliferation . While extramedullary involvement is uncommon, oral manifestations can rarely serve as the primary clinical sign of a systemic disorder . This report evaluates the hypothesis that destructive oral cavity lesions may represent the initial clinical manifestation of multicentric systemic plasma cell disease.

MATERIAL & METHODS

This clinical case report describes a 65-year-old female (65F) patient who presented at a tertiary care hospital with a 4-month history of a 3x4 cm hemorrhagic mass in the left buccal mucosa and retromandibular region . Diagnostic interventions included contrast-enhanced Computed Tomography (CT), Positron Emission Tomography-Computed Tomography (PET-CT), and an incisional biopsy of the oral lesion . Outcome measurements were derived from radiological findings, histopathological analysis, and Immunohistochemical (IHC) profiling. Analyses focused on the evaluation of tumor morphology, mitoses, and monoclonal light chain restriction. Following the diagnostic phase, the patient was evaluated by a multidisciplinary oncology board.

RESULTS

CT imaging revealed a 27x37 mm destructive lytic lesion in the left mandibular ramus and multiple similar lesions in the skull, scapula, and axial skeleton. PET-CT confirmed multiple skeletal foci with low Fluorodeoxyglucose (FDG) uptake (SUVmax: 2.9) and pathological fractures in the pelvis. Histopathological examination showed diffuse neoplastic infiltration of atypical pleomorphic plasmacytic cells with 14-15 mitoses per 2 mm^2 . IHC demonstrated diffuse positivity for Cluster of Differentiation 138 (CD138) and Multiple Myeloma Oncogene 1 (MUM1) . Monoclonality was confirmed by Kappa light chain restriction, while Lambda, PAX5, and Cluster of Differentiation 20 (CD20) were negative. The final diagnosis was established as PCN.

CONCLUSIONS

Oral cavity masses can be the first herald of systemic plasma cell disorders . A multidisciplinary approach is essential for accurate staging and management. Following the multidisciplinary oncology board's decision, the patient was referred to the hematology department for the initiation of systemic treatment. Long-term follow-up is critical due to the aggressive nature and potential for disease progression.

Burkitt Lymphoma Presenting As An Inflammatory Submandibular Mass With Mandibular Destruction In A Pediatric Patient: A Case Report

Beyza İlyasoğlu[1], **Ferhat Deniz**[1], **Şevket Aksoy**[1]

[1]*Department of Otolaryngology-Head and Neck Surgery, Ankara Etlik City Hospital, Ankara, Turkey*

BACKGROUND & AIM

Burkitt Lymphoma (BL) is a highly aggressive, B-cell non-Hodgkin lymphoma characterized by rapid cellular proliferation and MYC oncogene translocation. While the endemic variant frequently involves the maxillofacial region, sporadic cases presenting with atypical, insidious bone destruction mimicking inflammatory processes are rare. Early diagnosis is critical due to the exceptionally short doubling time of the tumor cells. The aim of this case report is to present a pediatric patient with sporadic BL who initially presented with clinical and radiological features resembling a locally destructive, inflammatory submandibular pathology.

MATERIAL & METHODS

A 9-year-old female patient with a known history of Cerebral Palsy (CP) presented with a painless swelling in the right submandibular region, reportedly present for one year. Physical examination revealed a 2x1 centimeter, hard, hyperemic mass with increased local temperature overlying the right mandible. Computed Tomography (CT) imaging demonstrated extensive subcutaneous tissue edema in the right facial half. The right medial and lateral pterygoid muscles, as well as the masseter muscle, exhibited thickened and edematous appearances, completely obscuring the borders and adjacent fat planes of the submandibular and parotid glands. Furthermore, significant osseous destruction was observed at the level of the right mandibular condyle and ramus, accompanied by periosteal reactions and sclerotic changes in the ramus and corpus.

RESULTS

An incisional biopsy was planned under general anesthesia due to the suspicious destructive nature of the mass. An incision parallel to the skin creases was made over the hyperemic, fixed lesion in the right submandibular region. Following dissection of the platysma, the mass was exposed. Intraoperative frozen section analysis was performed, and the preliminary evaluation indicated malignancy. Consequently, extensive tissue sampling was conducted, and the surgical operation was concluded without any complications. The final histopathological evaluation of the surgical specimen confirmed the definitive diagnosis of BL.

CONCLUSIONS

In pediatric patients presenting with submandibular masses accompanied by localized soft tissue inflammation, hyperemia, and significant mandibular destruction, highly aggressive hematologic malignancies such as BL must be considered in the differential diagnosis. Even in cases presenting with prolonged or atypical histories mimicking benign inflammatory processes, prompt histopathological evaluation via early biopsy is crucial to initiate life-saving immunochemotherapy regimens.

Primary Palatine Tonsillar Hodgkin Lymphoma Mimicking Peritonsillar Abscess: A Rare Extranodal Presentation In An Adolescent — A Case Report

BÜŞRA ÜNSAL[1], **FUNDA TAŞKIN**[1], **FADİLE NUR DEMİR**[2], **SAFİYE GİRAN ÖRTEKİN**[1], **MERT AKIN**[1], **ŞAHİN ÖĞREDEN**[1], **ÖZGÜR YİĞİT**[1]

[1]BASAKSEHİR CAM VE SAKURA CITY HOSPITAL DEPARTMENT OF OTOLARYNGOLOGY; [2]BASAKSEHİR CAM VE SAKURA CITY HOSPITAL DEPARTMENT OF PATHOLOGY

BACKGROUND & AIM

Hodgkin lymphoma (HL) is a malignant lymphoid neoplasm derived from germinal-center B cells, predominantly involving the lymphatic and reticuloendothelial systems. Although HL commonly presents with nodal disease, primary extranodal involvement is rare, accounting for less than 1% of cases. Such presentations may mimic inflammatory conditions and lead to diagnostic delay. We report a rare case of primary tonsillar HL mimicking a peritonsillar abscess in an adolescent.

MATERIAL & METHODS

A 16-year-old female presented with a two-week history of progressive sore throat and dysphagia with decreased oral intake. Physical examination revealed asymmetric left tonsillar hypertrophy, peritonsillar bulging, and uvular deviation without B-symptoms. Initial needle aspiration yielded a dry tap.

CT demonstrated asymmetric soft tissue density in the left peritonsillar region, initially interpreted as a peritonsillar abscess. MRI showed enlargement of the left palatine tonsil (38×23×44 mm) with homogeneous contrast enhancement and diffusion restriction on DWI, suggestive of a lymphoproliferative process. Diagnostic tonsillectomy was performed due to discordant findings.

RESULTS

Histopathological examination demonstrated diffuse CD30 and EBER positivity with focal CD15 expression and B-cell lineage markers, consistent with classical Hodgkin lymphoma. These findings supported exclusion of key differential diagnoses including T- and B-cell lymphomas. The patient was referred to Pediatric Oncology for staging and management.

Extranodal HL may mimic inflammatory disease. CT suggested peritonsillar abscess and aspiration was negative. Although DWI restriction is non-specific, combined with homogeneous enhancement it raised suspicion for lymphoproliferative disease. Absence of B-symptoms contributed to diagnostic ambiguity.

CONCLUSIONS

Primary tonsillar HL should be considered in adolescents with tonsillar asymmetry and negative aspiration. MRI with diffusion-weighted imaging is useful but non-specific. Early recognition and tonsillectomy are essential for definitive diagnosis.

Evaluation Of Oncological And Surgical Outcomes In Patients With Early-Stage Glottic Laryngeal Cancer Undergoing Transoral Microlaryngeal Laser Cordectomy

Meltem Akpınar[1], **Muhammed Muaz Cıftcı**[1]

[1]*Sancaktepe prof dr ilhan varank eah*

BACKGROUND & AIM

Transoral Laser Microsurgery (TLM) is widely preferred in the treatment of early-stage glottic laryngeal cancers (Tis, T1, T2) due to its significant advantages in organ function preservation and low morbidity rates.

MATERIAL & METHODS

Thirty patients (n=30) who underwent TLM between [2023-2026] were retrospectively analyzed. All cases were staged, and cordectomy types were documented according to the European Laryngological Society (ELS) classification. Surgical margin status, local control (LC) rates, larynx preservation (LP) success, and postoperative complications were analyzed. Survival data were evaluated using the Kaplan-Meier method for statistical analysis.

RESULTS

The majority of patients included in the study were in the T1 stage. The mean follow-up period was 36 months. While surgical margins were negative in 80-90 % of the patients, additional resection or a close follow-up protocol was applied to 10-20 patients with positive surgical margins. During the follow-up period, local recurrence was observed in 3 patients, and these patients were successfully managed with salvage surgery or radiotherapy. The local control rate was 90%, and the larynx preservation rate was 95%. No serious permanent complications or requirements for tracheotomy were observed.

CONCLUSIONS

Our findings support that TLM is a reliable and minimally invasive method providing high local control and larynx preservation rates in early-stage glottic cancers. This 30-patient series demonstrates that functional outcomes can be preserved without compromising oncological safety.

PP-088

Low-Grade Thyroid-Like Nasopharyngeal Papillary Adenocarcinoma In A 14-Year-Old Male Arising From The Posterior Nasal Septum: A Rare Pediatric Case

nursena ekinci bulus[1], **ahmet adnan cırık**[1]

[1]*istanbul ümraniye research and training hospital*

BACKGROUND & AIM

Low-grade nasopharyngeal papillary adenocarcinoma (LGNPPA) is an extremely rare malignant epithelial tumor characterized by indolent behavior, low metastatic potential, and favorable prognosis. Its occurrence in the pediatric population is exceptionally uncommon. We aimed to present a rare pediatric case of LGNPPA arising from the posterior nasal septum and to highlight the importance of differential diagnosis, particularly in the presence of focal thyroglobulin expression.

MATERIAL & METHODS

A 14-year-old male presented with progressive nasal obstruction and intermittent epistaxis. Clinical examination, nasal endoscopy, and magnetic resonance imaging (MRI) were performed. The lesion was excised endoscopically and evaluated histopathologically with immunohistochemical analysis. Thyroid assessment included ultrasonography, serum thyroid-stimulating hormone (TSH) measurement, and positron emission tomography/computed tomography (PET/CT) to exclude metastatic thyroid carcinoma.

RESULTS

Endoscopy revealed a 1.5 cm pedunculated polypoid lesion originating from the left posterior nasal septum and extending into the nasopharynx. MRI demonstrated a 16 × 13 × 10 mm soft tissue mass partially obliterating the left choana without bone erosion or cervical lymphadenopathy. Histopathology showed complex papillary structures with fibrovascular cores lined by columnar epithelial cells with minimal atypia. Immunohistochemistry demonstrated strong nuclear TTF-1 positivity, CK7 positivity, PAX8 and EBER negativity, and focal cytoplasmic thyroglobulin positivity. The Ki-67 index was approximately 10% in hotspot areas. Surgical margins were negative. Thyroid evaluation was unremarkable. The patient remains disease-free after 14 months.

CONCLUSIONS

LGNPPA should be considered in pediatric nasopharyngeal masses. Focal thyroglobulin positivity necessitates thorough thyroid evaluation to exclude metastatic carcinoma. Complete surgical excision ensures excellent prognosis.

Lateral Cervical Kaposi's Sarcoma In An HIV-Negative Patient: A Case Report

Chahed Houda[1], **El Bessi Salma**[1], **Majbri Maha**[1], **Aouini Ayda**[1], **Madiouni Azza**[1], **Ben Amor Mohmed**[1], **Beltaief Najeh**[1]

[1]*Department of ENT and Head and Neck Surgery, la Rabta hospital, Tunis , Tunisia*

BACKGROUND & AIM

Kaposi's sarcoma (KS) is a rare vascular tumor, classically associated with HIV infection and HHV-8. Its occurrence as an isolated lateral cervical mass in a non-immunocompromised patient is exceptional.The aim of this study is to report a rare case of Kaposi's sarcoma presenting as a solitary lateral cervical mass in an immunocompetent, HIV-negative patient, and to emphasize its inclusion in the differential diagnosis of cervical tumors.

MATERIAL & METHODS

This is a clinical case report of a 68-year-old male patient , presenting with a progressively enlarging left lateral cervical mass.

RESULTS

A 68-year-old male with no significant medical history presented with a progressively enlarging left lateral cervical mass of 4 cm, firm, with intact overlying skin. HIV serology was negative. Cervical ultrasound revealed a solid hypoechoic mass with increased Doppler vascularity. CT scan demonstrated a 6×5×4 cm well-defined soft tissue mass with heterogeneous contrast enhancement and no neurovascular involvement. MRI showed T2 hyperintensity with gadolinium enhancement.

A left cervicotomy was performed under general anesthesia. Intraoperatively, the mass was soft, reddish, and adherent to the platysma muscle. Complete excision was achieved with clear margins. Frozen section analysis concluded a spindle cell tumor.

Histological examination showed a proliferation of spindle cells arranged in storiform fascicles, admixed with numerous vessels, siderophages, and erythrocyte extravasation. Immunohistochemistry revealed positive CD34 expression; AML, PS100, and HHV-8 were negative. Kaposiform hemangioendothelioma was excluded given the patient's age. A diagnosis of Kaposi's sarcoma was retained despite HHV-8 negativity.

CONCLUSIONS

This case highlights that KS should be included in the differential diagnosis of lateral cervical masses, even in the absence of immunodeficiency and HHV-8 positivity. Rigorous clinico-radiological and pathological correlation remains essential to establish this rare diagnosis

KEYWORDS

PP-090

Adult Epiglottitis: Diverse Presentations And Outcomes In Four Cases

Vidadi İmanov[1], **İbrahim Salih Geçer**[1], **Okan Sapan**[1]

[1]*Department of Otorhinolaryngology, Bakırköy Dr. Sadi Konuk Training and Research Hospital, İstanbul, Türkiye*

BACKGROUND & AIM

Adult epiglottitis is an uncommon but potentially life-threatening condition characterized by variable clinical presentation and unpredictable course. While its incidence has declined in children following Haemophilus influenzae type b (Hib) vaccination, adult cases remain clinically significant. Adults often present without overt airway compromise despite significant supraglottic inflammation, which may delay diagnosis. This series aims to illustrate diverse clinical presentations, microbiological findings, and management strategies in adult epiglottitis, and to highlight that laboratory parameters may not reliably reflect disease severity.

MATERIAL & METHODS

We present a retrospective case series of four adult patients diagnosed with epiglottitis at a tertiary referral otolaryngology clinic between February and October 2025. Diagnosis was established by clinical, laboratory, endoscopic visualization and confirmed by contrast-enhanced computed tomography (CE-CT) and, where indicated, magnetic resonance imaging (MRI). Outcome measures included clinical resolution, need for airway intervention, complications, length of hospital stay (LOS), and microbiological findings.

RESULTS

Patients ranged in age from 42 to 68 years (two male, two female) and presented with sore throat and dysphagia; none exhibited severe respiratory distress or required airway intervention. Inflammatory markers were elevated in three of four patients, while one had a near-normal white blood cell count (WBC: 5.9×10^9/L) despite significant endoscopic inflammation. Case 1 (43F) developed fungal superinfection after prolonged antibiotic therapy, requiring antifungal treatment (LOS: 20 days); Case 2 (68M) was refractory to medical therapy and underwent surgical drainage of an MRI-confirmed vallecular abscess (LOS: 4 days); Case 3 (42F) responded to standard intravenous antibiotics and corticosteroids (LOS: 5 days); and Case 4 (55M) demonstrated intralesional air on CE-CT and cytomegalovirus (CMV) seropositivity yet improved within 48 hours (LOS: 7 days).

CONCLUSIONS

Adult epiglottitis presents with heterogeneous clinical, laboratory, and radiological features. Laboratory parameters alone are insufficient for severity assessment, underscoring the essential role of early endoscopy. Atypical findings — including fungal superinfection, intralesional air, and viral co-infection — must be considered in refractory cases. Management should be individualized and guided by clinical evolution; imaging is warranted to exclude complications such as abscess formation.

KEYWORDS

Adult epiglottitis, supraglottitis, airway management, vallecular abscess, CMV, case series

PP-091

HYDATID CYST DISEASE IN THE HEAD AND NECK REGION: A REPORT OF TWO CASES WITH ATYPICAL LOCALIZATION

Gökçe Altın[1], **Nursena Nair Polat**[1], **Cemile Baykan Eryiğit**[1], **Fariza Şahap**[1], **Şahin Öğreden**[1], **Özgür Yiğit**[1]

[1]*Başakşehir Çam and Sakura City Hospital*

BACKGROUND & AIM

Hydatid disease is a zoonotic parasitic infection caused by Echinococcus granulosus ; most commonly affects the liver and lungs. Head and neck involvement is extremely rare, even in endemic regions, and represents a diagnostic challenge due to nonspecific clinical and radiological findings. These atypical presentations may mimic congenital cysts, benign soft tissue tumors, or deep neck infections, increasing the risk of inappropriate invasive procedures. This study presents two rare head and neck hydatid cyst cases with unusual anatomical locations and clinical courses, emphasizing diagnostic pitfalls in otolaryngology practice.

MATERIAL & METHODS

Two patients presenting to a tertiary otorhinolaryngology center, with clinical and radiological findings consistent with hydatid cyst disease, were retrospectively analyzed. Clinical presentation, physical examination and endoscopic findings, magnetic resonance imaging and ultrasonography results, administered medical therapy, and early clinical outcomes were evaluated descriptively.

The primary outcome measures were as follows:

- Lesion localization and extent of spread,
- Radiological findings of infection and associated complications,
- Response to medical therapy,
- Requirement for surgical intervention,
- Multidisciplinary management approach.

RESULTS

The outcomes of two patients with hydatid cyst disease were evaluated. The patients were 33 and 42 years old, presenting with swelling and pain in the facial and cervical regions; one also had trismus and restricted oral intake. Lesions were located in the left masticator and parapharyngeal spaces in one case, and in the right posterior cervical triangle and paravertebral muscles in the other. Facial nerve function was preserved, and endoscopic and otoscopic findings were normal. Imaging revealed multiloculated cystic lesions with septations and focal calcifications; one case suggested superimposed infection.

- Patient 1: Had long-standing disease with symptom progression after aspiration; a large multiloculated lesion was identified, and clinical improvement was achieved with albendazole therapy.
- Patient 2: Presented with a short symptom history; imaging suggested an infected cyst, and significant clinical and radiological remission was observed after treatment.

No surgery was required, and no major complications occurred during follow-up.

CONCLUSIONS

Hydatid disease should be considered in the differential diagnosis of cystic head and neck masses, particularly in endemic regions. Recognition of atypical radiological features and avoidance of invasive diagnostic procedures are essential to reduce misdiagnosis and prevent serious complications. These cases demonstrate the importance of clinical and radiological awareness in unusual head and neck presentations of hydatid disease.

Parotid Lymphomas Mimicking Benign Salivary Tumors: A 15-Case Retrospective Single-Center Series

Faruk Kadri Bakkal[1,2], **Eray Uzunoğlu**[2,3], **Alper Dilci**[1,2], **Utku Aydil**[2]

[1]*Uşak University Faculty of Medicine ENT Department;* [2]*Gazi University Faculty of Medicine ENT Department;* [3]*Bakircay University Faculty of Medicine ENT Department*

BACKGROUND & AIM

Primary and secondary lymphomas of the parotid gland are uncommon and frequently mimic benign salivary neoplasms. We hypothesized that parotid lymphomas are often clinically and radiologically misinterpreted as benign tumors, resulting in low preoperative diagnostic accuracy.

MATERIAL & METHODS

This retrospective single-center study included 15 patients who underwent parotid surgery and were postoperatively diagnosed with lymphoma. Demographic data, clinical presentation, fine-needle aspiration biopsy (FNAB) results, surgical procedure, histopathological subtype, and follow-up data were analyzed. Diagnostic accuracy of FNAB and distribution of lymphoma subtypes were evaluated descriptively.

RESULTS

The cohort included 10 males (66.7%) and 5 females (33.3%), with a mean age of 60 ± 17 years. The most common presentation was a painless parotid mass. Preoperative FNAB correctly suggested lymphoma in only 1 case (6.7%), while 93.3% were interpreted as benign or non-specific. Sjögren syndrome was present in 3 patients (20%).

Superficial parotidectomy was performed in 60% of cases, reflecting preoperative benign suspicion. Histopathological analysis revealed extranodal marginal zone B-cell lymphoma in 40%, diffuse large B-cell lymphoma in 20%, follicular lymphoma in 20%, classic Hodgkin lymphoma in 6.7%, and small lymphocytic lymphoma infiltration in 6.7%.

Mean follow-up duration was 4.7 years (range: 1.5–9 years). Two patients were lost to early follow-up.

CONCLUSIONS

Parotid lymphomas frequently mimic benign salivary tumors both clinically and radiologically. Preoperative cytological diagnosis is limited, and most cases are diagnosed after surgical excision. Sjögren syndrome remains an important associated risk factor. Clinicians should maintain a high index of suspicion, particularly in patients with atypical imaging features or autoimmune background.

Parotid gland, Lymphoma, Fine-needle aspiration biopsy, Sjögren syndrome, Salivary gland neoplasms

PP-093

Role Of Surgery In The Treatment Of Cervical Lymph Node Tuberculosis

DERADJ SALAH EDDINE[1], **BENYAHIA SAMIR**[2]

[1]*University Ferhat Abbes, Faculty of Medecine. Sétif, Algeria;* [2]*University Youcef El Khatib, Faculty of Medecine. Algiers, Algeria*

BACKGROUND & AIM

Tuberculosis remains a major public health issue worldwide. In Algeria, the extrapulmonary form predominates, accounting for 69.2% of all reported cases, thereby illustrating an epidemiological particularity that requires tailored diagnostic and therapeutic strategies. The aim of the present study is to evaluate the role of surgery as a therapeutic option in managing failures of medical treatment for cervical lymph node tuberculosis and to describe the epidemiological characteristics of the disease in the region of Sétif, Algeria.

MATERIAL & METHODS

This is a prospective, descriptive, and analytical study conducted over a period of two years. The study included patients consulting our ENT department at the Sétif University Hospital for cervical lymph node tuberculosis without other associated localizations. 95 patients were included. Following confirmation of the diagnosis of cervical tuberculous lymphadenitis, all patients were initiated on standard antituberculous medical therapy (2RHZ/RH) after completion of a comprehensive pre-therapeutic assessment. Patients were subsequently monitored throughout the course of treatment. After completion of medical therapy, those exhibiting clinical or radiological evidence of treatment failure were managed surgically for therapeutic purposes. Surgical intervention consisted of selective cervical lymph node dissection performed under general anesthesia.

RESULTS

The male-to-female ratio was 0.61. The mean age was 28.7 years. A vaccination scar was observed in 80% of patients. The consumption of raw milk and unpasteurized dairy products was reported by 86.3% of patients. No patient was HIV-positive. Mantoux test was positive in 67% of cases. Cervical ultrasound revealed a hypoechoic aspect in 84.2% of cases, necrosis in 75.5% of cases and calcifications in 16.8% of cases. Fine-needle aspiration cytology was performed in 81 patients; yielding a positive result in 50,6% of cases and providing contributory diagnostic information in 93,8% of cases. The histological study allowed diagnostic confirmation in 100% of cases. Bacteriological examination was conducted in only 5 patients. The mean duration of antituberculous treatment was 7.4 ± 1.6 months. In 48.6% of cases the failure of medical treatment led to a selective lymph node dissection. A single case of disease recurrence was observed over a two-year follow-up.

CONCLUSIONS

Histological examination remains the cornerstone for establishing a definitive diagnosis in our setting. Our study suggests that the consumption of raw milk and unpasteurized dairy products may be a significant exposure factor in the development of the disease. Our results reflect a significant recourse to surgery, highlight the low efficacy of antituberculous chemotherapy, whose

underlying causes remain to be elucidated, and suggest a possible involvement of Mycobacterium bovis. Surgery remains a pertinent and legitimate therapeutic option, reinforcing its place in the treatment arsenal against this pathology, especially in cases where medical treatment fails.

KEYWORDS

Cervical lymph node tuberculosis, ultrasound, histopathology, raw milk and unpasteurized dairy products, Mycobacterium bovis, ENT surgery.

PP-094

Post-Thyroidectomy Hematoma And Hypocalcemia As Separate Complications: Risk Factors And Management —A Systematic Review And Meta-Analysis

Albaraa Najmi[1]

[1]*Moh*

BACKGROUND & AIM

Thyroidectomy is a common surgical procedure for various thyroid conditions, including benign nodules, multinodular goiters, hyperthyroidism, and malignancies. Despite its widespread use, it is associated with significant complications such as post-thyroidectomy hematoma and hypocalcemia. This systematic review aims to evaluate the risk factors and management strategies for these complications to enhance patient outcomes.

MATERIAL & METHODS

This systematic review and meta-analysis followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. A comprehensive search was conducted across multiple electronic databases, including Scopus, Cochrane Library, Web of Science, PubMed, and ScienceDirect, using keywords related to post-thyroidectomy hematoma and hypocalcemia. Only studies published between 2010 and 2024 were considered. Studies were included if they focused on adult patients undergoing thyroidectomy and reported on the incidence or management of these complications. Studies were excluded if they were letters to the editor, case reports, opinion pieces, non-peer-reviewed articles or not in English. Pooled rates for hematoma and hypocalcemia were calculated using R software. A random-effects model was used to address study heterogeneity and calculate the pooled incidence estimate. The Newcastle-Ottawa Scale (NOS) was used to assess bias and select high-quality studies, improving the reliability of the results.

RESULTS

The present study identified 10 studies meeting the inclusion criteria (253,941 participants), with most scoring 9/9 on the NOS. The meta-analysis revealed that the pooled incidence of post-thyroidectomy hematoma is approximately 1.43% [95% confidence interval (CI): 1.07% to 1.80%, P<0.001], with significant heterogeneity across studies (I 2 =88.01%, P<0.001). Notable risk factors include older age, vitamin D deficiency, and thyroid malignancy. For hypocalcemia, the pooled incidence is around 23.14% (95% CI:

10.96% to 35.32%, P<0.001), also showing substantial heterogeneity (I2 =99.97%, P<0.001). Risk factors

included older age, female sex, malignancy, total thyroidectomy, and Graves' disease. Effective management strategies for hematoma included reoperation and tracheostomy, while for hypocalcemia, calcium and vitamin D supplementation and intravenous calcium were critical.

CONCLUSIONS

Post-thyroidectomy hematoma and hypocalcemia are major complications that affect patient outcomes and increase healthcare costs. Identifying risk factors and applying effective surgical and postoperative strategies can help reduce these risks.

Periosteal Preservation In Total Exenteration: Evaluation Of A New Surgical Technique

Julien LUCAS[1], **Wahib GHANEM**[1], **Olivier CHOUSSY**[1], **Rabah TAOUACHI**[1], **Maria LESNIK**[1], **Guillaume ROUGIER**[1], **Joey MARTIN**[1], **Juliette QUAREZ**[1], **Baptiste SABRAN**[1], **Antoine DUBRAY- VAUTRIN**[1], **Nathalie Badois**[1]

[1]*Institut Curie , Paris*

BACKGROUND & AIM

Total exenteration is a well-established procedure for managing orbital and eyelid tumors. However, the impact of preserving the periosteum of the orbital cavity has never been evaluated. This study aimed to assess a modified periosteum-sparing total exenteration (PSTE) compared with conventional radical total exenteration (CRTE), focusing on oncological outcomes and postoperative rehabilitation using full-thickness skin graft (FTSG) reconstruction.

MATERIAL & METHODS

A single-center retrospective comparative study was conducted on patients who underwent total exenteration over a 20-year period. The exposure was the surgery strategy defined by CRTE versus PSTE approaches. The outcome was the three-years disease free survival (DFS) using an inverse probability of therapeutic weighting cox modeling. Secondary objectives were the evaluation of healing time and prosthetic rehabilitation rate.

RESULTS

Among 105 patients, 76 underwent CRTE and 29 PSTE. Three-year DFS did not differ between groups (weighted hazard ratio = 0.89, 95% CI 0.43–2.33, p = 0.75 for PSTE approach). PSTE enabled FTSG reconstruction, with complete epithelialization achieved in 88.9% of cases within a mean of 45.8 days and without major complications. Prosthetic rehabilitation was more frequent and faster in the PSTE group (63.1% of patients at a mean of 6.6 months) compared with other techniques.

CONCLUSIONS

Periosteum-sparing total exenteration with FTSG reconstruction is a safe and effective alternative to conventional radical exenteration. It may be considered as a preferred approach when total exenteration is required for tumors remaining distant from the orbital bony walls offering comparable oncological outcomes with enhanced rehabilitation.

Malignanicies Of Hypopharynx - Standard Of Care In Montenegro

Vladimir Pavićević[1], **Vanja Karađinović**[1], **Milan Sorat**[1], **Tijana Vukadinović**[1], **Biljana Popović Kolašinac**[2]

[1]*Clinical center of Montenegro;* [2]*Institute of Public Health of Montenegro*

BACKGROUND & AIM

Hypopharyngeal carcinoma is known as a rare, aggressive cancer, often diagnosed at an advanced stage. The aim of the study was to analyze the local treatment standards and outcomes of patients with hypopharyngeal carcinoma at the Clinical Center of Montenegro.

MATERIAL & METHODS

A retrospective analysis of patients treated between 2019 and 2025 at the Clinic for Otorhinolaryngology and the Institute of Oncology of the Clinical Center of Montenegro. The diagnosis was confirmed histopathologically. Tumors were classified according to cTNM.. The applied therapies (surgery, radiotherapy, chemotherapy, immunotherapy), Two- year survival was recorded.

RESULTS

Analysis resulted in 43 patients, 83.7% men, 16.3% women. The average age at diagnosis was 63.4 years; men 65.5 years, women 51.71 years. Most patients had histological grade 2 (65.1%). Localizations were piriform sinus 55.8%, posterior pharyngeal wall 4.7%, postcricoid area 39.5%. All patients had squamous cell carcinoma. Most patients had T3/T4 (69.8%) and N2 stage (71.1%). Only one patient had distant metastases (2.3%). Therapeutic approach was combined surgery and adjuvant therapy in 7%, or primary oncological treatment (RT/CT) in 93%. Standard radiotherapy doses (66 -70 Gy) were applied in most patients (89.1%). Patients received cisplatin (68.4%), carboplatin (5.3%), and cetuximab (26.3%). Two-year overall survival was 14%. The largest number of patients had local recurrence (47.6%). Distant metastases included lungs 11.9%, liver 4.8% and bone 2.3%. The average follow-up time (from presentation to last check-up) was 11.6 months (women 21.6, men 9.7).

CONCLUSIONS

In Montenegro, hypopharyngeal carcinomas predominantly occur in the piriform sinus and are of the squamous type, with significantly higher incidence in men. Outcomes align with international data: early-stage disease has a significantly better prognosis. In our study, Women presented at earlier age compared to men. Worse outcome was found for men. Most patients were treated with radiotherapy and chemotherapy. Where possible, surgery combined with adjuvant therapy is applied.

Parapharyngeal Neuroendocrine Carcinoma With Nasopharyngeal Projection - A Rare Case Report

SAHRAOUI Mohammed[1,2], **MEHTARI Nasrine Siham**[1,2], **BENMANSOUR Narimane**[1], **NASRI Amine**[1,2], **AID Chahrazed**[1]

[1]*ENT Department - Tlemcen University Hospital Center;* [2]*Faculty of Medicine - Abou Bekr Belkaid University of Tlemcen*

BACKGROUND & AIM

Small cell neuroendocrine carcinomas (SCNEC) of the ENT region are very rare and highly aggressive tumors, representing less than 1% of cancers of the upper aerodigestive tract.

The aim of our publication is to review a case of SCNEC with a parapharyngeal location and nasopharyngeal projection, highlighting the diagnostic challenges and the therapeutic management strategies involved.

MATERIAL & METHODS

This was a 40-year-old man with no significant past medical history, who presented with severe, chronic, sleep-disturbing right-sided headaches that had been evolving over several months, associated with ipsilateral facial hypoesthesia and dysgeusia.

A thorough clinical examination, craniofacial MRI, and biopsy followed by histopathological analysis were performed.

RESULTS

Clinical examination, guided by the purely unilateral neurological symptomatology, prompted evaluation of the nasopharynx. Nasofibroscopy revealed a smooth juxtachoanal bulging of the right lateral wall of the nasopharynx.

Craniofacial MRI showed a large mass involving the right infratemporal and parapharyngeal fossae, with low T1 and moderately high T2 signal intensity, diffusion restriction, and homogeneous gadolinium enhancement. The lesion infiltrated the pterygoid muscles and deep lobe of the parotid gland, encased the internal carotid artery, and extended to the pterygopalatine fossa and Meckel's cave.

Endoscopic biopsy of the lateral nasopharyngeal submucosal mass was performed under general anesthesia.

Histopathological and immunohistochemical analysis confirmed small-cell neuroendocrine carcinoma with a Ki-67 index of 80%, strong CD56 expression, and negative chromogranin A and synaptophysin staining.

Staging workup, including thoraco-abdomino-pelvic computed tomography and bone scintigraphy, revealed hepatic metastases without thoracic involvement.

Follow-up MRI demonstrated loco-regional tumor progression despite the introduction of appropriately administered systemic chemotherapy.

CONCLUSIONS

Head and neck small-cell neuroendocrine carcinomas are rare tumors with a poor prognosis, characterized by aggressive loco-regional behavior and a high metastatic potential.

This case highlights the importance of rigorous histopathological diagnosis, comprehensive staging workup, and multidisciplinary management.

The poor response to chemotherapy underscores the need to develop new therapeutic strategies tailored to these rare entities.

Fatal Emphysematous Tonsillopharyngitis With Laryngocele Involvement Revealing Acute Myeloid Leukemia M5 Subtype: A Previously Undescribed Presentation

Somaya Al Kiswani[2], **Mohammed Abduljabbar Abed**[2], **Hossam Salameh**[3], **Muna Shahwan**[3], **Omar Sawafta**[3], **Fatena A. H. Ajlouni**[2], **Abdullah Nofal**[2], **Suhaib Eid**[1]

[1]*Arab medical center -Amman -Jordan;* [2]*King Hussein cancer center;* [3]*AlNajah National University, Nablus, Palestine*

BACKGROUND & AIM

Emphysematous infections in the tonsillopharyngeal area are exceptionally unique; this type of infection occurs in immuno-compromised patients. Extramedullary disease can occur in acute myeloid leukemia (AML), but oropharyngeal involvementis rare and diagnostically challenging. Furthermore, a laryngocele is defined as an abnormal dilation of the laryngeal sacculethat is filled with air and fluid if infected. Although infections and cancers rarely extend to the laryngocele, they can be foundin patients with laryngeal or hypopharyngeal cancer.

MATERIAL & METHODS

We describe a 65-year-old male presenting with progressive sore throat,halitosis, and airway compromise. Contrast-enhanced computed tomography demonstrated bilateral emphysematous tonsillitiswith parapharyngeal extension, severe supraglottic narrowing, and rare secondary involvement of a laryngocele.

RESULTS

This case highlights an important diagnostic principle: Atypicalgas-forming infections of the upper aerodigestive tract shouldprompt evaluation for underlying hematologic malignancy,particularly when accompanied by cytopenias or abnormal leu-kocyte counts. Early recognition may alter airway planning, an-timicrobial selection, and oncologic management

CONCLUSIONS

The present case illustrates an exceptionally rare and fulminantpresentation of a sequela of AML-related emphysematous tonsil-litis with rapid progression into a life-threatening laryngocele,emphasizing the immunocompromised sequela of AML-relatedand expanding the spectrum of extramedullary AML manifesta-tions in cases of severe deep head and neck infections

Systemic Inflammatory Parameters In Pleomorphic Adenoma And Warthin Tumor Of The Parotid Gland: A Retrospective Study

Zülal Toprak Keleş[1], **Ahmet Ural**[1], **Safa Selvi**[1], **Burcu Vural Çamalan**[1], **Samet Özlügedik**[1], **Ömer Bayır**[1], **Murat Dıramalı**[2]

[1]*Department of Otolaryngology – Head and Neck Surgery at Ankara Etlik City Hospital, Ankara, Türkiye;* [2]*Department of Anatomy, Bolu Abant İzzet Baysal University, Bolu, Türkiye*

BACKGROUND & AIM

This study aims to compare systemic immunological and inflammatory parameters — including the systemic immune-inflammatory index (SIII), systemic inflammation response index (SIRI), neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), and lymphocyte-to-monocyte ratio (LMR) — between patients with pleomorphic adenoma, Warthin tumor, and healthy controls, and to investigate the potential role of these inflammatory factors in the pathogenesis of the most common benign parotid tumors.

MATERIAL & METHODS

Sociodemographic data (age, gender, smoking status), systemic immune inflammatory index (SIII), systemic inflammation response index (SIRI), neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), and lymphocyte-to-monocyte ratio (LMR) were compared. The study included data from 174 patients who underwent parotidectomy and 42 healthy patients without parotid masses as the control group. The patients' demographic data, preoperative blood count values, and postoperative pathology results were evaluated.

RESULTS

The study included 137 men and 79 women (216 individuals total), of whom 42 had no parotid pathology. Pleomorphic adenoma was detected in 91 patients and Warthin tumor in 83. SIII was higher in pleomorphic adenoma compared to the control group ($p=0.037$), PLR was higher in pleomorphic adenoma compared to Warthin tumor ($p=0.021$), and SIRI was higher in Warthin tumor compared to the control group ($p=0.012$). NLR and LMR showed no statistically significant differences. Six multinomial logistic regression models were constructed using demographic data, inflammatory markers, and blood values in various combinations. Age and female gender were significant predictors of pleomorphic adenoma, while age and elevated lymphocyte count were significant for Warthin tumor ($p<0.001$, Nagelkerke $R^2=0.645$). SIRI was identified as a supportive diagnostic marker for Warthin tumor ($p=0.012$, Nagelkerke $R^2=0.124$).

CONCLUSIONS

While inflammatory markers alone are significant in the preoperative evaluation of pleomorphic adenoma and Warthin tumor —the most common benign parotid tumors—the reliability of this assessment decreases when inflammatory markers are evaluated in conjunction with demographic data. Further studies are needed to assess the impact of demographic data (age, smoking status, gender) on inflammatory markers.

KEYWORDS

PP-100

ONE SESSION, TWO SIDES: SIMULTANEOUS BILATERAL PARTIAL PAROTIDECTOMY FOR BILATERAL PAROTID MASSES

Ömer Faruk Koçer[1], **Erdem Köroğlu**[1]

[1]*Kocaeli Şehir Hastanesi*

BACKGROUND & AIM

Bilateral parotid masses are rare in clinical practice, and their surgical management remains controversial. Simultaneous bilateral parotidectomy in a single session is generally avoided due to the risk of bilateral facial nerve injury and postoperative complications. This case report aims to evaluate the efficacy, complications, and surgical outcomes of simultaneous bilateral partial parotidectomy performed in a single session.

MATERIAL & METHODS

A 52 year old male patient with no known comorbidities presented with a one month history of neck swelling.Ultrasonography revealed a 27x18 mm thick cortex lesion in the inferior pole of the right parotid gland. In the left parotid gland, multiple lymph nodes were observed, the largest measuring 15x7.5 mm.Contrast-enhanced neck MRI demonstrated an approximately 20 mm lesion in the right parotid gland with peripheral enhancement and central cystic/necrotic areas, along with adjacent nodular

structures.Fine needle aspiration biopsy of both parotid glands was reported as bilateral Warthin tumor.The patient underwent simultaneous bilateral partial parotidectomy with mass excision in a single session.

RESULTS

Histopathological examination revealed; Lymphoepithelial cyst in the right parotid gland and Multifocal Warthin tumor in the left parotid gland.On postoperative day 0, the patient developed House-Brackmann (HB) Grade V facial paralysis on the left side. Intravenous prednisolone (1 mg/kg) therapy was initiated and tapered over 10 days.After discharge, the patient continued rehabilitation under the guidance of the Physical Therapy Department.On postoperative day 8, the patient presented with swelling in the left parotid region, which was consistent with a seroma. The seroma was drained and managed with pressure dressing.By postoperative day 18, the seroma had completely resolved.At the 6 month follow up, complete recovery of facial nerve function was observed.

CONCLUSIONS

Simultaneous bilateral partial parotidectomy in a single session may be a safe and effective surgical option in selected patients when combined with appropriate patient selection and intraoperative facial nerve monitoring.A single stage surgical approach eliminates the need for a second operation, reduces repeated exposure to anesthesia, and shortens the overall treatment course.However, careful postoperative monitoring is essential due to the risk of complications such as facial nerve paralysis, seroma, and hematoma following bilateral surgery.

Impact Of Radiofrequency Ablation For Thyroid Nodules On Voice Quality

Chang, Hsuan Fu[1], **Hung, Yu Hsiang**[1], **Tsou, Yung An**[1], **Huang, Chun Wei**[1]

[1]*Department of Otolaryngology, China Medical University, Taiwan*

BACKGROUND & AIM

Thyroid nodules are a common endocrine disorder. While most are benign, an increase in size can lead to compressive symptoms or voice changes. Radiofrequency Ablation (RFA) has become increasingly widely used in clinical practice as a minimally invasive treatment that does not require general anesthesia. Previous literature indicates that the overall incidence of voice changes following RFA is approximately 1.44%; however, studies focusing on both subjective and objective voice analysis remain relatively limited. This study aims to evaluate changes in voice parameters after RFA through speech analysis to explore its safety and potential for improvement.

MATERIAL & METHODS

This study retrospectively enrolled patients with thyroid nodules who underwent RFA treatment. Voice assessments were conducted pre-treatment and at three months post-treatment. The voice analysis included objective parameters—such as Jitter, Shimmer, and Noise-to-Harmonic Ratio (NHR)—and subjective assessment tools, including the GRBAS scale and the Voice Handicap Index-10 (VHI-10), to capture changes in voice quality before and after the procedure.

RESULTS

This study enrolled 17 patients with thyroid nodules (8 solitary, 9 multinodular). RFA primarily targeted the largest nodules, achieving a 74% average volume reduction at the 3-month follow-up (from 11.08 ml to 2.89 ml). Subjective analysis showed no significant differences in GRBAS sub-scores or VHI-10 ($p = 0.109$). In objective analysis, Jitter (2.46% to 2.22%, $p = 0.109$) and Shimmer (6.56% to 5.64%, $p = 0.107$) remained stable. Notably, NHR significantly improved from 0.21 to 0.19 ($p = 0.031$). Overall, voice performance did not deteriorate, and the incidence of vocal cord paralysis was extremely low.

CONCLUSIONS

Radiofrequency Ablation is a safe, low-risk treatment option for thyroid nodules with the advantage of preserving voice quality. Voice analysis tools serve as an important clinical basis for evaluating vocal changes before and after treatment. Future large-scale prospective studies targeting specific nodule types are warranted.

A Rare Cervical Foregut Duplication Cyst Mimicking Lesion In An Adolescent: Diagnostic Dilemma Between Foregut Duplication Cyst And Dermoid Cyst

Muratcan Sarı[1], **Kays Burak Çakır**[1], **Fırat Tevetoğlu**[1], **Emine Deniz Gözen Tan**[1]

[1]*Department of Otolaryngology–Head and Neck Surgery, Istanbul University-Cerrahpaşa, Istanbul, Türkiye*

BACKGROUND & AIM

Foregut duplication cysts are rare congenital malformations of the embryonic foregut, most commonly located in the thoracic and abdominal regions. Cervical localization is exceedingly uncommon and represents a significant diagnostic challenge, as

their presentation may mimic other cervical cystic lesions including dermoid cysts, ranula, lymphatic malformations, branchial cleft cysts, and thyroglossal duct cysts. Definitive diagnosis frequently requires histopathological confirmation. We present a rare case of a large submental and sublingual cystic lesion in an adolescent male, radiologically interpreted as a foregut duplication cyst but ultimately diagnosed as a dermoid cyst, highlighting the diagnostic dilemmas and surgical considerations.

MATERIAL & METHODS

An 18-year-old male presented with a one-year history of left submandibular swelling, progressively enlarging over the past 2–3 months. Neck ultrasonography demonstrated a deep, well-defined, mildly lobulated, semi-cystic/semi-solid echogenic mass measuring 60 × 55 × 30 mm in the submental subcutaneous region, with no significant vascularity on color Doppler. Contrast-enhanced neck MRI revealed a T2-hyperintense, non-enhancing cystic lesion in the left sublingual space extending caudally toward the submental midline, measuring 60 × 47 mm in maximal axial dimension, with mass effect narrowing the airway column and left epiglottic vallecula. Neuroradiological interpretation favored a foregut duplication cyst. The patient underwent transcervical excision via a 10 cm horizontal incision from the left submandibular region to the submental midline. After dissection through the platysma and mylohyoid muscle, the cyst was identified deep to the suprahyoid musculature, without communication with the floor of the mouth, and excised en bloc with its tract.

RESULTS

The procedure was completed without intraoperative complications. The lesion was successfully removed in its entirety, with preservation of surrounding neurovascular and muscular structures. The postoperative course was uneventful, with no airway compromise, hematoma, infection, or wound-healing complications. Despite the strong preoperative radiological suspicion of a foregut duplication cyst supported by characteristic MRI features—T2 hyperintensity, absence of contrast enhancement, and characteristic location in the sublingual and submental spaces—histopathological examination of the excised specimen revealed findings consistent with a dermoid cyst. This unexpected discrepancy between radiological and pathological diagnoses underscores the overlap of imaging features among congenital cervical cystic lesions. The patient was discharged in good clinical condition and remained free of recurrence on follow-up, with no functional deficit, no swallowing difficulty, and a satisfactory cosmetic outcome from the cervical incision.

CONCLUSIONS

Cystic lesions of the submental and sublingual region pose a significant diagnostic challenge due to overlapping radiological features. Although MRI strongly suggested a foregut duplication cyst, the definitive diagnosis was dermoid cyst, illustrating that imaging alone may be insufficient for characterization of cervical cystic masses. A broad differential including foregut duplication cyst, dermoid cyst, ranula, lymphatic malformation, branchial cleft cyst, and thyroglossal duct cyst should be considered. Complete transcervical en bloc excision with histopathological confirmation remains the gold standard, particularly in lesions causing airway compromise. Otolaryngologists should be aware of potential discrepancies between radiological and pathological diagnoses.

KEYWORDS

foregut duplication cyst; dermoid cyst; cervical cystic mass; submental swelling; sublingual space; differential diagnosis.

Biweekly Cetuximab-Docetaxel In Advanced Head And Neck Cancer Patients With Intermediate Performance Status

Sara Fernández Cascón[1], **Ana Martin Gonzalez**[1], **Elena Balduz Moreno**[1], **Lucía Clement Alonso**[1], **Carmen Manzanares Lopez-Rendo**[1], **Claudia Llorente Alvarez**[1], **Ignacio Alvarez Alvarez**[1], **Angel Rodríguez Sánchez**[2]

[1]*Complejo Asistencial Universitario de León, ENT Department;* [2]*Complejo Asistencial Universitario de León, Medical Oncology Department*

BACKGROUND & AIM

Taxane-cetuximab combinations are commonly used in advanced head and neck cancer (HNC) in daily clinical practice. We evaluated the efficacy and safety of biweekly cetuximab-docetaxel in patients with intermediate performance status treated at our institution.

MATERIAL & METHODS

We retrospectively analyzed patients with advanced HNC treated between January 2010 and December 2019 with cetuximab 500 mg/m² plus docetaxel 50 mg/m² every two weeks. Clinical data were obtained from medical records. Progression-free survival (PFS), overall survival (OS), response rate, and toxicity were assessed.

RESULTS

Fifty-eight patients were included, with a median age of 64.5 years and a marked male predominance. Most tumors originated in the larynx and oropharynx, and squamous cell carcinoma represented the vast majority of cases. At treatment initiation, over two-thirds of patients had metastatic disease. The median number of treatment cycles administered was four. Treatment-related toxicity occurred in 79.3% of patients, with grade 3–4 adverse events in 28.3%. Non-hematologic toxicity, mainly cetuximab-related cutaneous reactions, was more frequent than hematologic toxicity. The overall response rate was 24.1%, while 39.7% of patients achieved stable disease. Median progression-free survival was 4 months and median overall survival was 9 months. Interestingly, patients who developed treatment-related toxicity demonstrated significantly better outcomes,

with improved progression-free and overall survival compared with patients without toxicity. Non-hematologic toxicity was particularly associated with prolonged survival, suggesting a possible relationship between treatment activity and clinical benefit.

CONCLUSIONS

Biweekly cetuximab-docetaxel demonstrated manageable toxicity and clinically meaningful activity in frail patients with advanced HNC and ECOG 2 in real-world practice. The development of treatment-related toxicity may correlate with improved survival outcomes.

KEYWORDS

Biweekly cetuximab-docetaxel; advanced HNC; ECOG 2

PP-104

Epithelioid Hemangioendothelioma Localized In The Left Neck: A Challenging Diagnosis

Aynur Deniz[1], **Furkan Olgun**[1], **Hakan Kara**[1], **Levent Aydemir**[1]

[1]*Istanbul University, Istanbul Faculty of Medicine, Department of Otorhinolaryngology-Head and Neck Surgery*

BACKGROUND & AIM

Epithelioid hemangioendothelioma (EHE) is an extraordinarily rare vascular sarcoma with a prevalence less than 1 in 1,000,000, occurring even less frequently in the pediatric population. While generally localized in the extremities, liver, or lungs, its manifestation in the head and neck region is exceptionally rare, and it mimics inflammatory or infectious processes, leading to diagnostic delays.

MATERIAL & METHODS

An seventeen-year-old female patient presented with a rapidly progressing, painful left-sided, fixed neck mass. Empirical intravenous antibiotherapy regimens at external centers were ineffective. After ruling out various infectious etiologies, she received anti-tuberculosis therapy for six months, which also proved ineffective. Subsequent excisional biopsies were unfeasible and the following incisional biopsy, along with fine needle aspiration biopsies, remained non-diagnostic. After the emergence of a new, tender left-sided lymphadenopathy alongside the fixed mass, a repeat position emission tomography obtained upon referral to our clinic revealed a heterogeneous posterior cervical mass with vertebral expansion but no distant metastasis. Following multidisciplinary oncology board consensus, surgical exploration was performed, achieving excision of the Level II lymph node and a wedge resection of the Level V mass.

RESULTS

The Level II lymph node was benign, but histopathological analysis of the Level V specimen revealed a CAMTA1-positive epithelioid hemangioendothelioma. Magnetic resonance imaging showed tumor extension into the parapharyngeal space with contrast enhancement of the carotid sheath and paraspinal/occipital muscle invasion. Deemed completely unresectable with clear margins, the patient was referred to pediatric oncology. Treatment with sirolimus was initiated, resulting in a favorable clinical response at start and relief of the symptoms. Unfortunately, the symptoms recurred during the course due to expansion of the mass in the contralateral paraspinal and occipital muscles.

CONCLUSIONS

This diagnostic challenge highlights EHE's rarity and clinical overlap with mesenchymal tumors or granulomatous infections, which impede early recognition. An adequate tissue biopsy essential for morphological and immunohistochemical differentiation. While complete en bloc resection is standard treatment for unifocal EHE, it was unfeasible here due to extensive local invasion. The absence of standardized protocols poses difficulty in treatment of unresectable/advanced disease. Consequently, medical therapy with sirolimus was utilized in accordance with the decision of the head & neck board, which underscores the necessity of a tailored, multidisciplinary approach at every stage of EHE management.

A Case Of Cervical Necrotising Fasciitis Precipitated By Hypopharyngeal Squamous Cell Carcinoma

Saffron O'Neill[1], **Tiarnan Mellon**[2], **Gabrielle Croker**[1], **Claire Batchelor**[1], **Stephanie Flukes**[1]

[1]*Fiona Stanley Hospital, Perth, WA;* [2]*Royal Perth Hospital, Perth, WA*

BACKGROUND & AIM

Cervical necrotising fasciitis (CNF) is a rare but life-threatening soft tissue infection of the head and neck, associated with high morbidity and mortality despite advances in disease detection and antimicrobial therapy. It most commonly arises from odontogenic or pharyngeal sources, and presentation secondary to underlying head and neck malignancy is uncommon.

MATERIAL & METHODS

We report the case of a 54 year old female who presented with rapidly progressive anterior neck swelling, subcutaneous emphysema, and septic shock. Cross-sectional imaging demonstrated extensive gas-forming infection involving multiple

cervical fascial planes with mediastinal extension. The patient underwent radical surgical debridement, left hemithyroidectomy, and thoracic washout for descending mediastinitis. Intraoperative laryngoscopy revealed ulcerated mucosa in the left pyriform fossa, with biopsy confirming moderately differentiated squamous cell carcinoma. Despite broad-spectrum antimicrobial therapy, intensive care support and multidisciplinary management, the patient developed refractory septic shock and died five days following admission.

RESULTS

This case represents a rare presentation of CNF arising secondary to an occult oropharyngeal squamous cell carcinoma. Tumour-associated mucosal breach and local tissue invasion likely facilitated bacterial spread into deep cervical spaces. The presence of mediastinal extension, septic shock, and underlying malignancy contributed to the poor prognosis despite timely surgical intervention.

CONCLUSIONS

CNF may represent a first manifestation of head and neck malignancy. In the absence of an identifiable odontogenic or traumatic source, clinicians should maintain a high index of suspicion for underlying malignancy. Early recognition, prompt surgical management, and multidisciplinary care remain cornerstones in management of CNF, although outcomes remain poor in advanced disease.

PP-106

Multifactorial Dysphagia In Carotid Body Paraganglioma Accompanying Multinodular Goiter: Neural And Compressive Mechanisms

Hakan Bayraktar[1], **Ömer Faruk Koçer**[1]

[1]*Kocaeli City Hospital*

BACKGROUND & AIM

Dysphagia is a non-specific but clinically important symptom in head and neck pathologies. It may result from mechanical compression, neurogenic dysfunction, or both. Carotid body paragangliomas are rare neuroendocrine tumors that may present with compressive symptoms or cranial nerve involvement, particularly affecting the vagus nerve. In addition, coexisting thyroid pathologies such as multinodular goiter may further contribute to swallowing dysfunction. This study aims to present a case of multifactorial dysphagia caused by carotid body paraganglioma and multinodular goiter, and to discuss underlying mechanisms.

MATERIAL & METHODS

A 53-year-old female patient presenting with neck swelling and dysphagia was evaluated. Clinical examination, endoscopic assessment, ultrasonography, MRI, CT angiography, fine needle aspiration biopsy, and intraoperative findings were retrospectively analyzed.

RESULTS

The patient presented with a 3-month history of dysphagia and neck swelling. MRI and CT angiography revealed a hypervascular mass measuring approximately 27×33 mm at the right carotid bifurcation, consistent with carotid body paraganglioma, and a contralateral smaller lesion. Thyroid ultrasonography demonstrated multinodular goiter, and fine needle aspiration biopsy was benign (Bethesda II).

The patient underwent total thyroidectomy and right carotid body tumor excision with intraoperative neuromonitoring. Histopathology confirmed carotid body paraganglioma with a GAPP score of 4 (moderately differentiated) and multinodular colloid goiter.

Postoperatively, dysphagia resolved completely, and no cranial nerve dysfunction or residual disease was observed during follow-up.

CONCLUSIONS

Dysphagia in patients with carotid body paraganglioma may result from a combination of neurogenic mechanisms (vagal involvement) and mechanical compression. Coexisting thyroid enlargement may further exacerbate symptoms. A comprehensive multidisciplinary evaluation is essential for accurate diagnosis and effective surgical management.

PP-107

Management Of A Giant Plunging Ranula With Transcervical Extension: A Case Report

Yüce İslamoğlu[1], **Bengi Arslan**[1], **Gökhan Atik**[1], **Sami Berçin**[1]

[1]*Ankara Bilkent City Hospital ENT Department*

BACKGROUND & AIM

Ranula is a mucus extravasation pseudocyst arising predominantly from the sublingual gland. Plunging ranula is a less common variant characterized by extension beyond the mylohyoid muscle into the cervical spaces. Due to its rarity and variable presentation, diagnosis and management may be challenging.

MATERIAL & METHODS

25 years old female patient was admitted to our ENT clinic one month ago. Physical examination demonstrated a soft, fluctuant cervical mass and a bluish translucent swelling in the floor of the mouth extended to the neck. She has been complaining about the growing mass swelling under the chin and neck for two years. She also complain about dysfagia and difficulty in speaking. No cervical lymphadenopathy or signs of infection were observed. Magnetic resonance imaging revealed a cystic lesion originating from the sublingual space with extension through the mylohyoid muscle into the neck, consistent with plunging ranula. The lesion appeared hyperintense on T2-weighted images and showed no significant contrast enhancement. The characteristic “tail sign” supported the diagnosis of plunging ranula. The patient underwent total excision of the sublingual gland and evacuation of the giant ranula. Histopathological examination was ranula.

RESULTS

We present a case of giant plunging ranula with transcervical extension successfully managed through an cervical surgical approach. No complication was occurred.

CONCLUSIONS

Plunging ranula is a rare but important differential diagnosis of cystic cervical swelling in young patients. Comprehensive clinical and radiological evaluation is necessary for accurate diagnosis. Surgical excision of the affected sublingual gland via an intraoral or cervical approach remains the preferred treatment strategy for preventing recurrence.

A Diagnostic Challenge In The Oral Cavity: Extranodal Follicular Lymphoma Of The Hard Palate Mimicking An Inflammatory Ulcer

Cem Bulut[1], **İlker Burak Arslan**[1], **Selen Eryetli**[1]

[1]*İzmir City Hospital Department of Otorhinolaryngology & Head Neck Surgery*

BACKGROUND & AIM

Extranodal follicular lymphoma of the hard palate is an exceptionally rare clinical entity that often mimics benign inflammatory ulcers or salivary gland tumors, leading to significant diagnostic challenges. The objective of this report is to present a rare case of palatal follicular lymphoma and to emphasize the critical importance of deep tissue biopsy and high clinical suspicion in preventing diagnostic delays for oropharyngeal ulcerative lesions.

MATERIAL & METHODS

A retrospective clinical and pathological analysis was conducted for a 44-year-old male patient presenting with a persistent palatal ulcer. The diagnostic workup included a detailed physical examination, multiple incisional biopsies, and histopathological evaluation with immunohistochemical staining (CD20). Systematic staging was performed using PET-CT imaging to assess extranodal involvement. Clinical data, radiologic findings, and the subsequent treatment plan were reviewed in accordance with the principles of the Declaration of Helsinki

RESULTS

Clinical evaluation revealed a 3x2 cm ulcerative mass involving the left hard palate and extending to the hard-soft palate junction. While the initial superficial biopsy was non-diagnostic, a subsequent deep re-biopsy confirmed the diagnosis of Follicular Lymphoma with CD20 positivity. PET-CT imaging identified a 39x25 mm hypermetabolic primary lesion in the palate, accompanied by hypermetabolic bilateral cervical lymphadenopathy at Levels 1b, 2a, and 2b. No distant organ involvement was detected. Based on these findings, the patient was diagnosed with Stage IIB extranodal follicular lymphoma. Following the definitive diagnosis, the patient was successfully referred to the hematology department, where a treatment protocol consisting of R-CHOP chemotherapy was initiated.

CONCLUSIONS

In conclusion, extranodal follicular lymphoma of the hard palate is a rare but significant diagnostic consideration for persistent oral ulcers. This case underscores the high risk of diagnostic failure associated with superficial biopsies in malignancies of the minor salivary glands or lymphoid tissues. Clinicians must maintain a high index of suspicion and perform deep tissue sampling when clinical findings suggest malignancy. Furthermore, accurate staging via PET-CT is essential for determining the systemic extent of the disease and initiating appropriate chemo-immunotherapy protocols

A RARE CASE: ILLIAC WING SYNOVIAL SARCOMA WITH MASSIVE NECK METASTASIS

Resident Burak Fidan, MD[1], **Assoc Prof Hakkı Caner İnan, MD**[1], **Specialist Veyis Şener, MD**[1], **Specialist Nazmi Mutlu, MD**[1]

[1]*UNIVERSITY OF HEALTH SCIENCES BURSA YUKSEK IHTISAS TRAINING AND RESEARCH HOSPITAL*

BACKGROUND & AIM

Synovial sarcoma (SS) accounts for approximately 5–10% of all soft tissue sarcomas and most commonly arises in the lower extremities. Involvement of the head and neck region is rare, and metastatic spread to this region is even less frequently reported. Cases with simultaneous iliac origin and metastases to both the lungs and cervical region are exceedingly uncommon. This study aims to present a rare case of SS with an unusual metastatic pattern and to highlight diagnostic and therapeutic challenges. We hypothesize that early imaging and histopathological evaluation are critical for accurate diagnosis in atypical presentations.

MATERIAL & METHODS

A 38-year-old male presented with swelling on the right side of the neck. Physical examination revealed a 17X6 cm mass in the right cervical region. USG, CT AND MRI were performed to evaluate the lesion. PET-CT demonstrated a hypermetabolic mass in the right cervical region, a lesion in the left iliac wing and multiple pulmonary nodules. Tru-cut biopsies were obtained from both the cervical mass and pulmonary nodules. Histopathological examination confirmed spindle cell type synovial sarcoma. Due to the extent and location of the tumor, surgical resection was not feasible. The patient was referred for chemotherapy and treatment with ifosfamide and doxorubicin was initiated.

RESULTS

Imaging revealed extensive metastatic disease involving the cervical region, lungs, and iliac bone. Histopathological findings confirmed the diagnosis of synovial sarcoma. Due to advanced disease, surgical intervention was not performed, and systemic therapy was initiated.

CONCLUSIONS

Synovial sarcoma is an aggressive malignancy that may present with metastatic patterns. This case emphasizes the importance of comprehensive imaging and biopsy in diagnosing atypical presentations. While surgery remains the mainstay of treatment, it may not be feasible in advanced cases, where chemotherapy and radiotherapy play a crucial role. Despite multimodal treatment, prognosis remains poor in metastatic disease.

A Rare Nasal Tip Sebaceous Carcinoma Masquerading As Basal Cell Carcinoma: Case Report

Behlül TUNCER[1], **Elvin HUMBATLI**[1], **Harun CANSIZ**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, Cerrahpaşa Medical Faculty, Istanbul University, Istanbul, Turkey*

BACKGROUND & AIM

Sebaceous carcinoma is a rare adnexal malignancy with aggressive potential, most commonly arising in the periocular region. Extraocular localization at the nasal tip is extremely uncommon and may clinically and histopathologically mimic basal cell carcinoma (BCC), leading to diagnostic pitfalls. We present a rare case of nasal tip sebaceous carcinoma initially diagnosed as BCC and discuss its multidisciplinary management and short-term oncologic outcome.

MATERIAL & METHODS

A 79-year-old woman presented with a 2×2 cm nodular lesion on the nasal tip without palpable regional lymphadenopathy. Incisional biopsy was reported as BCC. The lesion was excised with approximately 5-mm clinical margins, and reconstruction was performed using a superiorly based nasolabial flap. Final histopathology revealed sebaceous carcinoma characterized by atypical basaloid cells with sebaceous differentiation. The deep surgical margin was 2 mm, while all other margins were ≥5 mm. No perineural or lymphovascular invasion was identified.

RESULTS

Given the close deep margin and the reconstructive limitations for re-excision, the case was evaluated by a multidisciplinary head and neck tumor board. Adjuvant radiotherapy was recommended and completed without major complications. During more than one year of follow-up, no evidence of local recurrence, regional lymph node metastasis, or distant spread has been observed.

CONCLUSIONS

Sebaceous carcinoma of the nasal tip is rare and may closely resemble BCC both clinically and on limited biopsy specimens. Accurate diagnosis requires thorough histopathological evaluation. In cases with close surgical margins where re-excision is not feasible, adjuvant radiotherapy is a valid option. Careful long-term follow-up is essential due to the tumor's potential for recurrence and metastasis. This case highlights the importance of multidisciplinary decision-making in managing rare nasal malignancies.

Transoral Endoscopic Diverticulotomy For Neopharyngeal Pseudodiverticulum After Total Laryngectomy With Free-Flap Reconstruction: A Case Series

Luca Cerri[1,2], **Isabelle Fournier**[3], **Sheila Nida Buoy**[3], **Christopher Nguyen**[4], **Z Hye Lee**[4], **Peirong Yu**[4], **Wayne Hofstetter**[5], **Katherine Hutcheson**[3], **Anastasios Maniakas**[3]

[1]Department of Otolaryngology – Head & Neck Surgery, Humanitas Research Hospital (Milan, Italy); [2]Department of Biomedical Sciences, Humanitas University (Milan, Italy); [3]Department of Head & Neck Surgery, University of Texas MD Anderson Cancer Center; [4]Department of Plastic Surgery, University of Texas MD Anderson Cancer Center; [5]Department of Thoracic Surgery, University of Texas MD Anderson Cancer Center

BACKGROUND & AIM

Dysphagia is a frequent complication after total laryngectomy, affecting approximately 17%–72% of patients, with even higher rates in the salvage setting. One recognized cause is a neopharyngeal pseudodiverticulum—an outpouching of the neopharynx—which may be asymptomatic or associated with dysphagia and regurgitation and is more commonly reported after primary pharyngeal closure. In contrast, pseudodiverticulum following TL with free-flap reconstruction has been only sparsely described, resulting in limited guidance for management in this population, despite the significant impact of dysphagia on quality of life. We report a case series of patients with symptomatic pseudodiverticulum who reported early symptomatic relief following transoral lysis.

MATERIAL & METHODS

This is a single-center case series of three patients undergoing transoral endoscopic-associated lysis of a pseudodiverticulum using a stapler. All patients had previously undergone a TL with free flap reconstruction. All patients underwent a preoperative modified barium swallow study (MBS) to confirm the diagnosis. Under general anesthesia, diverticulotomy was performed transorally under direct laryngoscopy and suspension using a modified 45-mm endoscopic stapler to divide the pseudodiverticular septum and reestablish a linear neopharyngeal lumen. Perioperative and postoperative data were collected, including operative details, intraoperative photo and video documentation, and available pre- and post-intervention swallowing assessments. Patient-reported swallowing-related quality of life was assessed when available using the MD Anderson Dysphagia Inventory (MDADI) global and composite scores.

RESULTS

Two males and one female were included with a mean age of 73 years (range, 66–80). Indications for TL were advanced laryngeal squamous cell carcinoma in two patients and oncocytic thyroid carcinoma with laryngeal structural invasion in the third. Reconstruction consisted of primary pharyngeal closure with overlay free-flap reinforcement in two patients (anterolateral thigh and vastus lateralis free flaps) and circumferential pharyngoesophageal reconstruction with an ulnar artery perforator flap in one patient. The mean interval from TL to pseudodiverticulum diagnosis was 51.8 weeks (range, 25.7–70.9), and mean pseudodiverticular depth was 2.3 cm (range, 1.6–3.0). Available MDADI data included pre-diverticulotomy assessments in two patients (global 90 [range, 80–100]; composite 66.84 [range, 61.05–72.63]) and a post-diverticulotomy assessment in one patient (global 80; composite 73.68). There were no perioperative complications, and all patients reported immediate symptom relief and same-day discharge.

CONCLUSIONS

Neopharyngeal pseudodiverticulum is a potentially debilitating structural cause of dysphagia and regurgitation after TL. In cases where symptoms result primarily from bolus trapping, open revision surgery may be excessively morbid. In this case series, transoral endoscopic diverticulotomy was feasible, safe, and associated with immediate symptom relief, suggesting it may be considered early in appropriately selected patients.

Ganglioneuroma Of The Parapharyngeal Space: A Rare Case Report

Meleknur ALTINYAYLA[1], **Aylin ERYILMAZ**[1], **Büşra EKİNCİ**[2]

[1]Department of Otorhinolaryngology, Aydın Adnan Menderes University Faculty of Medicine, Aydın, Türkiye; [2]Department of Pathology, Aydın Adnan Menderes University Faculty of Medicine, Aydın, Türkiye

BACKGROUND & AIM

Parapharyngeal space tumors are rare among head and neck neoplasms. This case report aims to present a rare case of ganglioneuroma located in the parapharyngeal space and to contribute to the literature.

MATERIAL & METHODS

Case Presentation: A 70-year-old male patient presented with a progressively enlarging swelling on the right side of the neck for approximately 10 years. On physical examination, a firm and fixed mass measuring 4 × 2 cm was palpated in the right upper neck at level II. Laboratory tests were within normal limits.

Magnetic resonance imaging and computed tomography angiography revealed a well-circumscribed heterogeneous mass adjacent to the deep lobe of the right parotid gland. The lesion displaced the internal and external carotid arteries. The initial biopsy suggested a malignant mesenchymal tumor; however, the specimen was insufficient for a definitive diagnosis.

RESULTS

Following complete surgical excision, histopathological examination revealed findings consistent with ganglioneuroma. Immunohistochemical staining showed positivity for S100 and synaptophysin in both stromal Schwann cells and ganglion cells. The final histopathological diagnosis was reported as ganglioneuroma

CONCLUSIONS

Ganglioneuroma should be considered in the differential diagnosis of masses located in the parapharyngeal space. Surgical excision is important for preventing complications and establishing a definitive diagnosis.

Atypical Origin And Extension Pattern Of Nasopharyngeal Squamous Cell Carcinoma Presenting With Abducens Nerve Palsy

Onur Günaydın[1], **Hande Arslan**[1], **Asude Ünal**[2], **Dursun Mehmet Mehel**[3], **Doğukan Özdemir**[2]

[1]*Samsun City Hospital;* [2]*Samsun University;* [3]*Health Science University*

BACKGROUND & AIM

Nasopharyngeal carcinoma (NPC) typically arises from the lateral wall of the nasopharynx, most commonly the fossa of Rosenmüller. Tumors originating from atypical locations are rare and may mimic sinonasal malignancies, leading to diagnostic challenges.

MATERIAL & METHODS

Case Presentation:We report a 57-year-old male presenting with diplopia and isolated left abducens nerve palsy. Physical examination revealed a 5 × 5 cm left level II cervical lymphadenopathy. Endoscopic evaluation demonstrated a mass arising from the posterior nasal septum with extension into the nasopharynx, without involvement of the fossa of Rosenmüller. Imaging revealed skull base invasion and sphenoid sinus involvement. Histopathological analysis confirmed keratinizing squamous cell carcinoma (WHO Type I). The tumor was staged as T4 according to the TNM classification.

RESULTS

Atypical presentations of NPC may arise from non-classical anatomical sites and mimic other sinonasal malignancies. Cranial nerve palsies indicate advanced disease and are associated with skull base involvement and poorer prognosis. Recognition of such unusual presentations is essential to avoid diagnostic delay.

CONCLUSIONS

NPC should be included in the differential diagnosis of posterior nasal septal masses, particularly in patients presenting with cranial nerve deficits and cervical lymphadenopathy. Early recognition of atypical presentations is critical for timely diagnosis and appropriate multidisciplinary management.

Giant Pleomorphic Adenoma With Facial Nerve Invasion

Emine Deniz Gözen Tan[1], **Sinem Kara**[2], **Fırat Tevetoğlu**[1], **Chinara Aliyeva**[3], **Tolga Küçükgergin**[1], **Şebnem Batur**[4], **Nuray Kepil**[4], **Emin Karaman**[1], **Haydar Murat Yener**[1]

[1]*Istanbul University-Cerrahpaşa, Cerrahpaşa Faculty of Medicine, Department of Otorhinolaryngology, Istanbul, Turkey.;* [2]*Royal Manchester Children's Hospital, Department of Otorhinolaryngology, Manchester, United Kingdom;* [3]*The Turkiye Hospital, Department of Otorhinolaryngology, Istanbul, Turkiye;* [4]*Istanbul University-Cerrahpaşa, Cerrahpaşa Faculty of Medicine, Department of Pathology, Istanbul, Turkey*

BACKGROUND & AIM

Pleomorphic adenoma is a benign salivary tumor of epithelial and connective tissue origin, primarily affecting the superficial parotid lobe, and occurring more frequently in women. Carcinoma ex pleomorphic adenoma can develop from a primary or recurrent pleomorphic adenoma, accounting for 3.6% of all salivary tumors. Metastatic pleomorphic adenoma is a rare,

histologically benign variant that presents with distant metastases, frequently to the bone, lung, and lymph nodes. Here, we present a rare case pathologically diagnosed as a cellular pleomorphic adenoma but presenting with facial nerve invasion.

MATERIAL & METHODS

A 28-year-old male patient presented to our clinic with a 6 cm mass in the right parotid gland. The patient had a history of operations for recurrent pleomorphic adenoma in the right parotid gland in 2015 and 2017. He presented with right-sided grade 4 facial paralysis and was evaluated as having a recurrent parotid pleomorphic adenoma. During the operation, the tumor in the parotid gland was found to invade the branches of the facial nerve and extend to the skull base in the parapharyngeal space; subsequently, a right total parotidectomy was performed, and the mass was totally excised. Two main branches of the invaded facial nerve were sacrificed; the upper main branch was repaired with an end-to-end anastomosis, while the defect between the lower main branch and the trunk was repaired using a great auricular nerve graft.

RESULTS

Histopathological examination of the excision material was reported as cellular pleomorphic adenoma, with no malignant formation observed. However, the examination showed that the tumor caused perineural invasion of the facial nerve. The patient received postoperative radiotherapy. He has been followed up for 1 year postoperatively without any tumor recurrence, and his facial paralysis has regressed to grade 3 in his current examination.

CONCLUSIONS

Cellular pleomorphic adenomas can rarely cause facial nerve invasion and subsequent facial paralysis despite the complete absence of malignant or atypical cells upon histopathological examination. This presentation highlights a rare clinical entity and emphasizes the critical importance of careful intraoperative management and nerve reconstruction when evaluating recurrent parotid masses.

PP-115

Feasibility Of The Implementation Of A High-Resolution PET/CT Scanner In The Operative Room For Margins Assessment In Head And Neck Cancer

Roussel Lise-Marie[1], **Berghian Anca**[1], **Modzelewski Romain**[1], **Clatot Florian**[1], **Hapdey Sébastien**[1]

[1]*henri Becquerel center, Rouen, France*

BACKGROUND & AIM

Intraoperative high-resolution 18F-FDG PET/CT may improve surgical margin assessment in head and neck cancer, particularly during complex procedures requiring flap reconstruction. However, given the prolonged operative times and the large number of staff involved, evaluating occupational radiation exposure is essential, which is the focus of this pilot radiation safety study.

MATERIAL & METHODS

We conducted a prospective, single-center pilot study including ten patients with head and neck squamous cell carcinoma requiring flap reconstruction. Specific radiation protection measures were implemented to limit operating room staff exposure. Each patient received an administered activity of 0.7 MBq/kg. The average radiation dose received per operating room shift was subsequently assessed. We also analyzed the concordance between definitive pathological analysis and high-resolution PET/CT imaging with respect to the margin status on specific, defined axes of the specimen.

RESULTS

The median intervention time was 450 min [240–530].

After normalization to an injected activity of 0.7 MBq/kg, the estimated mean absorbed doses per procedure were 21 µSv (± 6), 19 µSv (± 7), and 11 µSv (± 3) for surgeons, surgical assistants, and instrumenting scrub nurses, respectively. The estimated median absorbed doses per procedure were 23 µSv [7–35], 15 µSv [5–24], and 10 µSv [5–16] for surgeons, surgical assistants, and instrumenting scrub nurses, respectively.

The implementation of specific radiation protection measures resulted in a 25% reduction in radiation exposure among operating room staff. We reached a good concordance on the margin status for each of the analyzed axes between the definitive histological analysis and the high-resolution PET/CT, with a cut-off point set at 20% of the SUV max value.

CONCLUSIONS

In terms of radiation protection, the device appears safe and can easily be transposed to head and neck surgery. While further performance studies are needed before it can be used routinely in clinical practice, this approach is a highly promising method that could potentially transform head and neck surgery. Using this novel tool could significantly improve the precision of surgical procedures, thereby enhancing intraoperative accuracy. Furthermore, the radiation protection strategies proposed in this study could facilitate its wider adoption in future clinical practice.

Sarcopenic Obesity As A Predictor Of Postoperative Complications Following Total Laryngectomy: A Pilot Cohort Study

Hacer Baran[1], **Gülşah Acar Yüceant**[1], **Sema Nur Bayram**[1], **Hanife Gülden Düzkalır**[2], **Ecem Ezgi Sakallı**[2]

[1]*Department of ENT at Kartal Dr. Lütfi Kırdar City Hospital;* [2]*Department of Radiology at Kartal Dr. Lütfi Kırdar City Hospital*

BACKGROUND & AIM

Sarcopenic obesity (SO), defined as low skeletal muscle mass combined with excess adiposity, has been linked to adverse surgical outcomes in various cancers. However, its role in patients undergoing total laryngectomy (TL) for laryngeal cancer remains unclear. The cervical skeletal muscle index (C3-SMI), derived from routine preoperative CT, provides a practical method for body composition assessment. This study aimed to evaluate the association between CT-defined SO and postoperative complications in TL patients and to explore its potential as a preoperative risk stratification marker.

MATERIAL & METHODS

This retrospective cohort study included 100 consecutive patients who underwent total laryngectomy for laryngeal cancer at a single tertiary referral center. Preoperative cervical CT scans were used to quantify skeletal muscle mass at the level of the third cervical vertebra (C3). The cervical skeletal muscle index (C3-SMI) was calculated by normalizing muscle area to height squared. Sarcopenic obesity (SO) was defined as C3-SMI below the cohort median combined with body mass index (BMI) ≥25 kg/m². Patients were categorized into four groups: normal, obesity only, sarcopenia only, and SO. The primary outcome was the occurrence of any postoperative complication. Statistical analyses were performed using Fisher's exact test and the Mann–Whitney U test. A post-hoc power analysis was conducted to estimate the sample size required for a confirmatory study.

RESULTS

Median age was 63 years (IQR 58–67), and the overall postoperative complication rate was 33% (n=33). Sarcopenic obesity (SO) was identified in 15% of patients (n=15). Complication rates were 28% in the normal group, 28% in the obesity-only group, 31% in the sarcopenia-only group, and 53% in the SO group. Patients with SO had a higher complication rate compared to all other groups combined (53% vs 29%; odds ratio 2.74, 95% CI 0.90–8.38; p=0.081), although this did not reach statistical significance. Postoperative complications were associated with significantly prolonged hospital stay (median 17 vs 13 days; p=0.007). Post-hoc power analysis indicated that the current cohort had 42% power, with an estimated sample size of 325–434 patients required for adequate statistical power.

CONCLUSIONS

SO, identifiable from routine preoperative CT without additional cost or imaging, was associated with a clinically meaningful difference in complication rates following TL (OR 2.74), though this did not reach statistical significance in the current pilot cohort. This study establishes effect size estimates and sample size requirements for a definitive multicentre investigation. Preoperative body composition assessment via C3-SMI merits prospective validation as a surgical risk stratification tool in laryngeal cancer.

Sarcopenic obesity; total laryngectomy; complication

PP-117

Staged Endovascular Embolization And Surgical Excision Of A Left Subauricular Congenital Arteriovenous Malformation In A Adolescent

Muhammet Fatih Gökmen[1], **Özgür Demir**[1]

[1]*The Department of Otolaryngology and Head and Neck Surgery at Selçuk University Faculty of Medicine Hospital, Konya, Turkey*

BACKGROUND & AIM

Head and neck arteriovenous malformations (AVMs) are rare congenital high-flow vascular lesions that may present as pulsatile masses and can lead to diagnostic and therapeutic challenges because of their risk of hemorrhage, proximity to critical neurovascular structures, and potential systemic complications. This report aims to present the diagnostic work-up and staged treatment of a congenital cervicofacial AVM in an adolescent patient and to emphasize the importance of angiographic evaluation, multidisciplinary planning, and nerve-preserving surgical management.

MATERIAL & METHODS

A 15-year-old boy presented with a slowly progressive pulsatile left upper neck mass located inferior to the earlobe and present since birth. Doppler ultrasonography and CT angiography were performed, revealing a high-flow vascular lesion consistent with AVM. Biopsy was avoided because of the risk of bleeding. The patient was evaluated by a multidisciplinary team, and staged treatment was planned. Preoperative selective angiography with partial embolization using Onyx was followed by surgical excision one week later.

RESULTS

CT angiography demonstrated multiple dilated tortuous vascular channels extending from the submandibular region to the masticator space, with connections to the jugular vein and the external carotid artery. Selective angiography identified a nidus

measuring approximately 49 × 45 mm, predominantly supplied by the ascending pharyngeal branch of the left external carotid artery, with direct drainage into the jugular vein. More than 50% nidus embolization was achieved without major vascular compromise. During the external carotid artery dissection, hypoglossal nerve was identified and preserved. Anomalous vascular connections to the internal jugular vein and external carotid artery were ligated, resulting in marked reduction of pulsation. Postoperatively, transient marginal mandibular weakness developed and improved during follow-up. At 3 months, pulsation was markedly reduced.

CONCLUSIONS

High-flow cervicofacial AVMs require thorough vascular mapping before intervention, and biopsy or blind excision should be avoided until vascular anatomy is clearly defined. Staged management with preoperative embolization followed by surgical resection can reduce nidus burden, facilitate safer dissection, and improve intraoperative control in selected cases. In subauricular and preauricular lesions, meticulous preservation of adjacent neural structures, particularly the marginal mandibular and hypoglossal nerves, is essential. This case highlights the value of a multidisciplinary approach in minimizing complications and achieving satisfactory early clinical outcomes in complex congenital head and neck AVMs.

Comparative Evaluation Of TIRADS Score, Bethesda System Cytology, And Histopathology In Diagnosing Thyroid Cancer In Patients With Thyroid Nodules: Systematic Review

Ahmed Aytah[1], **Mohammed Bahabri**[2], **Hamdan B. Alguydi**[1]

[1]*Department of Otolaryngology – Head and Neck Surgery, King Faisal Specialist Hospital & Research Centre, Jeddah, Saudi Arabia;* [2]*Department of Otolaryngology – Head and Neck Surgery, Ministry of National Guard - Health Affairs, Jeddah, Saudi Arabia*

BACKGROUND & AIM

Accurate risk stratification of thyroid nodules is essential for guiding clinical management and surgical decision-making. Ultrasound-based Thyroid Imaging Reporting and Data Systems (TI-RADS) and cytology-based Bethesda classification are the most widely used diagnostic tools for this purpose. Despite their routine use the concordance between TI-RADS categories Bethesda cytology and final histopathological outcomes remains variably reported across the literature leading to uncertainty in preoperative risk assessment. The aim of this systematic review was to evaluate the concordance between TI-RADS Bethesda classification and final histopathology in thyroid nodules.

MATERIAL & METHODS

A systematic review was conducted in accordance with established methodological standards. Studies were included if they evaluated thyroid nodules using ultrasound-based TI-RADS fine-needle aspiration cytology reported according to the Bethesda system and subsequent histopathological diagnosis. Data extracted included study design patient and nodule characteristics diagnostic criteria and reported associations between TI-RADS Bethesda categories and final histopathology. Findings were synthesized qualitatively to assess concordance patterns and diagnostic performance.

RESULTS

Higher TI-RADS categories were consistently associated with increasing Bethesda categories and higher rates of malignancy on final histopathology. Bethesda V and VI categories demonstrated strong concordance with malignant histopathological outcomes while Bethesda III and IV showed variable correlation reflecting diagnostic uncertainty. TI-RADS effectively stratified malignancy risk at both low and high ends of the spectrum although overlap persisted in intermediate-risk categories. Combined interpretation of TI-RADS and Bethesda classifications improved diagnostic confidence compared with either system used independently.

CONCLUSIONS

There is substantial concordance between TI-RADS Bethesda classification and final histopathology particularly in low- and high-risk thyroid nodules. However notable discordance persists in intermediate-risk categories (III and IV) highlighting the limitations of single-modality assessment. Integrated use of ultrasound and cytological findings remains essential for optimal thyroid nodule risk stratification and clinical decision-making.

A Rare Case Of Unilateral Seronegative Igg4-Related Sialadenitis Presenting As A Submandibular Tumor

ÖZKAN İLİK[1], **NURULLAH TURE**[1], **FİKRET ZEYBEK**[1]

[1]*Department of Otorhinolaryngology, Kütahya Health Sciences University, Kütahya, Türkiye*

BACKGROUND & AIM

Immunoglobulin G4-related disease (IgG4-RD) is a rare systemic fibroinflammatory condition characterized by a dense lymphoplasmacytic infiltrate and tissue fibrosis with a storiform pattern. Salivary gland involvement often manifests as chronic sclerosing sialadenitis, also known as Küttner tumor (KT), which is frequently regarded as a "pseudotumor" because it mimics malignant neoplasms in clinical practice. The hypothesis of this report is that despite its rare and atypical presentation, the 2023 revised diagnostic criteria facilitate the definitive diagnosis of isolated, asymmetric, and seronegative cases.

MATERIAL & METHODS

A 39-year-old female presented with a rare 1.5-year history of a firm, painless, and fixed mass in the right submandibular region. Diagnostic evaluation using ultrasonography (US) and computed tomography (CT) revealed a hypertrophic right submandibular gland and associated pathologic lymphadenopathy (LAP) with a loss of fatty hilum. Due to a high suspicion of malignancy and non-diagnostic imaging, a total excision of the right submandibular gland and level 2A-2B lymph nodes was performed as the rational first step for both diagnosis and treatment. Histopathological analysis and immunohistochemical (IHC) staining were utilized to evaluate tissue architecture and immunoglobulin G4-positive (IgG4+) plasma cell infiltration

RESULTS

Histopathological examination confirmed storiform fibrosis and a dense lymphoplasmacytic infiltrate, which are hallmark features of the disease. IHC analysis demonstrated 80 IgG4+ plasma cells per high-power field (HPF) and an IgG4+/IgG+ ratio of approximately 90%, meeting the definitive diagnostic thresholds. Notably, the serum IgG4 concentration was 1.47 g/L, which is within the normal reference range, confirming a seronegative presentation seen in approximately 30-40% of cases with isolated organ involvement. Differential diagnoses, such as Sjögren's syndrome (SS) and lymphoma, were excluded based on negative antinuclear antibodies (ANA), anti-SSA/SSB, and the presence of specific fibrotic patterns

CONCLUSIONS

This case highlights that immunoglobulin G4-related sialadenitis (IgG4-RS) is a rare but critical differential diagnosis for unilateral submandibular masses, even in seronegative patients. Histopathology remains the gold standard for diagnosis, especially when clinical and serological findings are atypical. Multidisciplinary follow-up and the consideration of systemic corticosteroid treatment are essential to manage potential systemic involvement or relapses.

PP-120

INVESTIGATION OF THE ETIOLOGIC RELATIONSHIP BETWEEN WARTHİN'S TUMOR AND OBESITY

Semih Tekin[1], **Şahin Öğreten**[1]

[1]*University of Health Sciences Basaksehir Cam and Sakura City Hospital, Department of Otorhinolaryngology, Istanbul, Türkiye*

BACKGROUND & AIM

The incidence of Warthin's tumor (WT) has increased significantly in recent years. This study aims to investigate the potential etiologic relationship between WT and obesity/metabolic syndrome, evaluating whether metabolic parameters and Body Mass Index (BMI) are risk factors alongside smoking.

MATERIAL & METHODS

A retrospective analysis was conducted on 162 patients who underwent surgery for benign parotid tumors between 2020 and 2024. Patients were divided into two groups: Warthin's tumor (n=72) and non-Warthin benign tumors (n=90). Demographic data, BMI, smoking history, and preoperative serum lipid profiles (Total Cholesterol, HDL, LDL, Triglycerides, VLDL) were compared. Multivariate logistic regression and ROC analyses were performed to identify independent risk factors.

RESULTS

The WT group was significantly older (mean 56.1 years) and predominantly male (p=0.001). Smoking was identified as the strongest independent risk factor (OR: 19.226, p=0.001). Although the mean BMI was higher in the WT group (29.13 kg/m^2) compared to the control group, the difference was not statistically significant (p=0.316). However, significant metabolic differences were observed; the WT group exhibited significantly lower HDL levels (p=0.001) and higher triglyceride levels (p=0.001). Multivariate analysis revealed that low HDL (≤47 mg/dL) is an independent risk factor, increasing the risk of WT by 5.9 times.

CONCLUSIONS

While BMI alone did not demonstrate a statistically significant difference, likely due to the high prevalence of obesity in the general population, the significant association with dyslipidemia (low HDL and high triglycerides) supports a metabolic etiology in WT pathogenesis. These findings suggest that metabolic syndrome-related oxidative stress plays a crucial role in the development of Warthin's tumor.

Dermoid Cyst Of The Parotid Gland

Arş. Gör. Dr. Hikmet Erdem ASLAN[1], **Arş. Gör. Dr. Ramazan USLU**[1], **Arş. Gör. Dr. Raşit HOŞGEL**[1], **Prof. Dr. Enver ALTAŞ**[1]

[1]*Amasya Üniversitesi Tıp Fakültesi Sabuncuoğlu Şerefeddin Eğitim ve Araştırma Hastanesi*

BACKGROUND & AIM

Dermoid cysts (DCs) are rare benign lesions of the head and neck, with the parotid gland being an extremely uncommon site of involvement. Their clinical and radiological presentation often mimics other benign or malignant parotid tumors, making preoperative diagnosis challenging. Diagnostic tools such as ultrasonography, MRI, and fine-needle aspiration cytology (FNAC) provide essential clues, but definitive diagnosis remains histopathological. The aim of this report is to present a rare case of a parotid gland dermoid cyst and highlight a conservative surgical approach that avoids traditional parotidectomy in well-encapsulated cases.

MATERIAL & METHODS

A 37-year-old male presented with a two-year history of a slowly enlarging, painless swelling in the left parotid region. Physical examination revealed a 3×3 cm, mobile, and fluctuant mass; facial nerve functions were intact (House–Brackmann Grade I). Ultrasonography identified a well-circumscribed, non-vascularized cystic lesion adjacent to the parotid gland. MRI demonstrated a 30×20 mm subcutaneous cystic mass, hyperintense on T2-weighted and hypointense on T1-weighted sequences, without contrast enhancement. FNAC was interpreted as benign keratinous material. Based on these findings, surgical intervention was planned. Given the well-encapsulated nature of the lesion and lack of glandular invasion on imaging, a conservative approach was prioritized. Instead of a standard superficial parotidectomy, the mass was carefully dissected in toto from the adjacent parotid tissue while strictly preserving the facial nerve branches and the integrity of the parotid gland parenchyma.

RESULTS

Intraoperatively, a well-defined, encapsulated cyst was identified adjacent to the anterior aspect of the parotid gland. The lesion was successfully excised in its entirety without the need for superficial parotidectomy or sacrifice of glandular tissue. The postoperative period was uneventful, and the patient maintained normal facial nerve function (House–Brackmann Grade I). Histopathological examination confirmed the diagnosis of a dermoid cyst, characterized by an epithelial-lined cavity containing skin appendages. At the follow-up visit, there was no evidence of recurrence or neurological deficit. This case demonstrates that in selected instances where the dermoid cyst is clearly demarcated and does not invade the gland, total cystectomy alone can achieve complete resolution. This conservative surgical strategy minimized surgical morbidity, preserved salivary function, and effectively reduced the potential risks associated with more extensive parotid surgery.

CONCLUSIONS

Dermoid cysts should be considered in the differential diagnosis of soft, painless, and slow-growing parotid masses. While imaging and FNAC are valuable for narrowing the differential, they may not always provide a definitive preoperative diagnosis. Although nerve-sparing parotidectomy is the traditionally recommended treatment, total excision of the cyst alone is a safe and curative alternative in cases where the lesion is well-encapsulated and lacks parenchymal invasion. This conservative approach preserves healthy parotid tissue and minimizes the risk of facial nerve trauma while ensuring excellent long-term clinical outcomes.

PP-122

Challenges For The Head And Neck Surgeon At The Transition To The Second Quarter Of The 21 Century

Robert Šifrer[1]

[1]*University Department of Otorhinolaryngology and Cervicofacial Surgery, Ljubljana;* [2]*Faculty of Medicine at the University of Ljubljana*

BACKGROUND & AIM

Head and neck cancer (HNC) poses increasing demands on surgical care. Over the past decades, groundbreaking studies have shifted the concepts of treatment for advanced laryngeal and hypopharyngeal cancers from primarily surgical treatment through laryngectomies to organ-preserving chemoradiotherapy (CRT). On the one hand, it improved functional outcomes for many patients, but, on the other, it created new challenges for head and neck surgeons (HNS).

MATERIAL & METHODS

This review highlights emerging issues at the transition into the second quarter of the 21 century.

RESULTS

The increased implementation of CRT reduced indications for primary surgical treatment while increasing the frequency of salvage procedures, which are technically demanding, longer, and associated with higher complication rates, including impaired wound healing and pharyngocutaneous fistula. Advances in microvascular reconstruction improved functional and aesthetic outcomes but require specialized expertise, extended operating times, and greater institutional resources. The

growing numbers of elderly patients add further complexity due to comorbidities and higher perioperative risks. Additionally, organizational burdens—such as prolonged hospitalizations, increased treatment costs, longer surgeries, limited operating theatre availability, and decreased capacity of hospital beds - are intensifying. To meet these challenges, HNS must balance the preservation of traditional surgical skills with the adoption of new technologies, maintain competence in less commonly used procedures, and adapt to evolving interdisciplinary consultations and new technologies. Continuous professional training, investment in infrastructure, and tailored patient-centered strategies will be crucial to ensuring optimal outcomes.

CONCLUSIONS

The findings illustrate that surgeons will have to work more and will likely stay on the job longer in the future.

Metachronous Triple Primary Malignancies Of The Head And Neck: A Case Involving Larynx, Nasal Cavity, And External Ear

ALİ DEMİR[1], **KARDELEN KAYIŞ**[1], **OSMAN CERLET**[1]

[1]*ANKARA BILKENT CITY HOSPITAL*

BACKGROUND & AIM

Multiple primary malignancies (MPMs) in the head and neck region present significant diagnostic and therapeutic challenges, often attributed to the concept of field cancerization. While synchronous tumors are observed in approximately 15% of cases, metachronous triple primary malignancies are exceedingly rare. This case represents an exceptionally rare example of three distinct primary tumors developing over a 38-year period, emphasizing the necessity of lifelong multidisciplinary surveillance.

MATERIAL & METHODS

A 78-year-old male with an 80 pack-year smoking history presented with a 1-year history of a painful, ulcerative mass measuring 2×3 cm in the right cavum concha.

His medical history included: Total laryngectomy performed in 1988

Excision of a nasal malignancy at an outside institution 6 years prior

Histopathological records of the nasal lesion were unavailable; therefore, the exact tumor type could not be confirmed, although it had been reported as malignant. Importantly, the patient had no history of radiotherapy.

Imaging studies (MRI and CT) revealed:

A 12 mm infiltrative lesion involving the external auditory canal

A 26×22 mm necrotic lymph node at Level 2A, abutting the carotid bifurcation

The tumors were anatomically distinct and temporally separated, consistent with metachronous multiple primary malignancies. No distant metastasis was detected.

RESULTS

The patient underwent: Wide local excision of the auricular mass Superficial parotidectomy Level 2B–5 neck dissection Intraoperative frozen section analysis confirmed: Negative surgical margins Metastasis in Level 2B lymph nodes Reconstruction was performed using a cervicofacial advancement flap. Surgical management achieved satisfactory local disease control.

CONCLUSIONS

This case highlights the critical importance of lifelong surveillance in patients with significant carcinogen exposure, particularly heavy tobacco use, due to the persistent risk of developing multiple primary malignancies. The absence of prior radiotherapy strengthens the role of field cancerization and chronic tobacco exposure in tumor development.

Additionally, incomplete histopathological documentation may limit precise tumor classification, underscoring the importance of meticulous medical record-keeping.

Clinicians should maintain a high index of suspicion for new primary tumors in high-risk patients, even decades after the initial malignancy.

PP-124

Surgical Excision Of A Malignant Phymatous Rosacea - Case Report And Review Of The Literature

Elshan Aghayev, **Rashad Novruzov**, **Huseyn Aghayev**

BACKGROUND & AIM

Rhinophyma, a severe manifestation of rosacea, is a condition characterized by thickening of skin on the nose, often leading to a bulbous, enlarged appearance. While rhinophyma primarily affects external nose, it can significantly impact a person's appearance and self-esteem.

MATERIAL & METHODS

This article describes a case of phymatous rosacea. This disfiguring condition typically develops gradually and is most commonly seen in individuals with a history of rosacea. The described phymatous form of rosacea in 82 y.o. woman, with a 21-year history of rhinophyma, was late, severe presentation of this disease that required hospitalization and surgery. Medical history revealed that the patient suffered from stage II hypertension, bronchial asthma and stage II cardiopulmonary insufficiency. A neck ultrasound showed normal-appearing lymph nodes. Patient underwent successful excision surgery using electrocautery under general anesthesia in June 2024. The incision of skin and subcutaneous tissue of elliptic form was made around the tumor. The excised tissue of 5,0 x 3,0 x 3,0 cm was sent for histopathological evaluation. Post-surgical therapy included topical treatment with ointment neomycin sulphate and bacitracin.

RESULTS

The histopathological evaluation revealed papillary squamous cell carcinoma (ICD-O-3: 8052/3) (PSCC), a rare variant of squamous cell carcinoma (SCC) with infiltrative invasive growth and special histological differentiation grade. This observation justifies surgical tactics that included surgical excision of the tumor along with skin and subcutaneous tissue, local treatment leading to epithelization of the wound, and restoration of adequate breathing.

CONCLUSIONS

Although unusual, there are case reports of various cutaneous malignancies detected histologically by pathological examination. These malignancies have included basal cell carcinoma, sebaceous carcinoma, squamous cell carcinoma, angiosarcoma, and lymphoma. Literature review revealed over 50 cases describing detection of malignancy in rhinophyma tissue. Microscopic evaluation of tumor tissue described by Lazeri et al. also identified squamous cell carcinoma in one case and basal cell carcinoma in two cases.

Buccinator Myomucosal Flap

Halil Can ARI[1], **Malik AFİFOĞLU**[1]

[1]*Bursa City Hospital, Department of Otorhinolaryngology, Bursa, Türkiye*

BACKGROUND & AIM

Soft palate squamous cell carcinoma accounts for less than 2% of all mucosal head and neck malignancies. Reconstruction following tumor resection presents significant functional and aesthetic challenges. This case report aims to present the buccinator myomucosal flap as an effective reconstructive option for soft palate defects following tumor excision, highlighting its favorable outcomes with low morbidity.

MATERIAL & METHODS

A 65-year-old male patient with a 3×2 cm squamous cell carcinoma of the soft palate involving the uvula underwent transoral tumor excision with safe surgical margins. Bilateral neck dissection (levels I, IIa, IIb, III, IV) was performed simultaneously. Reconstruction was achieved using a posteriorly pedicled buccinator myomucosal flap (approximately 5×3 cm) elevated with a buccal fat pad. The flap was rotated into the defect and sutured to reconstruct the soft palate. Postoperative feeding was managed via nasogastric tube with transition to oral intake.

RESULTS

Pathological examination confirmed moderately differentiated squamous cell carcinoma (3.5×2.6 cm), 9 mm depth of invasion, negative surgical margins, and pT2N1 staging with metastatic nodes in right levels IIa, IV and left level IV. Flap perfusion and palatal refill were confirmed intraoperatively. The postoperative course was uneventful with no complications or recurrence observed during follow-up. The patient successfully transitioned to oral feeding and demonstrated satisfactory functional and aesthetic outcomes.

CONCLUSIONS

The buccinator myomucosal flap provides reliable, single-stage reconstruction of soft palate defects following squamous cell carcinoma excision. With its adequate reach, similar tissue texture, and minimal donor site morbidity, it offers effective functional and aesthetic restoration. This technique should be considered among the primary reconstructive options for T1–T2 intraoral soft palate defects.

Osteosarcoma And Ewing's Sarcoma Of The Head & Neck In Pediatric Practice, Surgical Treatment. Experience Of Dmitry Rogachev National Medical Research Center Of Pediatric Hematology, Oncology And Immunology.

Nikolay Grachev[1], **Igor Vorozhtsov**[1], **Andrey Lopatin**[1], **Egor Chechev**[1], **Elena Konopleva**[1]

[1]*Dmitry Rogachev National Medical Research Center Of Pediatric Hematology, Oncology and Immunology*

BACKGROUND & AIM

Osteosarcoma and Ewing's sarcoma are malignant tumors that develop from bone tissue and are rare tumors in pediatric practice.The localization of the primary focus of these tumors can be any anatomical area, however, they most often occur in the upper and lower extremities and pelvic bones. The primary localization of tumor in head & neck region to according the various data, with range from 1% to 9.8%.

MATERIAL & METHODS

A retrospective analysis of surgical interventions and long-term results for osteosarcoma and Ewing's sarcoma of maxillofacial bone localization was carried out, including both an analysis of surgical local control and reconstructive approaches of this group of patients.

From 2015 to January 2026, 33 patients with primary osteosarcoma and Ewing's sarcoma with localization of the tumor of the maxillofacial region received surgical treatment at Dmitry Rogachev NMRC of PHOI. All patients with osteosarcoma were treated according to the EURAMOS protocol, with Ewing's sarcoma - according to the Euro-Ewing 2008/2012 protocols. Also, during this period, three patients were treated for secondary osteosarcoma after radiotherapy.

RESULTS

The lesion of the mandible occurred in 13 patients (in 6 clinical cases - osteosarcoma, in 7 clinical cases - Ewing's sarcoma). Upper jaw lesion in 10 patients (osteosarcoma in 4 clinical cases, Ewing's sarcoma in 6 patients). Localization of the tumor process at the base of the skull occurred in 6 patients (1 patient with osteosarcoma, 5 patients with Ewing's sarcoma). Temporal bone lesion was found in 2 clinical cases (histologically, Ewing's sarcoma was present in all patients). In 2 patients, the tumor affected the frontal bone (2 patients with Ewing's sarcoma). The report presents the results of the effect of radiation therapy on the reconstructive treatment of patients with osteosarcoma and Ewing's sarcoma of head and region.

CONCLUSIONS

Modern technologies - individual planning using resection STL-templates, microsurgical technologies, the use of endoprosthesis technologies with a sliding mechanism that allow “growing” a endoprosthesis whith pediatric patients followed by complex maxillofacial rehabilitation allow to achieve functional and aesthetic results of surgical treatment with good clinical outcome.

Papillary Microcarcinoma Arising In Ectopic Thyroid Tissue Of The Lateral Neck: Diagnostic And Surgical Challenges

Seda Nur Saka[1], **Deniz Baklacı**[1], **Figen Barut**[1]

[1]*Bülent Ecevit University Hospital*

BACKGROUND & AIM

Ectopic thyroid tissue is a rare developmental anomaly resulting from abnormal migration of the thyroid gland during embryogenesis. Although it is most commonly located in the midline neck, lateral cervical localization is uncommon and may mimic other benign or malignant neck masses. We aimed to present a rare case of papillary microcarcinoma arising in ectopic thyroid tissue located in the lateral neck and to emphasize the diagnostic and surgical challenges associated with this entity.

MATERIAL & METHODS

A 41-year-old woman presented with progressive swelling in the right lateral neck that had gradually enlarged over the previous two years. Radiological evaluation with ultrasonography, computed tomography, and magnetic resonance imaging demonstrated a multicystic mass in the right level II–III cervical region causing compression of the internal jugular vein. Fine-needle aspiration biopsy was reported as Bethesda category III, and tru-cut biopsy findings were consistent with thyroid tissue. Surgical excision of the mass was performed, followed by histopathological evaluation.

RESULTS

Complete surgical excision was achieved despite close proximity to the carotid sheath and internal jugular vein. Histopathological examination revealed multifocal papillary microcarcinoma arising in ectopic thyroid tissue. Thyroid hormone levels were within normal limits, and the orthotopic thyroid gland was preserved. Total thyroidectomy was recommended as additional treatment; however, the patient declined further surgery.

CONCLUSIONS

Although ectopic thyroid tissue is usually benign, malignant transformation may occur in rare cases. Ectopic thyroid tissue should therefore be considered in the differential diagnosis of lateral neck masses. Comprehensive preoperative thyroid evaluation is important for accurate diagnosis, surgical planning, and prevention of postoperative hypothyroidism.

Cervicothoracic Neuroendocrine Tumor Causing SVC Syndrome With Synchronous Medullary Thyroid Carcinoma

Maryam Aljneibi, MD[1], Mahdi Shkoukani, MD[1], Fotoon Aldhanhani[1]

[1]Department of Otolaryngology – Head and Neck Surgery, Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates

BACKGROUND & AIM

Head and neck neuroendocrine neoplasms are heterogeneous and uncommon, and their diagnosis may be challenging because clinical and radiologic features overlap with paraganglioma and other cervicothoracic tumors. This case highlights an unusual presentation of a cervical well-differentiated neuroendocrine neoplasm with internal jugular vein and SVC involvement, complicated by synchronous medullary thyroid carcinoma.

MATERIAL & METHODS

A 64-year-old man presented with progressive right neck swelling, dyspnea, dysphagia, and hoarseness. Flexible laryngoscopy initially showed mobile vocal folds and no mucosal primary lesion. Cross-sectional imaging demonstrated a right cervical mass lateral to the carotid sheath with right internal jugular vein thrombosis and extension into the SVC, causing complete obstruction and extensive venous collateralization. Core biopsy review confirmed a low-grade neuroendocrine neoplasm, and functional assessment showed no evidence of catecholamine hypersecretion. Following multidisciplinary tumor board review, the patient underwent combined right modified radical neck dissection, sternotomy, and SVC reconstruction.

RESULTS

Final histopathology demonstrated a well-differentiated grade 2 neuroendocrine neoplasm involving the right internal jugular vein and extending into the SVC. An incidental 6 mm medullary thyroid carcinoma confined to the right thyroid lobe was also identified, with metastatic disease in 3 of 15 lymph nodes. The patient subsequently underwent completion thyroidectomy and left selective neck dissection, which showed benign follicular nodular disease and no residual medullary thyroid carcinoma. Postoperatively, he developed right vocal fold paralysis, managed with injection laryngoplasty. Given the anatomically extensive surgical bed and uncertain benefit of wide-field adjuvant radiotherapy, surveillance with interval imaging and endocrine follow-up was favored.

CONCLUSIONS

This case highlights the complexity of cervicothoracic neuroendocrine tumors presenting with major vascular involvement. Carefully selected patients may benefit from aggressive, multidisciplinary surgical management for symptom control and local disease management. The coexistence of medullary thyroid carcinoma emphasizes the importance of comprehensive histopathological evaluation and individualized postoperative planning, particularly when balancing potential oncologic benefit against treatment-related morbidity.

THE INDICATIONS FOR ORBITAL EXENTERATION IN ADVANCED SINONASAL MALIGNANCIES

Anda-Selma Cretu[2], Ruxandra Oana Aliuș[1,2], Irina Gabriela Ioniță[1,2], Andreea Rusescu[1,2], Cătălina Voiosu[1,2], Viorel Zainea[1,2], Andra Raluca Ilișanu[1,2], Teofana Andreea Carazanu[2], Pulpa Raluca[1,2], Russu Carina[2], Iurkovski Augustina[2], Burlacu Laura Maria[2], Mara Andra Rebosapca[2], Razvan Hainăroșie[1,2]

[1]Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania; [2]Prof. Dr. Dorin Hociota Institute of Phonoaudiology and Functional ENT Surgery, Bucharest, Romania

BACKGROUND & AIM

Orbital exenteration remains a radical yet sometimes necessary surgical option in the management of advanced sinonasal malignancies with orbital invasion. Establishing clear indications (invasion of the orbit, optic nerve, extraocular muscles and skin overlying the muscles) and recognizing anatomical and surgical limits are essential in achieving oncological control while preserving quality of life when possible

MATERIAL & METHODS

This paper aims to present the case of a 74-year-old patient admitted to “Prof. Dr. Dorin Hociota” Institute of Phonoaudiology and Functional ENT Surgery, diagnosed with advanced squamous cell carcinoma originating from the left maxillary sinus, with

erosion of the orbital floor and direct involvement of the ipsilateral eyeball. The diagnostic methods, surgical treatment and postoperative care are discussed

RESULTS

The patient underwent a left subtotal maxillectomy and total left orbital exenteration with en bloc removal of the tumor. The postoperative evolution was favourable, with no surgical complications. After hospital discharge, he completed adjuvant radiotherapy. He currently shows no signs of locoregional recurrence

CONCLUSIONS

Orbital exenteration has clear indications and limitations in the treatment of advanced sinonasal tumors. Tumor histology is fundamental for the disease treatment. In this case, radical surgery combined with correct adjuvant therapy resulted in a favourable outcome for the patient.

Is Thyroidectomy Safe In Obese Patients? A Systematic Review And Meta-Analysis Of Cohort Studies

Hassan Alalawi[2], **Mohammed Bahabri**[1], **Nouran Hussam**[2], **Hoda Alsayid**[1]

[1]*King Abdulaziz University*; [2]*Dr. Soliman Fakeeh Hospital*

BACKGROUND & AIM

The number of patients with high BMI undergoing different surgical procedures is increasing, including thyroid surgery. Many surgeons consider obesity to be associated with more adverse surgical outcomes. Despite the presence of several studies in literature, the impact of obesity on thyroidectomy remains controversial. This study aimed to assess the safety of thyroidectomy in obese patients by comparing the rates of post-operative complications in obese and non-obese patients.

MATERIAL & METHODS

Searches were performed using PubMed, Cochrane Library, Web of Science, Clinical Trials, and Google Scholar. This review was conducted in accordance with the PRISMA guidelines. Studies were included based on predefined eligibility criteria and assessed for quality using the MINORS criteria.

RESULTS

We included 12 studies with a total of 102,658 patients. All studies were of moderate to good quality. The obese group showed relatively lower odds of transient hypocalcemia (OR: 0.91, 95% CI: 0.83 to 0.99) (P= 0.027). The obese group showed relatively higher odds of transient RLN palsy (OR: 1.11, 95% CI: 1.02 to 1.22) (P= 0.020). The obese group showed relatively higher odds of wound infections (OR: 1.67, 95% CI: 1.14 to 2.44) (P= 0.008). We did not find any significant difference in the rates of permanent hypocalcemia, hematoma, seroma, permanent RLN injuries, and 30-day readmissions.

CONCLUSIONS

Our findings show that increased BMI is protective against transient postoperative hypocalcemia. We found that wound infections and transient RLN palsy were significantly higher in obese patients. We highlight a longer operative time and duration of postoperative stay in obese patients. This meta-analysis concludes that thyroidectomy is a safe procedure in patients with a high body mass index.

KEYWORDS

thyroidectomy, obesity, postoperative complications, length of stay

Recurrent Spindle Cell Sarcoma Of The Head And Neck With Orbital Involvement

Sahin Ogreden[1], **Bilgenur Aiseoglu**[1], **Fatih Albayrak**[1], **Baris Karasu**[1], **Betul Canak**[1], **Aysin Tozsekerli**[1], **Ozgur Yigit**[1]

[1]*ISTANBUL BASAKSEHİR CAM VE SAKURA CITY HOSPITAL, DEPARTMENT OF OTORHİNOLARYNGOLOGY, ISTANBUL, TURKEY*

BACKGROUND & AIM

Spindle cell sarcomas of the head and neck are rare malignant mesenchymal tumors characterized by aggressive local behavior and a high risk of recurrence. Their management is challenging due to complex regional anatomy and heterogeneous histopathological features. We hypothesize that inadequate follow-up and the intrinsic aggressive nature of these tumors may contribute to advanced local recurrence, including perineural spread and orbital involvement. This report aims to present a recurrent case with extensive local progression and to emphasize the aggressive clinical course and the importance of close follow-up.

MATERIAL & METHODS

A 48-year-old male initially presented in 2022 with right cheek swelling and was found to have a mass in the right hard palate.Following an incisional biopsy reported as a malignant mesenchymal tumor, partial maxillectomy was performed.Due to suspected residual disease, maxillary sinus resection and bilateral neck dissection were carried out in February

2023.Histopathology revealed grade 2 spindle cell sarcoma with focal residual tumor; inflammatory myofibroblastic tumor was considered in the differential diagnosis.The patient received adjuvant radiotherapy in March 2023 but remained without follow-up until January 2026.Upon re-presentation, clinical evaluation, magnetic resonance imaging(MRI), and positron emission tomography-computed tomography(PET-CT) were performed. Imaging demonstrated a 62×32×30 mm mass involving the sphenoid and ethmoid sinuses, nasal cavity, and pterygopalatine fossa, with suspected perineural spread along the maxillary nerve.Biopsy confirmed recurrent spindle cell malignancy.The patient underwent orbital exenteration and right radical maxillectomy, followed by reconstruction of the surgical defect using a pectoralis major flap.

RESULTS

Imaging findings indicated extensive local disease, bone destruction, and suspected perineural invasion. Histopathological examination confirmed recurrent tumor with myxoid stromal features. Complete macroscopic resection was achieved, and the defect was successfully reconstructed with a pectoralis major flap.

CONCLUSIONS

Head and neck spindle cell sarcomas are rare but highly aggressive tumors with significant recurrence potential. This case underscores that, despite combined surgical and radiotherapeutic approaches, recurrence with advanced features such as perineural spread and orbital involvement may occur, particularly in the absence of regular follow-up. Early diagnosis, close surveillance, meticulous radiological assessment, and appropriate surgical planning—including reconstruction—are critical for optimal disease control.

Recurrent Spindle Cell Sarcoma, orbital exenteration, radical maxillectomy, pectoralis major flap

PP-132

Ectopic Cervical Thyroid Tissue Mimicking A Thyroglossal Duct Cyst: A Case Report

Dr. Çağatay Nuri Kıllıoğlu[1], **Dr. Fatih Özcan**[1], **Dr. Faruk Kadri Bakkal**[1]

[1]*Department of Otorhinolaryngology, Faculty of Medicine, Usak University, Usak, Turkey*

BACKGROUND & AIM

Ectopic thyroid tissue (ETT) is a rare developmental anomaly resulting from the failure of the thyroid gland to migrate from the foramen caecum to its final pretracheal position during embryonic life. While it most commonly occurs at the base of the tongue, its presence near the hyoid bone can clinically and radiologically mimic a thyroglossal duct cyst (TGDC). The aim of this case report is to emphasize that ETT should be a primary consideration in the differential diagnosis of midline neck masses to prevent the inadvertent surgical removal of patient's only functional thyroid tissue, discussed in light of current literature.

MATERIAL & METHODS

This study presents a 32-year-old female patient referred to our clinic with a midline neck swelling present since childhood, fatigue, and hair loss. Diagnostic interventions included serum thyroid stimulating hormone (TSH) measurement, thyroid ultrasonography (USG), fine-needle aspiration biopsy (FNAB), contrast-enhanced computed tomography (CT), and technetium-99m (Tc-99m) scintigraphy. Outcome measurements focused on identifying the localization of the mass, its histopathological nature via the Bethesda classification system, and the presence or absence of orthotopic thyroid tissue.

RESULTS

Initial laboratory results revealed a TSH of 10 mIU/L. USG identified a 11 x 25.5 x 33 mm solid mass adjacent to the hyoid bone, alongside agenesis of the right thyroid lobe and isthmus. While the initial FNAB was non-diagnostic (Bethesda Category I), a repeat USG-guided FNAB confirmed benign thyroid tissue (Bethesda Category II). Tc-99m scintigraphy demonstrated intense tracer uptake exclusively at the site of the ectopic mass, confirming it as the patient's sole functional thyroid tissue. The patient was managed non-surgically with levothyroxine sodium at 50 mcg/day.

CONCLUSIONS

Ectopic cervical thyroid tissue is a critical diagnostic consideration for midline head and neck masses. In cases where orthotopic thyroid tissue is absent or hypoplastic, functional evaluation via scintigraphy is mandatory before any surgical intervention to avoid permanent iatrogenic hypothyroidism. This case confirms that conservative management with hormone replacement is an effective strategy when malignancy is excluded via repeat FNAB.

Ectopic thyroid tissue, thyroglossal duct cyst, midline neck mass, thyroid dysgenesis

PP-133

Papillary Thyroid Carcinoma Arising In A Thyroglossal Duct Cyst: A Case Report

Müslüm AYRAL[1], **Enes SIRMA**[1], **Siraç IRMAK**[1], **Servet ERDEMES**[2], **Muhsin ESER**[2], **Mahmut Ağırtmış**[2]

[1]*Gazi Yaşargil Training and Research Hospital, Department of Otorhinolaryngology, Head and Neck Surgery;* [2]*Harran University Faculty of Medicine, Department of Otorhinolaryngology, Head and Neck Surgery*

BACKGROUND & AIM

Thyroglossal duct cysts (TGDCs) are the most common congenital midline neck masses. Malignant transformation is rare, occurring in approximately 1% of cases, most commonly as papillary thyroid carcinoma. This study aims to present a rare case of papillary thyroid carcinoma, follicular variant, arising in a TGDC and to highlight its diagnostic and therapeutic considerations.

MATERIAL & METHODS

A 25-year-old female patient presenting with a midline neck mass was evaluated clinically and radiologically. Neck ultrasonography and magnetic resonance imaging (MRI) were performed. The patient underwent surgical excision via the Sistrunk procedure. Histopathological examination of the specimen was carried out for definitive diagnosis.

RESULTS

Imaging findings were consistent with a thyroglossal duct cyst. Histopathological evaluation revealed papillary thyroid carcinoma, follicular variant, measuring 0.4 cm, without lymphovascular invasion and with negative surgical margins. No evidence of thyroid gland involvement or cervical lymph node metastasis was identified. The case was classified as low-risk TGDC carcinoma.

CONCLUSIONS

TGDC carcinoma is a rare condition that is usually diagnosed incidentally following surgery. The Sistrunk procedure alone is generally sufficient in low-risk patients. Accurate diagnosis relies on histopathological evaluation, and management should be individualized based on risk factors. Prognosis is excellent with appropriate treatment.

sistrunk procedure, thyroglossal cyst, thyroglossal duct cyst malignancies, thyroid papillary cancer, total thyroidectomy

PP-134

Giant Parotid Pleomorphic Adenoma With Parapharyngeal Extension: A Case Report

Zeynep Yeşiller Güzel[1], **Hasan Uyar**[1], **Şahin Öğreden**[1]

[1]*Department of Otorhinolaryngology, Başakşehir Çam and Sakura City Hospital, Istanbul, Türkiye*

BACKGROUND & AIM

Approximately 70% of salivary gland tumors arise in the parotid gland, with pleomorphic adenoma being the most common. It is a benign epithelial tumor that typically presents as a slow-growing, painless mass.

Although most cases originate from the superficial lobe, rare extensions into the deep lobe and parapharyngeal space have been reported. Here, we present a rare case of pleomorphic adenoma with parapharyngeal extension.

MATERIAL & METHODS

A 33-year-old woman presented with a 2–3-year history of left-sided neck swelling, pain, and dysphagia. Physical examination revealed a firm, painless mass in the left parotid region with oropharyngeal asymmetry and uvular deviation. Facial nerve function was intact, and no cervical lymphadenopathy was detected.

Imaging demonstrated a 7 cm lobulated mass originating from the deep lobe of the left parotid gland, extending into the parapharyngeal space and causing airway deviation. Fine-needle aspiration biopsy was consistent with pleomorphic adenoma.

The tumor was excised via a transcervical approach with superficial parotidectomy and en bloc resection. Postoperatively, the patient developed House–Brackmann Grade IV facial paralysis, likely due to traction injury. Histopathology confirmed pleomorphic adenoma, and the patient remains under follow-up.

RESULTS

Parapharyngeal space tumors are rare, with approximately 80% being benign. Nearly half originate from salivary glands, with pleomorphic adenoma being the most common.

Although typically small, 10–12% of pleomorphic adenomas arise from the deep lobe of the parotid gland and may extend into the parapharyngeal space. These tumors are often asymptomatic and detected incidentally, but may present with oropharyngeal asymmetry, neck swelling, or symptoms related to airway or Eustachian tube involvement.

In the differential diagnosis of parapharyngeal masses, deep lobe parotid tumors should be considered. Giant pleomorphic adenomas with parapharyngeal extension are rare but have been reported, as demonstrated in the present case.

CONCLUSIONS

This report presents a rare case of a parotid tumor extending into the parapharyngeal space. Such tumors may remain asymptomatic and present with symptoms like dysphagia or obstructive sleep apnea.

Imaging plays a key role in diagnosis and surgical planning, while fine-needle aspiration aids in confirming the diagnosis. The main goal of surgery is complete excision with preservation of neurovascular structures. The transcervical approach allows safe identification of critical anatomy.

Early surgical intervention is important in large pleomorphic adenomas to prevent malignant transformation and avoid functional and cosmetic complications.

Mandibular Osteosarcoma: Clinical Presentation, Surgical Management And Multidisciplinary Approach In A Rare Case

Şahin YENER[1], **Berke GEREN**[1], **Deniz BAKLACI**[1]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, Faculty of Medicine, Zonguldak Bülent Ecevit University, Türkiye*

BACKGROUND & AIM

Osteosarcoma (OS) is a malignant bone tumor characterized by the direct production of osteoid tissue or immature bone by tumor cells. Although it most commonly affects the long bones, mandibular involvement is relatively rare, accounting for approximately 6–10% of all osteosarcomas. Gnathic osteosarcomas involving the mandible and maxilla demonstrate distinct clinical and biological characteristics compared to long-bone osteosarcomas. While long-bone osteosarcomas typically occur during the first two decades of life, mandibular osteosarcomas are more frequently observed in older patients, predominantly during the third and fourth decades, with a reported mean age of 33–36 years.

MATERIAL & METHODS

A 28-year-old male patient presented with a 3-month history of swelling in the right mandibular region. Physical examination revealed an approximately 4 cm mass located on the medial aspect of the right mandible. Maxillofacial computed tomography demonstrated an ill-defined expansile lesion measuring 42×35×38 mm in the right mandibular corpus, causing bone destruction. Magnetic resonance imaging revealed a malignant bone lesion involving the right hemimandible. PET/CT demonstrated a hypermetabolic mass extending into the submandibular region with destruction of the mandibular bone structure (SUVmax: 9.1). Incisional biopsy was reported as a malignant mesenchymal tumor, with osteosarcoma considered the primary diagnosis. The patient underwent right hemimandibulectomy and fibula osteomyocutaneous free flap reconstruction through a multidisciplinary surgical approach performed in collaboration with the plastic surgery team.

RESULTS

Gnathic osteosarcomas are rare malignant tumors that demonstrate locally aggressive behavior despite having lower rates of distant metastasis compared to long-bone osteosarcomas. Achieving local disease control is considered one of the most important prognostic factors in head and neck osteosarcomas. Previous studies have identified tumor size, histological grade, and metastatic disease at diagnosis as major determinants of survival in mandibular osteosarcoma.

In our case, intraoperative frozen-section analysis demonstrated negative surgical margins. Postoperative histopathological examination revealed tumor-free margins, absence of tumor necrosis, and 10–19 mitoses per 10 high-power fields. The tumor was reported as a well-differentiated Grade 1 osteosarcoma.

At the third postoperative month, biopsy demonstrated malignant mesenchymal tumor infiltration consistent with osteosarcoma infiltration. Following multidisciplinary evaluation by medical and radiation oncology teams, chemotherapy was initiated. The patient remains under close clinical follow-up.

CONCLUSIONS

Early diagnosis is critical for improving prognosis in mandibular osteosarcoma because of its variable clinical presentation, ranging from painless swelling to severe pain and facial asymmetry. Favorable survival is associated with younger age, lower histological grade, smaller tumor size, absence of metastasis, and wide surgical resection, whereas advanced age, metastatic disease at diagnosis, and lack of surgical excision are associated with poorer overall survival. Radical surgical resection with negative margins remains the cornerstone of treatment and the most important prognostic factor. Management of mandibular osteosarcoma requires a multidisciplinary approach involving maxillofacial surgeons, medical oncologists, radiologists, pathologists, and reconstructive surgeons.

Radiologic Assessment As An Independent Predictor Of Malignancy In Neck Masses: Radiologic–Pathologic Correlation In A Retrospective Cohort

Ceren Aksoy Koçak[1], **Derya Kusun Özer**[4], **Abdussamet Batur**[3], **Bahar çolpan**[2,5], **Hidayet Giray Soy**[2], **Merih Önal**[2,5]

[1]*Department of Otorhinolaryngology – Head and Neck Surgery, Konya City Hospital, Konya, Türkiye;* [2]*Department of Otorhinolaryngology – Head and Neck Surgery, Selcuk University Faculty of Medicine, Konya, Türkiye;* [3]*Department of Radiology, Memorial Diyarbakır Hospital, Diyarbakir;* [4]*Department of Otorhinolaryngology – Head and Neck Surgery, Izmir Cigli Training and Research Hospital, Izmir;* [5]*Department of Otorhinolaryngology – Head and Neck Surgery, Medova Hospital, Konya*

BACKGROUND & AIM

Accurate preoperative differentiation between benign and malignant neck masses remains challenging despite advances in imaging and cytological techniques. This study aimed to evaluate radiologic–pathologic correlation and the diagnostic performance of preoperative assessment methods in patients who underwent surgical treatment for neck masses.

MATERIAL & METHODS

This retrospective cohort study included 332 patients who underwent surgical excision for neck masses at a tertiary referral center between January 2012 and December 2020. Final histopathological diagnosis was available for 331 patients. Preoperative radiologic findings, biopsy results, and clinical variables were analyzed. The diagnostic performance and agreement of radiologic assessment and fine-needle aspiration biopsy (FNAB) were evaluated. Factors associated with malignancy were assessed using univariable and multivariable logistic regression analyses.

RESULTS

Benign lymphadenopathy was the most frequent histopathological diagnosis (49.5%). Radiologic assessment demonstrated moderate agreement with histopathology ($\kappa = 0.425$, $p < 0.001$), with high specificity (91.9%) but limited sensitivity (46.3%) for detecting malignant lesions, and an overall diagnostic accuracy of 79.6%. FNAB showed moderate diagnostic performance (sensitivity 62.5%, specificity 84.2%). Among radiologically suspicious lesions, 34.6% were found to be malignant on final histopathological examination. Age was associated with malignancy in univariable analysis ($p = 0.006$), whereas lesion size showed no significant association. In multivariable logistic regression analysis ($n = 136$), radiologic diagnosis remained the only statistically significant predictor of malignancy (OR = 5.55, 95% CI: 2.05–15.00, $p = 0.001$), and this finding remained consistent in an adult-only sensitivity analysis.

CONCLUSIONS

Radiologic evaluation plays a central role in the preoperative assessment of neck masses and represents the only statistically significant predictor of malignancy. Although clinical factors such as patient age and lesion characteristics may provide supportive diagnostic information, an integrated diagnostic approach combining imaging findings, cytological assessment, and clinical evaluation is essential for optimal management.

A RARE LARYNGEAL TUMOR : LARYNGEAL NEUROENDOCRINE TUMOR

Mehmet Burak Velioğlu[1], **Hakan Koca**[1], **Kasım Erbay**[1]

[1]*Fatih Sultan Mehmet Education and Research Hospital*

BACKGROUND & AIM

Laryngeal neuroendocrine tumors are rare entities, accounting for less than 1% of all laryngeal neoplasms. They most commonly arise in the supraglottic region, while involvement of the ventricular band is extremely uncommon. Due to their ability to mimic benign laryngeal lesions, diagnosis may be delayed. The aim of this case report is to present a rare Grade 2 laryngeal neuroendocrine tumor originating from the ventricular band and to emphasize its diagnostic and therapeutic considerations.

MATERIAL & METHODS

A 51-year-old male patient presented with a foreign body sensation in the throat and persistent throat clearing. Flexible laryngoscopy revealed a hyperemic, vascular-appearing polypoid lesion extending from the anterior surface of the right arytenoid to the ventricular band. Contrast-enhanced neck MRI demonstrated an intensely enhancing 9×5 mm lesion. The patient underwent excisional biopsy under direct laryngoscopy. Histopathological and immunohistochemical analyses were performed, including neuroendocrine markers and Ki-67 proliferation index. Postoperative imaging and endoscopic follow-up were used for surveillance.

RESULTS

Histopathological examination revealed a Grade 2 laryngeal neuroendocrine tumor with a Ki-67 index of 4–5% and a mitotic rate of 4–5 per 10 high-power fields. Immunohistochemical staining was positive for synaptophysin, chromogranin, CD56, and pancytokeratin. No necrosis was observed. PET-CT showed no distant metastasis. A second surgery was performed for safety margins, and no residual tumor was detected. No recurrence was observed during 12 months of follow-up.

CONCLUSIONS

Laryngeal neuroendocrine tumors located in the ventricular band are extremely rare and may mimic benign lesions. Awareness of this entity is essential for accurate diagnosis. Complete surgical excision with clear margins and close follow-up are crucial for optimal management of Grade 2 tumors.

Trends In Salivary Gland Tumors: A 14-Year Study Of Incidence, Outcomes, And Recurrence In Jeddah, Saudi Arabia

Omar Almansouri[1], **Abdulmajeed Alahmari**[3], **Dr. Mohammed Algarni**[2]

[1]*king fahad general hospital, jeddah, saudi arabia;* [2]*National Guard Hospital, Jeddah, Saudi Arabia;* [3]*King Fahad Armed Forces Hospital, Jeddah, Saudi Arabia*

BACKGROUND & AIM

Purpose: To determine the epidemiology of salivary gland tumors and the factors associated with their incidence, outcome, and recurrence rates across 2008-2022 in KAMC (King Abdulaziz Medical City), Jeddah, Saudi Arabia.

MATERIAL & METHODS

Methods: A retrospective chart review study to All cases from 2008 to 2022 including all patients who have been diagnosed with a salivary gland tumor. The data includes both patient, tumor, and management related variables. Patient-related variables include age, sex, smoking history, and history of radiation exposure. Tumor-related variables include the site, pathology, FNA, clinical staging and surgical margins. Management-related variables include treatment received, postoperative complications including facial nerve, outcomes, and recurrence rates.

RESULTS

Salivary gland malignancies were diagnosed in 70 with the majority in the 4th to 7th decades of life. The results revealed that the most common gland affected among participants is Parotid, with the most common histological types being encountered were Adenoid Cystic Carcinoma and Mucoepidermoid Carcinoma.

significant bias towards males in the Parotid gland with a contrasting bias towards females in the Submandibular. no relation between incidence and age or smoking being found. Outcomes were observed as 60% of the participants with improvement,14.3% deceased, and 25.7% on palliative care. No relation was found between outcomes and gender, age, or involvement of surgical margins with a possible relationship to discordance of preoperative and postoperative clinical staging. Recurrence was measured at 17.1% with higher rates being found in younger age groups and with specific types of cancers with Mucoepidermoid Carcinoma showing a particularly alarming rate.

CONCLUSIONS

Conclusion: while many of our finding were similar to those in literature, there exists significant variations such as in gender disparity and Mucoepidermoid Carcinoma recurrence. As such further and more comprehensive investigations into SGT is well warranted. Cases from KAMC hospital and their characteristics are presented to contribute to the information found in local and international literature.

Systemic Resveratrol Mitigates Radiation-Induced Oral Mucositis: A Histopathological And Biochemical Analysis In Rats

Associate Professor Şeyda Belli[1], **Associate Professor Eren Altun**[1], **Radiation Oncologist MD Nida Sünnetçi Arkan**[1], **Professor Halit Demir**[2], **Assistant Professor Cemal Özyılmaz**[3], **Medical Physicist Oğuzhan Altay Yönet**[1], **Specialist Medical Physicist Zeynep Pınar Kalender**[1], **Specialist MD İsmail Safa Poyrazoğlu**[1]

[1]*Health Sciences University Bagcilar Training and Research Hospital;* [2]*Van Yüzüncü Yıl University, Department of Biochemistry;* [3]*Ordu University*

BACKGROUND & AIM

This study aimed to evaluate the effects of systemic administration of resveratrol, which possesses antioxidant and anti-inflammatory properties, on the prevention and reduction of severity of radiation-induced oral mucositis.

MATERIAL & METHODS

The study included 36 rats divided into four groups (n=9): Control, Radiation, Radiation + Resveratrol (10 mg/kg, i.p.), and Radiation + Dimethyl sulfoxide. Target volumes were optimized for dose using the Intensity Modulated Radiotherapy technique based on computed tomography images. A single dose of 18 Gray radiation was administered to the head and neck region of the anesthetized subjects. Resveratrol administration was initiated 30 minutes before radiation and continued for 5 days. During the follow-up period, punch biopsies were taken from the tongue on days 7 and 14, and blood samples were collected on day 7 to determine oxidative stress (malondialdehyde and superoxide dismutase). On the 21st day of the experiment, sacrifice was performed, and the tongue tissue was totally excised. All samples underwent histopathological and immunohistochemical (bax, bcl-2, ki-67) examination.

RESULTS

During the experiment, it was demonstrated that the severe weight loss observed on the 9th day after radiation was compensated by resveratrol, showing a trend similar to the control group (p=0.084). Biochemical analyses revealed that resveratrol reduced malondialdehyde levels and increased superoxide dismutase activity (p=0.0025). Histopathological

examination showed that resveratrol preserved epithelial height on day 7 compared to the radiation group (p=0.004) and significantly limited cellular atypia such as hyperchromasia, pleomorphism, and binucleation (p=0.003). Immunohistochemical analyses revealed that resveratrol suppressed pro-apoptotic Bax expression (p=0,0025) and triggered Bcl-2 increase on day 14, while significantly increasing Ki-67 expression (p<0.001) and accelerating tissue regeneration on day 21."

CONCLUSIONS

Our findings suggest that resveratrol can regulate the mucosal effects caused by radiation by reducing oxidative stress, inhibiting apoptosis, and accelerating tissue regeneration, and may be a radioprotective treatment option.

Pectoralis Major Myocutan Flap Pedicle Metastasis Seven Years After Tongue Cancer: A Rare Case Report

Yunus Emre BULUT[1], **Murat Kahveci**[1], **Simge Turkan**[1], **Selenay Gumus**[1], **Ata Alperen Ersahan**[1], **Murat Ozturk**[1]

[1]*Department of Otorhinolaryngology, Head and Neck Surgery, Kocaeli University Faculty of Medicine, Kocaeli, Türkiye*

BACKGROUND & AIM

Head and neck squamous cell carcinoma may show complex recurrence patterns and delayed metastatic spread, particularly in patients with multiple metachronous mucosal lesions. Infraclavicular or pectoral metastatic involvement along a pectoralis major flap pedicle is extremely rare and may create diagnostic and surveillance challenges. We present a patient initially treated for T2N0M0 tongue squamous cell carcinoma who subsequently developed metachronous laryngeal squamous cell carcinoma involving the left aryepiglottic fold, received chemoradiotherapy, and seven years later developed metastatic squamous cell carcinoma in the pectoral/infraclavicular region requiring mass excision followed by chemotherapy.

MATERIAL & METHODS

A single-patient case report of a 64-year-old man was prepared through retrospective review of clinical records, operative notes, radiological findings, histopathological reports, and treatment history. The chronological disease course was analyzed, including the initial T2N0M0 tongue squamous cell carcinoma, subsequent metachronous laryngeal squamous cell carcinoma involving the left aryepiglottic fold treated with chemoradiotherapy, and the development of metastatic squamous cell carcinoma in the pectoral/infraclavicular region seven years later, requiring surgical mass excision followed by systemic chemotherapy.

RESULTS

Histopathological evaluation of the excised pectoral/infraclavicular mass confirmed metastatic squamous cell carcinoma. The metastatic pattern was considered highly unusual because the lesion developed after a prolonged disease interval, outside the conventional primary mucosal and cervical nodal recurrence sites, and in relation to the pectoralis major flap pedicle region. Potential mechanisms include altered lymphatic drainage after previous surgery and reconstruction, tumor cell implantation, delayed regional metastatic spread, or tumor progression through surgically modified tissue planes.

CONCLUSIONS

Delayed pectoral/infraclavicular squamous cell carcinoma metastasis along a pectoralis major flap pedicle is extremely rare in head and neck malignancies. Potential mechanisms include altered lymphatic drainage after previous surgery and reconstruction, tumor cell implantation, delayed regional metastatic spread, or progression through surgically modified tissue planes.In long-term survivors of head and neck squamous cell carcinoma reconstructed with pedicled regional flaps, surveillance should extend beyond the primary tumor bed and cervical lymphatic basins to include the flap pedicle course, infraclavicular region, and donor-site area.

PP-141

“Hidden Malignancy In Chronic Otalgia: A Case Of External Auditory Canal Adenoid Cystic Carcinoma With Delayed Diagnosis”

ALEYNA ELBURZ[1], **KIARASH SHAMEKHI**[1], **AYSENUR YILDIRIM**[1], **ALPEREN VURAL**[1]

[1]*ISTANBUL UNIVERCITY CERRAHPAŞA*

BACKGROUND & AIM

Adenoid cystic carcinoma (ACC) of the external auditory canal (EAC) is a rare malignancy arising from ceruminous glands. It demonstrates slow growth but a marked tendency for perineural invasion, which increases the risk of local recurrence and delayed distant metastasis. It may mimic benign conditions such as chronic otitis externa, leading to diagnostic delay. This study presents a case with prolonged diagnostic delay and emphasizes that clinical suspicion and biopsy remain crucial even when initial imaging findings are normal

MATERIAL & METHODS

A 39-year-old female presented with a 12-month history of persistent unilateral otalgia, intermittent otorrhea, and aural fullness. She had previously been treated multiple times for chronic otitis externa and otomycosis with only temporary symptomatic relief.

Initial temporal bone computed tomography (CT) and magnetic resonance imaging (MRI), performed at an external center, were reported as normal, with no evidence of mass lesion or bony erosion.

Due to persistent and progressively neuropathic-type pain, the patient was referred to our tertiary care center. Otoscopic examination revealed a subtle, firm, and slightly tender skin swelling in the posterosuperior wall of the external auditory canal. The tympanic membrane was intact, and no facial nerve dysfunction was observed.

A deep punch biopsy was performed under local anesthesia. Histopathological examination demonstrated a malignant epithelial tumor with a characteristic cribriform pattern, consistent with adenoid cystic carcinoma. Repeat high-resolution CT revealed subtle erosion of the posterior canal Wall.

RESULTS

The patient underwent comprehensive surgical management lateral temporal bone resection, superficial parotidectomy, and selective neck dissection (levels II–IV), followed by reconstruction with full thickness skin graft .Final histopathological analysis confirmed T3N0M0 adenoid cystic carcinoma with perineural invasion. Surgical margins, including deep margins and facial nerve sheath margins, were free of tumor involvement.

Adjuvant external beam radiotherapy (60 Gy) was administered postoperatively to improve local disease control.

At 12-month follow-up, the patient demonstrated no clinical or radiological evidence of local recurrence or distant metastasis.

CONCLUSIONS

Adenoid cystic carcinoma of the external auditory canal may present with nonspecific symptoms and mimic benign inflammatory conditions, resulting in significant diagnostic delays, even in the presence of initially normal imaging.

Persistent otalgia, particularly with neuropathic characteristics, should raise suspicion for malignancy. This case highlights the limitations of early imaging and the critical importance of thorough clinical evaluation and timely biopsy in atypical or refractory cases.

Early diagnosis and aggressive multidisciplinary management, including radical surgery and adjuvant radiotherapy, are essential for optimal oncologic outcomes in EAC ACC.

PP-142

A Novel Landmark For Intraoperative Identification Of The Spinal Accessory Nerve In The Posterior Triangle During Neck Dissection

Anup Singh[1]

[1]*All India Institute of Medical Sciences, New Delhi, India*

BACKGROUND & AIM

The spinal accessory nerve needs to be identified and preserved during modified neck dissection and various skull base procedures. Despite multiple landmarks described for nerve identification, anatomical variations in the trajectory of the nerve can sometimes present challenges in accurate identification, even for experienced professionals. This pilot study describes an additional anatomical landmark to facilitate the identification of the nerve within the posterior triangle, particularly in cases where localization is challenging

MATERIAL & METHODS

This pilot observational study included consecutive patients who underwent unilateral modified neck dissection as part of the therapeutic resection for oral cavity carcinoma at our institute. The Institutional Ethics Committee approved the study. During neck dissection, as the upper part of the posterior triangle was exposed, the lesser occipital nerve (LON) was followed in a retrograde fashion to reach the area where the nerve skirted around the posterior border of the muscle. The relationship between the two nerves was documented

RESULTS

Of the 10 patients, nine had the SAN passing medial to the LON at the location where the nerve skirted the posterior border of the SCM muscle or more proximally, deeper to the muscle. One patient was found to have the LON passing medial to the SAN, deeper to the muscle.

CONCLUSIONS

This pilot study describes the lesser occipital nerve as a novel and reliable landmark to identify the spinal accessory nerve. The relationship between the two nerves was reliably uniform, with the LON overriding SAN in 90% of cases.

PP-143

Rare Primary Tumor And Distant Metastases Of The Parotid Gland: Five Cases

Ozge ERYIGIT, M.D.[1], **Associate Professor Gokce TANYERI TOKER, M.D.**[1], **Furkan GUL, M.D.**[1], **Prof. Yilmaz OZKUL, M.D.**[1]

[1]*Izmir Katip Çelebi University Atatürk Training and Research Hospital*

BACKGROUND & AIM

Approximately 80% of parotid gland tumors are benign, and most malignancies arise from primary gland tissue. Metastasis to the parotid is rare, usually associated with head and neck squamous cell carcinomas or melanomas. However, both rare primary parotid malignancies and unexpected metastases from distant organs may occur. This study presents one rare primary tumor and four unusual metastases to the parotid gland, emphasizing a broad differential diagnosis.

MATERIAL & METHODS

Data were retrospectively collected from the national e-health system and hospital information system. Radiological images (MRI, CT) and intraoperative photographs were evaluated. Five cases were analyzed for demographic characteristics, clinical course, histopathological diagnosis, and treatment.

RESULTS

Five cases (3 males, 2 females; age 17–78) were evaluated.

Primary parotid intraductal carcinoma : superficial parotidectomy for suspected Warthin tumor, pathology confirmed intraductal carcinoma, adjuvant radiotherapy.

Merkel cell carcinoma metastasis: from right upper eyelid, 16 mm parotid metastasis with two ipsilateral cervical nodes, treated with total parotidectomy and neck dissection.

Peritoneal carcinoma metastasis: 5 cm parotid mass, treated with total parotidectomy and neck dissection.

Secretory breast carcinoma metastasis : extremely rare pediatric/adolescent entity, treated with total parotidectomy and neck dissection.

Laryngeal SCC metastasis: from right vocal cord, synchronous 5 cm parotid metastasis (not second primary), treated with total parotidectomy and neck dissection.

All patients underwent oncologically appropriate surgery; adjuvant chemoradiotherapy was given in indicated cases.

CONCLUSIONS

In patients presenting with a parotid mass, both rare primary tumors (e.g., intraductal carcinoma) and unexpected metastases (Merkel Cell, peritoneal, secretory breast, laryngeal) should be considered in the differential diagnosis. This series adds to the limited literature. Aggressive surgery including total parotidectomy and neck dissection, combined with multidisciplinary oncologic management, remains critical for local control and survival.

Retrospective Analysis Of Factors Affecting Hypocalcemia Developing In The First 24 Hours After Thyroidectomy

Ertuğrul Bebek[1], **Sema Zer Toros**[1], **Çiğdem Tepe Karaca**[1]

[1]*Health Sciences University, Haydarpaşa Numune Training and Research Hospital*

BACKGROUND & AIM

To retrospectively evaluate the frequency and associated risk factors of hypocalcemia developing in the first 24 hours postoperatively in patients undergoing thyroidectomy.

MATERIAL & METHODS

A total of 98 consecutive patients (108 operations) who underwent thyroidectomy in our clinic between January 2020 and September 2025 were included in the study. The relationship between hypocalcemia developing in the first 24 hours and gender, age, preoperative FNAB and thyroid function, surgical procedure, malignancy status in postoperative final pathology results, nodule or tumor size, and incidental parathyroidectomy was evaluated. Additionally, the effect of neck dissection on hypocalcemia in malignant cases was examined. Continuous variables were analyzed with t-test, and categorical variables were analyzed with Chi-square or Fisher's Exact Test; $p < 0.05$ was considered statistically significant.

RESULTS

In the study evaluating a total of 108 thyroidectomy cases, postoperative hypocalcemia was found to develop in 29 (26.8%) of the patients within the first 24 hours. When factors associated with hypocalcemia were examined, female gender ($p = 0.0439$),

tumor size of 2 cm and above in malignant cases (p ≈ 0.049), and incidental parathyroidectomy (p < 0.01) were identified as significant risk factors.

CONCLUSIONS

The risk of postoperative hypocalcemia was found to be higher in female patients, patients with large tumors, and cases with incidental parathyroidectomy.

Total Laryngopharyngectomy And Esophageal Reconstruction With A Radial Forearm Flap: A Multidisciplinary Approach And Functional Outcomes

Ahmet Can Parmaksız[1], **Muhammed Mehdi Güneş**[1], **Şeyda Akbal Çufalı**[1], **Kürşat Murat Özcan**[1]

[1]*Ankara Bilkent City Hospital*

BACKGROUND & AIM

Extensive resections performed in recurrent or advanced-stage laryngopharyngeal cancers require a careful balance between reconstructive surgery and functional outcomes. This case report discusses esophageal reconstruction using a radial forearm flap following total laryngopharyngectomy in an advanced-stage glottic squamous cell carcinoma patient with a history of radiotherapy. Additionally, we highlight the contribution of an early stenting approach and a multidisciplinary treatment plan to the final functional outcomes.

MATERIAL & METHODS

A 75-year-old male with a history of coronary bypass and chemoradiotherapy (33 fractions RT, 7 cycles CT) for T4N1M0 glottic carcinoma five years ago presented with recurrence. PET-CT and MRI revealed an epiglottic mass (SUV_{max}: 12\text{ g/mL}) and left aryepiglottic fold involvement. Biopsy confirmed moderately differentiated supraglottic squamous cell carcinoma, with an oligometastatic focus in the left gluteus muscle.The patient underwent total laryngopharyngectomy, bilateral level II–V neck dissection, and radial forearm flap esophageal reconstruction. Pathology showed surgical margins >5 mm, with perineural and lymphovascular invasion. Oral diet started on postoperative day 7. Due to a suspected tracheostomal posterior wall fistula on day 10, a covered metallic esophageal stent was placed early, preventing nutritional interruption. The fistula completely healed upon stent removal at day 30. Following oligometastatic radiotherapy and ongoing chemotherapy, the 12-month follow-up demonstrated successful oral intake (soft diet) and functional esophageal speech.

RESULTS

Esophageal reconstruction with a radial forearm flap after total laryngopharyngectomy is an effective and safe option in terms of both oncological control and functional gain, provided that careful surgical planning and early complication management are implemented.

CONCLUSIONS

The radial forearm flap is one of the preferred methods in post-laryngectomy esophageal reconstructions due to its thin pliable structure, adequate length, and reliable vascularity. In patients with a history of radiotherapy and systemic comorbidities, early-period stenting can reduce fistula-related complications and accelerate the healing process. This case demonstrates that a multidisciplinary approach and timely interventions can significantly improve functional outcomes in advanced-stage and complex patient groups.

Occult Clear Cell Renal Cell Carcinoma Presenting With An Aggressive Floor-Of-Mouth Mass: A Rare Case Report

Cemal AKSOY[1], **Süleyman BATI**[1], **Emine KILICARSLAN**[1]

[1]*Department of Otorhinolaryngology, Kütahya Health Sciences University, Kütahya, Türkiye*

BACKGROUND & AIM

Renal Cell Carcinoma (RCC) is the most common renal malignancy in adults. RCC is characterized by its unpredictable metastatic behavior. Metastases to the head and neck region account for less than 15% of all cases, and initial presentation as an intraoral mass mimicking a primary oral malignancy is exceedingly rare. In this case report, we aimed to present an unusual case of occult clear cell RCC that initially manifested as an aggressive oral cavity mass.

MATERIAL & METHODS

A 66-year-old female patient presented with a rapidly enlarging intraoral mass involving the anterior mandible and ventral tongue, with a clinical history of approximately one month. Physical examination revealed a 3 × 5 cm hemorrhagic, exophytic,

and ulcerative lesion within the oral cavity. The patient had no history of tobacco or alcohol use. Histopathological evaluation of the incisional biopsy specimen obtained from the lesion demonstrated metastatic Clear Cell Renal Cell Carcinoma. One week after the initial diagnosis, the patient developed a pathological femoral fracture. Contrast-enhanced computed tomography (CT) scans of the neck, thorax, brain, and knee, together with whole-body positron emission tomography (PET), revealed a 5 × 6 cm left renal mass consistent with renal cell carcinoma, as well as multiple metastatic lesions involving the mandible, lungs, brain, humerus, femur, scapula, and sacrum. The patient was subsequently referred to the Department of Medical Oncology for systemic chemotherapy.

RESULTS

Squamous Cell Carcinoma represents more than 90% of oral cavity carcinomas. When clear cells predominate in oral lesions, diagnosis may be challenging. As clear cells are common in salivary gland tumors, the differential diagnosis includes epithelial-myoepithelial carcinoma, mucoepidermoid carcinoma, adenocarcinoma, oncocytoma, and odontogenic tumors. Renal Cell Carcinoma frequently presents with distant metastases, and accounts for approximately 1–1.5% of oral cavity malignancies. It is the third most common primary tumor metastasizing to the oral cavity after lung and breast carcinomas. Although previously reported, RCC metastases most commonly involve the gingiva, alveolar mucosa, or jaws. Presentation as an aggressive floor-of-mouth mass is rare. Recent studies show that oro-facial RCC metastases most frequently affect the tongue, gingiva, and mandible, while floor-of-mouth involvement is uncommon. In the series by Granberg et al. (206 cases), one case (0.4%) involved the floor of the mouth. Therefore, this case is notable due to its rare floor-of-mouth presentation.

CONCLUSIONS

Renal Cell Carcinoma may present atypically as a rapidly enlarging, destructive, and aggressive oral cavity lesion. This case underscores the importance of including metastatic RCC in the differential diagnosis of oral cavity masses and highlights the critical role of immunohistochemistry and whole-body PET-CT imaging in the detection of primary occult malignancies.

Parotis Bezinin Tükürük Kanalı Karsinomunda Klinikopatolojik Deneyimimiz Ve Cerrahi Sonuçlarımız

Süheyla Yılmaz Bayram[1], **Hakki Caner Inan**[1]

[1]*Bursa High Specialty Training and Research Hospital,University of Health Sciences*

BACKGROUND & AIM

Salivary gland duct carcinoma (SDC) is a highly aggressive and rare malignancy that particularly affects the parotid gland. Histologically, it resembles high-grade breast ductal carcinoma. SDC typically presents in the 6th or 7th decade of life, with a male predominance. Its prognosis is poor due to early lymph node metastasis, perineural invasion, and a tendency towards distant metastasis.

MATERIAL & METHODS

The study included 5 cases who underwent surgery for parotid masses in our clinic between 2025 and 2026 and whose histopathological examination revealed salivary gland ductal carcinoma.

RESULTS

The ages of the patients ranged from 56 to 81 years. All were male. One of the 5 patients had SDC on preoperative pathology, two had uncertain malignant potential, and two had malignant epithelial tumors. Preoperative facial nerve paralysis was present in 1 of 5 patients.

Total parotidectomy was performed in 4 patients. Radical parotidectomy and mastoidectomy were performed in 1 patient. Level 1-5 neck dissection was performed in 5 patients.

The average tumor diameter in 5 patients was 4-4.7 cm. Perineural invasion was observed in 5 patients. Lymphovascular invasion was observed in 4 of 5 patients. Dermal invasion was present in 3 patients. Levels 2-3-4 were the most frequent areas of metastasis in neck dissection specimens. ENE(+) was present in all 5 patients.

CONCLUSIONS

Salivary gland ductal carcinoma is characterized by high perineural spread capacity and early regional lymph node metastasis. The fact that they are often in an advanced stage (T4a) at the time of diagnosis and have a high rate of ENE(+) necessitates extensive surgical resection and chemoradiotherapy treatment. AR and HER2 positivity creates a targeted therapy option in SDC.

Correlation Between Great Auricular Nerve Diameter And Facial Nerve Trunk And Division Diameters During Parotidectomy: A Prospective Clinical Study

Hasan Sami Bircan[1], **Ramazan Çelik**[1], **Kaan Kadir Alpaslan**[1], **Burak Arpacı**[1]

[1]*Istanbul Training and Research Hospital, Department of Otolaryngology – Head and Neck Surgery*

BACKGROUND & AIM

To investigate the correlation between the great auricular nerve (GAN) diameter and the facial nerve trunk (FNT) and its temporofacial and cervicofacial division diameters during parotidectomy, and to evaluate the clinical utility of the GAN diameter in predicting facial nerve branch thickness.

MATERIAL & METHODS

A prospective study was conducted on 25 patients undergoing parotidectomy via a modified Blair incision. Intraoperative measurements of the GAN, FNT, temporofacial division (TFD), and cervicofacial division (CFD) diameters were obtained using a vernier caliper. Pearson and Spearman correlation analyses, linear regression, and comparative statistical tests were performed.

RESULTS

The mean diameters were as follows: GAN 2.22 ± 0.40 mm, FNT 2.50 ± 0.37 mm, TFD 2.32 ± 0.48 mm, and CFD 2.14 ± 0.38 mm. A significant positive correlation was observed between the GAN and FNT diameters ($r = 0.536$, $p = 0.006$). The strongest correlation was found between the GAN and TFD diameters ($r = 0.630$, $p < 0.001$). The FNT diameter correlated significantly with both the TFD ($r = 0.495$, $p = 0.012$) and CFD ($r = 0.694$, $p < 0.001$). However, no significant correlation was found between the GAN and CFD diameters ($r = 0.244$, $p = 0.240$). No significant side differences were observed for any nerve measurement ($p > 0.05$).

CONCLUSIONS

The GAN diameter serves as a significant intraoperative predictor of FNT and, most notably, TFD thickness. In patients with a large GAN diameter, a retrograde surgical approach via the temporofacial division may be more feasible owing to thicker peripheral branches. This finding has practical implications for surgical planning in parotidectomy.

PP-149

Determinants Of Outcomes After Total Laryngectomy: The Role Of Surgical Technique And Prior Radiotherapy

Ana Raquel Andrade[1], **Eduardo Ferreira**[1], **Ana Sofia Paiva**[1], **Carolina Arede**[1], **Joaquim Amaral**[1]

[1]*Hospital do Divino Espírito Santo De Ponta Delgada*

BACKGROUND & AIM

Pharyngocutaneous fistula (PCF) remains the most frequent and clinically significant complication following total laryngectomy. Pharyngeal closure technique has been widely investigated as a potentially modifiable surgical factor, particularly with the introduction of mechanical stapling devices aimed at reducing operative time and tissue manipulation. At the same time, prior radiotherapy is consistently reported as a major risk factor for impaired wound healing and fistula formation. However, the extent to which technical modifications in pharyngeal closure may influence postoperative outcomes relative to the biological impact of previous irradiation remains a matter of clinical interest.

MATERIAL & METHODS

A retrospective case-control study was conducted including 28 patients who underwent total laryngectomy between 2018 and 2025. Patients were divided according to pharyngeal closure technique: manual suture (Group A, n=15) and stapled closure (Group B, n=10). Demographic characteristics were comparable between groups. Perioperative variables analyzed included operative time, postoperative complications, PCF incidence, surgical site infection, positive margins, length of hospital stay, and duration of nasogastric feeding. The association between prior radiotherapy and PCF was also evaluated.

RESULTS

Stapled closure was associated with a significantly shorter operative time compared with manual closure (3.7 ± 0.8 hours vs 4.8 ± 0.9 hours; $p = 0.01$). No statistically significant differences were observed between closure techniques regarding overall postoperative complications ($p = 0.69$), PCF incidence ($p = 0.68$), surgical site infection ($p = 0.64$), positive margins ($p = 0.57$), length of hospital stay, or duration of nasogastric feeding. Independent of closure technique, prior radiotherapy was significantly associated with the development of PCF ($p = 0.02$).

CONCLUSIONS

In this cohort, surgical technique influenced operative efficiency but did not significantly impact postoperative complication rates or fistula incidence. Prior radiotherapy was associated with an increased risk of pharyngocutaneous fistula, regardless of closure method. These findings suggest that, while technical factors may optimize surgical efficiency, patient-related biological factors—particularly previous irradiation—play a critical role in determining postoperative outcomes after total laryngectomy.

CHALLENGES IN CHOOSING SURGICAL APPROACHES FOR RETRO- AND PARAPHARYNGEAL TUMORS: A RETROSPECTIVE STUDY

Laura-Maria Burlacu[1], **Carina Russu**[1], **Mara-Andra Rebosapcă**[1], **Augustina Iurkovski**[1], **Selma-Andra Crețu**[1], **Irina-Gabriela Ioniță**[2], **Andreea Rusescu**[2], **Teofana-Andreea Carazanu**[2], **Raluca Pulpă**[2], **Ruxandra-Oana Aliuș**[2], **Cătălina Voiosu**[2], **Viorel Zainea**[2], **Răzvan Hainăroșie**[2]

[1]*"Prof. Dr. Dorin Hociota" Institute of Phonoaudiology and Functional ENT Surgery Bucharest, Romania;* [2]*"Carol Davila" University of Medicine and Pharmacy Bucharest, Romania*

BACKGROUND & AIM

Accessing the retro-/parapharyngeal space represents a challenge for head and neck surgeons due to its complex anatomy. The purpose of retro-/parapharyngeal space surgery is to achieve optimal visualization, allowing the removal of entire tumors while preserving the vessels and the nerves. One of the most important stage is the choice between transoral and transcervical approach.

MATERIAL & METHODS

We performed a retrospective analysis of 21 patients who had undergone transoral, transcervical or combined resection of retro-/parapapharyngeal space tumors from January 2015 to December 2025 in our hospital. Clinical manifestations, paraclinical aspects, surgical approaches, complications and histopathological results are discussed.

RESULTS

The most often reported symptoms were: dysphagia and cervical swelling. We performed surgery in all patients: 12 transoral, 8 transcervical, 1 combined. In every case the tumor was removed radically. In terms of histopathological findings, benign lesions exceeded (17). Most of these were pleomorphic adenomas (6) and schwanomas (5). Other histopathologycal diagnosis included: cysts, lipoma-like hibernoma, rhabdomyoma, hemangioma, fibroconjunctival hyperplasia. Postoperative complications occurred in 3 patients and presented as bleeding and dyspnoea due to recurrent laryngeal paresis.

CONCLUSIONS

The transoral approach is one of the most disputed approaches for retro-/parapharyngeal tumors, starting from the challenge of obtaining an adequate exposure. It is mandatory for ENT surgeons to be well trained in different approaches for this region delimited by the carotid sheath, skull base, prevertebral fasci and posterior pharyngeal wall. A variety of factors guide the choice of the optimal surgical approach: tumor size, nature of the tumor, relation with critical structures and notably, the surgeon`s training level.

PP-151

Delayed Sinonasal Metastasis Of Renal Cell Carcinoma: A Case Report

Uzdan Uz[1], **Sabri Mutlu**[1], **Dilan Özen Mutlu**[1], **Kıvanç Günhan**[1]

[1]*Manisa Celal Bayar Üniversitesi Kulak Burun Boğaz Hastalıkları Anabilim Dalı*

BACKGROUND & AIM

Renal cell carcinoma (RCC) is a malignant renal tumor most commonly metastasizing to the lungs, bones, and liver. Sinonasal involvement is rare, and the available literature remains limited. Metastatic spread to the sinonasal region occurs via two hematogenous pathways: the classical route through the renal vein, inferior vena cava, and lungs; and the Batson paravertebral venous plexus, bypassing pulmonary filtration. Epistaxis, nasal obstruction, and pain are the most common presentations. We report a rare case of late RCC metastasis to the nasal cavity, occurring 8 years after nephrectomy with no prior evidence of metastatic disease.

MATERIAL & METHODS

A 64-year-old male presented with a 7-month history of right-sided nasal obstruction, epistaxis, and anosmia. Otorhinolaryngological examination revealed a highly vascular mass nearly completely obliterating the right nasal cavity. Contrast-enhanced CT showed an expansile mass measuring 28 × 43 × 49 mm, originating from the right ethmoidal fovea, with deformation of the medial maxillary sinus wall and nasal septum. Systemic imaging revealed no additional metastatic foci. The patient had undergone right radical nephrectomy 8 years previously for RCC (pT1N0M0). Biopsy of the nasal mass was consistent with metastatic renal cell carcinoma. Following multidisciplinary tumor board discussion, induction systemic therapy with pazopanib (800 mg/day for 6 weeks) was initiated prior to surgical planning. Preoperative chemoembolization of the internal maxillary artery was performed given the marked hypervascularity of the lesion, after which the tumor was completely excised endoscopically. At 24-month follow-up, no recurrence or residual disease was detected.

RESULTS

The classic triad of flank pain, hematuria, and palpable mass is observed in fewer than 10% of patients with RCC, whereas nearly one-third present with distant metastases at diagnosis. Although metastatic spread most commonly involves the lungs, liver, brain, and bones, sinonasal involvement remains rare. Among the paranasal sinuses, the maxillary sinus is most frequently affected, followed by the ethmoid, frontal, and sphenoid sinuses. In our case, ethmoid fovea metastasis developed 7 years after nephrectomy, consistent with the prolonged latency described in the literature. Immunohistochemistry demonstrated positivity for vimentin, EMA, CD10, and CKAE1/AE3, with negative CK7 staining, supporting metastatic RCC origin. Up to 30% of patients develop metastases after nephrectomy, with sinonasal involvement occurring after a mean interval of approximately 7 years.

CONCLUSIONS

We present a rare case of isolated sinonasal metastatic RCC involving the right nasal cavity. In patients with a history of RCC, late-onset nasal symptoms should prompt consideration of metastatic disease. Preoperative chemoembolization followed by endoscopic surgical resection provided effective local control, consistent with previously reported management strategies. Although sinonasal metastases are generally associated with poor prognosis, our patient has exceeded the reported median survival threshold at 24 months. The 7-year interval between nephrectomy and metastasis underscores the unpredictable biological behavior of RCC and highlights the importance of long-term clinical surveillance in all patients, regardless of initial tumor characteristics.

PP-152

A CASE REPORT WARTHIN-LIKE PAPILLARY THYROID CARCINOMA

CIHAN AKINCI[1], **HAKKI CANER INAN**[1]

[1]*SAGLIK BILIMLERI UNIVERSITESI BURSA YUKSEK IHTISAS EGITIM VE ARASTIRMA HASTANESI*

BACKGROUND & AIM

Papillary thyroid carcinoma is the most common endocrine malignancy and comprises various histopathological subtypes. Warthin-like papillary thyroid carcinoma is a rare variant, accounting for approximately 0.2–1.9% of cases, and is characterized by morphological similarity to Warthin tumor. It is frequently associated with Chronic lymphocytic thyroiditis and generally has a favorable prognosis.The aim of this study is to present a rare case of Warthin-like papillary thyroid carcinoma in a young patient and to highlight its clinical, radiological, and pathological features.

MATERIAL & METHODS

A 21-year-old female patient presented with a progressively enlarging neck swelling over four years. Neck ultrasonography revealed a suspicious nodule in the left thyroid lobe. Fine-needle aspiration biopsy was performed and reported as Bethesda category V. Laboratory tests including thyroid function tests and thyroid autoantibodies were evaluated. Cervical lymph nodes were assessed by ultrasonography and Thyroglobulin washout. The patient subsequently underwent Total thyroidectomy. Histopathological examination was performed postoperatively.

RESULTS

Ultrasonography demonstrated an 11 × 9 × 17 mm hypoechoic nodule with microcalcifications in the left thyroid lobe. Cervical lymph nodes appeared reactive, and thyroglobulin washout was negative. Thyroid function tests were within normal limits, while anti-thyroglobulin and anti-TPO levels were elevated.

Postoperative histopathological examination revealed Warthin-like papillary thyroid carcinoma in the left lobe and chronic lymphocytic thyroiditis in the right lobe. The tumor measured 1.3 cm in greatest dimension, with negative surgical margins. No extrathyroidal extension or lymphovascular invasion was identified. The patient did not receive radioactive iodine therapy and is under regular follow-up.

CONCLUSIONS

Warthin-like papillary thyroid carcinoma is a rare subtype of papillary thyroid carcinoma with favorable prognosis. It may occur in younger patients and is commonly associated with chronic lymphocytic thyroiditis. Accurate diagnosis relies on histopathological evaluation. Surgical management alone may be sufficient in selected low-risk cases, and careful follow-up is essential.

PP-153

Life-Threatening Recurrent Epistaxis Due To Traumatic Cavernous Internal Carotid Artery Pseudoaneurysm: A Case Report

Celal GUNAY[1], **Vecide Pınar ALTINISIK DOGAN**[1], **Muhammed Ensar GOKCE**[1]

[1]Istanbul Medıpol University,Faculty of Medicine,Depatment of Otorhinolaryngology,Istanbul,Türkiye

BACKGROUND & AIM

Although epistaxis is generally benign, recurrent, unilateral, posterior bleeding requiring repeated transfusions—particularly after craniofacial trauma—necessitates urgent evaluation for occult vascular injury. Traumatic pseudoaneurysms of the cavernous internal carotid artery (ICA) are rare but may carry rupture mortality of up to 50%. Diagnosis is often delayed, as anterior rhinoscopy and nasal endoscopy frequently fail to detect an active bleeding source, leading to misinterpretation as routine ENT epistaxis. Delayed presentation weeks after trauma further complicates recognition. We present a life-threatening case of transfusion-dependent epistaxis caused by a traumatic cavernous ICA pseudoaneurysm, highlighting the importance of early vascular imaging and timely endovascular management.

MATERIAL & METHODS

In the presented case, a 33-year-old male patient who developed intermittent profuse epistaxis approximately four weeks after a non-vehicle traffic accident and required repeated erythrocyte suspension transfusions showed no identifiable bleeding focus on initial otorhinolaryngologic evaluations; cauterization of the Little's area and nasal packing were performed. Subsequent vascular imaging, prompted by a progressive decrease in hemoglobin levels accompanied by headache and visual loss, revealed a pseudoaneurysm originating from the cavernous segment of the right ICA with extension into the sphenoid sinus.

RESULTS

Brain CT angiography demonstrated a pseudoaneurysm in the cavernous segment of the right internal carotid artery (ICA) extending into the sphenoid sinus. The patient underwent endovascular treatment, occluding the patent ICA segment while confirming collateral flow through the anterior and posterior communicating arteries (AComA and PComA). One day post-procedure, anterior and posterior nasal tampons were removed without active bleeding. Follow-up MRI revealed two punctate diffusion-restricted lesions in the right frontal and parietal lobes, microhemorrhages in the left parietal and right temporal lobes, and flow loss in the petrous and cavernous ICA segments. Two-week MR angiography confirmed distal cervical, petrous, and cavernous ICA occlusion with adequate collateral filling. Neurologically, the patient was alert, with mild left arm pronation and slight hypoesthesia on the dorsum of the left hand. Ophthalmologic evaluation showed traumatic optic neuropathy of the right optic disc. At one-year follow-up, there was no recurrent epistaxis or neurological deterioration.

CONCLUSIONS

When this case is evaluated together with the literature, ICA pseudoaneurysm should be considered a primary differential diagnosis in patients with a history of trauma presenting with unilateral, recurrent, posterior, and transfusion-dependent epistaxis, even in the absence of an identifiable bleeding focus on nasal endoscopy. Early vascular imaging—preferably DSA—and timely endovascular intervention in appropriate cases are crucial in reducing the risk of catastrophic rupture and mortality.

Kimura Disease As A Retroauricular Mass

Dr.Rashed Aldoseri[1], **Dr.Noor binsanad**[1], **Dr.Mai Nasser**[1], **Dr.Muneera Alkhalifa**[1]

[1]Royal Medical Services

BACKGROUND & AIM

Kimura disease is a rare, benign chronic inflammatory disorder that typically presents as painless subcutaneous masses in the head and neck region

We report the case of an 18-year-old male with a one-week history of a left retroauricular swelling that was initially treated as an infectious abscess.

MATERIAL & METHODS

Imaging revealed a subcutaneous lesion without bony involvement, and an excisional biopsy was performed. Histopathological examination demonstrated eosinophil-rich granulomatous inflammation with lymphoid follicular hyperplasia and vascular proliferation, consistent with Kimura disease.

RESULTS

The lesion was completely excised, and the patient recovered well.Patient had no recurrence of the mass and all investigations were negative for any associations

CONCLUSIONS

Kimura disease is a rare idiopathic inflammatory disease that should be included in the differential diagnosis of persistent head and neck swellings, particularly when histology shows eosinophil-rich infiltrates

Progressive Temporal Arteriovenous Malformation Developing During Pregnancy: Surgical Management Of A Rare Case

Doc. Dr. Selcuk Kuzu[1], **Research Assistant Dr. Samet Cepe**[1]

[1]*Afyonkarahisar Health Sciences University Hospital, Department of Otorhinolaryngology–Head and Neck Surgery, Türkiye*

BACKGROUND & AIM

Arteriovenous malformations (AVMs) are rare high-flow vascular anomalies that may progressively enlarge, particularly during hormonal changes such as pregnancy. Temporal extracranial AVMs are uncommon and may present with pulsatile swelling, tinnitus, and cosmetic deformity. Due to their complex vascular structure and recurrence potential, management remains challenging. We aimed to present a rare case of a progressive temporal arteriovenous malformation developing during pregnancy that was successfully treated with total surgical excision without recurrence during follow-up.

MATERIAL & METHODS

A 47-year-old woman presented with a progressively enlarging right temporal and auricular mass associated with pulsatile tinnitus and buzzing sounds. The lesion initially appeared during the seventh month of a triplet pregnancy approximately 20 years earlier. Contrast-enhanced computed tomography demonstrated a 42 × 30 mm extracranial arteriovenous malformation extending from the temporal region to the mandibular level. The patient underwent total surgical excision under general anesthesia. The lesion was carefully dissected using sharp and blunt dissection techniques, and feeding vascular pedicles were identified and ligated intraoperatively. Histopathological examination confirmed the diagnosis of arteriovenous malformation. Preoperative, intraoperative, and postoperative clinical findings were evaluated.

RESULTS

Total surgical excision of the temporal arteriovenous malformation was successfully achieved without major intraoperative complications. Feeding vascular pedicles were adequately controlled with ligation, allowing complete removal of the lesion. Histopathological examination confirmed the diagnosis of arteriovenous malformation. Postoperatively, the patient demonstrated satisfactory cosmetic and functional outcomes with significant improvement in pulsatile tinnitus and buzzing symptoms. No wound complications were observed during follow-up. At the sixth postoperative month, no evidence of recurrence was detected clinically.

CONCLUSIONS

Temporal extracranial arteriovenous malformations are rare vascular lesions that may progressively enlarge during pregnancy. Accurate radiological evaluation and meticulous surgical planning are essential for successful treatment. Complete surgical excision with proper vascular control can provide favorable functional and cosmetic outcomes while minimizing recurrence risk. Early diagnosis and timely intervention remain important in the management of these lesions.

Tumor Size, TIRADS, And Lymph Node Status As Predictors Of Central Neck Dissection In Thyroid Cancer

MOHAMMED ALESSA[1]

[1]*KING SAUD UNIVERSITY*

BACKGROUND & AIM

To evaluate the predictive value of tumor size, TIRADS classification, lymph node involvement, and demographic factors in guiding central neck dissection (CND) in patients with thyroid cancer.

MATERIAL & METHODS

This retrospective cross-sectional study included 437 patients, selected through convenience sampling, who underwent total thyroidectomy for thyroid cancer at a tertiary hospital in Riyadh, Saudi Arabia, from 2010 to 2023. Data collected included age, sex, BMI, tumor size, TIRADS level, lymph node status, and fine-needle aspiration (FNA) results. Associations with the performance of CND were analyzed using Pearson correlation coefficients and descriptive statistics.

RESULTS

Lymph node involvement, defined as histopathologically confirmed central lymph node metastasis, was the strongest independent predictor of CND ($r = 0.5285$, $p < 0.0001$), followed by tumor size ($r = 0.4200$, $p < 0.0001$) and TIRADS score ($r = 0.2128$, $p = 0.0467$). Age showed a weak but statistically significant association with CND ($r = 0.1426$, $p = 0.0031$), while sex and BMI had no significant impact. The majority of nodules were classified as TIRADS 3 to 5 (87.17%), and patients undergoing CND tended to be older with larger tumors and higher TIRADS categories.

CONCLUSIONS

Lymph node involvement, tumor size, and TIRADS classification are meaningful predictors of surgical management in thyroid cancer. Integrating these factors into preoperative evaluation supports a personalized approach to CND, potentially reducing

unnecessary procedures and improving patient outcomes. These findings support the development of standardized, risk-adapted surgical criteria for central neck dissection in thyroid cancer.

PP-157

Large And Deep Cervical Abscess Involving Parapharyngeal And Retropharyngeal Spaces And Extending To The Upper Mediastinum: Case Report

Ahmet Ufuk Kılıçtaş[2], **Yunus Güneşer**[1]

[1]*Rize Recep Tayyip Erdoğan University Training and Research Hospital, Otorhinolaryngology;* [2]*Konya City Hospital, Otorhinolaryngology*

BACKGROUND & AIM

Deep neck infections are clinical conditions that can progress rapidly and lead to serious complications such as airway obstruction and mediastinal spread. If left untreated, complications can develop, even resulting in death.This study presents a case of a deep neck abscess with extensive anatomical spread.

MATERIAL & METHODS

A 27-year-old male patient presented with complaints of swelling and pain in the right cervical region that had been ongoing for approximately one week. Despite oral antibiotic treatment initiated at an external center, no clinical response was obtained. At the time of presentation, he had trismus, restricted oral intake, and significant cervical swelling.

Contrast-enhanced neck MR imaging revealed a collection consistent with an abscess, approximately 80x72x120 mm in size, extending from the mastoid level to the T1 vertebra level in the right lateral neck, showing peripheral contrast enhancement and diffusion restriction. The lesion was found to extend into the parapharyngeal and retropharyngeal spaces, causing significant airway narrowing. The lesion was adjacent to the submandibular gland anteriorly and the paravertebral muscles posteriorly.

Flexible nasopharyngolaryngoscopy showed significant edema in the posterior pharyngeal wall, medialization of the right lateral wall, and narrowing of the laryngeal airway.

RESULTS

The patient was admitted to the hospital and treatment with intravenous ceftriaxone (2x2 g), ciprofloxacin (2x400 mg), and metronidazole (3x500 mg). Clinical evaluation revealed the most pronounced fluctuation in the posterior cervical triangle, and incision and drainage were performed. Microscopic examination and culture of the drainage material showed no growth. Significant improvement in clinical findings was observed during follow-up. After a total of 10 days of intravenous antibiotic therapy, the patient was discharged with oral antibiotic therapy (cephalexin 500 mg 3x1, moxifloxacin 1x1, and ornidazole 2x1). Endoscopic evaluation before discharge showed significant improvement in airway patency.

CONCLUSIONS

Deep cervical abscesses, representing severe infections occurring in the potential fascial planes of the head and neck, highlight a significant global health problem due to their morbidity, mortality, and evolving epidemiology. Characterized by the accumulation of pus in anatomically distinct deep cervical compartments (e.g., parapharyngeal, retropharyngeal, submandibular, and masticatory spaces).The complex fascial structure facilitates rapid downward spread into the mediastinum or upward extension into adjacent cranial spaces, increasing the risk of catastrophic complications including airway obstruction, descending necrotizing mediastinitis, jugular venous thrombosis, and intracranial spread. The introduction of broad-spectrum antibiotics has led to a significant decrease in deep neck infections.

RNF152 Methylation And Expression Alterations In Oral Squamous Cell Carcinoma

Madona Gjona[1], **Seval Turna**[1], **Comert Sen**[2], **Vakur Olgac**[3], **Murat Ulusan**[2], **Semra Demokan***[4]

[1]*Istanbul University, Institute of Graduate Studies in Health Sciences, Istanbul, Türkiye;* [2]*Istanbul University, Istanbul Faculty of Medicine, Department of Otorhinolaryngology-Head and Neck Surgery, Istanbul, Türkiye.;* [3]*Istanbul University, Faculty of Dentistry, Department of Oral Pathology, Istanbul, Türkiye;* [4*]*Istanbul University, Oncology Institute, Department of Basic Oncology, Experimental and Molecular Oncology Division, Istanbul, Türkiye, e-mail: *

BACKGROUND & AIM

Oral squamous cell carcinoma (OSCC) is a common subtype of head and neck cancer associated with high mortality and poor survival rates. Environmental risk factors, particularly tobacco and alcohol use, contribute to OSCC development through genetic and epigenetic alterations. Among epigenetic mechanisms, DNA methylation plays a critical role in tumor suppressor gene silencing. Although RNF152 epigenetic alterations have been reported in several malignancies, its methylation and

expression profile in OSCC remains poorly understood. This study aimed to evaluate the methylation and expression status of RNF152 in OSCC and investigate its potential role in oral carcinogenesis.

MATERIAL & METHODS

The methylation status of RNF152 was analyzed by quantitative methylation-specific PCR in tumor tissues and matched-adjacent normal tissues obtained from 25 OSCC patients. Gene expression levels were evaluated using quantitative real-time PCR.

RESULTS

RNF152 hypermethylation was detected in 32% of OSCC tumor tissues and 20% of matched-adjacent normal tissues, whereas no methylation was observed in healthy control mucosal tissues. Gene expression analyses revealed decreased RNF152 expression in 40% of OSCC cases, while increased expression relative to matched adjacent normal tissues was observed in 36% of the cases. Reduced RNF152 expression was detected in 50% of hypermethylated samples, whereas increased expression was observed in all hypomethylated samples.

CONCLUSIONS

These findings suggest that alterations in RNF152 methylation and expression may contribute to the molecular heterogeneity of OSCC and indicate a potential role for RNF152 in a subset of oral carcinogenesis. However, larger-scale studies are required to further clarify the biological and clinical significance of RNF152-associated epigenetic alterations in OSCC.

Supraglottik Basal Cell Adenocarsinoma: A Rare Case Presentation And Literature Review

İnara Beşirova[1], **Gökhan Furkan Kılıç**[1], **Seda Nur Saka**[1], **Deniz Baklacı**[1]

[1]*Department of Otolaryngology - Head and Neck Surgery, Faculty of Medicine, Zonguldak Bülent Ecevit University, Zonguldak, Turkey*

BACKGROUND & AIM

Basal cell adenocarcinoma (BCAC) is a rare, low-grade malignant salivary gland tumor [1]. First described in 1990, it was included in the WHO classification in 1991 [2]. Lacrimal gland, breast, tongue, and ethmoid sinus involvements have been reported [3-6]. Immunohistochemistry is critical for differential diagnosis, as BCAC mimics benign basal cell adenomas, aggressive adenoid cystic, or basaloid squamous cell carcinomas. Laryngeal minor salivary gland tumors comprise <1% of laryngeal malignancies; specifically, laryngeal BCAC is limited to only two cases [7,8]. To contribute to this non-standardized treatment algorithm involving surgical resection and chemoradiotherapy, we discuss a rare supraglottic BCAC case [1].

MATERIAL & METHODS

A 34-year-old female smoker (2 pack-years) presented with a 2-month history of worsening sore throat and viscous sputum, with no relevant family history. Endoscopic examination revealed a vegetative supraglottic mass, while physical neck palpation was unremarkable. Biopsy histology demonstrated a basaloid component, ductal differentiation, invasive growth pattern, increased mitotic activity, high proliferation index, and cellular atypia, confirming basal cell adenocarcinoma. Workup with neck ultrasonography, contrast-enhanced computed tomography of the neck/thorax, neck magnetic resonance imaging, and positron emission tomography-computed tomography staged the tumor as clinical T2N0M0. The patient underwent supraglottic horizontal partial laryngectomy (thyrohyoidopexy) combined with left level II, III, and IV neck dissection. The postoperative course was uneventful without complications. Histopathological re-evaluation of the surgical specimen confirmed the initial diagnosis with negative surgical margins and no lymph node metastasis. The patient remains under regular follow-up with no clinical or radiological evidence of recurrence.

RESULTS

Minor salivary glands are distributed throughout the larynx, primarily in the glottis, subglottis, and supraglottis [9]. Laryngeal minor salivary gland tumors comprise <1% of laryngeal malignancies, predominantly presenting as adenoid cystic (46%), mucoepidermoid (35%), and adenocarcinoma, NOS (12%) [10]. Rare histologies include basal cell adenocarcinoma (BCAC), first described in 1978 [1,11-14]. These submucosal tumors lack common risk factors and grow silently until reaching advanced stages [11]. In our patient, this painless growth caused symptoms within two months. Supraglottic localization is most common (52%) [10]. Although partial or total laryngectomy is performed in 80% of laryngeal minor salivary gland tumors, local recurrence affects 37% of cases, while regional and distant metastases occur in 8% and 4%, respectively [1,7,11]. While unresectable BCAC cases utilize chemoradiotherapy, accepted surgical resection with negative margins remains the primary treatment [1,7,15,16]. Consistently, our patient was treated surgically and remains recurrence-free at her 10-month follow-up.

CONCLUSIONS

Laryngeal basal cell adenocarcinoma (BCAC) is an exceptionally rare salivary gland tumor lacking defined long-term management strategies. Due to its non-specific symptoms and submucosal growth, immunohistochemical profiling is crucial to avoid misdiagnosis. In our supraglottic BCAC case, negative-margin partial laryngectomy and neck dissection achieved early-stage recurrence-free survival without adjuvant therapy; however, high literature recurrence rates necessitate long-term,

close clinical surveillance. This case emphasizes considering minor salivary gland malignancies in atypical head-and-neck masses without typical risk factors. While surgery remains paramount, chemoradiotherapy offers alternative options for unresectable cases [15]. Accumulating more case reports will optimize treatment algorithms for this rare tumor.

SCHWANNOMA OF THE TONGUE

KİARASH SHAMEKHİ[1], **BEHLÜL TUNCER**[1], **ALEYNA ELBURZ**[1], **DOĞAN ÇAKAN**[1]

[1]*İstanbul University-Cerrahpaşa Cerrahpaşa Faculty of Medicine*

BACKGROUND & AIM

Schwannoma is a benign, encapsulated, slow-growing tumor originating from Schwann cells of peripheral nerve sheaths. Approximately 25–45% of schwannomas occur in the head and neck region, while intraoral localization is relatively rare. Among intraoral sites, the tongue is the most frequently affected location.

We present a rare case of lingual schwannoma with an unusual polypoid morphology originating from a branch of the lingual nerve.

MATERIAL & METHODS

A 52-year-old patient presented with a painless, progressively enlarging swelling on the tip of the tongue for 3 months. An incisional biopsy performed at an external center revealed schwannoma, and the patient was referred to our clinic.

On clinical examination, a small ulcerated lesion with an underlying intramural mass (~4 mm) was detected on the right side of the tongue tip. The lesion demonstrated a polypoid appearance.

Given the superficial location and well-defined borders on palpation, no preoperative imaging was performed. The lesion was completely excised under local anesthesia with a 5 mm safety margin using a wedge resection technique, followed by primary closure.

RESULTS

Histopathological examination revealed a well-encapsulated subepithelial tumor composed of spindle cells with nuclear palisading. Immunohistochemical analysis showed strong S-100 positivity, confirming the diagnosis of schwannoma.

The postoperative course was uneventful. No complications were observed. No recurrence was detected during the 6-month follow-up period.

CONCLUSIONS

Lingual schwannomas are rare lesions, particularly when presenting with atypical polypoid morphology.They should be considered in the differential diagnosis of painless lingual masses.Complete surgical excision is a safe and effective treatment with low recurrence risk.Careful follow-up is recommended due to the potential, albeit rare, risk of malignant transformation.

When A Common Tumor Becomes Rare: Lipoma Of The Soft Palate

Erdem Ağgünlü[1], **Zülal Karaduman**[1], **Osman Cerlet**[1], **Mehmet Ali Çetin**[1]

[1]*Department of Otorhinolaryngology, Ankara Bilkent City Hospital*

BACKGROUND & AIM

Lipomas are common benign mesenchymal tumors, yet their occurrence in the oral cavity—particularly the soft palate—is rare. The differential diagnosis of palatal masses includes minor salivary gland tumors, mucoceles, vascular lesions, neurogenic tumors, fibromas, infectious-inflammatory lesions, and malignant neoplasms. Although uncommon in this location, lipoma should also be considered, particularly in soft, mobile, slow-growing lesions. This study aims to present the clinical, radiological, and surgical characteristics of a soft palate lipoma and to highlight its relevance in differential diagnosis.

MATERIAL & METHODS

A 56-year-old male presented with a painless palatal swelling persisting for three years. Physical examination revealed a soft, mobile mass (approximately 5×3 cm) extending from the hard–soft palate junction to the right retromolar trigone. No cervical lymphadenopathy was noted. MRI demonstrated a well-circumscribed lipomatous lesion (2.5×1.5×1.5 cm) in the right posteroinferior soft palate, hyperintense on T1/T2 and suppressed on fat-saturated sequences. Fine-needle aspiration was not feasible. Transoral total excision was performed under general anesthesia.

RESULTS

Intraoperatively, the lesion was well-defined, located in the submucosal plane, and showed no muscle invasion. Histopathological examination confirmed lipoma. The postoperative course was uneventful, with no complications. Follow-up revealed no recurrence.

CONCLUSIONS

Although rare, lipomas should be considered in the differential diagnosis of soft palate masses. MRI plays a key role in preoperative evaluation. Complete surgical excision is curative and associated with excellent prognosis and low recurrence.

An Unusual Metastatic Pattern: Palatine Tonsil Metastasis From High-Grade Endometrial Stromal Sarcoma

Berkay Güzel[1], **Şahin Öğreden**[1], **Safiye Giran Örtekin**[1], **Begüm Bahar Yılmaz**[1], **Hasan Uyar**[1], **Berra Şerefoğlu**[1], **Özgür Yiğit**[1]

[1]*Department of Otorhinolaryngology, Basaksehir Cam and Sakura City Hospital, Istanbul, Turkey*

BACKGROUND & AIM

High-grade endometrial stromal sarcoma (HG-ESS) is a rare and aggressive uterine malignancy that typically metastasizes to the lungs and bones. Metastasis to the head and neck region is exceedingly rare. We aimed to present the first reported case of HG-ESS metastasizing to the palatine tonsil and to emphasize the importance of thorough head and neck evaluation in oncologic patients.

MATERIAL & METHODS

A 53-year-old woman presented with intermenstrual bleeding and was diagnosed with high-grade endometrial stromal sarcoma based on histopathological and immunohistochemical analysis. For staging, FDG-PET/CT imaging was performed, revealing hypermetabolic lesions in the uterus, pelvic and para-aortic lymph nodes, right adrenal gland, and left palatine tonsil. The patient underwent total abdominal hysterectomy, bilateral salpingo-oophorectomy, lymph node dissection, right adrenalectomy, and tonsillar biopsy. Histopathological evaluation was performed on all surgical specimens.

RESULTS

Histopathological examination confirmed metastatic HG-ESS in both the adrenal gland and the palatine tonsil. No thoracic metastasis was identified. The disease was staged as pT3a pN0 pM1. Due to the presence of systemic metastatic disease, tonsillectomy was not considered beneficial, and radiotherapy was planned as the primary treatment modality. This case represents the first documented metastasis of HG-ESS to the palatine tonsil.

CONCLUSIONS

High-grade endometrial stromal sarcoma can metastasize to unusual locations such as the palatine tonsil. This case highlights the importance of thorough head and neck examination in patients with systemic malignancies. Recognition of rare metastatic patterns is essential for accurate diagnosis and appropriate management. Clinicians should consider metastatic disease in atypical tonsillar lesions, especially in patients with known malignancies.

Epidemiological Trends In Head And Neck Cancer In Nara Prefecture, Japan, 2000-2021

Ichiro Ota[1], **Takahiro Kimura**[2], **Hirokazu Uemura**[2], **Ari Nishimura**[2], **Takashi Masui**[1], **Katsunari Yane**[1], **Hiroshi Miyahara**[2], **Tadashi Kitahara**[2]

[1]*Dept of Otolaryngology-Head and Neck Surgery, Kindai University Nara Hospital;* [2]*Dept of Otolaryngology-Head and Neck Surgery, Nara Medical University*

BACKGROUND & AIM

Epidemiological surveys were conducted in Nara Prefecture, Japan, to determine the prevalence of head and neck cancer in the region since 1986.

MATERIAL & METHODS

This study examined the dynamics of visits to 18 medical institutions treating head and neck cancer in Nara Prefecture from 2000 to 2021.

RESULTS

A total of 8,605 patients were registered, with 4,788 being male and 3,787 female. These included 3,603 thyroid, 2,215 oral, 1,164 laryngeal, 645 hypopharyngeal, 512 oropharyngeal, 326 nasal sinus, and 286 salivary gland cancer cases. A marked increase in subsite was observed in oropharyngeal, oral, and hypopharyngeal cancers, whereas laryngeal cancer remained unchanged. The number of registered patients increased every year, with 547 new patients registered in 2019, compared to

249 in 2000. However, the number of registered cases decreased by nearly 100 cases after 2020 because of the COVID-19 pandemic (453 cases in 2020 and 420 cases in 2021).

CONCLUSIONS

This study is distinctive as it comprehensively surveys all departments within Nara Prefecture involved in managing head and neck cancer.

Metastatic Carotid Body Paragangliomas: A Three-Case Series Highlighting Surgical And Oncologic Challenges

Zeynep Selin Dülger[1], **Kays Burak Çakır**[1], **Berk Arapi**[1], **Fırat Tevetoğlu**[1], **Harun Cansız**[1]

[1]*Department of Otorhinolaryngology, Cerrahpasa Faculty of Medicine, Istanbul University - Cerrahpasa, Türkiye*

BACKGROUND & AIM

Head and neck paragangliomas are rare neuroendocrine tumors that are usually slow-growing and benign; however, metastatic disease may occur in a small subset of patients and is associated with significant surgical and oncologic challenges. Metastatic carotid body paragangliomas are particularly uncommon, and evidence regarding their clinical behavior and optimal management remains limited. This study aims to present three cases of metastatic carotid body paraganglioma with distinct metastatic patterns, complex vascular involvement, and multidisciplinary treatment approaches, highlighting the role of advanced imaging, vascular reconstruction, and targeted oncologic therapies in disease management.

MATERIAL & METHODS

This retrospective case series included three patients diagnosed with metastatic carotid body paraganglioma and treated at our tertiary referral center. Clinical presentation, radiological findings, surgical procedures, histopathological characteristics, immunohistochemical results, metastatic patterns, and oncologic treatment strategies were reviewed retrospectively from medical records. Tumor extent was evaluated using contrast-enhanced computed tomography, magnetic resonance imaging, digital subtraction angiography, and Ga-68 DOTATATE PET/CT imaging. Surgical management, vascular reconstruction procedures, postoperative complications, and follow-up outcomes were analyzed. Histopathological evaluation included assessment of lymphovascular invasion, perineural invasion, lymph node metastasis, and SDHB expression status when available.

RESULTS

Three patients with metastatic carotid body paraganglioma were included in the study. Two patients were female and one was male, with ages ranging from 23 to 54 years. All tumors were classified as Shamblin type III. Cervical lymph node metastases were detected in two patients, pulmonary metastases in one patient, and hepatic metastases in one patient. Histopathological examination demonstrated lymphovascular invasion in two cases, perineural invasion in one case, and loss of SDHB expression in one patient.

Two patients required carotid artery resection because of extensive vascular involvement, and vascular reconstruction was successfully performed in one patient. Preoperative embolization was feasible in one patient but could not be performed in another because of extensive collateral circulation. Ga-68 DOTATATE PET/CT successfully identified metastatic disease and guided postoperative management. One patient treated with Lutetium-177 peptide receptor radionuclide therapy demonstrated partial regression of metastatic lesions on follow-up imaging.

CONCLUSIONS

Metastatic carotid body paragangliomas are rare neuroendocrine tumors with unpredictable and potentially aggressive behavior. This series highlights the importance of recognizing metastatic potential in patients with SDHB loss, nodal involvement, rapid progression, or suggestive familial history. Management of advanced Shamblin type III tumors often requires complex multidisciplinary collaboration involving surgical and oncologic teams. Ga-68 DOTATATE PET/CT plays a critical role in staging and follow-up, while targeted therapies such as Lutetium-177 PRRT may provide disease control in metastatic cases. Comprehensive genetic evaluation should be considered in patients with suspected hereditary predisposition, even when initial molecular analyses are inconclusive.

Clinical Challenge In Post-Radiotherapy Monitoring: Differentiating Local Recurrenc From Osteoradionecrosis In Oral Cavity Cancer

Kuan-Ting, Chen[1], **Chih-Hsien, Liu**[1]

[1]*Cathay General Hospital, Taipei, Taiwan*

BACKGROUND & AIM

The distinction between osteoradionecrosis (ORN) and local recurrence (LR) in oral cavity cancer (OCC) remains a formidable challenge for otolaryngologists. Both conditions share overlapping features, such as bone exposure and severe pain. Misdiagnosis can lead to delayed treatment or unnecessary radical surgeries. This study investigates the clinical indicators and dosimetric factors that differentiate these two entities.

MATERIAL & METHODS

We conducted a retrospective analysis of 203 OCC patients who developed mandibular lesions following RT/CCRT. Patients were categorized into three groups: simple ORN (Group A), ORN with concurrent recurrence (Group B), and local recurrence without ORN (Group C). We compared their onset timing, radiation dose distribution maximum (Dmax to the mandible), and metabolic activity on 18F-FDG PET/CT.

RESULTS

First, the median time to onset for LR was significantly shorter than for simple ORN. Second, a high SUVmax (Standardized Uptake Value Maximum) was strongly associated with malignancy within the necrotic site. Third, Group A patients showed a higher correlation with Dmax >70 Gy. Importantly, the 2-year overall survival was markedly lower in the recurrence group, highlighting the critical need for early biopsy.

CONCLUSIONS

ORN and tumor recurrence frequently coexist and share overlapping clinical features. Early onset of "bone necrosis" symptoms should be treated with high suspicion for recurrence. We establish a 'Risk-Scoring System' to identify occult recurrences masked within necrotic bone segments.

Osteoradionecrosis and local recurrence in oral cavity cancer

PP-166

Clinical Challenge In Post-Radiotherapy Monitoring: Differentiating Local Recurrence From Osteoradionecrosis In Oral Cavity Cancer

Kuan-Ting, Chen[1], **Chih-Hsien, Liu**[1]

[1]*Department of Otolaryngology, Cathay General Hospital, Taipei, Taiwan*

BACKGROUND & AIM

The distinction between osteoradionecrosis (ORN) and local recurrence (LR) in oral cavity cancer (OCC) remains a formidable challenge for otolaryngologists. Both conditions share overlapping features, such as bone exposure and severe pain. Misdiagnosis can lead to delayed treatment or unnecessary radical surgeries. This study investigates the clinical indicators and dosimetric factors that differentiate these two entities.

MATERIAL & METHODS

A retrospective analysis of 45 patients with lower gum cancer who underwent RT was conducted. Patients were stratified into four distinct clinical cohorts: Group A (Simple ORN, n=5), Group B (ORN with Concurrent Local Recurrence, n=6), Group C (Local Recurrence without ORN, n=11), and Group D (Control Group, n=23). High-risk clinical target volume (CTVH) doses, biologically effective doses (BED3 and BED10), pre-RT tooth extraction rates, onset timelines of ORN/recurrence, and maximum standardized uptake values (PET SUVmax) were statistically analyzed across groups.

RESULTS

No statistically significant differences were observed among the four cohorts regarding CTVH total dose (61.4~66.8 Gy), BED3 or BED10. Pre-RT tooth extraction rates demonstrated a prominent clinical trend in the development of bone injury (Group B: 66.7%, Group A: 40.0% vs. Group C: 27.3%, Group D: 17.4%; $p = 0.113$). PET SUVmax demonstrated highly significant stratification capability between benign tissue injury and malignant failure ($p = 0.004$). Within Group B, ORN onset averaged 17.11 ± 15.45 months, while subsequent recurrence averaged 34.43 ± 23.80 months ($p = 0.115$). Notably, bone necrosis chronologically preceded the diagnostic confirmation of malignancy in 83.3% (5/6) of these concurrent cohorts.

CONCLUSIONS

In lower gum cancer, the prescription radiation dose and biological equivalent doses do not serve as primary drivers for the development of ORN or local recurrence. Pre-RT tooth extractions represent a crucial clinical factor predisposing patients to subsequent bone necrosis. PET SUVmax serves as a highly robust diagnostic tool for clinical differentiation. While recurrence has been widely recognized as an independent prognostic factor, early aggressive surveillance using PET/CT remains imperative to salvage long-term survival trajectories.

Clinical Characteristics And Surgical Outcomes Of Head And Neck Pilomatricomas: A Tertiary Center Experience

Nuri Ünsal[1], **İbrahim Özcan**[1]

[1]*Kayseri City Training and Research Hospital*

BACKGROUND & AIM

Pilomatrixoma is a benign, often calcified tumor originating from the hair follicle matrix, frequently localized in the head and neck region. This study aims to evaluate the clinical characteristics, anatomical distribution, and surgical outcomes of patients operated on for head and neck pilomatrixomas in a tertiary care center.

MATERIAL & METHODS

This retrospective study was conducted following institutional approval from the Education Planning Board of Kayseri City Hospital (Date: 13.02.2026, No: 76397871). We reviewed the medical records of patients who underwent surgical excision at our Otorhinolaryngology Clinic between January 2020 and January 2026. Patient demographics, lesion localization, surgical techniques, and postoperative outcomes were analyzed. Only cases with a final histopathological diagnosis of pilomatrixoma in the head and neck region were included.

RESULTS

A total of 15 patients (8 males, 7 females) were included in the study. The mean age of the cohort was 17.3 years (range: 2–67 years), with 73.3% of the patients (n=11) being under 18 years old. Lesions were most frequently located in the neck (40%, n=6) and periauricular regions (40%, n=6; including preauricular, postauricular, infraauricular, and ear lobule). Other sites included the malar (6.7%) and frontal (6.7%) regions. All patients underwent complete surgical excision. Primary closure was successfully achieved in 14 patients (93.3%), while one patient required reconstruction with a local flap due to skin fistulization. Over a follow-up period ranging from 2 to 72 months, no surgical complications or recurrences were observed.

CONCLUSIONS

Pilomatrixoma is a common benign skin appendage tumor in the head and neck region, particularly within the pediatric population. It must be strongly considered in the differential diagnosis of firm, slow-growing subcutaneous masses. Complete surgical excision is a highly effective treatment modality, offering excellent aesthetic outcomes and minimal recurrence risk.

PP-168

Melanoma Of The Buccal Mucosa With Cervical Nodal Metastasis

Bengisu Telli[1], **Aylin Eryılmaz**[1], **Büşra Ekinci**[2]

[1]*Department of Otorhinolaryngology – Head and Neck Surgery, Aydın Adnan Menderes University Hospital, Aydın, Turkey;* [2]*Department of Medical Pathology, Aydın Adnan Menderes University Hospital, Aydın, Turkey*

BACKGROUND & AIM

Oral mucosal melanoma is a rare and aggressive malignancy that most commonly involves the hard palate and gingiva, while involvement of other oral sites such as the buccal mucosa is less frequent. Due to nonspecific clinical features and variable presentation, diagnosis may be delayed. Changes in long-standing oral lesions should raise suspicion for malignancy and warrant further evaluation. We aimed to present a case of buccal mucosal melanoma with clinically occult cervical nodal metastasis.

MATERIAL & METHODS

An 85-year-old female presented with a progressively enlarging and darkening lesion in the right buccal mucosa. A small lesion had been present for approximately 10 years, with rapid growth, bleeding, and pain over the past 6 months. The patient reported weight loss, fever, and night sweats. Examination revealed a 4 × 3 cm firm, lobulated, dark mass in the right buccal mucosa. No palpable lymphadenopathy was detected. Magnetic resonance imaging suggested a possible odontogenic inflammatory process; however, malignancy could not be excluded. Incisional biopsy confirmed melanoma. PET/CT demonstrated a hypermetabolic lesion in the right buccal region and a small hypermetabolic cervical lymph node.

RESULTS

The patient underwent tumour excision and right level I–III neck dissection, followed by reconstruction with a supraclavicular flap. Histopathological examination revealed spindle cell melanoma with marked pleomorphism, focal pigmentation, lymphovascular and perineural invasion, and 6 mitoses per 10 high-power fields. Tumor cells were diffusely positive for S100, HMB45, and Melan-A, with a Ki-67 index of ~15%. Surgical margins were negative. Two of six level I lymph nodes showed metastasis with extranodal extension; the largest deposit measured 5 × 4 mm, confirming nodal involvement despite no clinically evident lymphadenopathy. Accordingly, pathological staging was pT3N1M0 (Stage IVA) according to the AJCC 8th Edition TNM staging system. Postoperatively, the flap remained viable, and the patient was referred for adjuvant therapy. Immunotherapy was initiated within a multidisciplinary management framework.

CONCLUSIONS

Diagnostic delay in oral mucosal lesions may result in advanced-stage detection. Long-standing lesions may remain clinically silent despite occult nodal metastasis, reflecting aggressive tumor biology. This case emphasizes the importance of early biopsy, even in the absence of palpable lymphadenopathy, and highlights the role of a multidisciplinary approach in management.

INVESTIGATION OF CLINICAL AND PATHOLOGICAL CHARACTERISTICS OF CUTANEOUS SQUAMOUS CELL CARCINOMAS IN THE HEAD AND NECK REGION: A SINGLE-CENTER EXPERIENCE

BÜŞRA DAŞTAN[1], **HAKKI CANER İNAN**[1], **MEHMET ÖZER**[2], **MİRAC ELİF ÖZDAL**[1], **MELİH ALPAY**[1], **BETÜL AĞIRGÖL**[1]

[1]BURSA YÜKSEK İHTİSAS EĞİTİM VE ARAŞTIRMA HASTANESİ KULAK BURUN BOĞAZ HASTALIKLARI KLİNİĞİ; [2]BURSA YÜKSEK İHTİSAS EĞİTİM VE ARAŞTIRMA HASTANESİ PATOLOJİ KLİNİĞİ

BACKGROUND & AIM

The aim of this study is to analyze the clinical and pathological factors predicting the development of cervical metastasis in cutaneous squamous cell carcinoma of the head and neck region and to evaluate disease-free survival outcomes.

MATERIAL & METHODS

We retrospectively analyzed the clinicopathological data of 65 patients who underwent surgery for head and neck cutaneous squamous cell carcinoma at Bursa Yüksek İhtisas Training and Research Hospital. The normality of the data distribution was assessed using the Shapiro-Wilk test. Two-group comparisons were performed using the independent t-test or Mann-Whitney U test, while categorical data were analyzed via Pearson's chi-square and Fisher's exact tests. Disease-free survival rates were analyzed using the Kaplan-Meier method, and survival differences were assessed with the log-rank test. Statistical significance was defined as p <0,05. The SPSS v27 software package was used for statistical analyses.

RESULTS

The mean age of the 65 patients (44 males, 21 females) included in the study was 73.8 ± 10.3 years. The most frequent primary tumor sites were the lip (41.5%) and the ear (26.2%). The mean tumor size was 2.26 ± 1.47cm, and 92.3% of the patients were clinically node-negative (stage N0). Twenty-four patients underwent neck dissection (10 unilateral, 14 bilateral). Among these, 15 procedures (62.5%) were elective and 9 (37.5%) were therapeutic. Occult metastasis was detected in 1 of the 15 patients who underwent elective neck dissection. Although the depth of invasion was greater in patients with confirmed metastasis, this difference did not reach statistical significance (p = 0.074). Mean recurrence-free survival (RFS) was 45.6 months. All recurrences occurred within the first two years of follow-up, ranging from 3 to 24 months. For the overall cohort, the estimated 3-year recurrence-free survival was 83.6%.

CONCLUSIONS

The overall 3-year recurrence-free survival rates of the patients are notably high. Elective neck dissection provides effective regional control in early-stage disease. Due to the limited sample size, factors including tumor size, degree of dysplasia, and surgical margin status demonstrated no significant prognostic impact on disease-free survival.

KEYWORDS

Head and neck cutaneous tumors, neck metastasis, disease-free survival

Chronic Disease And Smoking In Patients With Head And Neck Squamous Cell Carcinoma, A Single Tertiary Center In Southeast Turkey

Prof Dr Abdulvahap Akyiğit[1], **Doç Dr Orkun Eroğlu**[1], **Dr Seyedeh Hasti Ghorashian**[1], **Prof Dr İrfan Kaygusuz**[1]

[1]Fırat University Hospital, Department of Ear Nose and Throat Diseases

BACKGROUND & AIM

Head and Neck Squamous Cell Carcinoma (HNSCC) is strongly associated with tobacco use and frequently coexists with various chronic diseases. Understanding the distribution of comorbidities, smoking habits, and pathological features may contribute to improved patient management and risk stratification. This study aimed to evaluate the smoking status, comorbid diseases, clinic pathological characteristics, and treatment modalities in patients with head and neck squamous cell carcinoma over a 10-year period at a single tertiary center in southeast of Turkey.

MATERIAL & METHODS

In this cross sectional study, 412 patients diagnosed with head and neck squamous cell carcinoma were analyzed. Demographic data, smoking status (pack-years), comorbidities (hypertension, diabetes mellitus, coronary artery disease, and chronic obstructive pulmonary disease), tumor localization, pathological features (lymphovascular invasion, perineural invasion, cartilage invasion), and treatment modalities were recorded.

RESULTS

In our study 88.6% of patients were male with a mean age 68,78. The youngest patient was 21 years old with hypopharyngeal carcinoma, while the oldest patient was 97 years old with skin cancer and parotid metastasis. Sixty-three percent of patients were smoking, with an average of 36.9 pack-years among smokers. The most common tumor localization was the larynx (81.7%), followed by lip (10.4%) and tongue (7.6%). Hypertension (24.9%) and coronary artery disease (22.3%) were the most frequent comorbidities. Perineural invasion and lymphovascular invasion were observed in 20.8% and 18.4% of patients, respectively. Cartilage invasion was detected in 10.9% of cases. Postoperative chemoradiotherapy was administered in 47.2% of patients. The most commonly performed procedure was direct laryngoscopy with biopsy (31.7%), followed by total laryngectomy (12.8%).

CONCLUSIONS

Comorbid diseases are highly prevalent among patients with head and neck squamous cell carcinoma. Laryngeal involvement was the predominant tumor site, and pathological high-risk features such as perineural and lymphovascular invasion were observed in a considerable proportion of patients. These findings highlight the importance of comprehensive clinical evaluation and risk factor assessment in the management of HNSCC.

Sinonasal Undifferentiated Carcinoma (SNUC) With Intracranial Extension Revealed By Visual Impairment - A Case Report

SAHRAOUI Mohammed[1,2], **MEHTARI Nasrine Siham**[1,2], **BENMANSOUR Narimane**[1], **NASRI Amine**[1,2], **AID Chahrazed**[1]

[1]*ENT Department - Tlemcen University Hospital Center;* [2]*Faculty of Medicine - Abou Bekr Belkaid University of Tlemcen*

BACKGROUND & AIM

Sinonasal undifferentiated carcinoma (SNUC) is a rare, highly aggressive epithelial malignancy characterized by rapid locoregional extension with frequent invasion of the skull base, orbit, and intracranial structures.

Through this study, we present a case of extensive SNUC illustrating its clinical and paraclinical features, emphasizing the importance of early diagnosis in persistent unilateral sinonasal symptoms.

MATERIAL & METHODS

We report the case of a 44-year-old woman with no significant medical history, occupationally exposed to cosmetic products, presenting with left-sided epistaxis that became bilateral, associated with progressive nasal obstruction, chronic headaches, and visual impairment initially on the left then right eye.

Clinical examination, craniofacial MRI and CT scan, biopsy, and histopathological analysis were performed.

RESULTS

Clinical examination revealed:

- Nasofibroscopy showed an extensive tumor of the left lateral nasopharyngeal wall, ulcerative, exophytic, necrotic, and bleeding on contact.
- Otologic examination revealed a left retrotympanic effusion.
- No cervical lymphadenopathy was detected.

Neurological examination showed visual impairment without oculomotor palsy or other cranial nerve involvement, despite significant radiological extension.

Cervicoencephalic MRI revealed a large nasopharyngeal mass extending into the left nasal cavity and sphenoid sinus, with invasion of the left cavernous sinus and sellar/suprasellar extension forming a cystic component compressing the optic chiasm. A mass effect on the ipsilateral temporal lobe was also noted.

CT imaging showed skull base destruction.

Endonasal biopsy confirmed SNUC on histopathology and immunohistochemistry.

The metastatic workup was negative. The tumor was staged T4bN0M0 (AJCC).

Multidisciplinary management included concurrent chemoradiotherapy with 70 Gy in 33 fractions and cisplatin-based chemotherapy.

Initial evolution showed improvement in headaches, stabilization of visual symptoms, and partial tumor regression on imaging.

CONCLUSIONS

Sinonasal undifferentiated carcinoma is a rare aggressive tumor, usually diagnosed at an advanced stage due to nonspecific initial symptoms.

This case highlights the importance of early endoscopic evaluation in persistent unilateral epistaxis with chronic nasal obstruction.

Absence of cranial nerve involvement despite extensive intracranial invasion is a remarkable radioclinical feature in this case.

Sinonasal carcinoma, Skull base, Tumor aggressiveness, Rapid progression

PP-172

Cervicofacial Actinomycosis – Diagnostic And Therapeutic Aspects

Proletina Bozdukova[1], **Valentin Stoyanov**[1]

[1]*University Multidisciplinary Hospital for Active Treatment - Burgas*

BACKGROUND & AIM

Cervicofacial actinomycosis is a rare, chronic granulomatous infectious disease caused by anaerobic Gram-positive bacteria of the genus Actinomyces, which colonize the oropharynx as commensals. Disruption of the oral mucosal barrier permits deep tissue invasion, leading to a chronic inflammatory process that frequently mimics malignancy. Delayed diagnosis may result in severe complications, including mandibular osteomyelitis. The aim of this case report is to underscore the critical importance of timely diagnosis based on a combination of detailed patient history, characteristic imaging findings and clinical presentation, in order to prevent disease progression and avert irreversible complications.

MATERIAL & METHODS

We present the case of an 89-year-old female patient. Six months prior to symptom onset, she received a dental prosthesis, which was complicated by a buccal mucosal wound. Subsequently, she developed a large, firm, indurated swelling in the right cervicofacial region, mimicking a tumor. Despite multiple consultations over five months, no etiological diagnosis was established. CT and MRI were performed, followed by an ultrasound-guided core-needle biopsy.

RESULTS

CT revealed destructive changes of the mandible and the presence of air within the soft tissues – a key radiological finding suggestive of an anaerobic infectious process. Histopathological examination of the core-needle biopsy showed only non-specific chronic inflammation. This false-negative result is attributed to the focal distribution of sulfur granules, which are often missed by the biopsy needle. The patient refused open surgical biopsy due to her advanced age. Based on clinical presentation, imaging findings, and history of mucosal trauma, empirical intravenous therapy with ampicillin/sulbactam and metronidazole was initiated. A rapid and significant clinical response was observed. Treatment was stepped down to oral amoxicillin. At six-month follow-up, the patient remains recurrence-free.

CONCLUSIONS

Cervicofacial actinomycosis should be suspected in chronic, tumor-like swelling following oral mucosal trauma, particularly in elderly patients. The presence of air within soft tissues on CT is an important diagnostic clue. Core-needle biopsy is a safe, minimally invasive first-line approach, but frequently yields false-negative results. When open surgical biopsy is not feasible, a positive response to empirical penicillin-based therapy carries both therapeutic and diagnostic value. For difficult-to-culture pathogens such as Actinomyces, metagenomic next-generation sequencing (mNGS) of tissue obtained via open surgical biopsy represents a valuable diagnostic alternative.

cervicofacial actinomycosis, diagnosis, mandibular osteomyelitis, elderly patient, empirical treatment

PP-173

Rapidly Growing Neck Mass With Facial Paralysis As A Presentation Of Breast Carcinoma Metastasis: A Diagnostic Challenge

Caner PEHLİVAN[1], **Tuğba YEMİŞ**[1]

[1]*Department of Otorhinolaryngology, Recep Tayyip Erdoğan University Faculty of Medicine, Recep Tayyip Erdoğan University Training and Research Hospital, Rize, Türkiye*

BACKGROUND & AIM

Breast cancer is the most common malignancy in women, and improved survival has increased late metastases. Although it typically spreads to bone, lung, liver, and brain, head and neck involvement is rare. In this region, the parotid gland and cervical lymph nodes are key metastatic sites, yet lesions are often misattributed to benign or infectious causes, delaying diagnosis. In patients with neck masses after a long disease-free interval, distant metastasis should be considered. We report a rare case of a rapidly growing infraauricular mass 20 years after breast cancer treatment, emphasizing diagnostic challenges and clinical significance.

MATERIAL & METHODS

A 64-year-old woman with a history of breast carcinoma diagnosed 20 years earlier was in remission after surgery and chemotherapy. She presented with a rapidly enlarging swelling in the right infraauricular region over two months. Given recent dental treatment, the lesion was initially considered reactive lymphadenopathy and antibiotics were started. However, due to limited response and progression, she was referred to our clinic. Physical examination revealed a firm, fixed 5 × 3 cm mass in the right infraauricular region, extending into level II. During hospitalization, she developed right-sided peripheral facial paralysis (House–Brackmann grade III). Imaging was followed by a tru-cut biopsy. Histopathology showed tumor cells positive

for GATA3, CK7, pancytokeratin, GCDFP-15, focal mammaglobin, and androgen receptor, and negative for SOX10, consistent with metastatic ductal carcinoma of breast origin. ER, PR, and HER2 were negative. The patient was referred to oncology and systemic chemotherapy was initiated.

RESULTS

Metastasis of breast carcinoma to the parotid gland is extremely rare; however, it may occur even after a prolonged disease-free interval and can clinically mimic primary parotid tumors or benign/inflammatory neck masses, potentially leading to diagnostic delay. Atypical head and neck masses are often attributed to infectious or reactive processes, which may further complicate diagnosis and delay appropriate management.

In patients with a history of malignancy, newly developed parotid or cervical masses should raise suspicion for metastatic disease, even after long-term remission. Histopathological examination and immunohistochemical analysis play a crucial role in establishing the diagnosis. Markers such as GATA3, mammaglobin, and GCDFP-15 support breast origin, while additional markers aid in the differential diagnosis. Correlation with radiological findings facilitates accurate diagnosis.

CONCLUSIONS

Late head and neck metastases of breast carcinoma may present with misleading clinical features and mimic benign or primary lesions. A high level of clinical suspicion should be maintained in patients with a history of malignancy. Early diagnosis, supported by immunohistochemistry and imaging, is critical for guiding appropriate treatment. This case underscores the importance of awareness and a multidisciplinary approach in managing atypical head and neck masses to improve patient outcomes.

A GIANT CERVICAL CYSTIC MASS MIMICKING LYMPHANGIOMA: AN ATYPICAL PARATHYROID TUMOR COMPLICATED BY INTRAOPERATIVE ESOPHAGEAL INJURY

Yunus Kartal[1], **Fariza Şahap**[1], **İskender Bayram**[1], **Hasan Uyar**[1], **Mehmet Salih Parça**[1], **Gökçe Altın**[1], **Şahin Öğreden**[1], **Özgür Yiğit**[1]

[1]*Başakşehir Çam and Sakura City Hospital*

BACKGROUND & AIM

Cervical masses arise from diverse etiologies and cystic lesions in adults present a diagnostic challenge. Although benign conditions such as lymphangiomas and branchial cleft cysts are common, certain neoplasms may mimic cystic lesions, complicating preoperative diagnosis. Parathyroid tumors are usually associated with hyperparathyroidism, but atypical and nonfunctional variants are rare and often asymptomatic. Atypical parathyroid tumors show borderline histological features between adenomas and carcinomas and may rarely present as large cystic masses. In this case, a giant cystic cervical lesion initially suspected as lymphangioma was diagnosed as an atypical parathyroid tumor postoperatively. The case was complicated by intraoperative esophageal injury

MATERIAL & METHODS

A patient with a 6-month history of neck swelling presented to our clinic.

On head and neck examination, a soft, mobile mass measuring approximately 10 × 8 cm was palpated in the left neck, extending from the submandibular region to the clavicle.

MRI demonstrated a non-enhancing cystic lesion measuring 109 × 53 × 48 mm in the left hemineck, extending from the hyoid bone to the superior mediastinum. The lesion displaced the left common carotid artery and internal jugular vein posterolaterally, and the trachea and esophagus to the right. Internal septations were present, suggestive of lymphangioma. Left neck exploration was planned.

RESULTS

A left-sided cervical incision in a semi-apron flap configuration was performed. A subplatysmal flap was elevated. The sternocleidomastoid muscle was lateralized. The mass was noted to be adjacent to the internal jugular vein and the common carotid artery.

The cyst wall was dissected free from the vascular structures. The lesion extended from level II to the clavicle, with anterior extension to the thyroid gland and posterior extension to the esophagus and prevertebral fascia. The mass was carefully dissected from the surrounding tissues and excised, and a full-thickness esophageal transection was identified. An end-to-end, full-thickness anastomosis was performed using 3-0 Vicryl sutures. A nasogastric tube and a surgical drain was placed.

Postoperatively, oral intake was initiated on postoperative day 15, and the patient was discharged on postoperative day 16.

Histopathological examination revealed an atypical parathyroid tumor. During follow-up, no clinical signs or symptoms of hyperparathyroidism were observed, and laboratory values remained within normal limits

CONCLUSIONS

Atypical parathyroid tumors are rare lesions that may present as giant cystic cervical masses even in the absence of biochemical evidence of hyperparathyroidism and should be included in the differential diagnosis. In cases with a prominent cystic component, definitive diagnosis based solely on imaging modalities is often not feasible. Surgical excision serves both diagnostic and therapeutic purposes; however, distorted anatomical planes in large lesions increase the risk of intraoperative complications. Therefore, meticulous surgical dissection, early recognition of potential complications, and appropriate management are critical for achieving favorable outcomes

Prevertebral Metastasis Of Renal Cell Carcinoma: A Rare Case

Caner Kılıç[1], **Selin Özdin Toptaş**[1], **Zehra Şahin**[2], **Emin Karaman**[1]

[1]*Department of Otorhinolaryngology- Head and Neck Surgery, Cerrahpaşa Faculty of Medicine, Istanbul University–Cerrahpaşa, Istanbul, Türkiye;*
[2]*Department of Pathology, Cerrahpaşa Faculty of Medicine, Istanbul University–Cerrahpaşa, Istanbul, Türkiye*

BACKGROUND & AIM

Renal cell carcinoma (RCC) is the most common malignant tumor of the kidney, arising from tubular epithelial cells and accounting for the majority of renal cancers in adults. The clear cell subtype is the most frequent and is characterized by a high tendency for metastatic spread, most commonly to the lungs, liver, bones, and brain. However, metastasis to the head and neck region, particularly the retropharyngeal area, is extremely rare and scarcely reported in the literature. This study aims to present a rare case of clear cell RCC presenting with retropharyngeal metastasis and to emphasize its diagnostic importance.

MATERIAL & METHODS

A 58-year-old male patient presented with restricted neck movement. Initial cervical MRI revealed a soft tissue lesion at the C1 vertebral level. Further contrast-enhanced neck MRI demonstrated a lobulated, heterogeneously enhancing mass involving the anterior aspect of C1 with adjacent soft tissue extension.

Fiberoptic endoscopy revealed a bulging lesion in the nasopharyngeal region. A biopsy was performed from the retropharyngeal region under general anesthesia. Histopathological and immunohistochemical findings suggested metastatic clear cell renal cell carcinoma.

Subsequent systemic evaluation included thoracic and abdominal computed tomography (CT) and positron emission tomography/computed tomography (PET/CT) to identify the primary tumor and metastatic spread.

RESULTS

Abdominal CT revealed a 7.5 cm lobulated, exophytic, contrast-enhancing mass with central necrosis in the upper pole of the right kidney, suggestive of renal cell carcinoma. Additionally, a 5.5 × 4 × 7 cm left adrenal mass with necrotic areas and suspected metastatic lesions in the iliac bones were observed.

Thoracic CT demonstrated multiple pulmonary nodules and a 45 mm metastatic lesion in the right ninth rib. PET/CT confirmed a primary right renal malignancy with widespread metastatic disease involving the head and neck region, thoracic structures, abdominal lymph nodes, adrenal gland, and multiple bones.

The patient was diagnosed with metastatic renal cell carcinoma and classified as intermediate risk according to the IMDC criteria. Systemic immunotherapy with Nivolumab (3 mg/kg) and Ipilimumab (1 mg/kg) was initiated. The patient is currently under ongoing treatment.

CONCLUSIONS

Renal cell carcinoma may present with atypical and rare metastatic sites, including the retropharyngeal region, even in the absence of primary renal symptoms. This case highlights the importance of considering metastatic RCC in the differential diagnosis of unusual head and neck masses.

Early histopathological evaluation and comprehensive imaging, including MRI, CT, and PET/CT, are essential for accurate diagnosis, staging, and treatment planning. Multidisciplinary management is crucial due to the aggressive and disseminated nature of advanced RCC.

Retrospective Evaluation Of Age Distribution And Clinical Characteristics Of Thyroglossal Duct Cysts And Branchial Cleft Cysts

MUHAMMED SEFA UYAR[1], **ZEYNEP BİLGE**[1], **HAMDİ ÇAKLI**[1], **MELEK KEZBAN GÜRBÜZ**[1], **MEHMET ÖZGÜR PINARBAŞLI**[1]

[1]Department of Otorhinolaryngology–Head and Neck Surgery at Eskişehir Osmangazi University Faculty of Medicine, Türkiye

BACKGROUND & AIM

Thyroglossal duct cysts (TGDC) and branchial cleft cysts (BCC) are among the most common congenital neck masses encountered in otorhinolaryngology practice. Although these lesions are generally associated with childhood, they may also present clinically in adulthood. The increasing number of adult cases has highlighted the need for reevaluation of their age distribution and clinical characteristics.

To evaluate the age distribution and clinical characteristics of patients operated for TGDC and BCC at a tertiary referral center.

MATERIAL & METHODS

This retrospective single-center study included patients who underwent surgery for TGDC or BCC between January 2010 and January 2026 in the Department of Otorhinolaryngology, Eskişehir Osmangazi University. Demographic data, age distribution, clinical characteristics, and surgical outcomes were evaluated from hospital records. Patients were classified as pediatric (<18 years) or adult (≥18 years).

RESULTS

A total of 202 patients were included in the study. Of these, 111 underwent surgery for BCC and 91 for TGDC. In the BCC group, 10 patients were younger than 18 years, whereas 101 were adults. In the TGDC group, 22 patients were younger than 18 years and 69 were adults. Adult patients outnumbered pediatric patients in both lesion groups. TGDC lesions were predominantly located in the midline, whereas BCC lesions were mainly located in the lateral neck.

CONCLUSIONS

Although TGDC and BCC are traditionally considered congenital pediatric neck masses, a substantial proportion of patients in our series were diagnosed and treated during adulthood. These findings suggest that congenital neck masses may also be encountered with clinically significant frequency in adults. Retrospective evaluation of such patient series may contribute to a better understanding of their clinical characteristics.

Synergistic Osteogenic Effect Of A Biocompatible Graphene Oxide/Black Phosphorus Nanocomposites On Mandibular Bone Regeneration In Rats

İbrahim EROĞLU[1], Abdulvahap AKYİĞİT[1], Zafer EROĞLU[2], Tansel Ansal BALCI[3], H. İbrahim ÖZERCAN[4], Nevin İLHAN[5], Orkun EROĞLU[1], İrfan KAYGUSUZ[1], Turgut KARLIDAĞ[1]

[1]Firat University Faculty of Medicine, Department of ENT, Elazig, Türkiye.; [2]Department of Chemistry, College of Sciences, Koç University, Istanbul, Türkiye.; [3]Department of Nuclear Medicine, School of Medicine, Firat University, Elazig, Türkiye.; [4]Department of Pathology, Faculty of Medicine, Firat University, Elazig, Türkiye.; [5]Department of Biochemistry, Faculty of Medicine, Fırat University, Elazıg, Türkiye.

BACKGROUND & AIM

In craniofacial bone defects caused by head and neck cancers, the development of biocompatible and osteoinductive nanomaterials offers a promising approach for the effective regeneration of bone loss. In this study, the possible synergistic effects of graphene oxide (GO)/black phosphorus (BP) nanocomposites at different concentrations on bone regeneration were comprehensively investigated in a bone defect model created in the mandibular corpus. The osteogenic response was evaluated using histopathological healing scores, bone mineral density (BMD) measurements, and serum biochemical parameters.

MATERIAL & METHODS

Following the synthesis of GO via the Hummers method and BP via chemical vapor deposition, the materials were physically combined at Koç University under the supervision of Zafer Eroğlu. The study was conducted on 55 male Sprague-Dawley rats (8–10 weeks old, weighing 225–300 g), which were randomly assigned into six groups: Group 1 (untreated control), Group 2 (surgical defect without medication), Group 3 (surgical defect + GO nanostructure), Group 4 (surgical defect + BP nanostructure), Group 5 (surgical defect + GO/5% BP nanocomposite), and Group 6 (surgical defect + GO/15% BP nanocomposite). On day 28 of the experimental period, all animals were euthanized; blood samples were collected, and right mandibles were dissected at the symphysis for histological and densitometric analyses. Bone healing scores, BMD results, and serum parathyroid hormone (PTH), osteocalcin (OC), calcium (Ca), and phosphorus (P) levels were statistically evaluated.

RESULTS

Histopathological analyses demonstrated a significant difference between the control and defect groups ($p < 0.05$). While GO treatment alone did not result in significant improvement compared to the defect group, the BP, GO/BP5 and GO/BP15 groups exhibited statistically significant increases in healing scores. Although a higher healing tendency was observed in the GO/BP15 group compared to the GO/BP5 group, the difference was not statistically significant. No statistically significant differences were detected among the groups in terms of BMD or serum biochemical parameters (PTH, OC, Ca, and P) ($p > 0.05$).

CONCLUSIONS

The findings indicate that the GO/BP nanocomposite exhibits a more pronounced osteogenic effect on mandibular bone regeneration compared to GO or BP applied individually. This synergistic effect is thought to arise from the mineralization-promoting properties of BP combined with the surface characteristics of GO that enhance cellular adhesion and proliferation. To the best of our knowledge, this is the first experimental study investigating the effects of GO/BP nanocomposites on mandibular bone regeneration. The present work is expected to open a new research avenue and provide an innovative pathway toward translational applications of GO/BP nanocomposites in mandibular bone regeneration.

Radiological Illusion In The Submental Region: Multimodal Management Of Intermediate-Risk Solitary Fibrous Tumor

Kays Burak Çakır[1], **Tolga Küçükgergin**[1], **Beyza Mercan**[1], **Fırat Tevetoğlu**[1], **Zehra Şahin**[2]

[1]*Istanbul University-Cerrahpaşa, Cerrahpaşa Faculty of Medicine, Department of Otorhinolaryngology, Istanbul, Turkey.*; [2]*Istanbul University-Cerrahpaşa, Cerrahpaşa Faculty of Medicine, Department of Pathology, Istanbul, Turkey.*

BACKGROUND & AIM

Solitary fibrous tumor (SFT) is a rare mesenchymal neoplasm primarily originating from the pleura, with infrequent presentation in the head and neck. While traditionally characterized as slow-growing and benign, risk stratification models incorporating mitotic count, tumor size, and the presence of necrosis are decisive for predicting clinical behavior and malignant potential.

MATERIAL & METHODS

A 45-year-old female patient presented with an 3-month history of right submental swelling. Despite multiple courses of antibiotic therapy at external centers, the mass continued to grow. Consequently, an MRI was performed, which reported a 4 cm mass suspicious for hemangioma, leading to the patient's referral to our clinic. A trucut biopsy performed by interventional radiology revealed CD34 and STAT6 positivity on immunohistochemical analysis, confirming the diagnosis of 'Solitary Fibrous Tumor,' and the patient underwent total surgical excision. Post-operative pathological examination revealed a tumor size of 5.9 cm, with significant features including a high mitotic rate (16/10 HPF), 10% tumor necrosis, and vascular invasion. Although surgical margins were clear (0.1 cm), the case was classified as "Intermediate Risk." Following evaluation by the multidisciplinary head and neck tumor board, adjuvant radiotherapy (RT) was recommended.

RESULTS

Solitary fibrous tumor is rare in the head and neck and often mimics vascular tumors like hemangiomas clinically and radiologically. Immunohistochemical analysis is critical in the differential diagnosis of SFT; specifically, STAT6 nuclear expression is considered the gold standard for distinguishing this tumor from other mesenchymal and vascular lesions. In our case, the co-expression of CD34 and STAT6 histopathologically confirmed the diagnosis. Although these neoplasms are generally defined in the literature as slow-growing and benign, certain rare forms can exhibit rapid growth and an aggressive clinical course. In this case, the "high-risk" features including a tumor diameter exceeding 5 cm, vascular invasion, and a high mitotic index (16/10 HPF) reflect this aggressive potential and significantly increase the risk of local recurrence and malignant transformation.

CONCLUSIONS

Solitary fibrous tumor should be considered in the differential diagnosis of submental masses despite its radiological mimicry. In cases exhibiting aggressive histopathological features or those categorized as "intermediate risk," adjuvant radiotherapy following surgical excision is an essential component of the multimodal treatment strategy to ensure regional control.

PP-179

Langerhans Cell Histiocytosis Presenting As Chronic Gingival Ulceration In An Adult Patient: A Case Report

Ahmet Furkan Gümüş[1], **Kamil Akdağ**[1], **Yavuz Uyar**[1]

[1]*University of Health Sciences Prof. Dr. Cemil Taşcıoğlu City Hospital , Department of Otorhinolaryngology, Istanbul, Turkey*

BACKGROUND & AIM

Langerhans cell histiocytosis (LCH) is a rare disorder characterized by clonal proliferation of Langerhans cells, most commonly seen in pediatric populations. Oral involvement in adults is uncommon and may mimic chronic inflammatory or infectious lesions, leading to delayed diagnosis.

MATERIAL & METHODS

This study was designed as a single patient case report.

RESULTS

Histopathological examination of the incisional biopsy specimens revealed findings consistent with Langerhans cell histiocytosis.Following the diagnosis, the patient underwent surgical excision of the gingival lesions. The postoperative course was uneventful, and satisfactory healing of the surgical site was observed.

CONCLUSIONS

This case emphasizes that LCH, although rare in adults, should be included in the differential diagnosis of chronic, non-healing gingival lesions. Early biopsy plays a critical role in diagnosis and prevents delays in appropriate treatment.

Comparison Of Long Term Functional Outcomes According To Reconstruction Modality In Patients Undergoing Glossectomy Due To Malignancy

Dr. Tülay Günsay[1], **Prof. Dr. Bora Başaran**[1], **Op. Dr. Cömert Şen**[1], **Ecem Nur Demirsoy Demirci**[1]

[1]*Istanbul University İstanbul Medical Faculty, Otorhinolaryngology and Head-Neck Surgery Department*

BACKGROUND & AIM

A major clinical challenge following partial or total glossectomy in oral cavity cancers is preserving the tongue's dynamic functions. Reconstruction aims not only for anatomical closure of the defect but also for maintaining swallowing and speech functions at an acceptable level. This study aimed to compare long term functional outcomes (nutrition, articulation, quality of life) of patients undergoing pedicled versus free flap reconstruction after tongue resection for malignancy and to identify other factors influencing these results.

MATERIAL & METHODS

Data from patients who underwent oncological resection for T2-T4 stage tongue cancer and were reconstructed with pedicled (Group 1) or free flaps (Group 2) were analyzed through a 5-year retrospective review. Swallowing function was evaluated using Fiberoptic Endoscopic Evaluation of Swallowing (FEES), Functional Oral Intake Scale (FOIS), and Functional Swallowing Scale (FOSS). FEES results were scored using Penetration Aspiration Scale (PAS) and Yale Pharyngeal Residue Severity Rating scales. Articulation was documented with the Sesletim Sesbilgisi Testi (SST), while quality of life was assessed via EAT-10 and Voice-Related Quality of Life (V-RQOL) scales.

RESULTS

Total 52 patients (26 per group) were included. Group 1 involved 11 PMMF (21.2%), 12 PMMCF (23.1%), 2 SCM rotation (3.8%), and 1 latissimus dorsi (1.9%) flaps. Group 2 included 25 RFFF (48.1%), 1 RAM (1.9%) flaps. No significant differences existed in clinical characteristics except for age (Group 1 64.9±11.3, Group 2 51.7±13.9; $p<0.0001$). FEES revealed lower aspiration ($p=0.001$) and pharyngeal pooling ($p=0.016$) during liquid intake in Group 2. 6 patients in Group 1 and 2 patients in Group 2 were unable to tolerate oral nutrition with solid foods. Although Group 2 showed better nutritional values for semi solids and solids, these were not statistically significant ($p>0.05$). Articulation was significantly better in free flap patients ($p<0.001$). No significant differences were found in EAT-10 or V-RQOL scores ($p=0.447$, $p=0.568$). Adjuvant radiotherapy (RT), extensive resection, advanced T stage, and nodal metastasis negatively impacted functional outcomes; specifically, adjuvant RT significantly reduced QoL ($p<0.001$).

CONCLUSIONS

Flap selection significantly influences functional outcomes in tongue reconstruction, with free flaps being associated with superior speech and swallowing parameters. However, it is essential to recognize that non flap factors, such as adjuvant therapies and the extent of resection, remain decisive determinants of long term functional success.

PP-181

Synchronous Warthin Tumor And Basal Cell Adenoma Of The Parotid Gland: A Rare Case Report

Murat AKIN[1], **Orhan Kemal KAHVECİ**[2], **Selçuk KUZU**[2], **Erkan YILDIZ**[2]

[1]*Department of Otorhinolaryngology, Dr. Halil Ibrahim Ozsoy State Hospital, Afyonkarahisar, Türkiye;* [2]*Department of Otorhinolaryngology, Afyonkarahisar Health Sciences University, Faculty of Medicine, Afyonkarahisar, Türkiye*

BACKGROUND & AIM

Synchronous benign tumors occurring within the same parotid gland are extremely rare, especially when composed of different histological subtypes. We aimed to present a rare case of synchronous Warthin tumor and basal cell adenoma, emphasizing the diagnostic challenges and surgical management of multifocal parotid lesions.

MATERIAL & METHODS

A 71-year-old male patient presented with two painless right parotid masses. Clinical examination, ultrasonography, magnetic resonance imaging, and fine-needle aspiration biopsy were performed preoperatively. Both lesions were surgically removed by superficial parotidectomy with preservation of the facial nerve. Histopathological and immunohistochemical analyses, including CD117, p63, and Ki-67 staining, were used for definitive diagnosis.

RESULTS

Imaging demonstrated two separate lesions: one cystic preauricular mass and one solid lesion in the inferior parotid gland. Histopathological examination confirmed synchronous coexistence of Warthin tumor and basal cell adenoma. Immunohistochemical findings supported the benign nature of both tumors and excluded malignant counterparts. Postoperative recovery was uneventful, and facial nerve function remained intact.

CONCLUSIONS

Synchronous benign parotid tumors with different histological origins are rare and may cause diagnostic pitfalls. Comprehensive radiological evaluation, careful intraoperative exploration, and detailed histopathological assessment are essential for accurate diagnosis and optimal treatment. Superficial parotidectomy remains a safe and effective management option.

KEYWORDS

Parotid gland; Warthin tumor; Basal cell adenoma; Synchronous tumors; Superficial parotidectomy

PP-182

Lingual Perineurioma: A Rare Mesenchymal Tumor – A Case Report

Enes SIRMA[1], **Siraç IRMAK**[1], **Müslüm AYRAL**[1]

[1]*Gazi Yaşargil Training and Research Hospital, Diyarbakır,Türkiye*

BACKGROUND & AIM

Perineurioma is a rare benign peripheral nerve sheath tumor originating from perineurial cells (1). Its occurrence in the oral cavity, particularly in the tongue, is extremely uncommon (2). Due to its rarity and nonspecific clinical presentation, it may be misdiagnosed as other benign mesenchymal tumors (3). Accurate diagnosis relies on histopathological and immunohistochemical evaluation, especially EMA positivity and S100 negativity (4). We present a rare case of lingual perineurioma and discuss its clinical, radiological, and pathological features.

MATERIAL & METHODS

Case: A 33-year-old male presented with a painless swelling on the left side of the tongue, persisting for approximately three years with gradual enlargement. Magnetic resonance imaging revealed a well-defined lesion measuring 10×7 mm, hypointense on T1-weighted images, hyperintense on STIR sequences, without diffusion restriction, and showing homogeneous contrast enhancement. Ultrasonography demonstrated a 12×6 mm hypoechoic, heterogeneous solid lesion with arterial flow on Doppler imaging. The lesion was excised under local anesthesia.

RESULTS

Histopathological examination revealed a mesenchymal tumor composed of spindle to oval-shaped cells with alternating cellular and hypocellular areas, without significant mitotic activity or necrosis. Immunohistochemically, tumor cells showed diffuse positivity for EMA and focal positivity for SMA, while S100, Desmin, Factor XIIIa, CD31, and CD34 were negative (1,4). CD68 showed weak focal positivity. The Ki-67 proliferation index was approximately 8%. Based on morphological and immunohistochemical findings, the lesion was diagnosed as perineurioma.

CONCLUSIONS

Lingual perineurioma is an extremely rare benign tumor that should be considered in the differential diagnosis of tongue masses (2,3). Clinical and radiological findings are often nonspecific, making histopathological and immunohistochemical evaluation essential for accurate diagnosis. Complete surgical excision is the treatment of choice; however, close follow-up is recommended in cases with positive surgical margins.

Perineurioma; Tongue; Mesenchymal tumor; Case report

PP-183

An Alternative Solution For Persistent Pharyngocutaneous Fistula: Mechanical Closure With Voice Prosthesis

Nuri ÜNSAL[1], **Altan Kaya**[1], **Ali Bayram**[1]

[1]*Kayseri City Training and Research Hospital*

BACKGROUND & AIM

The aim of this case report is to discuss the challenges in managing a pharyngocutaneous fistula (PCF) following total laryngectomy and to highlight a practical, minimally invasive method for managing persistent cases.

MATERIAL & METHODS

A 70-year-old male underwent a total laryngectomy and bilateral neck dissection for a T3 supraglottic squamous cell carcinoma, with horizontal primary closure of the neopharynx. On postoperative day 6, a 3 cm neopharyngeal dehiscence developed at the base of the tongue, requiring the creation of a pharyngostoma. After conservative wound care using Balsam of Peru and boric acid, the defect was reconstructed using pectoralis major myocutaneous (PMMF) and deltopectoral flaps on day 25. Due to the histopathological finding of extranodal extension, the patient proceeded with adjuvant radiotherapy (60 Gy) despite the fistula not being entirely closed, prioritizing oncological control.

RESULTS

Following radiotherapy, the defect narrowed due to fibrosis, leaving only a small, persistent fistula tract directly above the tracheal stoma. To address this without further high-morbidity surgery, a tracheoesophageal voice prosthesis (TEP) was inserted directly into the tract. The silicone flanges of the prosthesis provided bilateral mechanical compression, successfully sealing the salivary leak. Consequently, the nasogastric tube was removed, allowing the patient to safely resume oral feeding while simultaneously restoring phonation.

CONCLUSIONS

For small, persistent PCFs that have lost their healing potential following radiotherapy, subsequent surgical interventions carry high morbidity. A silicone TEP can function effectively not only as a speech rehabilitation device but also as a minimally invasive mechanical "plug." This technique safely occludes the fistula, enables safe swallowing, prevents infection, and should be considered as a highly viable management strategy in selected cases of challenging post-laryngectomy complications.

Recurrent Pleomorphic Adenoma Of The Salivary Gland: A Rare Case Of Benign Metastasizing Pleomorphic Adenoma

Abdulmajeed Alahmari[1]

[1]*Prince Sultan Military Medical City, Riyadh*

BACKGROUND & AIM

Pleomorphic adenoma, commonly referred to as a benign mixed tumor, is the most prevalent neoplasm of the salivary glands, particularly affecting the parotid gland. This case report details a unique instance of recurrent pleomorphic adenoma in a 41-year-old female patient, highlighting the complexities of its management. The patient presented with a left submandibular swelling that recurred three years after an initial surgical excision. Comprehensive pathological evaluation confirmed the diagnosis of recurrent pleomorphic adenoma, with the identification of a satellite tumor nodule raising the possibility of benign metastasizing pleomorphic adenoma (BMPA).

RESULTS

Pleomorphic adenoma, recognized as the most prevalent salivary gland neoplasm, presents a notable challenge in clinical management due to its potential for recurrence. The recurrence rates for pleomorphic adenomas can vary significantly, ranging from 2% to 45%, often influenced by factors such as the adequacy of surgical excision and tumor characteristics (3). In our case, a 41-year-old female with a history of recurrent pleomorphic adenoma underwent surgical excision of the left submandibular gland. Despite the initial complete excision, the patient experienced a recurrence three years post-surgery. The recurrence was confirmed through histopathological examination, which also identified a satellite tumor nodule adjacent to a lymph node, suggesting the possibility of benign metastasizing pleomorphic adenoma (BMPA). This case underscores the complexities associated with pleomorphic adenoma management and the critical need for rigorous follow-up.

CONCLUSIONS

This case report illustrates the complexities involved in the management of recurrent pleomorphic adenoma of the salivary gland, particularly in a 41-year-old female patient who experienced a recurrence despite undergoing complete surgical excision. The identification of a satellite tumor nodule adjacent to a lymph node raises important considerations regarding the behavior of pleomorphic adenomas and the potential for benign metastasizing pleomorphic adenoma (BMPA). This highlights the necessity for thorough surgical approaches and vigilant follow-up to mitigate the risk of recurrence and potential complications.

Intraparotid Ectopic Thyroid Tissue Mimicking A Parotid Tumor: A Rare Diagnostic Challenge

Fırat Tevetoğlu[1], **Ceren Öztürk Aygün**[1], **Musa Musayev**[1], **Serhat Kaymaz**[1,2], **Tülin Öztürk**[2], **Haydar Murat Yener**[1]

[1]*Istanbul University – Cerrahpasa, Cerrahpasa Faculty of Medicine, Department of Otorhinolaryngology, Istanbul, Turkiye;* [2]*Istanbul University – Cerrahpasa, Cerrahpasa Faculty of Medicine, Department of Pathology, Istanbul, Turkiye*

BACKGROUND & AIM

Ectopic thyroid tissue is a rare developmental anomaly resulting from aberrant migration of thyroid tissue during embryogenesis. It is most commonly encountered in the lingual region, whereas intraparotid localization is exceptionally rare. To date, only two cases of intraparotid ectopic thyroid tissue have been reported in the literature. In this report, we present a case of intraparotid ectopic thyroid tissue that initially presented as a slowly enlarging parotid mass and was preoperatively suspected to be a primary parotid tumor.

MATERIAL & METHODS

We present the case of a 44-year-old woman with a gradually enlarging painless right parotid mass. Her medical history was significant for total thyroidectomy performed 11 years earlier for benign thyroid nodules, and she was receiving levothyroxine replacement therapy with normal thyroid function at presentation. Ultrasonography demonstrated a 35 × 26 × 19 mm lesion in the superficial lobe of the right parotid gland extending toward the deep lobe, and fine-needle aspiration cytology was interpreted as consistent with Warthin tumor. The patient underwent superficial parotidectomy with partial deep lobe excision. Histopathological examination revealed hyperplastic thyroid tissue with colloid-containing follicles within the parotid gland, with no evidence of malignancy. The lesion was diagnosed as intraparotid ectopic thyroid tissue. At two-year follow-up, the patient remained asymptomatic with no recurrence.

RESULTS

Ectopic thyroid tissue within the parotid gland is an exceptionally rare entity and should be considered in the differential diagnosis of parotid masses, particularly in patients with a history of thyroid disease. Intraparotid ectopic thyroid may clinically as well as cytologically mimic a primary parotid neoplasm. Establishing the diagnosis may therefore be challenging and requires careful histopathological evaluation. Metastatic thyroid carcinoma must always be excluded in the differential diagnosis.

CONCLUSIONS

The treatment decisions should be individualized and based on the symptoms, cosmetic concerns, the status of orthotopic thyroid tissue, histopathological findings, thyroid hormone status, and the response of the ectopic tissue to medical therapy. In our case, surgery was performed because the lesion was initially suspected to represent a primary parotid neoplasm based on preoperative imaging and cytological findings. To the best of our knowledge, this case represents the third reported instance in the literature.

PP-186

Challenging Liposarcoma Of The Head And Neck

Müge Ugurlar[1], **Luaay Aziz**[1]

[1]*Department of Otorhinolaryngology , Sahlgrenska University Hospital*

BACKGROUND & AIM

Lipomas are benign tumors of mesenchymal origin, located in the subcutaneous fatty tissue but they may also arise within muscle or deeper soft tissues.Approximately 13–17% occur in the head and neck region.Liposarcomas represent about 1% of all primary head and neck malignancies.Although rare,prognosis and management is essential.Most cases occur in adults with a male predominance.Liposarcomas are classified into several histological subtypes,including well-differentiated, myxoid,pleomorphic,round cell,and dedifferentiated variants.Well-differentiated and myxoid types are the most common and generally considered low-grade tumors,whereas pleomorphic, round cell, and dedifferentiated variants are more aggressive.The mainstay of treatment is wide surgical excision, often followed by adjuvant radiotherapy.

MATERIAL & METHODS

Case Presentation:

A 61-year-old male with a history of recurrent lipoma in the left temporal region underwent four previous surgical excisions, the last of which was performed 2.5 years ago and reported as benign lipoma on histopathology. The patient presented with a progressively enlarging mass over the last four months in the same region. Clinical examination revealed a swelling in the left temporal area. Computed tomography and magnetic resonance imaging demonstrated a 50 × 54 × 28 mm mass extending inferiorly toward the zygomatic arch and infiltrating the temporalis muscle. Incisional biopsy confirmed the diagnosis of liposarcoma.

RESULTS

The patient underwent wide local excision, and the defect was reconstructed using a free lateral thigh vascular flap. Postoperative radiotherapy was planned.

CONCLUSIONS

Liposarcoma of the head and neck is rare and may mimic benign lesions, particularly in cases of recurrent lipoma. A high index of suspicion, appropriate imaging, and histopathological evaluation are crucial for early diagnosis and optimal management.

Anterior Commissure Involvement As An Independent Predictor Of High-Risk Histopathology In Laryngeal Leukoplakia: A Comparative Analysis With Systemic Inflammatory Biomarkers

Burcu Vural Çamalan[1], **Nazlım Hilal Taraf**[1], **Efe Yetişgin**[2], **Samet Özlügedik**[1]

[1]*Ankara Etlik City Hospital, Otorhinolaryngology Head and Neck Surgery Department;* [2]*Ankara Etlik City Hospital, Pathology Department*

BACKGROUND & AIM

Laryngeal leukoplakia encompasses a spectrum ranging from benign hyperkeratosis to invasive squamous cell carcinoma. Biopsy is often deferred in lesions with preserved vocal fold mobility and non-suspicious endoscopic features, despite uncertain safety. This study aimed to determine the prevalence of high-risk histopathology and identify independent predictors.

MATERIAL & METHODS

This retrospective cohort study included 130 consecutive patients who underwent direct laryngoscopy and biopsy for leukoplakic vocal fold lesions at a tertiary care center between October 2022 and February 2026. Patients were stratified into low-risk (benign, mild dysplasia) and high-risk (severe dysplasia , carcinoma in situ [CIS], invasive SCC) groups based on a two-tier risk stratification adapted from the 2017 World Health Organization (WHO) classification. Clinical and endoscopic features and preoperative hematological parameters were recorded. Statistical analyses were performed using SPSS software.

RESULTS

High-risk histopathology was identified in 76 patients (58.5%), including severe dysplasia (33.1%), carcinoma in situ (CIS) (13.8%), and invasive SCC (11.5%). Anterior commissure involvement was significantly more frequent in the high-risk group (30.3% vs. 9.3%; p = 0.004). NLR, lymphocyte count, and PNI differed significantly between groups (p = 0.033, 0.021, and 0.046, respectively). Spearman's analysis showed weak but significant correlations between histopathological grade and lymphocyte count (ρ = −0.284; p = 0.001), PNI (ρ = −0.250; p = 0.004), NLR (ρ = 0.210; p = 0.017), and monocyte count (ρ = −0.184; p = 0.036). In multivariable logistic regression (Nagelkerke R^2 = 0.153; Hosmer–Lemeshow p = 0.212), anterior commissure involvement was the only independent predictor of high-risk histopathology (adjusted OR = 4.98; 95% CI: 1.70–14.59; p = 0.003), while no inflammatory index remained significant.

CONCLUSIONS

High-risk histopathology was identified in a substantial proportion of patients with laryngeal leukoplakia at initial biopsy. Anterior commissure involvement was the only independent predictor, associated with a nearly fivefold increase in the odds of high-risk pathology, and should be considered a key endoscopic indicator for biopsy decision-making. In contrast, systemic inflammatory indices showed limited and no independent predictive value.

Diagnostic Efficacy Of Fine Needle Aspiration Biopsy Versus Excisional Biopsy In Suspicious Cervical Lymphadenopathy

D. B. Colak Unlu[1], **I. G. Demirci**[1], **S. Tanisman**[1], **S. Zer Toros**[1], **C. Tepe Karaca**[1]

[1]*Department of Otorhinolaryngology & Head and Neck Surgery, Haydarpaşa Numune Training and Research Hospital, Istanbul, Turkey.*

BACKGROUND & AIM

Cervical lymphadenopathy is a common clinical presentation, often requiring definitive histopathological diagnosis to rule out malignancy. Fine needle aspiration biopsy (FNAB) is routinely used as an initial diagnostic tool; however, its reliability compared to excisional biopsy remains a subject of clinical debate. This study aims to evaluate the malignancy rate in suspicious cervical lymph nodes following excisional biopsy and to compare the diagnostic accuracy of FNAB against the gold standard excisional biopsy.

MATERIAL & METHODS

We conducted a retrospective analysis of 55 patients who underwent excisional biopsy for suspicious cervical lymphadenopathy. Patients referred predominantly from internal medicine and hematology departments were included. The cohort was evaluated based on the application of preoperative FNAB. 20 patients proceeded directly to excisional biopsy without prior FNAB. For the 35 patients who underwent both procedures, cytological findings from FNAB were cross-analyzed with definitive histopathological results from excisional biopsies. Diagnostic performance metrics, including sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and overall accuracy, were calculated.

RESULTS

The definitive histopathological examination of 55 excisional biopsies revealed malignancy in 63.6% (n=35) of the cases, while 36.4% (n=20) were benign or reactive. In the comparative subgroup of 35 patients who underwent both FNAB and excisional biopsy, FNAB demonstrated a sensitivity of 79.1% and a specificity of 81.8% in detecting malignancy. The positive predictive value (PPV) was high at 90.4%, whereas the negative predictive value (NPV) was moderately low at 64.2%. The overall diagnostic accuracy of FNAB in our cohort was 80.0%. Notably, five patients with benign FNAB cytology were subsequently diagnosed with malignancy via excisional biopsy (false negatives).

CONCLUSIONS

FNAB serves as a highly reliable initial diagnostic tool when indicating malignancy, owing to its excellent positive predictive value. However, a negative or benign FNAB result does not safely exclude malignancy (NPV 64.2%). In cases with high clinical suspicion, proceeding directly to excisional biopsy is strictly recommended to prevent potential diagnostic delays.

Secondary Healing In Head And Neck Surgery: A Case-Based Review

Marija Pastorčić Grgić[1], **Ana Đanić Hadžibegović**[1], **Pavao Perše**[2], **Boris Stubljar**[2], **Marko Velimir Grgić**[2], **Marina Hršak**[1]

[1]*University Hospital Centre Zagreb;* [2]*University Hospital Centre Sestre milosrdnice*

BACKGROUND & AIM

Secondary healing (healing by secondary intention) through granulation, contraction, and epithelialization is a therapeutic modality that head and neck surgeons should effectively utilise, facilitate, and govern. While often considered inferior to primary closure, it remains invaluable in specific clinical scenarios.

MATERIAL & METHODS

This process includes several actions. Maintaining a clean wound bed by continuous surgical debridement (necrectomy), targeted systemic antibiotics, and bacteriostatic dressings (silver- or iodine-impregnated) to eliminate biofilms. Preventing premature epithelialization by inhibiting early skin edge migration until a healthy, robust bed of granulation tissue is established across the entire defect. Promoting granulation by application of hypertonic hydrogels to stimulate cell proliferation and autolytic debridement. Reducing hypergranulation by lowering exuberant granulation tissue slightly below the level of the surrounding epithelium to allow keratinocyte migration. Facilitating final epitelisation under a balanced, moist environment. Timely placement of sutures to assist edge approximation and accelerate final closure.

RESULTS

This methodology was applied across diverse head and neck scenarios:

- Case 1 (Cutaneous BCC): Intentionally selected for a small lateral nasal defect near the medial eye canthus, delivering excellent cosmesis and direct oncological surveillance.
- Case 2 (Orocutaneous Fistula): Utilised as a forced choice following complete fibular free flap failure and subsequent partial radial forearm free flap failure.
- Case 3 (Primary pharyngocutaneous fistula): Management of a large pharyngocutaneous fistula following total laryngectomy in a non-irradiated patient, probably triggered by severe gastric reflux.
- Case 4 (Complex pharyngocutaneous fistula): Successful contraction over 10 weeks in a vessel-depleted neck following bilateral pectoralis major flap reconstruction, demonstrating that viable regional flaps may still fail to prevent fistula formation.
- Case 5 (Donor Site Morbidity): Complete secondary epithelialization over an exposed flexor tendon at 16 weeks following partial skin graft failure at a radial forearm free flap donor site in a patient with severe comorbidities.

CONCLUSIONS

The therapeutic potential of secondary healing is generally underestimated. Interventions promoting secondary healing can lead to success without new surgical interventions and extra donor morbidity.

A Benign Polyp Hiding The Underlying Tonsil Malignancy: A Near Miss

Hayfa Sheikh[2], **Faizan Shah**[1], **Mr Tom Bradish**[1], **Mr Anas Gomati**[1], **Mr Muhammad Shakeel**[1]

[1]*ENT department, Aberdeen, Scotland, UK;* [2]*University of Aberdeen Medical School, Aberdeen, UK*

BACKGROUND & AIM

A 48 years old man was routinely referred to us because of his long standing nasal blockage secondary to previous nasal trauma. During the consultation he confirmed worsening of his snoring as well. No other red flag symptoms were reported. He

also alerted us about a longstanding polyp in his mouth. The nasal examination revealed significant septal deviation to the right and hypertrophied inferior turbinates. A large benign looking polyp was seen arising from the upper pole of the left tonsil (Figure 1). On palpation the left tonsil felt firm. No cervical lymphadenopathy was noticed and the laryngoscopy was normal.

MATERIAL & METHODS

The histology revealed a benign tonsil polyp but more surprisingly there was squamous cell carcinoma in the left tonsil.

The detailed report shows that macroscopically there was a fragment of tonsil measuring 3 x 3.2 x 1.5cm. Protruding from the mucosal surface was a large, polypoid lesion measuring 2.5 x 1.5 x 1cm. The overlying mucosa was pale yellow and smooth. The polypoid lesion had a slightly nodular appearance. The polypoid lesion became detached from the rest of the tonsil during preparation.

Histology showed sections of tonsil in which there was a moderate to poorly differentiated invasive, focally basaloid, squamous cell carcinoma. In places the tumour was keratinising and there was adjacent carcinoma in-situ. The invasive tumour is at least 5 mm in depth, although the tissue was not well orientated. The P16 was positive, HPV luminex positive, and high risk HPV 16 was detected.

RESULTS

Overlying the malignant lesion there was a polypoid lesion corresponding to the polyp identified macroscopically. The polypoid lesion had an unusual appearance with a core of dense vascular connective tissue covered by benign squamous epithelium.

Staging:

The patient was discussed in the MDT meeting after the staging CT scan. There was no cervical lymphadenopathy or distant spread and the staging was agreed as T1N0M0. He was recommended to undergo radical radiotherapy with curative intent which he completed successfully.

Outcome:

The patient has remained disease free 4 years after completion of his treatment.

Discussion:

1. Blessing in disguise that he sought attention for his nasal blocage
2. Good that he reported the presence of the left tonsil polyp
3. Good that the ENT surgeon decided to deal with the tonsil polyp
4. Good that he was offered total tonsillectomy rather than polyp excision only
5. Differential diagnosis of the tonsil polyp

CONCLUSIONS

Learning points:

1. Important to investigate tonsil polyps
2. Best to carry out total tonsillectomy
3. Just removing the polyp has got a potential to miss the underlying malignancy

KEYWORDS

polyps, tonsils, HPV, malignancy

Impact Of Low Muscle Mass Index On Prognosis And Survival In Patients With Operated Advanced Laryngeal Cancer

Mustafa Burak Karahan[1], **Mehmet Özgür Pınarbaşlı**[1], **Melek Kezban Gürbüz**[1], **Uğur Toprak**[2], **Muhammed Sefa Uyar**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, Faculty of Medicine, Eskisehir Osmangazi University, Eskisehir, Turkey;* [2]*Department of Radiology, Faculty of Medicine, Eskisehir Osmangazi University, Eskisehir, Turkey*

BACKGROUND & AIM

Low skeletal muscle mass index (SMI) is an important prognostic factor associated with decreased survival in patients with head and neck cancer. Measurement of SMI at the level of the third cervical vertebra (C3) is widely used to estimate whole-body muscle mass. Recent studies have suggested that temporal muscle thickness may also reflect systemic muscle loss and prognosis. This study aims to evaluate the prognostic value of low muscle mass by assessing both C3-based SMI and temporal muscle thickness in patients with operated advanced-stage laryngeal cancer, with the hypothesis that their combined assessment may provide a more comprehensive prognostic evaluation.

MATERIAL & METHODS

Male patients who underwent surgery for advanced-stage laryngeal cancer in our clinic between 2018 and 2023 were included in the study Preoperative neck computed tomography scans were used to measure the cross-sectional muscle area at the C3 level, which was normalized for height to calculate SMI Temporal muscle thickness was measured bilaterally and mean values were recorded. . Patients were categorized into low and normal SMI groups based on predefined cutoff values. Associations with prognosis and survival were analyzed statistically.

RESULTS

A total of 35 patients were included in the study. Low SMI was significantly associated with reduced survival according to Kaplan–Meier analysis (p = 0.007). Cox regression analysis demonstrated that low SMI independently increased the risk of mortality (p = 0.014).In contrast, although low temporal muscle thickness was not statistically significantly associated with survival (p = 0.104), a decrease in survival rates was observed.

CONCLUSIONS

Low SMI at the C3 level is significantly associated with poorer survival in advanced-stage laryngeal cancer patients. While temporal muscle thickness alone did not reach statistical significance, it demonstrated a tendency toward reduced survival. The combined evaluation of these parameters may provide a more comprehensive assessment of muscle loss and its clinical implications. Multimodal muscle assessment in the preoperative period may improve risk stratification and patient management. This is a preliminary study, and more comprehensive and meaningful results may be obtained with a longer time period and a larger number of patients.

Metastatic Papillary Thyroid Carcinoma Discovered In A Clinically Reactive Lymph Node During Excision Of A Branchial Cleft Cyst: A Case Report

Dr.Mehmet AY[1], **Asst. Prof. Tuğba YEMİŞ**[1]

[1]*Recep Tayyip Erdoğan University Training and Research Hospital, Otorhinolaryngology*

BACKGROUND & AIM

Branchial cleft cysts are common benign causes of lateral neck masses in adults. During surgical excision, adjacent cervical lymph nodes are frequently encountered and often interpreted as reactive based on macroscopic appearance. However, in patients with a history of differentiated thyroid carcinoma, particularly papillary thyroid carcinoma (PTC), such lymph nodes may harbor occult metastatic disease despite benign clinical and radiological features. The aim of this report is to emphasize the importance of routine excision and histopathological evaluation of intraoperatively encountered lymph nodes during branchial cleft cyst surgery in patients with prior thyroid malignancy.

MATERIAL & METHODS

We report a single case of a 53-year-old female patient with a history of total thyroidectomy performed in 2005 for PTC. The study design is a retrospective case report. The patient presented with a 2–3-month history of a right-sided neck mass. Ultrasound demonstrated a 42×18 mm lymph node in the right submandibular region with loss of fatty hilum. Contrast-enhanced magnetic resonance imaging revealed a 44×26 mm well-circumscribed cystic lesion, suggestive of a branchial cleft cyst. Core needle biopsy showed non-specific squamous epithelium, lymphoid tissue, and fibromuscular fragments. The patient underwent surgical excision of the lesion. Intraoperatively, a lymph node adjacent to the cyst with a reactive appearance was also excised.

RESULTS

Histopathological examination revealed a branchial cleft cyst and metastatic papillary thyroid carcinoma in the excised lymph node. Immunohistochemistry demonstrated HBME-1 and CK19 positivity, galectin-3 negativity, and absence of BRAF V600E mutation, supporting metastatic PTC. No statistically evaluable comparative analysis was performed due to the single-case design.

CONCLUSIONS

Lymph nodes encountered during branchial cleft cyst surgery should not be assumed reactive based on gross appearance alone. In patients with a history of papillary thyroid carcinoma, routine excision and histopathological evaluation of adjacent lymph nodes is essential, as clinically occult metastasis may be present even decades after initial treatment.

Vacuum-Asisted Closure-Asisted Reconstruction Of Extensive Anterior Cervical Necrotizing Fasciitis: A Case Report

Deniz Hancı[1], **Öykü İzel Onaran**[2], **Bürge Dereli**[1], **Veysel Tacit Topalan**[1], **Yavuz Uyar**[1]

[1]*Department of Otorhinolaryngology, University of Health Sciences Prof. Dr. Cemil Taşcıoğlu City Hospital, Istanbul, Turkiye;* [2]*Department of Otorhinolaryngology Çerkezköy State Hospital , Tekirdag, Turkiye*

BACKGROUND & AIM

Necrotizing fasciitis (NF) is a rapidly progressive, life-threatening soft tissue infection. While the extremities and trunk are most commonly affected, the anterior cervical region represents

a rare site and poses additional risks due to its proximity to vital structures such as major vessels and the airway. Prompt diagnosis and aggressive management are critical for patient survival.

MATERIAL & METHODS

We report a 44-year-old previously healthy male who presented with a one-week history of worsening anterior neck infection, pain, and tissue necrosis. Laboratory tests revealed elevated acute-phase reactants, and tissue cultures grew Klebsiella pneumoniae. Imaging demonstrated subcutaneous gas and fluid collections extending from the neck into the anterior chest wall. The patient underwent seven surgical procedures, including six sessions of serial debridement and split-thickness skin grafting harvested from bilateral femoral regions. The final procedures were followed by vacuum-assisted closure (VAC) therapy to control exudate and promote graft integration. After successful graft incorporation, adjunctive hyperbaric oxygen therapy was administered.

RESULTS

With intensive care support, pathogen-targeted antibiotic therapy, repeated surgical debridements, and meticulous wound care, the patient achieved full recovery. At the one-year follow-up, he remained in good condition without complications.

CONCLUSIONS

Anterior cervical NF, although rare and high-risk, can be successfully treated with early diagnosis, serial surgical debridement, skin grafting, VAC therapy, and adjunctive hyperbaric oxygen therapy. This case emphasizes the importance of multidisciplinary management in treating complex cervical wounds.

Immunotherapy And Surgery In Head And Neck Squamous Cell Carcinoma: Synergies, Challenges And Clinical Outcomes

Joana Guimarães[1], **Mafalda Martins Sousa**[1], **Joaquim Castro Silva**[1]

[1]*Portuguese Oncology Institute of Porto Francisco Gentil*

BACKGROUND & AIM

Head and neck squamous cell carcinoma (HNSCC) has seen few therapeutic advances; despite surgery and adjuvant radiotherapy with or without cisplatin, roughly one-third of patients relapse within a year. Immune checkpoint inhibitors (ICIs) have reshaped recurrent/metastatic (R/M) disease and are now entering the curative-intent perioperative setting.

MATERIAL & METHODS

We reviewed pivotal anti–PD-1/PD-L1 trials across R/M and locally advanced HNSCC and their implications for surgery.

RESULTS

In R/M disease, nivolumab (CheckMate-141) and pembrolizumab (KEYNOTE-040) improved survival over chemotherapy, and pembrolizumab (KEYNOTE-048) became first-line standard of care. Adding ICIs to chemoradiotherapy in non-operated locally advanced disease failed (KEYNOTE-412, JAVELIN HN100, IMvoke010). Conversely, the perioperative KEYNOTE-689 trial was the first positive phase 3 study: neoadjuvant plus adjuvant pembrolizumab improved event-free survival (hazard ratio 0.66 for CPS ≥10) and induced major pathological responses, lowering rates of high-risk pathology and adjuvant cisplatin use. Neoadjuvant-window trials (IMCISION, neoCHANCE-1) confirmed feasibility without compromising resection.

CONCLUSIONS

Immunotherapy is shifting from palliative to curative-intent perioperative use in HNSCC. Pathological response is emerging as a pivotal biomarker, requiring close integration with surgical planning, margins and de-escalation strategies.

Temporal Bone Embryonal Rhabdomyosarcoma Presenting As Mastoiditis: Two Pediatric Cases

Atilla Can Sarıkaya[1], **Ahmet Tokaç**[1], **Halime Adıyaman**[1], **Yunus Kartal**[1], **Fariza Şahap**[1], **Begüm Bahar Yılmaz**[1], **Zeliha Kapusuz Gencer**[1], **Özgür Yiğit**[1]

[1]*Başakşehir Çam and Sakura City Hospital*

BACKGROUND & AIM

Temporal bone embryonal rhabdomyosarcoma is a rare but aggressive pediatric malignancy that can present with a clinical picture mimicking complicated mastoiditis. Patients may initially exhibit persistent otorrhea, postauricular swelling, external auditory canal obliteration, and facial nerve palsy, while radiologic evaluation may reveal temporal bone destruction with extension to the skull base, intracranial structures, and deep neck spaces. We present two pediatric cases with mastoiditis-like onset and aim to highlight the importance of early recognition of these warning signs for accurate diagnosis and appropriate multidisciplinary treatment.

MATERIAL & METHODS

We retrospectively reviewed two pediatric cases of temporal bone embryonal rhabdomyosarcoma managed at our center. Demographic data, initial symptoms, otolaryngologic examination findings, cervical lymph node status, imaging findings, intraoperative observations, histopathologic and molecular analyses, oncologic treatment protocols, surgical interventions, and follow-up data were obtained from medical records. Radiologic evaluation comprised temporal bone computed tomography, contrast-enhanced magnetic resonance imaging of the temporal bone and neck, and PET/CT for staging. The cases were descriptively assessed according to tumor extent, skull base and adjacent space involvement, multimodal treatment approach, and post-treatment clinical and pathologic outcomes.

RESULTS

Case 1: A 3-year-old girl was referred from an outside institution with an initial diagnosis of chronic otitis with intratemporal complications and presented with persistent purulent otorrhea, postauricular fistulization, polypoid external auditory canal obstruction, pre- and postauricular swelling, bilateral cervical lymphadenopathy, and House-Brackmann grade IV facial palsy. Imaging demonstrated temporal bone-middle ear-mastoid tumor with spread to the parapharyngeal and retropharyngeal spaces, pterygoid muscles, skull base, superior orbital fissure, cavernous sinus, and probable intracranial compartment, with cervical nodal metastases. Biopsy confirmed embryonal rhabdomyosarcoma. She received neoadjuvant chemoradiotherapy followed by modified radical mastoidectomy for residual disease.

Case 2: A 2-year-old boy presented with progressive left ear swelling, persistent otorrhea, external auditory canal stenosis, and a growing periauricular mass with intermittent bloody-purulent discharge. Biopsy confirmed embryonal rhabdomyosarcoma. He received neoadjuvant chemotherapy, radical mastoidectomy, and adjuvant chemoradiotherapy. Imaging demonstrated a primary temporal bone tumor with middle ear/mastoid, nasopharyngeal, maxillary, skull base, and probable intracranial extension.

CONCLUSIONS

Temporal bone embryonal rhabdomyosarcoma is a rare but aggressive pediatric malignancy that may closely mimic complicated mastoiditis at presentation. Persistent otorrhea, external auditory canal obstruction, postauricular fistulization or swelling, facial nerve palsy, and radiologic evidence of temporal bone destruction with extension to the skull base, intracranial structures, or deep neck spaces should raise suspicion for malignancy. Early recognition of these alarming findings, prompt biopsy, and multidisciplinary management are essential for accurate diagnosis and appropriate treatment. These cases highlight the importance of considering rhabdomyosarcoma in children with atypical, progressive, or treatment-resistant otologic and mastoid inflammatory findings

PP-196

Metachronous Bilateral Warthin Tumor Mimicking Necrotic Lymphadenopathy: A Case Report

Ayse Serra Kirici[1], **Ahmet Gur**[1], **Semih Usaklioglu**[1]

[1]*Sultangazi Haseki Trainig and Research Hospital*

BACKGROUND & AIM

Warthin tumor is the second most common benign salivary gland tumor and is strongly associated with smoking, with smokers having up to an eightfold increased risk (1,2). It may present as bilateral or multifocal lesions (3,4). Due to its cystic nature and lymphoid stroma, it can radiologically mimic lymphadenopathy (3,5). We report a metachronous bilateral Warthin tumor case with atypical radiological findings.

MATERIAL & METHODS

A 52-year-old male with a 60 pack-year smoking history presented in 2021 with a left parotid swelling. Magnetic resonance imaging (MRI) revealed a 55×42 mm necrotic-appearing lesion at left level I–II. Additionally, a 15 mm lesion was incidentally noted in the right parotid gland. Ultrasonography suggested a lesion in the deep lobe of the left parotid gland. Fine-needle aspiration biopsy was consistent with Warthin tumor. The patient underwent left superficial parotidectomy in March 2022, and histopathology confirmed Warthin tumor.
In 2026, the patient presented with right-sided parotid swelling. Imaging revealed a cystic mass approximately 6×5 cm in the inferior part of the superficial lobe of the right parotid gland, anterior to the sternocleidomastoid muscle. Differential diagnosis included Warthin tumor and lymphadenopathy. Fine-needle aspiration biopsy was non-diagnostic. Right parotidectomy was performed.

RESULTS

Histopathological examination of the right parotidectomy specimen confirmed Warthin tumor. The case was interpreted as metachronous bilateral Warthin tumor with atypical radiological presentation mimicking necrotic lymphadenopathy.

CONCLUSIONS

Warthin tumor should be considered in the differential diagnosis of cystic or necrotic-appearing parotid and upper neck lesions, especially in heavy smokers. Bilateral and metachronous presentations may occur and can lead to diagnostic confusion with lymphadenopathy. Surgical excision remains both diagnostic and therapeutic in ambiguous cases.

warthin tumor, bilateral parotid tumor, parotid neoplasm, necrotic lymphadenopathy

PP-197

Diagnostic Challenges In Palatal Lesions Mimicking Malignancy: Report Of Two Cases

Irene Oliver Laguna[1], **Carlos Ramón Franco Fente**[1], **Alejandro Pozuelo Moreno**[1], **María Nazaret Benítez Lobón**[1], **Blanca Torroja Soto**[2], **Consuelo Ortega Fernández**[1], **Cristina Valor García**[1]

[1]*Infanta Sofía University Hospital;* [2]*La Princesa University Hospital*

BACKGROUND & AIM

Palatal lesions with atypical clinical features often raise suspicion of malignancy, particularly when presenting as chronic ulcerative or exophytic masses. However, not all such lesions are neoplastic, as certain infectious and benign epithelial conditions may closely mimic cancer, creating significant diagnostic challenges. Oral tuberculosis is a rare extrapulmonary manifestation that typically presents as a chronic ulcer and may represent the first sign of systemic disease. Squamous papilloma is a benign epithelial proliferation that can appear as an exophytic lesion resembling malignancy. We report two cases of palatal lesions initially suspected to be malignant that were ultimately diagnosed as non-neoplastic conditions.

MATERIAL & METHODS

Two patients presenting with suspicious palatal lesions were evaluated through clinical examination, endoscopic assessment, imaging, and histopathological analysis. Case 1: A 45-year-old female presented with several months of nonspecific pharyngeal discomfort. Examination revealed a 3 cm ulcer on the soft palate with raised borders and a granulating base. Initial biopsy showed necrotizing granulomatous inflammation without malignancy. Due to persistence, cervico-thoracic imaging and repeat biopsy with microbiological analysis including PCR were performed. Case 2: An 80-year-old male presented with a painless 2.5 cm exophytic lesion on the hard palate. Endoscopic evaluation was unremarkable. Imaging and incisional biopsy with histopathological and immunohistochemical analysis were carried out.

RESULTS

Case 1: Despite the absence of systemic symptoms, imaging revealed pulmonary findings suggestive of infectious disease. PCR testing confirmed Mycobacterium tuberculosis infection, establishing the diagnosis of oral tuberculosis with probable pulmonary involvement. Targeted therapy led to clinical improvement. Case 2: Histopathological examination showed papillary squamous proliferation without dysplasia, and immunohistochemistry was negative for p16 and HPV. A diagnosis of benign squamous papilloma was established, and complete excision was curative.

CONCLUSIONS

These cases illustrate that palatal lesions with a strong clinical suspicion of malignancy may correspond to non-neoplastic conditions of infectious or benign origin. Oral tuberculosis should be considered in chronic ulcerative lesions, even in the

absence of systemic symptoms, given its potential to mimic malignancy and to represent the first sign of systemic disease. Similarly, benign exophytic lesions such as squamous papilloma may clinically resemble premalignant or malignant tumors, particularly in elderly patients. Histopathological confirmation remains essential, and when initial biopsy is inconclusive, repeat sampling and microbiological testing are critical to establish the diagnosis and avoid mismanagement.

BACKGROUND & AIM

Paragangliomas (PGs) are rare neuroendocrine tumors, with primary involvement of the thyroid gland being exceptionally uncommon. Thyroid paragangliomas typically present as slowly enlarging thyroid nodules over several years and are most often nonfunctional. Due to their rarity, these tumors are frequently misdiagnosed as more common thyroid neoplasms. This report aims to highlight a rare case of primary thyroid paraganglioma and to increase awareness of its clinical and pathological characteristics in order to avoid diagnostic and therapeutic pitfalls.

MATERIAL & METHODS

We present a case of a patient diagnosed with a primary thyroid paraganglioma. Clinical presentation, imaging findings, histopathological features, and immunohistochemical characteristics were reviewed to establish the diagnosis and differentiate it from other thyroid neoplasms.

RESULTS

The patient presented with a long-standing, gradually enlarging thyroid nodule with no evidence of hormonal hypersecretion, consistent with a nonfunctional tumor. Histopathological examination and immunohistochemical profiling confirmed the diagnosis of primary thyroid paraganglioma, distinguishing it from more common thyroid malignancies.

CONCLUSIONS

Primary thyroid paraganglioma is an extremely rare entity that can closely mimic other thyroid neoplasms. Increased awareness of this rare diagnosis and its distinctive features is essential to ensure accurate diagnosis and appropriate management, thereby preventing unnecessary or inappropriate therapeutic interventions.

B-Cell Dysfunction In Tumor-Draining Lymph Nodes Predicts Relapse In Oral Squamous Cell Carcinoma

V. Liljeström[1], **S. Kumlien Georén**[1], **L.-O. Cardell**[1], **Krzysztof Piersiala**[1]

[1]*Karolinska institutet*

BACKGROUND & AIM

Oral squamous cell carcinoma (OSCC) presents a persistent clinical challenge, with high recurrence rates and limited improvements in survival despite therapeutic advances. Tumor-draining lymph nodes (TDLNs) are key immunological sites where anti-tumor responses are orchestrated, yet the prognostic relevance of B-cell phenotypes in TDLNs remains underexplored.

MATERIAL & METHODS

TDLNs from 49 OSCC patients treated at Karolinska University Hospital were prospectively analyzed. Single-cell suspensions were examined using multicolor flow cytometry to characterize B-cell subsets (naïve, memory, plasma cells) and expression of immunoregulatory markers (CD11c, CD24, CXCR5, CD73, HLA-DR, PD-L1). B-cell profiles were correlated with clinical outcomes, including disease-free survival (DFS) and overall survival (OS).

RESULTS

Disease-free patients exhibited a distinct B-cell profile marked by a higher proportion of naïve B cells, strong CXCR5 and CD11c expression, and increased plasma cell differentiation. Recurrence was associated with elevated CD24, CD73, and HLA-DR expression—markers linked to immunoregulatory or dysfunctional B-cell states. Interestingly, high PD-L1 expression on memory B cells correlated with improved prognosis, suggesting a context-dependent immune function.

CONCLUSIONS

B-cell phenotypes in OSCC TDLNs are strongly associated with patient outcomes. A microenvironment enriched in naïve and functionally active B cells supports durable tumor control, whereas regulatory/exhausted phenotypes are linked to recurrence. These findings position B-cell markers as promising prognostic indicators and therapeutic targets in OSCC, warranting validation in larger cohorts.

Giant Cervico-Mediastinal Desmoid-Type Fibromatosis Mimicking A Retrosternal Thyroid Mass: A Challenging Airway Case

Reshad Guvalov, MD[1], **Ahmet Aksoy, MD**[2]

[1]*Otorhinolaryngology, Liv Bona Dea Hospital, Baku, Azerbaijan;* [2]*Department of Otorhinolaryngology, Faculty of Medicine, Sivas Cumhuriyet University, Sivas, Türkiye*

BACKGROUND & AIM

Desmoid-type fibromatosis (DTF) is a rare benign fibroblastic tumor characterized by locally aggressive, infiltrative growth without metastatic potential. Involvement of the head and neck region is uncommon, and cervico-mediastinal extension is exceptionally rare. Owing to their location and growth pattern, such lesions may mimic thyroid-origin masses, resulting in considerable diagnostic complexity and potential airway compromise.

MATERIAL & METHODS

A 62-year-old woman presented with progressively worsening dysphagia and airway-related symptoms. She reported having undergone a presumed thyroid surgery 25 years earlier for similar complaints, after which she experienced prolonged symptomatic relief. Over the preceding five years, her symptoms gradually recurred, with marked deterioration during the final year. Contrast-enhanced computed tomography of the neck and chest revealed a giant 12-cm mass occupying the left thyroid lobe, with posterior extension into the paravertebral space and inferior extension into the superior mediastinum, mimicking a retrosternal thyroid mass. Complete surgical excision was successfully achieved via a transcervical approach. Histopathological and immunohistochemical evaluation confirmed the diagnosis of DTF. Histopathological examination revealed a spindle cell mesenchymal neoplasm. Immunohistochemistry showed diffuse positivity for Vimentin and SMA, and crucially, nuclear positivity for Beta-catenin. Markers for other mesenchymal tumors (CD34, S100, Desmin, CD117, DOG1) were negative. The final diagnosis was DTF.

RESULTS

No complications were observed during the early postoperative period or at the 6-month follow-up. The patient remains under clinical observation.

CONCLUSIONS

This case highlights a rare presentation of giant cervico-mediastinal desmoid-type fibromatosis associated with significant airway compromise, underscoring the critical importance of radiologic–pathologic correlation and a multidisciplinary management approach.

Head And Neck Sarcomas: Report Of Three Cases

AMEL BOUKERCHE[1,2], **NASSEREDDINE OMAR OUSLIM**[1,2], **SOUMIA BELLAL**[1,2], **IBRAHIM FERGOUG**[1,2]

[1]*Oto-Rhino-Laryngology, Head and Neck Surgery Department, EHU, Oran, Algeria;* [2]*Faculty of Medicine / Oran University, Algeria*

BACKGROUND & AIM

Head and neck sarcomas are rare and heterogeneous malignant tumors of mesenchymal origin. They are characterized by aggressive behavior, diagnostic difficulty, and a high risk of local extension and distant dissemination. Their management remains challenging due to complex anatomical locations and the absence of standardized therapeutic protocols.

We report three cases of head and neck sarcomas managed in our department and to analyze their epidemiological, clinical, histopathological, therapeutic, and outcome features.

MATERIAL & METHODS

We report three cases of otolaryngological sarcoma of different locations in the cervical region, the parapharyngeal space and the laryngeal region.

RESULTS

Case 1: A 50-year-old woman presented with a chondrosarcoma of the parapharyngeal space extending to the skull base. Following discussion at a multidisciplinary tumor board, exclusive radiotherapy was performed. At 8 months' follow-up, the disease remained stable without distant metastasis.

Case 2: A 65-year-old man was diagnosed with laryngeal sarcoma. He underwent complete surgical excision followed by adjuvant radiotherapy. This case represented the only potentially curative treatment among the three patients.

Case 3: A 57-year-old man presented with a sarcoma revealed by necrotizing cervical cellulitis with thoracic and axillary extension. Despite initiation of chemotherapy, the clinical course was rapidly unfavorable, leading to death.

In all cases, the diagnosis was confirmed by histopathological examination with immunohistochemical analysis.

CONCLUSIONS

Head and neck sarcomas are uncommon but highly aggressive malignancies associated with poor prognosis. Early diagnosis and multidisciplinary management are crucial. Whenever technically feasible, complete surgical excision remains the cornerstone and the only potentially curative treatment modality.

Transoral Robotic Excision Of A Parapharyngeal Spindle Cell Mesenchymal Tumor With Concurrent Tonsillectomy: A Case Report

özlem özüm[1], **zeynep sude tekin**[1], **deniz odluyurt**[1], **şahin öğreden**[1], **özgür yiğit**[1]

[1]*Başakşehir Çam and Sakura City Hospital, Department of Otorhinolaryngology, Istanbul, Türkiye*

BACKGROUND & AIM

Parapharyngeal space tumors are rare and represent a surgical challenge due to their deep location and proximity to vital neurovascular structures. Transoral robotic surgery (TORS) offers a minimally invasive approach with improved visualization andreduced morbidity.

MATERIAL & METHODS

This case report presents a patient who was evaluated and treated in our department. Clinical data were obtained retrospectively from the patient's medical records. The diagnostic workup included detailed history taking, physical examination, and relevant imaging studies. The patient underwent appropriate medical and/or surgical management, and follow-up findings were recorded. All procedures were performed in accordance with standard clinical practice.

A 68-year-old male presented with dysphagia and a palpable mass in the oropharynx. The patient reported noticing a swelling in November 2025 and was referred to our clinic following initial imaging performed at an external center.

Intraoral examination revealed a spindle-shaped mass extending from the right peritonsillar region to the soft palate. Radiological evaluation with contrast-enhanced CT and MRI demonstrated a well-defined mass in the right parapharyngeal space with extension toward the oropharynx, without evidence of pathological lymphadenopathy.

Further evaluation included excisional biopsy, and the patient underwent appropriate management and follow-up.

RESULTS

Excisional biopsy revealed a spindle cell mesenchymal tumor, with immunohistochemical staining positive for desmin, and vimentin. Following multidisciplinary evaluation, the patient underwent transoral robotic surgery (TORS) with complete excision of the lesion and concurrent right tonsillectomy. The postoperative course was uneventful. Final histopathological evaluation is pending.

CONCLUSIONS

Transoral robotic surgery is a safe and effectiveminimally invasive technique for selectedparapharyngeal mesenchymal tumors. It offers favorable functional and cosmetic outcomes.

PP-203

Interarytenoid Embryonal Rhabdomyosarcoma: A Rare Laryngeal Case

Mehmet Birinci[1]

[1]*Department of Otorhinolaryngology, Faculty of Medicine, Recep Tayyip Erdoğan University, Rize, Türkiye*

BACKGROUND & AIM

Laryngeal embryonal rhabdomyosarcoma (ERMS) is an exceptionally rare malignant mesenchymal neoplasm in adults. Its occurrence in the interarytenoid region is particularly unusual and presents a diagnostic challenge due to its rarity in this subsite. This report aims to present a unique case of adult laryngeal embryonal rhabdomyosarcoma arising from the

interarytenoid area. We discuss the clinical presentation and the successful management of this aggressive tumor using a combined multimodal treatment approach

MATERIAL & METHODS

A 49-year-old male ex-smoker (3 pack-years) presented with a one-year history of hoarseness. Physical examination revealed an irregular, polypoid mass attached to the interarytenoid region; bilateral vocal cords were mobile. Neck MRI identified a 7 mm midline polypoid soft tissue lesion at the glottic level exhibiting peripheral contrast enhancement. Following these clinical and radiological evaluations, an initial surgical excision of the mass was performed to establish a definitive histopathological diagnosis

RESULTS

Histopathology confirmed the diagnosis of embryonal rhabdomyosarcoma. A multidisciplinary decision was made to widen the surgical margins, followed by adjuvant chemoradiotherapy (CRT) to ensure local control. The patient successfully completed the treatment protocol. At the 3-year follow-up, clinical examination and imaging demonstrated no signs of local recurrence or distant metastasis. This successful outcome contrasts with other adult cases where standard organ-preservation strategies without initial surgical control failed to eradicate the disease

CONCLUSIONS

Adult laryngeal embryonal rhabdomyosarcoma involving the interarytenoid region can be successfully managed with early detection and aggressive multimodal therapy. This case illustrates that a combination of surgical margin control followed by adjuvant chemoradiotherapy can provide excellent local control for adult laryngeal sarcomas. Although less common in adults than children, a high index of suspicion is required for irregular glottic lesions. Regular follow-up remains mandatory given the high aggressive potential of these rare laryngeal malignancies even after successful treatment.

PP-204

Primary Cervical Hydatid Cyst: A Rare Entity Mimicking Branchial Cleft Cyst

Dr. Kübra AYDIN YILDIRIM[1], **Dr. Ayça TAN**[2], **Dr. Görkem ESKİİZMİR**[3]

[1]*Resident, Manisa Celal Bayar University, Department of Otorhinolaryngology-Head and Neck Surgery, Manisa-TURKIYE;* [2]*Associate Professor, Manisa Celal Bayar University, Department of Pathology, Manisa-TURKIYE;* [3]*Professor, Manisa Celal Bayar University, Department of Otorhinolaryngology-Head and Neck Surgery, Manisa-TURKIYE*

BACKGROUND & AIM

Hydatid disease, caused predominantly by Echinococcus granulosus, is a zoonotic parasitic infection that most commonly involves the liver and lungs due to portal and pulmonary filtration. Head and neck involvement is exceedingly rare, accounting for less than 1% of all cases, and isolated primary cervical localization is particularly uncommon. Clinically and radiologically, cervical hydatid cysts generally mimick cystic lesions of the neck; thereby leading to frequent preoperative misdiagnosis.

MATERIAL & METHODS

A 60-year-old female presented with a 45-day history of a painless, non-progressive swelling in the right lateral neck. She had no systemic symptoms or relevant exposure history. Physical examination revealed a well-circumscribed, non-tender cervical mass. Contrast-enhanced computed tomography demonstrated a 48 × 26 mm multiloculated cystic lesion with peripheral wall enhancement, located posteromedial to the right parotid gland beneath the sternocleidomastoid muscle. Based on radiological findings, an infected branchial cleft cyst or deep neck abscess was initially suspected. The patient underwent complete surgical excision of the lesion.

RESULTS

Intraoperatively, a well-defined cystic mass containing internal particulate material was identified and excised in toto. Histopathological examination revealed laminated acellular membranes consistent with a hydatid cyst, confirming the diagnosis. Postoperative systemic evaluation showed no evidence of hepatic or pulmonary involvement, supporting a diagnosis of “primary cervical hydatid disease”. To reduce the risk of recurrence, albendazole therapy (400 mg/day) was administered in three cycles (3 weeks on treatment followed by 1-week intervals), with regular hematologic and hepatic monitoring. The patient remains disease-free on 2-year follow-up.

CONCLUSIONS

Primary cervical hydatid cyst is a rare and frequently misdiagnosed clinical entity. Definitive diagnosis relies on histopathological confirmation due to nonspecific clinical and radiological features. Complete surgical excision without cyst rupture, combined with adjunctive antihelminthic therapy, provides excellent outcomes. Awareness of this rare disease is essential for the differential diagnosis of cystic neck masses particularly in endemic regions.

PP-205

CASE PRESENTATION OF NECK METASTASIS OF RENAL CELL CARSINOMA

Hakkı Caner Inan[1], **Melih Alpay**[1], **Pınar Erses**[1]

[1]*BURSA HIGH SPECIALIZATION TRAINING AND RESEARCH HOSPITAL*

BACKGROUND & AIM

Renal cell carcinoma (RCC) accounts for approximately 3% of all adult malignancies. It is the sixth most common cancer in men and the ninth in women, and its incidence has been steadily increasing. At the time of diagnosis, approximately 15% of patients present with metastatic disease, while an additional 20% develop metastases following nephrectomy. RCC is considered the third most common infraclavicular tumor metastasizing to the head and neck region. The thyroid gland is the most frequent site of metastasis in this region.

MATERIAL & METHODS

In this case report, we present a 43-year-old male patient who underwent right nephrectomy due to RCC. During follow-up, a control PET-CT scan revealed suspicious lymph node involvement in the left supraclavicular region. The patient's only distant metastasis was located in the neck. Although rare, cervical lymphadenopathy may represent the first clinical manifestation of RCC.A left level III–IV–V neck dissection was performed. Postoperative histopathological examination revealed metastatic lymph nodes consistent with RCC. In postoperative follow-up, PET-CT imaging demonstrated a hypermetabolic lesion in the operated left supraclavicular region and suspicious lymphadenopathies in the aortocaval region. Based on these findings, systemic therapy was initiated, and the patient was started on cabozantinib. Treatment is currently ongoing.

RESULTS

Surgery plays a significant role in the management of metastatic RCC. Surgical resection of metastatic lesions may lead to complete remission due to the removal of biologically active tumor tissue. Despite advances in systemic therapies, international guidelines continue to recommend surgical treatment of metastases in appropriate patients.

CONCLUSIONS

The literature includes numerous single case reports and small case series describing head and neck metastases of RCC.In this case report, we discuss the rare but clinically significant presentation of head and neck metastases of RCC through our case.

Preoperative Selective Arterial Embolization Using Microspheres In Clinically Node-Negative Oropharyngeal Cancer Patients Undergoing Transoral Robotic Surgery

Tomonori Terada[1], **Yasukazu Kako**[2], **Yuichiro Shinoda**[1], **Masataka Nakamura**[1], **Hiroshi Kono**[3], **Syuntaro Takeda**[1], **Junko Fukutake**[1], **Koichiro Yamakado**[2], **Kenzo Tsuzuki**[1]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, Hyogo Medical University, Nishinomiya, Japan;* [2]*Department of Radiology, Hyogo Medical University, Nishinomiya, Japan;* [3]*Department of Diagnostic Pathology, Hyogo Medical University, Nishinomiya, Japan*

BACKGROUND & AIM

Transoral robotic surgery (TORS) is a minimally invasive approach for oropharyngeal cancer that preserves function while reducing morbidity. However, postoperative hemorrhage (3–13%) remains a serious concern, requiring reliable vascular control. Prophylactic arterial ligation reduces bleeding risk but necessitates an external cervical incision in clinically node-negative (cN0) patients, compromising the minimally invasive advantage of TORS.

Preoperative transarterial embolization may provide an alternative without external incision. Permanent embolic materials, such as spherical microspheres, enable sustained vascular occlusion.

This study evaluated the safety and feasibility of preoperative embolization using microspheres in patients with early-stage cN0 oropharyngeal cancer undergoing TORS.

MATERIAL & METHODS

This retrospective case series included consecutive patients with cN0 T1–T2 oropharyngeal squamous cell carcinoma treated with preoperative embolization followed by TORS (September 2022–February 2025). Patients with nodal metastasis were excluded.

Selective embolization of tumor-feeding branches of the lingual and/or facial artery was performed using calibrated spherical microspheres (Embosphere™). TORS was conducted four days later using the da Vinci Xi system without prophylactic arterial ligation.

Endoscopic evaluation was performed before embolization, one day after, and on the day of surgery. Primary outcomes were intraoperative blood loss and postoperative hemorrhage requiring intervention. Secondary outcomes included complications, feasibility of TORS, and pathological findings.

Resected specimens were evaluated for tumor size, T classification, margins, necrosis, and presence of microspheres. The study was IRB-approved, with consent waived.

RESULTS

Twelve patients were included (lateral wall, n=9; anterior wall, n=3; T1, n=1; T2, n=11), all cN0.

Endoscopy showed ischemic changes after embolization, with tumor pallor and necrosis observed the next day and further shrinkage before TORS.

TORS was completed in all patients without conversion. One patient required additional surgery due to rapid progression (pT4a). Blood loss was ≤10 mL in all cases, and no postoperative hemorrhage occurred.

Pathological downstaging was observed in 8 patients; three showed no change and one was upstaged. Histology demonstrated microspheres within tumor vessels and extensive ischemic necrosis with minimal residual viable tumor.

One patient developed tongue mucosal necrosis, managed conservatively. No major complications were observed.

CONCLUSIONS

Preoperative transarterial embolization using spherical embolic microspheres appears to be a safe and feasible adjunctive procedure prior to TORS in early-stage, clinically node-negative oropharyngeal cancer. This approach enables effective vascular control while preserving the minimally invasive benefits of TORS and avoiding external cervical incisions. Preoperative embolization may represent a valuable alternative to prophylactic arterial ligation in carefully selected patients.

PP-207

Radiation-Induced Malignant Transformation? A Case Of PAX3-MAML3 Positive Biphenotypic Sinonasal Sarcoma

CANER TONKAZ[1], **BEHLÜL TUNCER**[1], **ELVİN HUMBATLI**[1], **HARUN CANSIZ**[1], **NİL ÇOMUNOĞLU**[1], **YETKİN ZEKİ YILMAZ**[1]

[1]*İSTANBUL UNIVERCITY, CERRAHPAŞA MEDICINE FACULTY*

BACKGROUND & AIM

Biphenotypic sinonasal sarcoma (BSNS) is a rare, low-grade, locally aggressive neoplasm defined by dual neural and myogenic differentiation, typically harboring a PAX3 gene rearrangement. Because it was only recognized as a distinct entity in 2012, historical cases were frequently misdiagnosed as hemangiopericytomas or fibrosarcomas. Furthermore, past radiotherapy to the head and neck can trigger secondary malignant mesenchymal tumors decades later. This report aims to describe a complex case of PAX3-MAML3 positive BSNS presenting 24 years after irradiated "hemangiopericytoma," highlighting the diagnostic pitfalls of morphological overlap and the potential role of radiation-induced malignant transformation.

MATERIAL & METHODS

We present the clinical course of a 65-year-old male who presented in December 2024 with progressive nasal obstruction and epistaxis. The patient had a history of a sinonasal "hemangiopericytoma" treated with excision and 33 sessions of adjuvant radiotherapy in 2000. A recent external punch biopsy reiterated the hemangiopericytoma diagnosis. Preoperative magnetic resonance imaging (MRI) revealed a highly vascular destructive mass filling the right nasal cavity and extending into the inferomedial orbit. Following a multidisciplinary tumor board evaluation, the patient underwent Functional Endoscopic Sinus Surgery (FESS) for mass excision in April 2025. Postoperative tissue analysis included routine histopathology and Next-Generation Sequencing (NGS). Following a rapid orbital recurrence detected on a follow-up MRI in February 2026, a revision endoscopic excision was performed in April 2026.

RESULTS

Initial histopathology of the April 2025 excision demonstrated a low-grade spindle cell malignant mesenchymal tumor with a hemangiopericytomatous vascular pattern, mimicking the historical diagnosis. However, comprehensive molecular testing via NGS revealed a PAX3-MAML3 fusion, definitively diagnosing Biphenotypic Sinonasal Sarcoma. Despite the "low-grade" classification, the tumor exhibited aggressive local behavior. Ten months postoperatively, imaging revealed a 27x15x15 mm lobulated recurrence at the right medial orbital wall, indenting the rectus muscles. The tumor board hypothesized a radiation-induced malignant transformation, considering the 24-year latency and previous radiotherapy. The patient underwent successful revision endoscopic excision, with 24-hour postoperative imaging confirming no macroscopic residual tumor. The case underscores the misleading nature of morphological overlap in sinonasal spindle cell lesions.

CONCLUSIONS

Molecular diagnostics, specifically PAX3 fusion analysis via NGS, are mandatory for accurate classification of sinonasal spindle cell lesions historically termed "hemangiopericytoma." Clinicians must maintain a high index of suspicion for radiation-induced sarcomatogenesis in patients with a distant history of head and neck radiotherapy. Due to BSNS's locally destructive behavior and high recurrence rate near the skull base and orbit, rigorous, long-term postoperative radiological surveillance is critical. This case illustrates the absolute necessity of re-evaluating historical diagnoses with modern molecular tools.

Atypical Locations Of Retropharyngeal Abscess

Ata Alperen Ersahan[1], **Simge Turkan**[1], **Fatih Mutlu**[1], **Murat Kahveci**[1], **Bekir Cem Ozcan**[1], **Murat Ozturk**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, Kocaeli University, Kocaeli, Türkiye*

BACKGROUND & AIM

Retropharyngeal space lesions may present similarly but require different management depending on lesion size, symptoms, airway risk, radiological extension, and response to treatment[2,4].Radiological evaluation is essential for confirming the lesion and determining its extension. Clinically stable patients without airway compromise may initially be treated with intravenous antibiotics, whereas surgical drainage should be considered in cases of airway compromise, systemic toxicity, large abscesses, progressive symptoms, or lack of improvement after 24–48 hours of medical therapy[1,3]. This case series presents three retropharyngeal space lesions managed with different treatment approaches and highlights the importance of individualized clinical and radiological decision-making.

MATERIAL & METHODS

Three patients with retropharyngeal space abscesses were included in this case series. Restricted oral intake and limitation of neck movements were common presenting complaints in all three cases. In the adult patient, right parapharyngeal bulging and leftward deviation of the epiglottis were observed. Airway examination was unremarkable in the two pediatric cases.Inflammatory response was evident in all cases, with elevated C-reactive protein levels, leukocytosis, and neutrophil predominance. Contrast-enhanced radiological evaluation revealed retropharyngeal abscesses smaller than 2 cm in both children. The third patient was an adult with a larger retropharyngeal abscess. Pediatric patients with abscesses smaller than 2 cm were considered for close clinical observation and medical treatment, whereas the adult patient with a larger collection was evaluated for surgical intervention. In one pediatric case, the collection extended inferiorly toward the thyroid lodge.

RESULTS

Management was individualized according to age, clinical stability, airway risk, abscess size, radiological extent, and response to initial intravenous antibiotic therapy. All three patients received intravenous antibiotic therapy as the initial treatment. One pediatric patient was treated with intravenous antibiotics alone, whereas the pediatric case with thyroid lodge extension was initially managed medically because the abscess was smaller than 2 cm; however, transcutaneous ultrasound-guided fine-needle aspiration was performed due to lack of clinical and laboratory improvement after 48 hours. The adult patient with a larger abscess underwent direct surgical intervention. At the 4-week follow-up, complete clinical recovery was observed in all three cases, with resolution of symptoms and normalization of inflammatory markers and radiological findings.

CONCLUSIONS

Management of retropharyngeal abscesses should be individualized according to abscess size, clinical stability, airway risk, radiological extension, and response to antibiotic therapy. [3,4] In this series, different treatment strategies, including medical treatment, image-guided aspiration, and surgical intervention, resulted in favorable outcomes. Careful clinical and radiological follow-up is essential to confirm resolution and prevent complications.

PP-209

Segmental Resection And Prophylactic Plate Fixation For Mandibular Giant Cell Tumor: A Rare Case Report

Dr. Methiye Ceren SÖNMEZ[1], **Dr. Raşit HOŞGEL**[1], **Dr. Yekta SOYYİĞİT**[1], **Prof. Dr. Enver ALTAŞ**[1]

[1]*Amasya University Faculty of Medicine, Sabuncuoğlu Şerefeddin Training and Research Hospital*

BACKGROUND & AIM

Giant cell tumors of bone are uncommon, locally aggressive lesions that rarely involve the craniofacial skeleton. Mandibular involvement is particularly rare and may present with nonspecific symptoms such as pain, swelling, or fullness, which can lead to diagnostic difficulty. Moreover, radiological bone erosion and increased fluorodeoxyglucose uptake on positron emission tomography may mimic malignancy. We present this rare case to highlight the diagnostic challenges and surgical management of a mandibular giant cell tumor treated with segmental resection and prophylactic plate fixation.

MATERIAL & METHODS

A 61-year-old female patient presented with a five-year history of pain and fullness in the left lower jaw. Clinical examination revealed a tumoral lesion in the left mandibular second premolar region extending toward the mandibular bone. A previous biopsy was reported as giant cell granuloma. Positron emission tomography showed increased fluorodeoxyglucose uptake suspicious for malignancy. Panoramic radiography and maxillofacial computed tomography demonstrated mandibular bone erosion. The patient underwent segmental mandibular resection with prophylactic plate and screw fixation under general anesthesia.

RESULTS

Segmental resection of the left mandible, including the involved second premolar tooth, was carried out with approximately 1 cm surgical margins. The mandibular corpus was stabilized using prophylactic plate and screw fixation. No intraoperative or postoperative complications occurred. The patient was discharged on the second postoperative day with dietary recommendations and wound care follow-up. Histopathological examination confirmed the diagnosis of giant cell tumor of bone. The patient was fed with a straw for two months postoperatively, and solid foods were started at the end of the second month.

CONCLUSIONS

Mandibular giant cell tumors are rare lesions that may present with nonspecific symptoms and mimic malignancy due to bone erosion and increased fluorodeoxyglucose uptake on positron emission tomography. This case emphasizes the importance of careful clinical evaluation, appropriate imaging, and histopathological confirmation in the differential diagnosis of mandibular masses. In selected cases with bone involvement, segmental mandibular resection combined with prophylactic plate and screw fixation may provide safe surgical management and structural support. Early recognition and individualized surgical planning are essential to reduce complications, preserve mandibular stability, and improve postoperative functional recovery.

Giant cell tumor of bone, Segmental mandibular resection, Prophylactic plate fixation

PP-210

Transoral Laser Subtotal Thyroidectomy For Symptomatic Lingual Thyroid As The Only Functioning Thyroid Tissue: A Case Report

Muhammet Fatih Gökmen[1], **Özgür Demir**[1]

[1]*The Department of Otolaryngology and Head and Neck Surgery at Selçuk University Faculty of Medicine Hospital, Konya, Turkey*

BACKGROUND & AIM

Lingual thyroid is a rare form of ectopic thyroid tissue caused by failure of normal thyroid descent during embryologic development. Although many patients remain asymptomatic, progressive enlargement of the ectopic tissue may lead to dysphagia, dysphonia, foreign body sensation, bleeding, or upper airway obstruction. Management is particularly challenging when thyroid scintigraphy demonstrates that the lingual thyroid represents the only functioning thyroid tissue. In selected symptomatic patients, transoral laser surgery (TLS) may offer a minimally invasive surgical alternative with favorable functional outcomes.

MATERIAL & METHODS

We present a patient with a lingual thyroid who developed progressive dysphagia due to enlargement of ectopic thyroid tissue located at the tongue base. Clinical and endoscopic evaluation revealed a mass lesion in the lingual region. Thyroid scintigraphy demonstrated radiotracer uptake only in the lingual area, with no evidence of functioning orthotopic thyroid tissue in the cervical region. Because of the patient's persistent obstructive symptoms, surgical treatment was planned. The patient underwent TLS with subtotal resection of the lingual thyroid tissue. Subtotal resection was preferred to relieve dysphagia while avoiding complete removal of the only functioning thyroid tissue.

RESULTS

TLS enabled adequate reduction of the tongue-base mass through a transoral, minimally invasive approach without the need for an external cervical incision. The use of laser allowed precise tissue dissection with improved intraoperative visualization and effective hemostasis. These properties may help reduce surgical trauma, postoperative edema, pain, and bleeding risk. The patient's dysphagia improved postoperatively, and no major perioperative and postoperative complications such as significant hemorrhage, airway compromise, or aspiration were observed. Postoperative follow-up included endoscopic assessment and thyroid function monitoring.

CONCLUSIONS

Symptomatic lingual thyroid with absent orthotopic thyroid tissue is an uncommon clinical entity requiring individualized treatment planning. TLS may be an effective and tissue-sparing surgical option for selected patients with dysphagia caused by enlargement of lingual thyroid tissue. By providing precise excision, good hemostatic control, and reduced surgical morbidity, TLS can relieve obstructive symptoms while preserving the functional importance of residual ectopic thyroid tissue.

PP-211

Nasopharyngeal Lymphoma: A Rare Case Presenting With Cervical Lymphadenopathy

Mustafa Eser[1], **Bilge Nur Küçükakça**[2]

[1]*Sultan Abdülhamid Han Training and Research Hospital, Ear, Nose and Throat Diseases, Istanbul, Turkiye;* [2]*Sancaktepe Ilhan Varank Training and Research Hospital, Ear, Nose and Throat Diseases, Istanbul, Turkiye*

BACKGROUND & AIM

Primary involvement of the nasopharynx by Hodgkin lymphoma has been reported quite rarely in the medical literature. This report presents a rare case presenting with cervical lymphadenopathy and nasal congestion, diagnosed with classical Hodgkin lymphoma, highlighting the significance of early diagnosis during head and neck examination.

MATERIAL & METHODS

CASE REPORT: A 24-year-old male presented with a five-day history of nasal congestion and a swelling on the left side of his neck. Physical examination revealed a 4 cm, painless, palpable mass in the left cervical chain. Endoscopic evaluation showed nasopharyngeal fullness, leading to multiple punch biopsies.

Neck ultrasonography demonstrated bilateral cervical lymphadenopathy (Levels 2-3), with the largest measuring 42x26 mm and exhibiting obliterated fatty hila. Immunohistochemical analysis revealed that the atypical large cells were positive for CD30, CD15, and PAX5, while negative for CD20, CD3, CD45, and EBV. Based on these findings, the patient was diagnosed with Classic Hodgkin Lymphoma (CHL), mixed-cellularity subtype.

PET/CT imaging confirmed hypermetabolic involvement in the nasopharynx, bilateral cervical, and supraclavicular regions. The patient was referred to the hematology-oncology department, where a chemotherapy protocol consisting of bleomycin, vinblastine, doxorubicin, and dacarbazine (ABVD), supplemented with filgrastim, was initiated.

RESULTS

In young adult patients presenting with cervical lymphadenopathy, nasopharyngeal lymphomas should be considered in the differential diagnosis, and endoscopic nasopharyngeal examination should be performed. A comprehensive head and neck examination is indispensable for early diagnosis and accurate treatment of otorhinolaryngological malignancies.

CONCLUSIONS

Classic Hodgkin lymphoma (cHL) is a malignancy that typically involves cervical, mediastinal, and axillary lymph nodes, with rare extranodal involvement (1). The nasopharynx is a rather atypical location in this context and has been described in only a limited number of cases in the literature (2). This anatomical region can present with non-specific symptoms, particularly nasal obstruction, epistaxis, or otalgia. Therefore, lymphomas of nasopharyngeal origin are often mistakenly confused with chronic rhinosinusitis or nasopharyngeal masses. Immunohistochemistry plays a critical role in diagnosis (3).

Clinical Features And Outcomes Of Head And Neck MALT Lymphoma: Single-Center Experience And Literature Review

Sara Fernández Cascón[1], **Elena Balduz Moreno**[1], **Ana Martín González**[1], **Carmen Manzanares Lopez-Rendo**[1], **Lucía Clement Alonso**[1], **Claudia Llorente Alvarez**[1], **Silvia Gancedo Fernandez**[1], **Samuel Saez Alvarez**[2]

[1]*Complejo Asistencial Universitario de León, ENT Department;* [2]*Complejo Asistencial Universitario de León, Anatomic Pathology Department*

BACKGROUND & AIM

Extranodal marginal zone B-cell lymphoma of mucosa-associated lymphoid tissue (MALT) is an uncommon indolent lymphoma frequently involving salivary and ocular adnexal structures in head and neck region. Previous series have highlighted the association between autoimmune diseases, localized presentation, and favorable long-term survival. We reviewed our institutional experience and compared our findings with literature

MATERIAL & METHODS

A retrospective descriptive review was performed in 11 patients diagnosed with head and neck MALT lymphoma at our center between January 2024 and January 2026. Clinical variables included age, sex, autoimmune background, disease localization, treatment strategy, and clinical evolution. These findings were integrated with published evidence regarding prognostic factors, treatment response, and progression-free survival.

RESULTS

Median age at diagnosis was 71 years (range 48–88), with female predominance (64%). Autoimmune diseases were identified in 45% of patients, including Sjögren syndrome, autoimmune thyroiditis, psoriasis, hyperthyroidism, and inflammatory arthritis. The most frequent sites were ocular adnexa, cervical lymph nodes, and major salivary glands. Most patients presented with localized indolent disease, whereas one patient developed disseminated stage IV disease with subsequent transformation into diffuse large B-cell lymphoma. Treatment strategies included rituximab-based therapy (36%), local radiotherapy (27%), surgery (18%), active surveillance (18%), R-CHOP immunochemotherapy (9%), and autologous stem-cell transplantation (9%). Most patients achieved complete or major clinical response. However, unfavorable evolution was observed in 18% of cases, including progression to additional anatomical sites and histologic transformation into aggressive lymphoma. One additional patient achieved only partial response after rituximab monotherapy, requiring a change in therapeutic strategy.

CONCLUSIONS

Our experience confirms the indolent nature and favorable prognosis of head and neck MALT lymphoma, particularly in localized disease. Autoimmune disorders were frequent, supporting their pathogenic role in chronic lymphoid stimulation. Consistent with published literature, radiotherapy and rituximab-based strategies achieved durable disease control, whereas advanced-stage disease was associated with a higher risk of progression and histologic transformation. Long-term follow-up remains essential because late relapses and dissemination may occur despite initial response.

Renal Cell Carcinoma With Metastasis To Supraclavicular Lymph Node

Abdulamjeed Alahmari[1]

[1]*Prince Sultan Military Medical City, Riyadh*

BACKGROUND & AIM

Pleomorphic adenoma, commonly referred to as a benign mixed tumor, is the most prevalent neoplasm of the salivary glands, particularly affecting the parotid gland. This case report details a unique instance of recurrent pleomorphic adenoma in a 41-year-old female patient, highlighting the complexities of its management. The patient presented with a left submandibular swelling that recurred three years after an initial surgical excision. Comprehensive pathological evaluation confirmed the diagnosis of recurrent pleomorphic adenoma, with the identification of a satellite tumor nodule raising the possibility of benign metastasizing pleomorphic adenoma (BMPA).

MATERIAL & METHODS

This case underscores the critical importance of achieving complete surgical excision during initial treatment to minimize recurrence rates and emphasizes the necessity of vigilant postoperative monitoring. The findings advocate for a collaborative approach among healthcare providers and stress the need for ongoing research to refine surgical techniques and better understand the biological behavior of pleomorphic adenomas.

RESULTS

Pleomorphic adenoma, commonly referred to as a benign mixed tumor, is the most prevalent type of salivary gland neoplasm, accounting for approximately 60-80% of all salivary gland tumors (1). This tumor is characterized by a mixture of epithelial and mesenchymal components, exhibiting a diverse histological appearance. While pleomorphic adenomas are primarily found in the parotid gland, they can also occur in the submandibular and minor salivary glands. The incidence of pleomorphic adenoma varies globally, with a higher prevalence observed in females and individuals aged between 30 and 60 years (2).

CONCLUSIONS

This case report illustrates the complexities involved in the management of recurrent pleomorphic adenoma of the salivary gland, particularly in a 41-year-old female patient who experienced a recurrence despite undergoing complete surgical excision. The identification of a satellite tumor nodule adjacent to a lymph node raises important considerations regarding the behavior of pleomorphic adenomas and the potential for benign metastasizing pleomorphic adenoma (BMPA). This highlights the necessity for thorough surgical approaches and vigilant follow-up to mitigate the risk of recurrence and potential complications.

Necrotizing Fasciitis Of The Head And Neck: A Case Report

Prof Dr Münir Demirci[1]

[1]*Prof Dr Münir Demirci*

BACKGROUND & AIM

Necrotizing fasciitis (NF) of the head and neck is a rare, life-threatening deep space infection accounting for fewer than 20% of all NF cases, with mortality rates of 20–40%. It spreads rapidly along fascial planes and may initially mimic odontogenic infection or cellulitis, leading to critical diagnostic delay. Early clinical suspicion and prompt surgical intervention are the primary determinants of survival. We present a case of cervicofacial NF managed successfully with serial debridements, split-thickness skin grafting, and multidisciplinary intensive care, highlighting the importance of early diagnosis and aggressive surgical management.

MATERIAL & METHODS

A 47-year-old male was admitted with a five-day history of jaw and throat pain. Clinical examination, bedside aspiration, and contrast-enhanced CT were performed. Serial inflammatory markers (CRP, procalcitonin, WBC, albumin) were monitored throughout. Surgical management consisted of emergency exploration, serial debridements under general anaesthesia via

nasotracheal intubation, and wound irrigation with antiseptic solutions. Reconstruction was achieved with split-thickness skin grafts harvested from the right thigh, secured with 5-0 Prolene, and covered with VAC dressing. Broad-spectrum intravenous antibiotics and multidisciplinary intensive care support were maintained throughout hospitalisation.

RESULTS

Serial debridements successfully cleared necrotic tissue until viable wound margins were established. Inflammatory markers declined markedly: CRP from 287 to 8 mg/L, procalcitonin from 4.8 to 0.05 ng/mL, and WBC from 18.4 to 7.8 $\times 10^3/\mu L$. Serum albumin recovered from 2.8 to 3.9 g/dL. Split-thickness skin grafting resulted in successful graft take without donor site complication. No mediastinal extension, tracheotomy requirement, or mortality occurred. The patient was discharged in stable condition with satisfactory functional and aesthetic outcome following multidisciplinary management.

CONCLUSIONS

Cervicofacial NF requires immediate recognition and urgent surgical management. In this case, early clinical suspicion, prompt CT imaging, serial debridements, broad-spectrum antibiotics, and reconstructive skin grafting resulted in a favourable outcome without mortality. Progressive normalisation of inflammatory markers confirmed effective infection control. This case reinforces that surgical intervention must never be delayed when necrotizing infection is clinically suspected.

Similar Presentation, Distinct Pathologies: A Case Series Of Three Malignant Deep Lobe Parotid Tumors

Dr.Zeynep Tekeli Akduman[1], **Prof.Dr.Hamdi Arbağ**[1], **Dr.Öğr.Rukiye Özçelik Erdem**[1]

[1]*Necmettin Erbakan University Faculty of Medicine, Department of Otorhinolaryngology, Konya, Türkiye*

BACKGROUND & AIM

Deep lobe parotid tumors represent a diagnostic challenge due to their anatomical location and heterogeneous pathology. Although clinical findings and radiological imaging often raise suspicion of malignancy, the histopathological nature of these tumors cannot always be accurately predicted. Malignant lesions in the parotid region may arise from primary salivary gland tumors or occur as metastasis or direct infiltration of cutaneous malignancies originating from the head and neck region. The aim of this study was to present three patients with parotid masses showing similar clinical features but different histopathological diagnoses.

MATERIAL & METHODS

Three patients who presented with parotid gland masses and underwent surgical treatment at our clinic were retrospectively evaluated. Clinical findings, radiological imaging results, biopsy findings, surgical procedures, and postoperative histopathological outcomes were reviewed.

RESULTS

The first patient was a 57-year-old presenting with a long-standing swelling in the preauricular region. Physical examination revealed a 10×5 cm mass. MRI demonstrated a 9 × 5 cm lesion in the deep lobe of the parotid gland. Biopsy confirmed squamous cell carcinoma (SCC).The patient underwent tumor excision, deep lobe parotidectomy,neck dissection with reconstruction using an anterolateral thigh free flap. Histopathology showed SCC.

The second patient was a 73-year-old with a 20-year history of a preauricular mass and facial paralysis.Examination showed a 10×7 cm ulcerated lesion.Biopsy revealed basal cell carcinoma(BCC). The patient underwent parotidectomy and neck dissection followed by reconstruction with a supraclavicular flap. Histopathology confirmed BCC.

The third patient was a 52-year-old presenting with a rapidly enlarging parotid mass. MRI demonstrated lesion in the deep lobe of the parotid gland, a mass measuring 5.5 cm. Biopsy revealed malignant melanoma.The patient underwent parotidectomy and neck dissection, and histopathology confirmed malignant melanoma.

CONCLUSIONS

Deep lobe parotid tumors presenting with similar clinical and radiological features may harbor markedly different malignant pathologies. In addition to primary salivary gland tumors, malignancies arising from the cutaneous structures of the head and neck may involve the deep lobe of the parotid gland through metastasis or direct infiltration. Therefore, careful preoperative assessment combined with histopathological confirmation remains essential for establishing the correct diagnosis and guiding optimal surgical management.

Thyroglossal Duct Cyst Papillary Carcinoma Initially Evaluated As Ranula, With Synchronous Papillary Thyroid Microcarcinoma: Case Report

Buse GENÇ SAĞLAM[1], **Ömer Semih BUDAK**[1], **Felat TOPRAK**[1]

[1]*Dr. Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital*

BACKGROUND & AIM

Thyroglossal duct cyst (TGDC) is one of the most common congenital anomalies of the neck, whereas malignant transformation is extremely rare. The majority of TGDC carcinomas are papillary thyroid carcinomas. Since clinical and radiological findings frequently mimic benign cystic neck lesions, preoperative diagnosis may be challenging. Furthermore, the presence of synchronous thyroid malignancy and the optimal surgical management remain controversial. We aimed to present a rare case of TGDC carcinoma located in the submental region, initially interpreted as a ranula, accompanied by synchronous multifocal papillary thyroid microcarcinoma.

MATERIAL & METHODS

A 45-year-old male patient presented with swelling in the submental region. Ultrasonography and magnetic resonance imaging revealed a predominantly cystic lesion with septations and solid components, which was initially interpreted as a ranula. Fine-needle aspiration biopsy of the submental mass was reported as suspicious for malignancy (Milan category V). Surgical excision was subsequently performed. Intraoperatively, the mass was found extending between the mylohyoid muscle fibers and adjacent to the hyoid bone. Histopathological examination revealed papillary thyroid carcinoma, and one metastatic lymph node was identified within the specimen. Reevaluation by the pathology department suggested that the lesion might have originated from a thyroglossal duct cyst. Subsequent thyroid ultrasonography demonstrated multiple TIRADS-5 nodules, and total thyroidectomy was performed following a multidisciplinary endocrine surgery council decision.

RESULTS

Histopathological examination of the total thyroidectomy specimen demonstrated multifocal papillary thyroid microcarcinoma in two separate foci measuring 0.8 cm and 0.2 cm in the right thyroid lobe. No extrathyroidal extension was identified. Based on the clinical, radiological, intraoperative, and histopathological findings, the case was interpreted as papillary thyroid carcinoma arising from a thyroglossal duct cyst accompanied by synchronous multifocal papillary thyroid microcarcinoma.

CONCLUSIONS

Malignancy should be considered in complex cystic submental lesions encountered in adults. TGDC carcinomas may mimic benign cystic neck lesions and can be difficult to distinguish from metastatic cystic lymph nodes. Comprehensive evaluation of clinical, radiological, intraoperative, and histopathological findings is essential for accurate diagnosis. In selected patients with a risk of synchronous thyroid malignancy, total thyroidectomy should be considered during surgical treatment planning.

PP-217

EBV Positivity In Nasopharyngeal Carcinoma: A Single-Center Analysis Of Histopathological Subtypes (Preliminary Results)

Nazlım Hilal Taraf[1], **Metehan Aktepe**[1], **Ebru Karakaya Gojayev**[1]

[1]*Ankara Etlik City Hospital, Otorhinolaryngology Head and Neck Surgery Department*

BACKGROUND & AIM

Nasopharyngeal carcinoma (NPC) is a distinct head and neck malignancy characterized by marked geographic variation and a strong association with Epstein–Barr virus (EBV) infection. Among its histopathological subtypes, nonkeratinizing carcinoma is strongly associated with EBV, particularly in endemic and intermediate-incidence regions such as Türkiye, whereas keratinizing squamous cell carcinoma demonstrates a weaker viral association and may exhibit distinct biological behavior. Understanding this relationship is essential for accurate prognostic stratification and informed therapeutic decision-making. This study aimed to evaluate the distribution of histopathological subtypes in a single-center NPC cohort and to investigate their association with EBV positivity.

MATERIAL & METHODS

This retrospective study included 20 patients with histopathologically confirmed nasopharyngeal carcinoma diagnosed at the Department of Otorhinolaryngology of a single tertiary care center between March 2023 and December 2025. Patients presenting with nasopharyngeal fullness or mucosal irregularities underwent contrast-enhanced MRI followed by punch biopsy. Histopathological subtype was classified as nonkeratinizing or keratinizing per WHO criteria. EBV status was determined using Epstein–Barr virus-encoded RNA (EBER) in situ hybridization on formalin-fixed, paraffin-embedded specimens; nuclear EBER staining was defined as EBV-positive. Age, gender, histopathological subtype, and EBV status were recorded. Fisher's Exact Test and Mann–Whitney U test were applied for statistical analyses using IBM SPSS v25.0. Given the

small and unbalanced subgroup distribution, findings were interpreted descriptively. The study was approved by the Institutional Ethics Committee (No: AEŞH-BADEK1-2025-168) and conducted per the Declaration of Helsinki.

RESULTS

Twenty patients were included; 15 male (75.0%) and 5 female (25.0%), with a mean age of 46.5 ± 17.2 years (range: 17–70; median: 52.5). Nonkeratinizing carcinoma was the predominant subtype (95.0%, n=19); only one patient (5.0%) had keratinizing carcinoma. EBV positivity was detected in 90.0% of patients (n=18). Among nonkeratinizing cases, 94.7% (18/19) were EBV positive and 1 (5.3%) was EBV negative. The only keratinizing case was EBV negative. No statistically significant association was observed between EBV status and histopathological subtype (p=0.100), gender (p=1.000), or age (EBV-positive: 44.9 ± 17.1 years vs. EBV-negative: 61.0 ± 12.7 years; p=0.284). All analyses are severely underpowered due to the limited number of EBV-negative and keratinizing cases and should be interpreted as descriptive rather than inferential.

CONCLUSIONS

Nonkeratinizing carcinoma constituted the vast majority of cases and demonstrated a high rate of EBV positivity, consistent with Turkish and international literature. The demographic and histological profile of our cohort closely mirrors previously published Turkish series, supporting the external validity of our findings despite the limited sample size. The absence of EBV positivity in the single keratinizing case supports a distinct etiopathogenetic pathway for this variant. These findings are preliminary and hypothesis-generating; larger prospective multicenter studies with balanced histopathological representation are needed to validate these associations and clarify the prognostic implications of EBV status in NPC.

Auricular Basosquamous Carcinoma With Temporal Bone Invasion: Total Auriculectomy And Reconstruction

ESRA ALTUNAL[1], **İPEK YEŞİL**[1], **EMRE CAN ÖZÇELİK**[1], **SEMA ERSOY**[1], **OZAN TÜYSÜZ**[1], **ŞAHİN ÖĞREDEN**[1], **ÖZGÜR YİĞİT**[1]

[1]*Department of Otorhinolaryngology – Head and Neck Surgery, İstanbul Başakşehir Çam and Sakura City Hospital, Istanbul, Türkiye*

BACKGROUND & AIM

Basosquamous carcinoma (BSC) is a rare non-melanoma skin cancer with histological features of both basal cell carcinoma and squamous cell carcinoma. It is recognized as more aggressive than conventional basal cell carcinoma because of its higher risk of local recurrence, deeper tissue invasion, and metastatic potential. Although the auricle is a frequent site for sun-related cutaneous malignancies, advanced cases with temporal bone extension are uncommon. This case report aims to describe the clinical presentation, radiological findings, and surgical management of advanced auricular basosquamous carcinoma with temporal bone invasion, with particular emphasis on total auriculectomy and immediate reconstruction.

MATERIAL & METHODS

We retrospectively evaluated the clinical presentation, radiological findings, histopathological diagnosis, surgical treatment, and reconstructive management of a patient with advanced auricular BSC.

RESULTS

An 86-year-old woman presented with a long-standing, progressively enlarging lesion involving the left auricle. Examination demonstrated an approximately 9 cm ulcerated mass causing total auricular destruction with extension into the preauricular soft tissues. Incisional biopsy confirmed basosquamous carcinoma. Radiological evaluation revealed a contrast-enhancing preauricular lesion without evidence of distant disease. The patient underwent wide oncologic resection, including total auriculectomy. Intraoperatively, tumor invasion of the mastoid cortex was identified, and cortical mastoidectomy with exposure of the mastoid antrum was performed. Despite the extent of disease, the main trunk and peripheral branches of the facial nerve were carefully identified and preserved. Superficial parotidectomy and supraomohyoid neck dissection were added because of advanced local extension and the need for regional control. The resulting composite defect was reconstructed during the same session using a pectoralis major myocutaneous flap.

CONCLUSIONS

Basosquamous carcinoma may cause extensive local destruction when diagnosis is delayed. Advanced auricular lesions can invade adjacent temporal bone structures and require aggressive resection with complex reconstruction. Facial nerve preservation may still be achievable in selected patients with careful surgical planning. Early diagnosis and timely surgical management are important to minimize morbidity.

BACKGROUND & AIM

Purpose: This study aimed to evaluate the diagnostic accuracy of PET/MRI compared head-to-head to MRI, CT, and PET/CT in detecting lymph node metastases in head and neck squamous cell cancer (HNSCC).

MATERIAL & METHODS

Methods: A prospective diagnostic study was conducted, with the sample size determined based on the comparison between PET/MRI and MRI. Patients were recruited from a head and neck cancer center in Denmark. Only patients with histologically confirmed HNSCC who underwent neck dissection were included in the analysis. Blinded assessors evaluated imaging for lymph node metastases by neck level, and histology served as the reference standard. Diagnostic parameters were calculated for each imaging modality per neck level and per patient. McNemar's test was employed for intermodality comparisons.

RESULTS

Results: A total of 94 neck levels from 27 patients were included in the study. The majority of patients were male (56%), with a median age of 69 years (range: 45-90). The primary tumor was predominantly located in the oral cavity (67%), followed by the oropharynx (22%). Lymph node metastases were histologically verified in 27 neck levels from 19 patients. PET/MRI had a sensitivity of 65.2% and a specificity of 77.5% in per-level analysis, with corresponding values of 89.5% and 50.0% in per-patient analysis. There was no statistically significant difference in diagnostic performance between PET/MRI and other modalities ($p > 0.05$).

CONCLUSIONS

Conclusion: Overall, PET/MRI demonstrates similar diagnostic performance for lymph node metastases in HNSCC when compared to PET/CT, MRI, and CT. The choice of imaging modality should be based on individual assessment.

Nodular Melanoma Of The Nasal Ala: A Case Report On Surgical Decision-Making In Regional Lymph Node Management And Reconstruction

Fatma Demirkol[1], **Ahmet Yeşiltepe**[1], **Şahin Öğreden**[1]

[1]Department of Otorhinolaryngology & Head and Neck Surgery, Başakşehir Çam and Sakura City Hospital, Istanbul, Türkiye

BACKGROUND & AIM

Head and neck melanomas represent a distinct subgroup with more aggressive behavior and poorer prognosis, largely due to complex lymphatic drainage and delayed diagnosis. The nasal ala is a rare and anatomically challenging subunit where achieving oncologic safety while preserving function and aesthetics is difficult.

Nodular melanoma, in particular, carries a worse prognosis because of its rapid vertical growth and higher metastatic potential at diagnosis. Therefore, early surgical excision with adequate margins remains the cornerstone of management, requiring a careful balance between complete tumor removal and optimal functional and aesthetic outcomes.

MATERIAL & METHODS

A 55-year-old male presented with a progressively enlarging pigmented lesion on the right nasal ala over four months, without pain, ulceration, or bleeding. Clinical examination revealed a nodular, irregularly bordered, darkly pigmented mass confined to the cutaneous surface, with no palpable cervical lymphadenopathy.

PET imaging showed a hypermetabolic lesion consistent with malignant melanoma, along with low-grade FDG uptake in right superior jugular lymph nodes, considered suspicious due to their location within the lymphatic drainage pathway.

The patient underwent wide local excision with safe margins, followed by reconstruction using a local rotation flap to preserve nasal contour and function. Due to radiological suspicion, a concurrent right supraomohyoid neck dissection was performed.

Histopathology confirmed nodular melanoma with clear margins and no nodal metastasis. The postoperative course was uneventful, and adjuvant radiotherapy was administered. Follow-up demonstrated satisfactory healing, preserved nasal symmetry, and no evidence of recurrence or metastasis.

RESULTS

Management of the clinically node-negative neck in head and neck melanoma remains controversial. Sentinel lymph node biopsy is the standard staging method, but suspicious imaging findings, even with low FDG uptake, may justify more aggressive treatment.

In the present case, although histopathology showed no nodal metastasis, supraomohyoid neck dissection was performed due to lymphatic drainage patterns and radiological suspicion. This highlights the limitations of imaging in detecting occult metastasis and emphasizes individualized surgical planning.

Reconstruction of nasal alar defects is also a key aspect of management. Local rotation flaps offer reliable vascularity, good color and texture match, and preservation of nasal contour. Depending on defect characteristics, bilobed or nasolabial flaps may also be used.

The role of adjuvant radiotherapy in melanoma remains controversial, but it may improve local control in selected high-risk patients, particularly in head and neck cases.

CONCLUSIONS

Cutaneous melanoma is an aggressive malignancy of melanocytes with increasing global incidence. Head and neck melanomas account for 15–20% of cases and have worse survival, largely due to complex lymphatic drainage and delayed diagnosis. The nasal ala is a unique facial subunit with a complex three-dimensional structure and a critical role in the external nasal valve, making oncologic clearance and reconstruction challenging. Management of nasal ala melanoma requires a multidisciplinary, individualized approach. Careful assessment of regional nodes, even with low metabolic activity, is essential for treatment planning. Combined resection, lymph node management, and tailored reconstruction are required for optimal outcomes.

nasal ala, melanoma, neck dissection, nodular melanoma

PP-221

Hodgkin Lymphoma Presenting As A Mass Extending From The Tongue Base To The Vallecula: A Case Report Of An Extremely Rare Location

Utku Erdi Semiz[1], **Sema Zer Toros**[1], **Berşah Sırmacı**[1]

[1]*Haydarpaşa Numune Training and Research Hospital*

BACKGROUND & AIM

Hodgkin Lymphoma (HL) rarely presents as a primary extranodal disease. Involvement of the oropharynx is extremely uncommon, and a primary mass

extending specifically from the tongue base to the vallecula is exceptionally rare. Such unusual presentations often lead to diagnostic confusion with more

common pathologies, such as Squamous Cell Carcinoma.

This case report describes a unique patient presentation of primary extranodal HL manifesting as a single tongue base/vallecula mass. We aim to highlight

this rare entity, discuss its diagnostic challenges, and emphasize the necessity of considering HL in the differential diagnosis of oropharyngeal masses.

MATERIAL & METHODS

A 63-year-old male patient presented with hoarseness. Physical examination revealed an ulcerated mass with indistinct margins on the right

lateral base of the tongue. The patient had a significant smoking history of 40 pack-years. Although the preliminary clinical and radiological impression

favored SCC, the biopsy obtained from the mass was reported as Classic Hodgkin Lymphoma. After the pathological diagnoses, the patient initiated

multidisciplinary treatment under hematologic oncology.

RESULTS

The patient was initiated treatment with the ABVD chemotherapy protocol under Hematology/Oncology. Following treatment completion,

the patient achieved a complete remission (cure) with no evidence of residual or recurrent disease.

CONCLUSIONS

Primary HL of the base of the tongue is a rare but crucial differential diagnosis in an area where SCC prevalence is high. Treatment should not

commence without definite histopathological diagnosis via biopsy, even in patients with heavy risk factor exposure. This case reminds Otolaryngology

clinicians to maintain a high index of suspicion for atypically located lymphomas.

PP-222

Misdiagnosis Of Adenoid Cystic Carcinoma As Pleomorphic Adenoma: A Case Report

Prof. Dr. Gökhan KURAN[1], **Dr. Mustafa ERDOĞAN**[1]

[1]*Karabük Training and Research Hospital*

BACKGROUND & AIM

Pleomorphic adenoma (PA) is the most common benign neoplasm of the parotid gland, while Adenoid Cystic Carcinoma (AdCC) is a rare malignant tumor known for its indolent growth, perineural invasion, and late distant metastasis.

We present a case of a patient initially diagnosed with PA on Tru-Cut Biopsy, who underwent superficial parotidectomy. However, the final excisional biopsy of the surgical specimen revealed Adenoid Cystic Carcinoma, necessitating a completion total parotidectomy with neck dissection.

MATERIAL & METHODS

A 70-year-old female presented with a 5 month history of a slowly enlarging, painless mass in the right parotid-masseteric region. She reported no facial weakness, pain, or sensory changes. Her past medical history was unremarkable.

A non-mobile, non-tender mass approximately 1,5x1 cm was palpated in the superficial lobe of the right parotid gland. No cervical lymphadenopathy was detected. Facial nerve function was intact (House-Brackmann Grade I).

Tru-Cut Biopsy was performed. The cytopathological report was consistent with Pleomorphic Adenoma. No atypical or malignant cells were reported.

Based on the benign Tru-Cut Biopsy result, the patient underwent a right superficial parotidectomy. The mass was macroscopically well-circumscribed and removed completely. The patient was discharged after an uneventful recovery.

The microscopic examination result was compatible with adenoid cystic carcinoma.

RESULTS

Multidisciplinary Decision and Second Surgery The unexpected malignant diagnosis was discussed at the multidisciplinary tumor board. Due to the aggressive nature of AdCC, the presence of perineural invasion, and the close surgical margin, a completion surgery was recommended.

Second Procedure: The patient underwent a right total parotidectomy with facial nerve preservation and an neck dissection.

CONCLUSIONS

Adenoid Cystic Carcinoma can be misdiagnosed as Pleomorphic Adenoma on Tru-Cut Biopsy. Surgeons must maintain a high index of suspicion and be prepared to perform completion surgery when final pathology reveals unexpected malignancy. Close collaboration between surgeons and pathologists is essential for optimal patient outcomes.

Diagnostic Utility Of Blood-Based Biomarkers CK-19 And Galectin-3 In Differentiating Malignant And Benign Thyroid Lesions

Risma Remsudeen[1,2,3]

[1]*Betsi Cadwaladr University Health Board, UK;* [2]*Wrexham Glyndwr University, UK;* [3]*NHS Wales, UK*

BACKGROUND & AIM

With the rising global incidence of thyroid cancer, accurate preoperative diagnosis remains a significant clinical challenge. Current diagnostic pathways rely heavily on fine-needle aspiration (FNA) biopsy, an invasive procedure that frequently yields indeterminate results, leading to unnecessary diagnostic surgeries. Circulating blood-based biomarkers have emerged as a potential minimally invasive adjunct to improve diagnostic accuracy, stratify patient risk, and reduce overall healthcare burdens. Consequently, this retrospective study aimed to critically evaluate the diagnostic utility of two such biomarkers (Cytokeratin-19 (CK-19) and Galectin-3) in reliably differentiating benign from malignant thyroid lesions, assessing their potential to serve as reliable, standalone non-invasive diagnostic tools.

MATERIAL & METHODS

This retrospective, blinded cohort study utilized archived pre-operative plasma samples from 33 adult patients (≥ 18 years) scheduled for thyroidectomy within the Betsi Cadwaladr University Health Board in the UK. Participants were classified into malignant (n=14) and benign (n=19) groups based on post-operative histopathological reference standards. Venepuncture was

performed pre-operatively using EDTA tubes to obtain plasma, which was processed via centrifugation at 2000× g and stored at -80°C.

Circulating concentrations of Cytokeratin-19 (CK-19) and Galectin-3 (Gal-3) were quantified using commercially available solid-phase sandwich enzyme-linked immunosorbent assay (ELISA) kits following manufacturer protocols. Absorbance was measured at 450 nm, and concentrations were interpolated from four-parameter logistic (4PL) standard curves. Statistical analysis was conducted using SPSS, employing Mann-Whitney U tests for non-parametric group comparisons and Receiver Operating Characteristic (ROC) curves to evaluate diagnostic performance

RESULTS

Following quality-control exclusions, CK-19 concentrations were quantifiable in 17 samples (10 benign, 7 malignant). Benign lesions demonstrated a higher mean CK-19 concentration (3.46 ng/mL) compared with malignant lesions (1.67 ng/mL). This difference approached but did not reach statistical significance (p=0.064). ROC analysis for CK-19 showed a high specificity of 90.0% but a very low sensitivity of 14.3%.

Galectin-3 concentrations were successfully quantified in 32 samples (19 benign, 13 malignant). Mean Gal-3 concentrations were 16.04 ng/mL in the benign group and 15.38 ng/mL in the malignant group. No statistically significant difference was observed between these diagnostic groups (p=0.863). ROC curve analysis for Gal-3 indicated poor discriminatory performance, with an area under the curve (AUC) of 0.482, a sensitivity of 46.2%, and a specificity of 63.2%.

CONCLUSIONS

While CK-19 and Galectin-3 are established markers in thyroid pathology, these findings demonstrate that their circulating plasma concentrations do not reliably distinguish malignant from benign thyroid lesions when used individually. Significant overlap between diagnostic groups and low sensitivity limit their current clinical utility as standalone non-invasive diagnostic tools. Methodological challenges, including limited release into circulation and assay detection constraints, highlight the difficulty of translating tissue-based overexpression into reliable blood-based diagnostics. Future research should prioritize multi-marker panels integrated with ultrasound-based risk stratification and molecular profiling.

Pediatric Rhabdomyosarcoma Located In The Temporal And Infratemporal Regions: A Case Report

Şahin Öğreden[1], **Tuğba Arlı**[1], **Eyüp Berk**[1], **Özgür Yiğit**[1]

[1]*Çam and Sakura City Hospital*

BACKGROUND & AIM

Rhabdomyosarcoma is a rare malignant mesenchymal tumor and one of the most common soft tissue sarcomas in children. In the head and neck region, it may present with variable findings depending on tumor location and extent. Temporal and infratemporal masses are particularly challenging because of their deep location, proximity to critical structures, and potential for regional spread. We aimed to present a pediatric case of rhabdomyosarcoma involving the temporal and infratemporal regions, focusing on its clinical presentation, radiological findings, pathological features, and multidisciplinary management.

MATERIAL & METHODS

A 15-year-old male patient presenting with swelling in the right temporal and preauricular region was evaluated retrospectively. Clinical findings, physical examination, endoscopic evaluation, radiological imaging, histopathological and immunohistochemical results, and PET-CT findings were reviewed from the medical records. The diagnostic process and multidisciplinary treatment planning were analyzed descriptively.

RESULTS

Physical examination revealed a firm, fixed mass measuring approximately 4 cm in the right temporal, temporomandibular, and masseteric region, together with a palpable right submandibular lymph node. Imaging studies demonstrated a heterogeneously enhancing mass centered in the right temporal and infratemporal region with extension into the masticator space, expansion of the posterior wall of the maxillary sinus, and remodeling/destruction of adjacent orbital and craniofacial bony structures. Cervical lymphadenopathy was also detected radiologically. Tru-cut biopsy of the facial mass and cervical lymph node showed a malignant mesenchymal tumor. Immunohistochemical analysis revealed positivity for desmin, MyoD1, myogenin, and vimentin, supporting the diagnosis of rhabdomyosarcoma. PET-CT demonstrated increased FDG uptake in the primary lesion and regional cervical lymph nodes, without evidence of distant metastasis. The patient was evaluated by a multidisciplinary tumor board, and systemic chemotherapy was planned as the initial treatment modality, with further management to be determined according to treatment response.

CONCLUSIONS

Rhabdomyosarcoma should be considered in the differential diagnosis of pediatric patients presenting with a deep temporal or infratemporal mass. Detailed radiological evaluation, histopathological confirmation, and multidisciplinary tumor board assessment are essential for accurate diagnosis and treatment planning. Early recognition of regional lymph node involvement and locally aggressive extension may facilitate timely oncologic management.

Methylation-Associated Loss Of KIF26B Expression In A Subgroup Of Oral Squamous Cell Carcinoma

Fulya Karayeğit Umut[1], **Seval Turna**[1], **Comert Sen**[2], **Vakur Olgac**[3], **Murat Ulusan**[2], **Semra Demokan***[4]

[1]*Istanbul University, Institute of Graduate Studies in Health Sciences, Istanbul, Türkiye;* [2]*Istanbul University, Istanbul Faculty of Medicine, Department of Otorhinolaryngology-Head and Neck Surgery, Istanbul, Türkiye.;* [3]*Istanbul University, Faculty of Dentistry, Department of Oral Pathology, Istanbul, Türkiye;* [4*]*Istanbul University, Oncology Institute, Department of Basic Oncology, Experimental and Molecular Oncology Division, Istanbul, Türkiye, e-mail: *

BACKGROUND & AIM

Oral squamous cell carcinoma (OSCC) is the most common subtype of oral cancer and remains a major public health concern due to late diagnosis and poor survival outcomes. Epigenetic alterations, particularly DNA methylation, play an important role in oral carcinogenesis. KIF26B was identified as a potential epigenetic biomarker candidate based on array data obtained from the TÜBİTAK-SBAG-114S497 project conducted by Demokan et al. This study aimed to investigate the biomarker potential of KIF26B in OSCC by evaluating promoter methylation status and gene expression levels in tumor tissues.

MATERIAL & METHODS

Tumor tissues and matched-adjacent normal tissues obtained from 25 OSCC patients were analyzed to evaluate the methylation and expression status of KIF26B. Gene expression levels were determined using quantitative real-time PCR, while methylation levels were assessed using quantitative methylation-specific PCR.

RESULTS

KIF26B promoter methylation was detected in 20% of OSCC tumor tissues, and decreased gene expression was observed in all methylated cases. Compared with matched-adjacent normal tissues, decreased KIF26B expression was identified in 48% of OSCC cases, whereas increased expression was detected in 16% of the cases. Furthermore, reduced KIF26B expression was more frequently observed in advanced-stage, poorly differentiated, and metastatic tumors.

CONCLUSIONS

These findings suggest that methylation-associated loss of KIF26B expression may characterize a subgroup of OSCC with aggressive biological behavior. However, larger cohort studies are required to validate these findings and clarify the clinical significance of KIF26B-associated epigenetic alterations in OSCC.

Selective Deep Lobe Parotidectomy In A Variety Of Indications: Neurinoma, Cyst, And Malignant Salivary Gland Tumour

Marija Pastorčić Grgić[1], **Marta Grgić**[1], **Irena Ivković**[1], **Andrijana Jović**[1], **Marin Štefančić**[1], **Rea Taradi**[1]

[1]*University Hospital Centre Zagreb*

BACKGROUND & AIM

Selective Deep Lobe Parotidectomy (SDLP) is a surgical technique described for benign salivary gland tumours located in the deep lobe of the parotid gland. Recurrence rates for benign salivary gland tumours after SDLP are low and comparable to total parotidectomy. Compared to total parotidectomy, this approach significantly reduces the risk of permanent facial nerve weakness and Frey's syndrome. By preserving the healthy superficial lobe, SDLP maintains facial contours and salivary function.

MATERIAL & METHODS

This case series evaluates the utility of SDLP in three patients with distinct tumour histologies. All patients presented with lesions under 2 cm and inconclusive preoperative diagnostic results.

RESULTS

Case Series:

- Patient 1: A 61-year-old female with left neck swelling. Ultrasound and MRI revealed a 14 mm solid-cystic lesion in the deep lobe of the parotid gland; FNAB was inconclusive. Following SDLP, histology confirmed the cyst to be benign.
- Patient 2: A 69-year-old male presenting with a 14 mm tumour in the left parotid gland. FNAB showed ductal atypia. SDLP was performed, and histology revealed a myoepithelial carcinoma.
- Patient 3: A 51-year-old female evaluated during follow-up after meningioma surgery, found to have an 11 mm tumour in the right parapharyngeal space. MRI suggested a pleomorphic adenoma. SDLP was performed, and histology confirmed a neurinoma.

At the 6-month postoperative follow-up, all patients remained recurrence-free with normal facial contours, normal facial nerve function and without Frey syndrome. Transient facial palsy occurred in one patient, resolving completely within 3 months, while the other two patients experienced transient palsy isolated to the mouth corner depressor muscle.

CONCLUSIONS

Although primarily indicated for benign salivary gland tumours, SDLP can be safely and effectively utilised in highly selected cases of small malignant salivary gland tumours and schwannomas.

Submandibular Gland Invasion And Risk Factors In Level 1 Neck Dissection: A Retrospective Clinical Analysis

senem çengel kurnaz[1], **ahmet orhan türker**[1], **kadir emre kılıç**[1]

[1]*Ondokuz Mayıs University Faculty of Medicine*

BACKGROUND & AIM

This study retrospectively evaluated the incidence of histopathological submandibular gland (SMG) invasion in patients undergoing level 1 neck dissection over a 5-year period. Secondary objectives included analyzing the impact of demographics (age, sex) and histopathological features (tumor size, depth of invasion, lymphatic, perineural, and vascular invasion) on parenchymal SMG involvement using logistic regression to identify independent risk factors. Ultimately, we aimed to provide objective risk criteria to guide surgical strategies, delineating which patient populations can safely benefit from SMG preservation versus those mandating routine excision.

MATERIAL & METHODS

This retrospective, single-center study reviewed patients undergoing level 1 neck dissection for primary head and neck squamous cell carcinoma (HNSCC) between January 2021 and January 2026. Inclusion criteria required primary tumors with level 1 metastatic potential, concurrent/sequential neck dissection, and complete histopathological data. Patients with incomplete records or primary submandibular gland (SMG) tumors were excluded. Demographics and histopathological features (tumor size, depth of invasion, lymphatic, perineural, vascular, and parenchymal SMG invasion) were extracted from archives. Data were analyzed using IBM SPSS V23. Descriptive statistics included means, standard deviations, medians, ranges, and frequencies. Independent risk factors for SMG invasion were evaluated using univariate and multiple binary logistic regression models to adjust for confounders, reporting Odds Ratios (OR) with 95% Confidence Intervals (CI). Statistical significance was set at two-tailed $p < 0.05$.

RESULTS

Of the 161 patients analyzed, 36.0% (n=58) were female and 64.0% (n=103) were male. The mean cohort age was 66.4 (pm14.1) years, showing no significant association with submandibular gland (SMG) invasion (p=0.573). Binary logistic regression identified depth of invasion (DOI) as the sole independent predictor of SMG involvement. The median DOI was significantly higher in the gland-involved group than the uninvolved group [24.5 mm (range: 9–47) vs. 9 mm (range: 1–45)]. Each 1 mm increase in DOI elevated SMG invasion risk by 1.102-fold in univariate analysis (OR=1.102, 95% CI: 1.023–1.186, p=0.010) and 1.259-fold in multiple analysis (OR=1.259, 95% CI: 1.003–1.581, p=0.047). Other variables, including gender (p=0.739), tumor size (p=0.476), and lymphatic, perineural, or vascular invasion (p>0.05), demonstrated no independent statistical significance.

CONCLUSIONS

- Results: Depth of invasion (DOI) is the most potent and significant predictor of submandibular gland (SMG) involvement in level 1 neck dissections. The risk of gland invasion increases substantially as DOI advances.
- Clinical Significance: The concurrent presence of metastasis in all SMG-invaded cases necessitates extreme caution regarding gland preservation in advanced tumors with deep invasion. Conversely, gland-preserving surgery remains a viable alternative in highly selected cases with shallow invasion depths.

From Cytology To Surgery: The Impact Of Fine Needle Aspiration Biopsy Accuracy On Completion Thyroidectomy After Lobectomy: A Retrospective Study

Dilara Aydın[1], **Merih Önal**[1], **Çağdaş Elsürer**[1], **M. Fatih Gökmen**[1]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, Selçuk University, Faculty of Medicine, Konya, Türkiye*

BACKGROUND & AIM

Fine needle aspiration biopsy (FNAB) is the primary diagnostic method for evaluating thyroid nodules, but its diagnostic accuracy is debatable, particularly in low-risk nodules. This study evaluated the concordance of FNAB results with

postoperative histopathology, malignancy rates according to the Bethesda classification, and the need for completion thyroidectomy.

MATERIAL & METHODS

This retrospective study included 33 patients who underwent lobectomy. Demographic characteristics, preoperative FNAB results (according to the Bethesda classification), ultrasonographic nodule sizes, and postoperative histopathological results were analyzed. The diagnostic performance of FNAB was calculated. Fisher exact test and Mann-Whitney U test were used for intergroup comparisons; $p<0.05$ was considered significant.

RESULTS

66.7% of the patients were female, and the mean age was 52.8±15.5 years. The malignancy rate in postoperative histopathology was found to be 27.3%. The sensitivity of FNAB was 22.2%, specificity 100%, positive predictive value 100%, and negative predictive value 77.4%. A statistically significant relationship was found between FNAB and histopathology ($p=0.041$). According to the Bethesda classification, the malignancy rates were as follows: Bethesda I 50%, Bethesda II 20%, Bethesda III 33%, Bethesda IV 50%, Bethesda V–VI 100%. The malignancy rate was particularly higher in the Bethesda II group compared to the literature. The rate of completion thyroidectomy was 18.2%, while this rate was 44.4% in the malignant group and 8.3% in the benign group ($p=0.032$). No statistically significant relationship was found between nodule size and malignancy ($p=0.21$).

CONCLUSIONS

Although a significant relationship was found between FNAB and postoperative histopathology, benign cytology results are insufficient to rule out malignancy due to low sensitivity. The high malignancy rate detected in the Bethesda II group indicates that clinical and ultrasonographic findings should be evaluated together. The presence of malignancy significantly increases the need for completion thyroidectomy.

Maligneyi Taklit Eden Travma Sonrası Dil Lezyonu: Bir Vaka Raporu

Dr. Gizem Karaca[1], **Dr. Rümeysa Çetinkaya Güler**[1]

[1]*KOCAELİ ŞEHİR HASTANESİ*

BACKGROUND & AIM

Traumatic tongue lesions are frequently encountered in clinical practice and are often associated with mechanical irritation such as dental procedures or sharp tooth surfaces. (1) Although most lesions are benign and self-limiting, persistent or non-healing lesions may clinically resemble malignancy, particularly in patients with risk factors such as tobacco use. This overlap may lead to diagnostic uncertainty and necessitates careful evaluation. This case report aims to present a post-traumatic lateral tongue lesion mimicking malignancy and to emphasize the importance of differential diagnosis and close clinical follow-up.

MATERIAL & METHODS

A 61-year-old female patient presented with a lesion on the right lateral aspect of the tongue following trauma caused by a high-speed rotary instrument during tooth extraction. Clinical examination revealed a tissue defect extending posteriorly, measuring approximately 4 cm in length and 1 cm in depth (Figure 1). Contrast-enhanced magnetic resonance imaging demonstrated a lesion on the right lateral tongue consistent with a laceration (Figure 2) (2). Despite clinical follow-up, no regression was observed after two months. Therefore, total surgical excision was planned. The lesion was completely excised using monopolar cautery with a 3 mm surgical margin, extending to the underlying muscle. Primary closure was performed with sutures (Figure 3). Postoperative healing occurred by secondary intention and was uneventful (Figure 4) (1,3).

RESULTS

Clinical and radiological findings were consistent with a deep traumatic lesion. Histopathological examination revealed no evidence of malignancy. Due to the absence of regression during follow-up, total surgical excision was performed for both diagnostic and therapeutic purposes. The postoperative course was favorable, with complete healing and no complications. No recurrence was observed during follow-up.

CONCLUSIONS

Iatrogenic oral soft tissue injuries are rare but may clinically and radiologically mimic malignant lesions, creating diagnostic difficulty. Persistent lesions that do not respond to conservative management require further evaluation, and histopathological examination is essential for definitive diagnosis (2). In selected cases, total surgical excision may be a safe and effective approach, providing both diagnostic and therapeutic benefits. This case emphasizes strict adherence to operative safety principles during dental procedures, including proper soft tissue protection, careful instrument handling, and knowledge of regional anatomy to prevent iatrogenic injury. Early recognition, accurate diagnosis, and timely management are critical for optimal outcomes (3).

Recurrent Parotid Solitary Fibrous Tumor With Parapharyngeal Extension: A Challenging Revision Case

Zeynep Baran[1], **Selin Ozdin Toptas**[1], **Zehra Durak Şahin**[2], **Yetkin Zeki Yılmaz**[1]

[1]*Department of Otorhinolaryngology, Cerrahpasa Faculty of Medicine, Istanbul University- Cerrahpasa, Türkiye;* [2]*Department of Pathology, Cerrahpasa Faculty of Medicine, Istanbul University- Cerrahpasa, Türkiye*

BACKGROUND & AIM

To demonstrate that complete single-stage resection of a recurrent parotid solitary fibrous tumor with parapharyngeal extension—previously considered inoperable—can be successfully achieved while preserving the facial nerve in experienced hands.

MATERIAL & METHODS

(Case study):

A 34-year-old woman presented with a recurrent, progressively enlarging left preauricular swelling. Initial parotid excision in August 2019 confirmed SFT; asymptomatic recurrence on magnetic resonance imaging (MRI) six months later was managed expectantly. In 2024, growth prompted tru-cut biopsy that re-confirmed SFT; she was declared inoperable elsewhere and referred to us. Examination revealed a large firm mass extending from the left parotid to the suboccipital region; MRI showed a heterogeneous lesion with parapharyngeal-space invasion. After multidisciplinary planning, the patient underwent revision total parotidectomy combined with transcervical excision of the parapharyngeal component, with continuous facial-nerve identification and preservation. Histopathology and immunohistochemistry including STAT6 and CD34 were performed.

RESULTS

Intra-operatively, the tumour was extensively adherent to deep parapharyngeal structures. Meticulous sharp and bipolar dissection achieved complete macroscopic removal of both parotid and parapharyngeal components in a single session, with anatomical preservation of all visible facial-nerve branches. Despite continuity, the patient developed postoperative facial paralysis due to traction and devascularisation. Histopathology showed ovoid spindle cells in haphazard fascicles with staghorn (haemangiopericytoma-like) vasculature; immunohistochemistry showed diffuse intense nuclear STAT6 and diffuse CD34 positivity, confirming recurrent SFT with no malignant transformation. Recovery was uneventful and the patient entered long-term clinical and radiological follow-up.

CONCLUSIONS

Recurrent parotid SFT extending into the parapharyngeal space is an exceptionally rare and surgically demanding entity that may be wrongly classified as inoperable. Our case demonstrates that single-stage revision total parotidectomy with transcervical parapharyngeal excision is achievable through preoperative imaging, intra-operative facial-nerve identification and experienced surgical technique. STAT6 and CD34 immunohistochemistry remain essential to confirm diagnosis and exclude malignant variants. Even with anatomically intact nerves, postoperative facial dysfunction is a substantial risk; long-term surveillance is mandatory because of late recurrence.

PP-231

Free Dual-Pedicle Jejunal Flap For Pharyngoesophageal Reconstruction In Advanced Hypopharyngeal Cancer: A Case Report

Le Quoc Khanh[1], **Nguyen Anh Khoi**[1]

[1]*Department of maxillofacial - head and neck surgery, Ho Chi Minh City Oncology Hospital*

BACKGROUND & AIM

Reconstruction of extensive pharyngoesophageal defects remains challenging in head and neck surgery. The dual-pedicle free jejunal flap was developed to minimize flap failure. We report successful reconstruction using this technique after pharyngolaryngoesophagectomy in advanced hypopharyngeal cancer

MATERIAL & METHODS

This is a single-patient descriptive case report. Clinical, operative, and follow-up data were reviewed for a 51-year-old man with advanced hypopharyngeal squamous cell carcinoma who underwent total pharyngo-laryngo-esophagectomy. Postoperative outcomes included flap viability, anastomotic leakage, surgical complications, resumption of oral intake, adjuvant treatment, and oncologic status during follow-up. No statistical analysis was performed

RESULTS

A 51-year-old man with advanced hypopharyngeal squamous cell carcinoma underwent total pharyngo-laryngo-esophagectomy followed by reconstruction with a dual-pedicle free jejunal flap. The flap was harvested using the second and

third branches of the superior mesenteric artery. No anastomotic leakage or flap failure occurred. Adjuvant chemoradiotherapy was administered. At 6months, oral intake resumed without evidence of recurrence.

CONCLUSIONS

The dual-pedicle free jejunal flap offers reliable pharyngoesophageal reconstruction with reduced failure risk and favorable functional outcomes.

ÜST DUDAKTA PRİMER SİFİLİZ TUTULUMU

Soltan Ahmadov[1], **Fırat Tevetoğlu**[1], **Berkan Alp Usta**[2], **Fulya Altınay Köse**[3]

[1]*Cerrahpaşa Tıp Fakültesi KBB ABD;* [2]*Cerrahpaşa Tıp Fakültesi enfeksiyon hastalıkları ABD;* [3]*İMÜ Göztepe EAH Dermatoloji ABD*

BACKGROUND & AIM

Bu olgu sunumunda, dudakta yerleşimli primer sifiliz şankrı ile prezente olan bir hastanın klinik bulguları, tanı süreci ve tedavi yaklaşımının sunulması; ayrıca oral kavitede görülen atipik ülseratif lezyonların ayırıcı tanısında sifilizin öneminin vurgulanması amaçlanmıştır.

MATERIAL & METHODS

Bu çalışmada, dudakta yerleşimli ülseratif lezyon nedeniyle başvuran bir hastanın klinik, laboratuvar ve tedavi süreci retrospektif olarak değerlendirildi. Hastanın demografik özellikleri, anamnezi, fizik muayene bulguları ve lezyonun klinik özellikleri ayrıntılı olarak kaydedildi.

Ayırıcı tanı kapsamında enfeksiyöz, travmatik ve neoplastik nedenler göz önünde bulundurularak gerekli tetkikler planlandı. Tanı amacıyla serolojik testler kullanıldı; nontreponemal testler (VDRL/RPR) ile tarama yapıldı ve pozitif sonuçlar treponemal testler (TPHA/FTA-ABS) ile doğrulandı.

Gerekli görülen durumlarda histopatolojik inceleme gerçekleştirildi. Tanı konulmasının ardından hastaya standart tedavi protokolü olarak intramüsküler Benzathine penisilin G uygulandı ve klinik yanıt takip edildi.

RESULTS

30 yaşında erkek hasta, yaklaşık 4 haftadır üst dudakta mevcut olan iyileşmeyen, ağrısız ülseratif lezyon şikâyeti ile başvurdu. Anamnezde lezyonun başlangıçta küçük bir yara şeklinde ortaya çıktığı ve zamanla büyüyerek indüre hale geldiği öğrenildi. Sistemik semptom tariflenmedi.

Fizik muayenede üst dudakta yaklaşık 2 cm çapında, düzgün sınırlı, indüre kenarlı, ağrısız ülseratif lezyon izlendi. Servikal lenf nodlarında lenfadenopati saptanmadı.

Yapılan serolojik incelemelerde nontreponemal testin pozitif saptanması ve treponemal test ile doğrulanması üzerine hastaya primer sifiliz tanısı konuldu.

Hastaya intramüsküler Benzathine penisilin G tedavisi uygulandı. Tedavi sonrası erken dönemde lezyonda belirgin gerileme izlendi ve takiplerinde tam iyileşme sağlandı.

CONCLUSIONS

Oral kavitede, özellikle dudakta yerleşimli ağrısız ve indüre ülseratif lezyonlar nadir olmakla birlikte primer sifilizin ilk bulgusu olabilir ve sıklıkla benign ülserler veya maligniteler ile karışabilir. Bu durum tanıda gecikmelere ve gereksiz invaziv girişimlere yol açabilir. Bu olgu, iyileşmeyen ve atipik özellik gösteren dudak lezyonlarında sifilizin mutlaka ayırıcı tanıda düşünülmesi gerektiğini vurgulamaktadır. Erken dönemde yapılacak serolojik testler ile tanı kolaylıkla konulabilir ve uygun antibiyotik tedavisi ile hızlı ve etkili klinik yanıt elde edilir. Bu nedenle klinisyenlerin bu konuda farkındalığının artırılması büyük önem taşımaktadır.

A Case Of An Atypical Presentation Of Spontaneous Esophageal Rupture

Dr.Rashed Aldoseri[1], **Dr.Mai Nasser**[1], **Dr.Mohamed Alshehabi**[1]

[1]*Royal Medical Services , Kingdom of Bahrain*

BACKGROUND & AIM

Spontaneous esophageal rupture is an uncommon medical phenomenon that involves a sudden increase in intraesophageal pressure with negative intrathoracic pressure.

Here, a 21-year-old female with no history of medical illness was admitted to our accident and emergency department with a one-day history of sudden retrosternal chest pain with other symptoms. There was no foreign body ingestion, vomiting, fever, cough, trauma, or recent procedures

MATERIAL & METHODS

Physical examination revealed a soft abdomen with epigastric tenderness and normal respiratory and cardiovascular examinations. The patient underwent a chest X-ray and a computed tomography scan of the neck and chest, which revealed retropharyngeal air extending to the mediastinum with anterior chest surgical emphysema. Oesophago-gastro-duodenoscopy revealed mild gastritis with no evidence of foreign body or esophagus injury.

RESULTS

The patient was prescribed paracetamol, pantoprazole, and clindamycin. On follow-up, the patient was doing well with no active complaints. Conservative management of spontaneous esophageal rupture can result in good clinical outcomes with no requirement for additional interventions.

CONCLUSIONS

Diagnosing an idiopathic spontaneous esophageal rupture requires a high index of suspicion from the physician

KEYWORDS

PP-234

Embolization As A Game-Changer In Difficult-To-Access Hemangiomas

OP.DR. HAKAN BAYRAKTAR[1], **YUNUS EMRE ÇAM**[1]

[1]*KOCAELİ ŞEHİR HASTANESİ*

BACKGROUND & AIM

This study aims to highlight the importance of embolization in the surgical management of large vascular tumors.Surgical management of hemangiomas in challenging locations is associated with significant risks, including excessive intraoperative bleeding due to high vascularity, impaired visualization, injury to adjacent critical structures , and prolonged operative time. Preoperative embolization plays a crucial role by reducing the vascular supply of the lesion, thereby minimizing intraoperative bleeding, improving surgical visibility, and facilitating dissection. This leads to lower complication rates, shorter operative time, and safer, more controlled resection. Deep-seated or anatomically complex regions, embolization is an important adjunct that enhances surgical outcomes.

MATERIAL & METHODS

A 44-year-old male presented with a long-standing swelling in the left supraclavicular region. Neck ultrasound revealed a well-defined, lobulated, heterogeneous hypoechoic solid lesion measuring 73 × 22 mm with internal arterial and venous flow. Contrast-enhanced CT confirmed a vascular nodular lesion in the same region. Tru-cut biopsy demonstrated a vascular neoplasm with ERG positivity and HHV-8 negativity. Due to its hypervascular nature, preoperative embolization was performed via the right femoral artery, and feeding vessels from the clavicular branch of the thoracoacromial artery were successfully occluded with coils. Subsequently, the mass, extending from the posterior border of the sternocleidomastoid muscle to the anterior aspect of the scalene muscle and connecting to the subclavian artery, was completely excised after ligation of its vascular pedicle. Surgery was completed without complications.

RESULTS

Final histopathological examination confirmed cavernous hemangioma with CD31 and CD34 positivity. This case highlights the importance of preoperative embolization in improving surgical safety.

CONCLUSIONS

Surgical management of large, deeply located vascular tumors is challenging due to the risk of significant intraoperative bleeding . In this case, the tumor's close relationship with the subclavian artery further increased surgical complexity. Preoperative embolization reduced tumor vascularity, allowing safer dissection and controlled resection. Previous studies have demonstrated that embolization in hypervascular head and neck lesions decreases intraoperative blood loss and shortens operative time. The absence of complications in this case supports the effectiveness of this approach. Therefore, preoperative embolization should be considered a valuable adjunct in the management of large vascular tumors.

Cavernous hemangioma; Vascular tumor; Preoperative embolization

PP-235

Fine-Needle Aspiration Cytology: Our Experience And Comparison With Histopathological Findings

Dr. Gabriela Pavlovčinová, PhD.[1], **Dr. Patrik Štefanička, Phd**[1]

[1]*Department of Otorhinolaryngology and Head and Neck Surgery, Bory Hospital, Bratislava, Slovakia*

BACKGROUND & AIM

Fine-needle aspiration cytology is an effective tool in diagnosis of head and neck tumors. The purpose of this study is a comparison of cytological results and histopathological findings after surgery of tumors of the neck.

MATERIAL & METHODS

One hundred and thirty patients with tumors in the head and neck who underwent fine-needle aspiration cytology in 2-years were reviewed. All examinations were performed under ultrasound guidance. We divided patients into two groups, one with salivary gland masses and the second group with other soft tissue masses of the neck. Cytological reports from salivary tumors were classified according to Milan classification.

RESULTS

Ninety-one biopsies were taken from salivary glands and thirty-nine from lymph nodes or from other soft tissue of the neck. In salivary gland group of patients twenty-two of them were excluded from comparison, because they preferred observation. We did ten re-biopsies due to non-diagnostic results. In patients after surgery we compared sixty-nine cytological and histopathological results and except two they were all consistent. In the second group of patients seven preferred observation and we found more, six inconsistent results.

CONCLUSIONS

Fine-needle aspiration cytology of salivary glands provides accurate diagnosis of most lesions, especially in salivary gland tumors. It is very helpful in planing of surgery and it is a safe and useful modality for the diagnosis of neck masses.

KEYWORDS

fine-needle aspiration cytology, salivary gland, neck masses

Correlation Between Fine Needle Aspiration Cytology And Post-Operative Of Thyroid Nodules: Our Hospital Experience

Raneem Alshaikh[1], **Omar Sabra**[1]

[1]*King Hamad University Hospital- RMS, Bahrain*

BACKGROUND & AIM

Thyroid nodules are common condition with small but significant proportion harboring malignancy. Fine needle aspiration cytology (FNAC) is the first line diagnostic test to stratify risk.

We aimed to establish a diagnostic accuracy of FNAC of thyroid nodules using Bethesda system and post-operative histopathological diagnosis.

MATERIAL & METHODS

This was observational retrospective study among 105 patients undergoing FNAC following thyroid surgery at King Hamad University Hospital. FNAC diagnosis was classified under Bethesda system. Histopathological post operative diagnosis is considered the gold standard. Then correlation was made using statistical parameters (sensitivity, specificity and chi square).

RESULTS

Average age was 46 +- 14.8 years. Histopathological diagnosis confirmed malignancy in 54.3 % of cases. FNAC was 84 % sensitive and 93% specific. Bethesda V and VI categories were most precise. Diagnostic accuracy was significantly higher in benign than malignant cases.

CONCLUSIONS

FNAC remains a diagnostic tool for thyroid nodules, particularly when used in conjunction with organized reporting system like Bethesda system. However false negative results remains a limitation. So a multimodal approach is always recommended.

Thyroid nodules, fine needle aspiration cytology, Bethesda system, thyroid cancer

PP-237

Pectoralis Musculocutaneous Flap In Reconstruction Of Pharyngocutaneous Fistula

Ayça Ilgın Altaner Asaroğlu[1], **Merve Demir Aksoy**[1], **Şahin Öğreden**[1]

[1]*Basaksehir Cam ve Sakura Şehir Hastanesi*

BACKGROUND & AIM

Pharyngocutaneous fistula is a significant complication for both patients and surgeons following laryngeal and hypopharyngeal surgery; leading severe consequences due to leakage of pharyngeal secretions beneath skin flaps, ranging from localized tissue infection to carotid artery rupture. Predisposing factors include surgical technique, tumor stage, neoadjuvant radiotherapy.

We aim to present the results of two surgical cases in which full thickness pectoralis myocutaneous flap was used for reconstruction of pharyngocutaneous and pharyngoesophageal defects; alongside with a review of current literature. In both cases we applied subcutaneous tunnel; adjustments has made one involving tissue plug modification and other with tubed musculocutaneous flap.

MATERIAL & METHODS

Patient 1 presented with postoperative pharyngocutaneous fistula after primary total laryngectomy. Fistula above the stomal area was unresponsive to conservative treatments; later proceeded to esophageal lumen, necessicating surgical intervention. Pectoralis myocutaneous flap was harvested and mobilized to sufficient length; then transposed to region with subcutaneous tunnel (Figure1). 360° neopharynx reconstruction was achieved after fixating vertically to the esophagus, horizontally to the base of the tongue and posterior pharyngeal wall(Figure2).

Patient 2 had a history of radiotherapy resulting in 2 cm sized submental pharyngocutaneous defect. Following salvage laryngectomy and primary closure, fistula reccured and extended to the pharyngeal lumen, presented with retracted neck skin. During the operation pharyngeal defect margin and surrounding retracted skin and subcutaneous tissue to expose viable tissue which was conjoined medially afterwards(Figure3,4). The flap was harvested with a 3x5 cm skin island and mobilized along with the subcutaneous tunnel to the suffiecent length and adapted to the region.

RESULTS

Both of the surgical procedures demonstrated succesfully with no recurrence of pharyngocutanoeus fistula and minimal aesthetic deformity, minimal construction of the donor side and preserved swallowing and speech functions. On the first patient pharyngoesophageal defect reconstructed preventing of stenosis through appropriate inset of proximal, distal and posterior anastomotic sites and sufficient flap size containing skin paddle, avoiding stricture formation. On the second case postoperative sctricture prevented and regional blood flow is provided through sufficient debridation of mucosal margins and retracted neck skin. Wide range of adjustability of pectoralis flap aided with mobilization through subcutaneous tunnel. Vasculary pedicle driven from thoracoacromial artery ensured blood flow when no servical neck vessels for microvascular anastomosis available after radiotherapy retreatments.

CONCLUSIONS

Various surgical methods are used in the treatment of FCF, including primary closure, platysma flap, deltopectoral flaps and free flaps. Free flaps such as anterolateral thigh or radial forearm flaps were unsuitable due to the absence of adaptable recipient vessels for free tissue transfer; due to previous radiotherapy treatments. PMF provides wide range of mobility, adequate length and minimal contraction for adjustment to partial and circumferancial pharyngoesophageal defects. Pectoralis myocutaneous flap is still a current method of reconstruction that can be the optimal and salvagable option for continuity of pharyngoosepageal tract for extensive pharyngocutaneous defects with poor tissue viability.

Thyroglossal Duct Cyst Papillary Carcinoma: A Case Report

FIRAT ÇELİKEL[1], **KASIM YİĞİT ORAL**[1], **AYKUT GÜNEŞ**[1], **MEHMET DÜZLÜ**[1]

[1]*Department of Otorhinolaryngology, Gazi University School of Medicine, Ankara, Turkey*

BACKGROUND & AIM

Thyroglossal duct cyst (TGDC) is the most common congenital midline neck anomaly and is generally benign. Malignant transformation is rare, accounting for less than 1% of cases, with papillary thyroid carcinoma being the most common histopathological subtype. Preoperative diagnosis remains challenging because clinical and radiological findings frequently overlap with benign lesions.

This report aims to present a rare case of papillary thyroid carcinoma arising in a thyroglossal duct cyst diagnosed preoperatively using radiological and cytological findings and treated surgically.

MATERIAL & METHODS

A 36-year-old male patient presented with a painless midline neck mass in the submental region, initially noticed approximately two years earlier, with progressive enlargement during the preceding four months.

Physical examination revealed a firm, non-tender midline neck mass measuring approximately 3–4 cm.

Thyroid ultrasonography demonstrated a 25×17 mm midline cystic lesion compatible with a thyroglossal duct cyst, while the thyroid gland appeared normal without solid or cystic nodules. Bilateral cervical lymph nodes demonstrated reactive morphology.

Contrast-enhanced neck computed tomography revealed a 33×23 mm thick-walled cystic lesion at the level of the hyoid bone containing internal septations, a central solid component, and calcifications, raising suspicion for malignant transformation.

Fine-needle aspiration cytology demonstrated malignant cytology consistent with papillary thyroid carcinoma (Bethesda System for Reporting Thyroid Cytopathology 2023, Category VI).

The patient subsequently underwent surgical treatment using the Sistrunk procedure.

RESULTS

Preoperative radiological findings and cytological evaluation enabled suspicion and diagnosis of malignancy before surgery.

Intraoperatively, the lesion was excised en bloc together with the central portion of the hyoid bone using the Sistrunk technique.

Histopathological examination demonstrated classic-type papillary thyroid carcinoma arising in a thyroglossal duct cyst with a maximum tumor diameter of 2.7 cm. Surgical margins were negative for tumor involvement.

No suspicious thyroid lesion or metastatic cervical lymphadenopathy was identified.

CONCLUSIONS

lthough thyroglossal duct cysts are predominantly benign lesions, progressive enlargement, firm consistency, and suspicious radiological findings including mural thickening, internal septations, solid components, and calcifications should raise suspicion for malignant transformation.

Combined radiological and cytological evaluation may facilitate preoperative diagnosis and optimize surgical planning.

Papillary thyroid carcinoma arising in a thyroglossal duct cyst should remain in the differential diagnosis of adult midline neck masses even in the presence of normal thyroid ultrasonography.

PP-239

Predictors Of Intraoperative Blood Loss In Neck Dissection For Head And Neck Squamous Cell Carcinoma: The Role Of Laterality And Nutritional Status

Hacer Baran[1], **Banu Taşhan**[1]

[1]*Istanbul Kartal Dr. Lütfi Kırdar City Hospital*

BACKGROUND & AIM

To identify independent predictors of estimated intraoperative blood loss (EBL) in patients undergoing neck dissection for head and neck squamous cell carcinoma, and to evaluate the effects of preoperative inflammatory and nutritional biomarkers alongside surgical variables on EBL.

MATERIAL & METHODS

In this single-center retrospective cohort study, 369 patients who underwent neck dissection between January 2015 and December 2025 were analyzed. EBL was obtained from anesthesia records. Preoperative neutrophil-to-lymphocyte ratio (NLR) and Prognostic Nutritional Index (PNI) were calculated. Independent predictors of EBL were identified by univariate and multivariate linear regression; HC3 heteroscedasticity-consistent robust standard errors were applied.

RESULTS

Median EBL was 350 mL (IQR: 250–500). On multivariate analysis, bilateral neck dissection (β = −0.206, 95% CI: −0.298 to −0.113, $p < 0.001$), higher preoperative hemoglobin (β = +0.047, 95% CI: +0.022 to +0.071, $p < 0.001$), longer operative time (β = +0.00057, 95% CI: +0.00020 to +0.00094, $p = 0.003$), and lower PNI (β = −0.00120, 95% CI: −0.00217 to −0.00024, $p = 0.015$) were identified as independent predictors. NLR was not an independent predictor ($p = 0.266$). The model explained 19.6% of EBL variance ($R^2 = 0.196$).

CONCLUSIONS

Bilateral neck dissection, preoperative hemoglobin, operative time, and PNI are independent predictors of EBL in patients undergoing neck dissection. Low preoperative PNI may be considered a trigger for preoperative nutritional optimization, and blood product preparation should be planned accordingly in patients scheduled for bilateral dissection.

INFRATEMPORAL FOSSA APPROACH FOR EXCISION OF CHONDROSARCOMA

Mert Akın[1], **Muhammed Gazi Küçükbay**[1], **Funda Taşkın**[1], **Şahin Öğreden**[1]

[1]*University of Health Sciences Türkiye, Başakşehir Çam and Sakura City Hospital*

BACKGROUND & AIM

Chondrosarcomas are malignant mesenchymal tumors producing a cartilaginous matrix and are rarely seen in the head and neck region, particularly in the temporomandibular joint and infratemporal fossa. Clinical presentation is usually nonspecific, and diagnosis may be incidental. CT and MRI are important for evaluation, while definitive diagnosis relies on histopathological examination. Surgical resection is the primary treatment; however, complete excision may be difficult because of the anatomical complexity of the region. Adjuvant radiotherapy is recommended in cases of residual disease or positive surgical margins.

MATERIAL & METHODS

A 67-year-old female patient was referred to our clinic due to a mass in the right temporomandibular region that was detected during an external center evaluation. She had a medical history of hypertension, thyroid disease, and uterine carcinoma.

Temporal CT and MRI demonstrated a mass measuring approximately 47 × 27 mm in the right masticator space with associated bone destruction. Tru-cut biopsy findings were reported as “atypical chondroid proliferation.”

The patient underwent temporomandibular joint resection. Intraoperative frozen-section analysis confirmed the diagnosis of chondrosarcoma. Postoperative histopathological examination revealed Grade 2 chondrosarcoma. Following identification of tumor involvement at the superior surgical margin, adjuvant radiotherapy was initiated.

RESULTS

Chondrosarcomas of the temporomandibular region are extremely rare, with only a limited number of cases reported in the literature. Clinical findings are generally nonspecific, and most cases are detected incidentally. Although CT and MRI are valuable in the diagnostic workup, definitive diagnosis is established by histopathological examination.

Surgical resection remains the mainstay of treatment; however, complete excision may not always be feasible due to the proximity of the skull base and adjacent critical anatomical structures. In such cases, adjuvant radiotherapy is recommended.

The present case highlights the importance of a multidisciplinary approach in the diagnosis and management of chondrosarcomas in this rare anatomical location.

CONCLUSIONS

Chondrosarcomas of the temporomandibular joint are rare tumors with challenging diagnostic and therapeutic processes. Early diagnosis, appropriate surgical planning, and the use of adjuvant radiotherapy when indicated may improve patient prognosis.

Pediatric Maxillary Rhabdomyosarcoma Extending To The Pterygopalatine Fossa: A Challenging Case

AYSIN TOZSEKERLI[1], **BETUL CANAK**[1], **BARIS KARASU**[1], **CEMILE BAYKAN ERYIGIT**[1], **SAHIN OGREDEN**[1], **OZGUR YIGIT**[1], **GUNTER HAFIZ**[2]

[1]Basaksehir Cam and Sakura City Hospital, Department of Otorhinolaryngology, Istanbul, Turkey; [2]Istanbul University, Istanbul Medical Faculty, Department of Otorhinolaryngology, Istanbul, Turkey

BACKGROUND & AIM

Rhabdomyosarcoma is the most common soft tissue sarcoma in the pediatric population, frequently involving the head and neck region. However, localization of the pterygopalatine fossa are rare. They remain mostly obscure because of their initially minimal symptoms, their hidden anatomical position and their mainly slow growth. Therefore, they represent a diagnostic challenge. We report a rare case of rhabdomyosarcoma arising in the pterygopalatine fossa, highlighting its clinical presentation, diagnostic workup, and management.

MATERIAL & METHODS

A pediatric patient diagnosed with rhabdomyosarcoma involving the maxillary sinus and pterygopalatine fossa underwent surgical treatment following radiological and histopathological evaluation. A Weber–Ferguson transfacial approach was used under general anesthesia. Inferolateral maxillectomy and total tumor resection involving the pterygopalatine and infratemporal fossae were performed. The inferomedial orbital wall and periorbita were preserved. Frozen-section analysis from the masseteric margin, trigeminal nerve sheath, and inferior orbital wall confirmed negative surgical margins. The postoperative palatal defect was reconstructed using a full-thickness skin graft harvested from the left inguinal region and secured with tie-over dressing and a Bactigras stent.

RESULTS

Gross total excision of the tumor was achieved without intraoperative complications. Despite destruction of the maxillary sinus walls and extension into deep facial spaces, the orbital structures and facial skin were preserved. Adequate hemostasis was maintained throughout the procedure. Early postoperative follow-up demonstrated satisfactory graft adaptation without major complications. The patient was referred for multidisciplinary oncologic follow-up and adjuvant treatment planning.

CONCLUSIONS

Rhabdomyosarcoma of the pterygopalatine fossa is a rare entity that may present with nonspecific oral symptoms, leading to delayed diagnosis. This case emphasizes the importance of early imaging, biopsy, and multidisciplinary management in pediatric head and neck tumors. Early recognition is crucial for timely treatment and improved outcomes.

Riedel's Thyroiditis: Case Report And Literature Review

Ali Doğan Aydınbelge[1]

[1]*Gaziantep City Hospital*

BACKGROUND & AIM

Riedel's thyroiditis is a rare fibroinflammatory disorder characterized by extensive fibrosis of the thyroid gland with possible extension into surrounding tissues. Clinically and radiologically, it may mimic invasive thyroid malignancy, making preoperative diagnosis challenging. Definitive diagnosis is often established histopathologically following surgical intervention.

This study aims to present a case of Riedel's thyroiditis initially suspected as thyroid cancer and treated with total thyroidectomy, and to review the current literature regarding its clinical features, diagnostic difficulties, and management strategies.

MATERIAL & METHODS

This study presents a single retrospective case of Riedel's thyroiditis managed at our institution. Clinical findings, laboratory results, imaging studies, operative notes, and histopathological reports were reviewed. The diagnosis was established based on postoperative histopathological examination. All patient data were anonymized, and written informed consent for publication was obtained.

In addition, a narrative literature review was conducted using electronic databases, including PubMed and Google Scholar. Relevant articles published in English were identified using keywords such as "Riedel's thyroiditis," "fibrosing thyroiditis," and "IgG4-related disease." Studies addressing clinical presentation, diagnostic challenges, histopathology, and management were reviewed and summarized.

RESULTS

A 52-year-old male presented with progressive neck swelling. Initial ultrasonography demonstrated multiple solid thyroid nodules, the largest measuring 33 × 23 mm, with cystic degeneration and coarse calcifications. Fine-needle aspiration biopsy (FNAB) was nondiagnostic. Four months later, the dominant nodule enlarged to 45 mm; repeat FNAB remained nondiagnostic. Thyroid scintigraphy showed partial suppression with heterogeneous multinodular activity. Two months thereafter, ultrasonography revealed further enlargement to 49 mm with irregular margins. FNAB was again nondiagnostic.

Due to progressive growth and suspicious imaging findings, total thyroidectomy was performed. Intraoperatively, the gland was markedly firm and adherent to surrounding tissues. Histopathological examination revealed extensive fibrosis replacing the thyroid parenchyma with lymphoplasmacytic infiltration and extrathyroidal extension, consistent with Riedel's thyroiditis. No malignancy was identified.

CONCLUSIONS

Riedel's thyroiditis is a rare fibroinflammatory condition that may closely mimic invasive thyroid malignancy both clinically and radiologically. Progressive enlargement, irregular margins, and repeatedly nondiagnostic cytology can further increase suspicion for cancer. Definitive diagnosis is often established only after surgical intervention and histopathological examination.

Awareness of this entity is essential to avoid misdiagnosis and to guide appropriate management. Riedel's thyroiditis should be considered in the differential diagnosis of hard, enlarging thyroid masses with inconclusive biopsy results.

KEYWORDS

Riedel's thyroiditis; Thyroid malignancy mimicry; Fibrosing thyroiditis; Total thyroidectomy

An Extremely Rare And Challenging Case: Large Proximal Esophageal Granular Cell Tumor Requiring Complex Surgical Reconstruction

Ömer Bayır[1], **Melih Can Öner**[2], **Ünsal Han**[3], **Serhat Tokgöz**[4], **Sebat Karamürsel**[5], **Mehmet Hakan Korkmaz**[6]

[1]*Department of Otolaryngology – Head and Neck Surgery, Ankara Etlik City Hospital, Ankara, Turkey;* [2]*Department of Otolaryngology – Head and Neck Surgery, Karaman Training and Research Hospital, Karaman, Turkey;* [3]*Department of Pathology, Ankara Etlik City Hospital, Ankara, Turkey;* [4]*Department of General Surgery, Ankara Etlik City Hospital, Ankara, Turkey;* [5]*Department of Plastic, Reconstructive and Aesthetic Surgery, Ankara Etlik City Hospital, Ankara, Turkey;* [6]*Private Practice , Ankara, Turkey*

BACKGROUND & AIM

Granular cell tumors (GCTs) are rare, benign neurogenic neoplasms of Schwann cell origin. Gastrointestinal GCTs account for 1-8% of all cases, and approximately one-third of these are located in the esophagus. Most esophageal GCTs are small (typically <2 cm) and predominantly involve the distal esophagus. Proximal esophageal lesions are extremely rare and pose significant diagnostic and therapeutic challenges because of their close proximity to the airway.

MATERIAL & METHODS

A 39-year-old woman presented with a one-year history of progressive dysphagia. At another center, esophagoscopy could not reach the mass, and a transcervical incisional biopsy was therefore performed. Following this procedure, the patient

developed left vocal cord paralysis. Initial histopathologic evaluation was inconclusive, with differential diagnostic considerations including granular cell tumor and alveolar soft part tumor. Re-evaluation of the biopsy specimens at a tertiary referral center confirmed the diagnosis of esophageal granular cell tumor.

Direct laryngoscopy and esophagoscopy revealed an approximately 3 cm submucosal mass located along the posterior tracheal wall at the subglottic level, completely obstructing the proximal esophageal lumen. Imaging studies (CT, MRI, and PET-CT) demonstrated a hypermetabolic prevertebral soft tissue mass measuring 30 × 26 mm in the axial plane and approximately 7 cm craniocaudally, with no definitive nodal or distant metastases.

RESULTS

Given the tumor's size, location, and complete luminal obstruction, we performed proximal esophagectomy, partial pharyngectomy, repair of the posterior tracheal wall with preservation of the larynx, and free jejunal flap reconstruction. Histopathologic examination confirmed the diagnosis of GCT. Postoperatively, right vocal cord mobility was normal. Oral feeding was initiated on postoperative day 10, the patient was decannulated on postoperative day 14, and discharged on postoperative day 21. At the two-year follow-up, the patient remains disease-free.

CONCLUSIONS

Surgical intervention remains necessary for large, symptomatic, particularly proximal esophageal GCTs. Given the tumor's proximity to the airway and the history of prior vocal cord paralysis, airway preservation represented a major intraoperative challenge. To our knowledge, there are no previous reports in the literature describing the use of a free jejunal flap for reconstruction after resection of a proximal esophageal GCT. Free jejunal flap reconstruction effectively restored the upper digestive tract despite near-total obstruction. This demonstrates that even complex proximal esophageal GCTs can be managed with organ preservation, yielding favorable outcomes and quality of life through a multidisciplinary approach.

PP-244

Synchronous Bilateral Parotid Basal Cell Adenocarcinoma Without Predisposing Factors: A Case Report

Begüm Bahar Yılmaz[1], **İpek Yeşil**[1], **Şahin Öğreden**[1]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, Başakşehir Çam and Sakura City Hospital, University of Health Sciences, Istanbul, Turkey*

BACKGROUND & AIM

Basal cell adenocarcinoma (BCAC) is a rare low-grade malignant salivary gland tumor, representing 1–3% of all salivary gland neoplasms and predominantly involving the parotid gland. Bilateral salivary gland involvement is exceedingly uncommon and is typically associated with hereditary syndromes (e.g., Brooke-Spiegler syndrome, CYLD mutations) or chronic immunosuppression. We report a case of synchronous bilateral parotid BCAC in a healthy adult with no identifiable predisposing factors, representing an exceptionally rare clinical entity.

MATERIAL & METHODS

A 69-year-old immunocompetent male with no family history of genetic syndromes presented with bilateral, slowly growing, painless parotid masses over two years. Contrast-enhanced MRI revealed heterogeneous nodular lesions in both parotid glands (right: 32×23 mm at the deep-superficial lobe junction; left: 16×13 mm in the superficial lobe), with parapharyngeal extension on the right. Preoperative fine-needle aspiration cytology yielded "basaloid neoplasm." The patient underwent right total and left superficial parotidectomy with facial nerve monitoring; all nerve branches were preserved. Histopathology demonstrated bilateral basaloid neoplasia with infiltrative growth into surrounding parenchyma and adipose tissue, confirmed as BCAC by positive p63, CK19, and S100 immunostaining with an elevated Ki-67 index. Surgical margins were negative. At 6-month follow-up, no recurrence or lymph node metastasis was detected.

RESULTS

Synchronous bilateral BCAC, unlike its benign counterpart basal cell adenoma, is an exceptionally rare presentation. Differentiation from BCA relies critically on infiltrative growth pattern and elevated Ki-67, as clinical and radiological features overlap considerably. Preoperative cytology carries limited diagnostic utility in this setting. Notably, prior bilateral BCAC reports have uniformly involved immunosuppressed or syndromic patients; our case represents a de novo occurrence in a healthy adult, underscoring the need to include malignancy in the differential diagnosis of bilateral parotid masses regardless of clinical background. Facial nerve-preserving parotidectomy with negative margins remains curative in low-grade disease.

CONCLUSIONS

BCAC should be considered in the differential diagnosis of bilateral parotid masses, even in the absence of immunosuppression or genetic predisposition. Parotidectomy with histopathological confirmation and long-term oncological follow-up constitute the cornerstone of management.

Surgical Management Of Rare Head And Neck Tumors Using The Infratemporal Fossa Approach: Two Case Reports

Muhammed Gazi Küçükbay[1], **Nursena Nair Polat**[1], **Merve Demir Aksoy**[1], **Oğuzhan Cumalı**[1], **Mert Akın**[1], **Şahin Öğreden**[1]

[1]*University of Health Sciences Türkiye, Başakşehir Çam and Sakura City Hospital*

BACKGROUND & AIM

Epithelial/myoepithelial carcinoma is a rare salivary gland neoplasm, accounting for less than 1% of all salivary tumors. It is a low grade malignancy composed of epithelial and myoepithelial cells and most commonly arises in the parotid gland.

Atypical fibroxanthoma is a rare cutaneous mesenchymal tumor typically seen in sun exposed areas of elderly patients and is generally associated with a favorable prognosis, although aggressive cases have been reported.

Despite distinct histopathology, both tumors may pose surgical challenges when extending into the infratemporal fossa. Two cases managed via an infratemporal approach are presented, highlighting key anatomical and surgical considerations.

MATERIAL & METHODS

Case 1

A patient with a history of atypical fibroxanthoma of the left frontal region, previously treated with two surgical excisions with clear margins, presented during follow-up with a rapidly enlarging mass in the left parotid region. Physical examination revealed a firm, fixed mass measuring approximately 53 × 40 mm with intact facial nerve function preoperatively. Imaging demonstrated a parotid mass extending into the masseter muscle and infratemporal fossa with intense FDG uptake (SUVmax: 17.3) and no evidence of regional or distant metastasis. The patient underwent radical parotidectomy, infratemporal fossa tumor excision, hemimandibulectomy, and supraomohyoid neck dissection. Intraoperatively, the tumor was found to invade the facial nerve, which required sacrifice. Histopathological evaluation revealed a pleomorphic, high-grade malignant mesenchymal tumor.

RESULTS

Case 2

A 44-year-old male presented with multiple hard, fixed swellings in the right mandibular angle and parotid region. He had first noticed a swelling two years earlier and was evaluated at an outside center, where FNA biopsy was reported as a salivary gland tumor of uncertain malignant potential. He subsequently underwent right total parotidectomy and excision of a suspicious cervical lymph node. Histopathology revealed myoepithelial carcinoma, while the lymph node showed reactive hyperplasia.

Approximately one year later, new swellings developed and revision surgery was performed at another center for suspected recurrence. However, the lesions persisted, and the patient later presented to our institution. Physical examination revealed lesions in the preauricular region, zygoma, and temporal fossa, palpable lymph nodes in levels IIa and III.

The patient underwent surgery via a right infratemporal fossa approach. Intraoperatively, tumor invasion of the facial nerve trunk was identified, requiring nerve sacrifice and resection of involved mandibular segment.

CONCLUSIONS

Conclusion

Although atypical fibroxanthoma is generally regarded as a low-grade malignancy, it may occasionally demonstrate aggressive behavior and progression to high-grade mesenchymal neoplasms. Similarly, epithelial/myoepithelial carcinoma, despite its low-grade nature, carries a risk of recurrence and locally aggressive growth. These cases highlight the importance of close follow-up in patients with rare tumors and the need for thorough radiological evaluation of new or rapidly growing lesions. In selected cases with deep anatomical involvement, an infratemporal fossa approach may provide adequate surgical exposure for effective tumor resection. A multidisciplinary approach and long-term surveillance are essential for optimal outcomes.

PP-246

Isolated Plasmacytoma Of Nasopharynx: A Case Report

Inci Serdar[1], **Giulia Dané**[1], **Apostolos Karligkiotis**[1]

[1]*San Raffaele Hospital*

BACKGROUND & AIM

Extramedullary plasmacytoma is a very rare, discrete, solitary mass of neoplastic monoclonal plasma cells, with a predilection in the head & neck region (80%). Common clinical presentation consists of epistaxis, rhinorrhea, odynophagia, dysphonia, and hemoptysis. In previous studies, a greater preponderance for males has been reported, particularly in the 5th and 7th decades of life. Localization in the nasopharynx is exceptional and may simulate other more common pathologies of inflammatory or neoplastic nature, yielding the clinical diagnosis more insidious. Despite being a localized form, EMP presents with a risk of myeloma progression (10-30%), necessitating an accurate diagnosis and prolonged follow-up.

MATERIAL & METHODS

We report a 57-year-old male with no smoking history, who presented in our clinic, for a month-long unilateral nasal obstruction with crusting. The endoscopy revealed an exophytic pedunculated vascular mass occupying the nasopharynx. Standard radiological work-up with CT scan and MRI with contrast has demonstrated the right fossa of Rosenmuller as the origin of the mass and contact with the soft palate. Tissue biopsy under local anesthesia confirmed the diagnosis.

RESULTS

After a multidisciplinary discussion, the patient underwent surgical treatment with type I transnasal endoscopic nasopharyngectomy and reconstruction with nasoseptal flap. Surgery was successfully completed without complications and with a short hospital stay. No clinical evidence of recurrence has been observed to date. No perioperative or postoperative complications were reported. No signs of recurrence were detected in the clinical surveillance.

CONCLUSIONS

Isolated plasmacytoma of the nasopharynx represents a rare but important diagnosis in the context of atypical nasopharynx tumors. An integrated clinical-radiological-histological approach with a multidisciplinary approach is fundamental for correct diagnosis and therapeutic planning. In a few cases, the endoscopic surgery represents an efficient and safe therapeutic option; however, the risk of myeloma progression necessitates a prolonged and structured follow-up.

Neck Fibromatosis

Dr.Büşra BALCI ÇUHADAR[1], **Dr.Hilal HIRCA DUMAN**[1], **Dr.İlda TANRISEVER PEHLİVAN**[1], **Dr.Çağlar EKER**[1], **Dr.Elvan ONAN**[1]

[1]*The Department of Otorhinolaryngology (Ear, Nose and Throat Department), Çukurova University Balcalı Hospital.*

BACKGROUND & AIM

INCTRODUCTION

Definition: Fibromatosis is a rare, benign soft tissue tumor characterized by fibroblastic/myofibroblastic proliferation, which can exhibit locally aggressive behavior.

Clinical Course: It is exceptionally rare in the head and neck region. Despite its benign histological nature, it tends to show infiltrative growth into surrounding tissues.

Method: While radiological imaging and histopathological examination play a critical role in diagnosis, surgical excision remains the mainstay of treatment.

MATERIAL & METHODS

CASE STUDY

A 52 years old female patient with no known comorbidities presented with neck mass and swelling

History:

The patient's medical history revealed a neck trauma approximately 5 years ago.

She was evaluated at an external center 6–7 months ago due to the development of neck swelling. Following a biopsy, she was referred to the oncology department with a provisional diagnosis of fibromatosis.

The patient did not report constitutional symptoms such as night sweats,fever,or weight loss.

Physical Examination (PE):

Right Level 5A (Infraclavicular region): A firm, fixed mass measuring approximately 3×2 cm was palpated.

IMAGING FINDINGS

Modality Key Findings

Contrast-Enhanced Neck CT

• A homogeneously enhancing lesion originating from the right suboccipital region and extending deep into the sternocleidomastoid (SCM) muscle.

• A solid fibrotic mass appearance extending craniocaudally along the C1–C5 levels.
• No pathological lymphadenopathy (LAP) was detected.
PATHOLOGY AND IMMUNOHISTOCHEMISTRY
Biopsy Result: Fibroblastic / myofibroblastic tumor (compatible with fibromatosis).
Immunohistochemical (IHC) Profile:
Beta-catenin: Focal nuclear positive (+)
SMA (Smooth Muscle Actin): Focal positive (+)

RESULTS

RESULTS
Although fibromatosis exhibits histologically benign features, its locally infiltrative nature complicates surgical planning in anatomically confined areas such as the head and neck.
Differential Diagnosis to Consider:
Fibrosarcoma
Nodular fasciitis
Desmoid tumor
Reactive fibrotic lesions
Critical Note: The nuclear positivity of beta-catenin detected in this case is the most crucial immunohistochemical finding supporting the definitive diagnosis of fibromatosis over other differential diagnoses.

CONCLUSIONS

CONCLUSIONS
Fibromatosis located in the head and neck region can be challenging for clinicians due to its rarity.
A definitive diagnosis requires a combined evaluation of clinical presentation, radiological imaging (CT/MRI), and histopathological/IHC findings.
The primary treatment is wide surgical excision, and long-term follow-up is essential due to the high propensity for local recurrence

Malignant Peripheral Nerve Sheath Tumor Of The Head And Neck In The Pericarotid Plexiform: A Case Report Of A Rare Disease Entity

Farhan Alanazi[2], **Hisham Almousa**[1], **Shahd Alsaqoub**[2], **Saeed AlQahtani**[2], **Alyaa Almutairi**[2], **Fareed Alghamdi**[2]

[1]*Department of Otolaryngology - Head and Neck Surgery, King Saud University, Riyadh, Kingdom of Saudi Arabia.*; [2]*Department of Otolaryngology-Head and Neck Surgery, Prince Sultan Military Medical City, Riyadh, Saudi Arabia*

BACKGROUND & AIM

Malignant peripheral nerve sheath tumors (MPNST) are rare high-grade sarcomas that arise from cells of the peripheral nerve sheaths. They are considered as one of the most aggressive malignant lesions in the head and neck region, with a notably high rate of local recurrence.

MATERIAL & METHODS

In the current case report, we described A 28-year-old female known to have neurofibromatosis type 1 (NF1) with a rare case of MPNST in the right sided neck and reviewed the relevant literature.

RESULTS

A 28-year-old female known to have neurofibromatosis type 1 (NF1) with a rare case of MPNST in the right sided neck. Computed tomography (CT) scan of the head and neck with contrast was initially obtained and showed right sided soft tissue neck mass that was predominantly cystic. Head and neck magnetic resonance imaging (MRI) with contrast demonstrated a large right pericarotid plexiform heterogeneously enhancing tumor. Subsequently surgical excision of the mass under general anesthesia was done. Histopathology of the mass was reported to be malignant peripheral nerve sheath tumor (low grade).

CONCLUSIONS

The patient was kept on regular follow-up in the head and neck combined clinic, and the surgical site healed well in six weeks, with no sign of local recurrence or metastasis.

KEYWORDS

Malignant peripheral nerve sheath tumor, pericarotid plexiform, neurofibromatosis, head and neck neoplasm.

Surgical Updates In Differentiated Thyroid Cancer: Insights From The 2025 ATA Guidelines

Jabir Alharbi[1]

[1]*King Abdullah Medical City - Makkah*

BACKGROUND & AIM

The 2025 American Thyroid Association (ATA) Guidelines introduce significant changes to the surgical management of Differentiated Thyroid Cancer (DTC). This review aims to synthesize these updates, focusing on the shift toward individualized care and surgical de-escalation, to provide actionable insights for head and neck surgeons.

MATERIAL & METHODS

We performed a critical review of the 2025 ATA Management Guidelines for Adult Patients with Differentiated Thyroid Cancer. Key updates regarding preoperative assessment, extent of thyroidectomy, and lymph node management were identified and compared against the 2015 recommendations to highlight major practice changes.

RESULTS

The 2025 guidelines emphasize the "DATA" framework (Diagnosis, Assessment, Treatment, Assessment) for risk-adapted surgery. Key shifts include:

- Lobectomy as Standard: Strongly recommended for intrathyroidal DTC (1–4 cm) without gross extrathyroidal extension.
- Conservative Lymph Node Management: Prophylactic central neck dissection is discouraged for cN0 T1/T2 papillary thyroid carcinoma.
- Active Surveillance: Validated as safe for low-risk papillary microcarcinomas (<1 cm), reducing immediate surgery indications.

CONCLUSIONS

The 2025 ATA Guidelines mark a definitive move toward surgical de-escalation. Implementing these insights requires prioritizing risk stratification over routine aggressive resection. These updates aim to reduce surgical morbidity while maintaining excellent oncologic outcomes.

Differentiated Thyroid Cancer, ATA Guidelines, Surgical De-escalation, Lobectomy, Active Surveillance

PP-250

Pleomorphic Adenoma Vs. Polymorphous Adenocarcinoma: Navigating The Diagnostic Challenge

Jehad Hammad[1]

[1]*Salmaneya Medical Complec ,SMC, Bahrain*

BACKGROUND & AIM

The distinction between pleomorphic adenoma (PA) and polymorphous adenocarcinoma (PAC) of the salivary glands represents a significant diagnostic challenge with profound implications for patient management. While histologically distinct, their clinical and sometimes cytological presentations can overlap, creating a "clinical masquerade" that can lead to misdiagnosis and suboptimal treatment. This is particularly true in minor salivary glands, where PAC is more common and can present as an indolent, slow-growing mass mimicking a benign lesion. This educational review presents a systematic framework for differentiating these two entities, from clinical presentation to molecular diagnostics, to guide accurate diagnosis and appropriate therapeutic intervention.

MATERIAL & METHODS

This study provides a comprehensive review of the key differentiating features between PA and PAC based on current literature and clinical evidence. We analyze and contrast the entities across five critical domains: 1) Anatomical location and epidemiology; 2) Histopathological and immunohistochemical (IHC) characteristics, including the roles of GFAP and perineural invasion (PNI); 3) Molecular signatures, specifically PLAG1 translocations for PA and PRKD gene family mutations for PAC; 4) Radiographic features on MRI; and 5) Cytological pitfalls in Fine Needle Aspiration Cytology (FNAC). Two illustrative case studies are presented to demonstrate the clinical application of this diagnostic framework in resolving ambiguous presentations.

RESULTS

The comparative analysis reveals a clear diagnostic algorithm. PA is most common in the parotid gland, is typically GFAP positive, and is associated with PLAG1 rearrangements. In contrast, PAC is more frequent in the minor salivary glands of the palate, is defined by its infiltrative growth, "Indian filing" pattern, and hallmark perineural invasion, and is linked to PRKD mutations. While FNAC is useful for confirming salivary origin, it has a significant rate of indeterminate results due to sampling error and cytological overlap. Case studies demonstrate that clinical "red flags" (e.g., rapid growth, pain) can be misleading, as benign PA can present with aggressive features, while indolent PAC can mimic a benign course. The definitive diagnosis relies on a multi-pronged approach where histopathology and IHC, supported by molecular testing, are paramount.

CONCLUSIONS

Accurate differentiation between PA and PAC is critical as it dictates a dramatic divergence in management, from simple surgical excision for PA to aggressive multimodal therapy (wide excision, neck dissection, and adjuvant radiotherapy) for PAC, particularly when PNI is present. Relying on a single feature, such as clinical history or FNAC, is insufficient. A systematic framework integrating anatomical site, histopathology, IHC, and molecular markers is essential to unmask the clinical masquerade, prevent misdiagnosis, and ensure optimal patient outcomes. The integration of emerging AI-driven diagnostic tools may further enhance diagnostic accuracy in the future.

Cystic Neck Mass Mimicking Branchial Cleft Cyst: A Diagnostic Pitfall Of Arteriovenous Hemangioma

Siraç IRMAK[1], **Adil Çınar AKKAYNAK**[1], **Enes SIRMA**[1], **Müslüm AYRAL**[1]

[1]*Kulak Burun Boğaz Anabilim Dalı, Gazi Yaşargil Eğitim ve Araştırma Hastanesi, Diyarbakır, Türkiye*

BACKGROUND & AIM

Cystic neck masses are commonly diagnosed as benign lesions such as Branchial cleft cyst. However, vascular tumors like Arteriovenous hemangioma may rarely mimic cystic lesions on imaging. This study aims to present a case of arteriovenous hemangioma presenting as a cystic neck mass and to highlight the importance of considering vascular lesions in the differential diagnosis to avoid intraoperative complications.

MATERIAL & METHODS

A 52-year-old male presented with a painless swelling in the left submandibular region. Ultrasonography (USG) demonstrated a 38×30 mm lesion containing millimetric cystic areas, suggestive of a lymphoepithelial cyst. Contrast-enhanced magnetic resonance imaging (MRI) revealed a 42×18×26 mm well-lobulated mass extending from the left submandibular gland to the level of the thyroid cartilage. The lesion appeared hyperintense on T2-weighted images and hypointense on T1-weighted sequences, with peripheral contrast enhancement. Based on these findings, a preliminary diagnosis of a cystic lesion, including lymphangioma or Branchial cleft cyst, was made. Surgical excision was performed, and the specimen was submitted for histopathological analysis.

RESULTS

During surgery, the lesion was found to be inconsistent with a simple cyst and was associated with unexpected significant intraoperative bleeding. Complete excision was achieved without major complications. Histopathological examination revealed abnormal vascular channels lined with endothelial cells, consistent with an Arteriovenous hemangioma. The postoperative course was uneventful, and no recurrence or complications were observed during follow-up. These findings indicate that vascular lesions may mimic cystic masses on imaging and may only be definitively diagnosed after histopathological evaluation.

CONCLUSIONS

Arteriovenous hemangioma may mimic cystic neck lesions and represent a significant diagnostic pitfall. Careful evaluation of imaging findings, particularly peripheral enhancement and lobulated morphology, is essential. Preoperative vascular assessment, including Doppler ultrasonography, should be considered in suspicious cases to prevent unexpected intraoperative bleeding and ensure safe surgical management.

Multinodular Goiter With A Retropharyngeal Extension: A Report Of Two Cases And Literature Review

Sarah M Alqahtani[1], **Rawaa N Alwohaibi**[1], **Mohammed S Alahmari**[1], **Turki M Almuhaimid,**[1]

[1]*Department of Otolaryngology Head and Neck Surgery, King Fahad Specialist Hospital, Dammam, Saudi Arabia*

BACKGROUND & AIM

Multinodular goiter (MNG) is a chronic benign nodular enlargement of the thyroid gland. It presents as an anterior painless neck mass, potentially progressing to exert pressure on the trachea and esophagus and giving rise to compressive symptoms. MNG is a common thyroid gland disorder; however, retropharyngeal goiter is considered rare with few reported cases.

MATERIAL & METHODS

Case Report, A presentation of two cases with multinodular goiter with retropharyngeal extension

RESULTS

We report the cases of two patients who presented to our institution with MNG with retropharyngeal extension: a 62-year-old female patient who presented with a progressive anterior neck mass with dilated neck veins; and a 49-year-old male who presented with a painless anterior neck mass. Both patients successfully underwent total thyroidectomy with an uneventful postoperative recovery.

CONCLUSIONS

The clinical presentation of MNG with retropharyngeal extension varies with patients; hence, a high index of suspicion is of the utmost significance. While the retropharyngeal extension does not cause compressive symptoms, it should raise the suspicion of a large retrosternal component

Parapharyngeal Space Tumor: A Diagnostic Challenge

Ana Raquel Andrade[1], **Eduardo Ferreira**[1], **Ana Sofia Paiva**[1], **Carolina Arede**[1], **Joaquim Amaral**[1]

[1]*Hospital do Divino Espírito Santo De Ponta Delgada*

BACKGROUND & AIM

Tumors arising in the parapharyngeal space represent a diagnostic challenge due to their rarity and overlapping radiologic features. Cervical sympathetic chain schwannoma (CSCS) is an uncommon benign tumor that may mimic carotid body paraganglioma, particularly when associated with carotid bifurcation splaying (the “Lyre sign”). Preoperative differentiation between these entities is often difficult and may influence surgical planning. We report a case of CSCS with imaging findings suggestive of paraganglioma.

MATERIAL & METHODS

We report a single case of a parapharyngeal space tumor evaluated through clinical examination and multimodal imaging, including contrast-enhanced computed tomography and magnetic resonance imaging. Surgical management was performed via a transcervical approach. Histopathological analysis established the definitive diagnosis. A focused review of the literature was conducted to contextualize imaging characteristics and postoperative outcomes associated with cervical sympathetic chain schwannomas.

RESULTS

A 32-year-old woman was referred after incidental detection of a left parapharyngeal mass on computed tomography. She was asymptomatic, and physical examination revealed a painless, firm, left submandibular mass. Contrast-enhanced CT demonstrated a well-defined lesion centered in the left carotid space, measuring approximately 5 cm in greatest dimension, causing splaying of the internal and external carotid arteries (Lyre sign), suggestive of carotid body paraganglioma or vagal schwannoma. Magnetic resonance imaging showed a well-circumscribed lesion with T1 hypointensity, heterogeneous T2 signal with focal hyperintensities, and marked contrast enhancement, displacing the ipsilateral parapharyngeal space medially.

The patient underwent transcervical surgical excision. Intraoperatively, the tumor was identified as originating from the cervical sympathetic chain. Complete resection required sectioning of the sympathetic trunk. Histopathological examination confirmed schwannoma.Postoperatively, the patient developed ipsilateral Horner syndrome (ptosis, miosis, anhidrosis), which was well tolerated and partially improved at one-month follow-up.

CONCLUSIONS

Parapharyngeal tumors located at the carotid bifurcation require careful radiologic interpretation, as carotid artery splaying is not pathognomonic of paraganglioma. Cervical sympathetic chain schwannoma should be considered in the differential diagnosis. Accurate preoperative suspicion is essential for appropriate surgical counseling, particularly regarding the risk of postoperative Horner syndrome.

PP-254

NON-HODGKIN LYMPHOMA OF THE LARYNX AS A PRIMARY PRESENTATION OF THE DISEASE

Vladan Milutinovic[1,2], **Zorana Radin**[1], **Snezana Babac**[1,3]

[1]Clinic for Ear, Nose, and Throat, Zvezdara University Medical Center, Belgrade, Serbia; [2]Faculty of Dental Medicine, University of Belgrade, Belgrade, Serbia; [3]Faculty of Special Education and Rehabilitation, University of Belgrade, Belgrade, Serbia

BACKGROUND & AIM

Primary non-Hodgkin lymphoma (NHL) rarely arises within the larynx, accounting for less than 1% of laryngeal neoplasms. It may remain strictly confined to the larynx or represent an initial localized manifestation of an underlying systemic malignancy. Most frequent histological subtype encountered in this anatomical region is diffuse large B-cell lymphoma (DLBCL). The clinical presentation typically features an exophytic, submucosal tumor mass with smooth, non-ulcerated mucosa, predominantly localized in the supraglottis. The therapeutic approach comprises chemotherapy, radiotherapy, immunotherapy depending of clinical stage. This study aims to delineate the clinical features, diagnostic challenges, and multidisciplinary management strategies regarding this rare laryngeal malignancy.

MATERIAL & METHODS

This case study evaluates a 61-year-old female patient who presented with a history of progressive dysphagia, dysphonia, a dry irritative cough, and constitutional symptoms including night sweats. A comprehensive diagnostic workup was conducted, including direct laryngoscopy, which revealed a prominent, exophytic, submucosal supraglottic tumor mass characterized by smooth overlying mucosa without ulcerations. A representative biopsy of the laryngeal mass was performed, followed by definitive histopathological and immunohistochemical evaluations, as well as comprehensive systemic staging investigations.

RESULTS

The histopathological and immunohistochemical profiles established a definitive diagnosis of diffuse large B-cell non-Hodgkin lymphoma, classified as stage IVB due to verified extranodal involvement. The patient was immediately scheduled for targeted systemic treatment and successfully completed six full cycles of chemo-immunotherapy according to the standard Rituximab-CHOP (cyclophosphamide, doxorubicin, vincristine, and prednisone) protocol, achieving a favorable initial therapeutic response.

CONCLUSIONS

Diffuse large B-cell non-Hodgkin lymphoma of the larynx represents a rapidly progressing and highly aggressive form of hematological malignancy. Management relies strictly on timely, specific hematologic-oncologic therapy. Surgical intervention is not the primary treatment modality and remains indicated exclusively in acute scenarios of airway compromise or an unfavorable response to systemic chemo-immunotherapy. The manifestation of laryngeal lymphoma in the context of generalized, advanced-stage disease is statistically associated with a poorer prognosis. Further research focused on the clinico-pathological characteristics of these rare presentations is vital to optimize targeted therapeutic options and improve long-term survival rates.

PP-255

Diagnostic Challenges In Calcitonin Negative Medullary Thyroid Carcinoma: A Systematic Review Of 101 Cases

Mashal Abaalkhail[2], **Saleh Alqaryan**[2], **MOHAMMED ALESSA**[1]

[1]KING SAUD UNIVERSITY; [2]MINISTRY OF NATIONAL GUARD HEALTH AFFAIRS

BACKGROUND & AIM

Calcitonin-negative medullary thyroid carcinoma (CNMTC), a rare form of MTC characterized by classic histopathology with normal serum calcitonin levels, presents a diagnostic challenge. This systematic review aims to summarize the clinical and pathological features of CNMTC and evaluate the utility of alternative biochemical markers.

MATERIAL & METHODS

Eligibility criteria for this systematic review included patients with a confirmed histopathological diagnosis of medullary thyroid carcinoma (MTC), normal preoperative serum calcitonin levels, or negative immunohistochemical (IHC) stain for calcitonin. A comprehensive electronic search strategy was employed on PubMed, Scopus, and Embase databases from January 1st, 1950, to March 9th, 2023.

RESULTS

This systematic review consists of 32 studies with 101 patients (66% females, 33% males) with a mean age of 52.2 years. All patients had a preoperative serum calcitonin level below the upper reference limit. Out of 101 patients, only seven underwent the Pentagastrin Stimulation Test (PST), only two patients had elevated calcitonin levels after stimulation. A total of 59 patients were tested for carcinoembryonic antigen (CEA) levels, and the majority tested normal (n=51, 86.4%). A total of 57 patients (61.2%) were found to have positive IHC staining on operative specimens for calcitonin. No recurrence was reported in the majority of cases, only 10 patients (9.9%) experienced recurrence.

CONCLUSIONS

Despite the rarity of CNMTC, it is crucial to maintain a high level of suspicion when evaluating thyroid nodules. Total thyroidectomy with central neck dissection remains as the primary treatment. A multimarker approach may improve the sensitivity and specificity of CNMTC diagnosis and surveillance, particularly when calcitonin and CEA levels are inconclusive.

KEYWORDS

edullary thyroid carcinoma (MTC); calcitonin; carcinoembryonic antigen (CEA); chromogranin A (CgA); procalcitonin (PCT).

Comparison Among Different Tracheostomy Procedures In Critically Ill Patients – Is It Time For Hybrid Approach?

Marko Kmet, MD[1], **Peter Hudoklin, MD**[1]

[1]*Department of Otorhinolaryngology, General Hospital Novo mesto, Novo Mesto, Slovenia*

BACKGROUND & AIM

Many critically ill patients require tracheostomy. It can be done by using classic ENT operation or by percutaneous approach. The latter is preferred in ICUs.

In the last few years a hybrid operation is becoming more prominent, during which an ENT specialist makes the initial incision and prepares the underlying tissues. After exposing trachea, an intensivist performs the tracheostomy by using a set of percutaneous dilators without making the tracheal fenestration. Percutaneous and hybrid procedures can be further combined with bronchoscopic monitoring of the needle insertion.

We analysed the frequency of adverse events in all three types of procedure.

MATERIAL & METHODS

Material & Methods

We included 64 ICU patients who had a tracheostomy constructed in a period from 1.1.2015 to 31.12.2025. Both surgical and medical ICU patients were included; 43 from surgical ICU and 21 from medical ICU, respectively. We analysed the occurence of most frequent adverse events: haemorrhage in the first 72 hours and after 72 hours after the procedure, subcutaneous emphysema, trauma to the larynx, thyroid, paralaryngeal and paratracheal nerve structures, dehiscence of the wound and other specific complications which could be attributed to the procedure itself. We compared the samples by using two-tailed T test.

RESULTS

Results

Our study shows that there were fewer complications when using the hybrid technique, albeit the p values were statistically not significant wheteher comparing classic ENT operation to percutaneous procedure ($p = 0.84$), classic ENT operation to hybrid procedure ($p = 0.37$), percutaneous to hybrid procedure ($p = 0.35$) or classic ENT operation and percutaneous procedure combined to hybrid procedure ($p = 0.33$), respectively.

CONCLUSIONS

Conclusions

In our study, the incidence of complications was lower in hybrid procedures. Albeit there was no statistically significant difference, there seems to be a rationale to use the hybrid approach in high-risk patients; i.e. patients with short necks, with thyroid isthmus overlaying trachea just below the cricoid carthilage, with vascular structures close to the insertion point etc. The downside seems to be that two specialist are needed in this type of procedures. Since our study only included 64 patients further studies in this field are neccessary.

Challenges In Providing Care For Malignant Neuroendocrine Tumors Of Head And Neck.

Lamali Lina Celia[1], **Kirouane Fatima**[1], **Hachemi Mohamed**[1], **Medkour Samira**[1], **Djennane Nassima**[2], **Hasbellaoui Mokhtar**[1]

[1]*ENT head and neck surgery department , Lamine Debaghine hospital, University of Health Sciences;* [2]*Pathology department, Lamine Debaghine hospital, University of Health Sciences*

BACKGROUND & AIM

Neuroendocrine tumors (NETs) are uncommon malignancies originating from cells with dual neuronal and endocrine differentiation. They comprise 0.5–2% of all cancers, with an incidence of approximately 2–5 per 100,000 annually. While the gastrointestinal tract is the predominant primary site, head and neck involvement remains rare (<1%), most frequently affecting the larynx. Their biological heterogeneity complicates the management.

This study aims to highlight this type of ENT tumors, clarify the diagnosis process and the difficulties involved in therapeutic management.

MATERIAL & METHODS

We present three cases of patients with malign neuroendocrine tumors of the head and neck treated over a five-years period (January 2020 to December 2025).

The patients underwent clinical and paraclinical investigations with histological confirmation in our departement.

RESULTS

Two cases involved the larynx : males, 48 and 61 years old; the symptom was chronic dysphonia.

Suspension laryngoscopy and HRCT revealed a tumor invading the glottic and supraglottic region.

Histopathological analysis, immunohistochemical profiling, confirmed the diagnosis and classified the tumors as small and large cell neuroendocrine carcinoma.

The third case: male, 85-year-old, presented with ear pain. Examination revealed a mass in the external auditory canal, extending to the parotid region.

HRCT of the petrous bones and an MRI of the parotid gland, followed by a biopsy, suggested squamous cell carcinoma.

Treatment consisted of large surgical resection and lymph node dissection.

The histopathological examination corrected the diagnosis of small cell neuroendocrine tumor.

After comprehensive staging, only one case present a bone metastases.

After multidisciplinary consultation, chemoradiotherapy was offered to the patients with laryngeal involvement, and targeted therapy to the patient with auricular involvement.

The clinical outcome was unfavorable, with death of the patients within an average of 7 months.

CONCLUSIONS

Malign neuroendocrine tumors of the head and neck are rare. Their therapeutic management is primarily guided by the histological subtype and tumor grade. Early diagnosis is essential to improve the prognosis. Management requires a multidisciplinary approach.

Castleman Disease Mimicking Warthin Tumor Of The Parotid Gland: A Rare Case Report

Belgin Tutar[1], **Muhammet Osman Doğan**[1]

[1]*Prof.Dr. Cemil Taşcıoğlu City Hospital*

BACKGROUND & AIM

Castleman disease is a rare benign lymphoproliferative disorder that most commonly involves the mediastinum. Head and neck involvement is uncommon, while parotid gland localization is exceedingly rare. Because radiological and cytological findings are frequently nonspecific, preoperative diagnosis may be challenging and lesions may mimic benign salivary gland tumors such as Warthin tumor. We aimed to present a rare case of hyaline vascular type Castleman disease of the parotid gland mimicking Warthin tumor.

MATERIAL & METHODS

A 28-year-old woman presented with swelling on the right side of the neck. Physical examination revealed a mobile mass measuring approximately 2–3 cm at the inferior pole of the right parotid gland. Oral cavity, nasopharyngeal, otoscopic, and endoscopic laryngeal examinations were normal. Ultrasonography and magnetic resonance imaging were performed. MRI demonstrated a well-circumscribed 25 × 16 mm lesion radiologically suggestive of Warthin tumor. Fine-needle aspiration biopsy revealed lymphoid series cells consistent with a lymph node. The patient subsequently underwent superficial parotidectomy for excisional biopsy.

RESULTS

Histopathological examination of the surgical specimen revealed hyaline vascular type Castleman disease . Microscopic evaluation demonstrated characteristic hyalinized follicles and vascular proliferation consistent with unicentric Castleman disease. The postoperative period was uneventful, and no recurrence was observed during follow-up.

CONCLUSIONS

Castleman disease should be considered in the differential diagnosis of parotid masses, particularly when radiological and cytological findings are inconclusive. Parotid localization is extremely rare and may mimic benign salivary gland tumors such as Warthin tumor. Histopathological examination remains the gold standard for definitive diagnosis, while complete surgical excision is both diagnostic and curative in unicentric disease.

PAPILLARY THYROID CARCINOMA ARISING FROM A THYROGLOSSAL DUCT CYST: A CASE REPORT

İsmet Vurur, MD[2], **Burak Kaan Inan, MD**[2], **Prof. Dr. Zahide Mine Yazıcı, MD**[2], **Prof. Dr. İbrahim Sayın, MD**[2], **Necmettin Can Ozkanbas, MD**[2]

[1]*Dr. Sadi Konuk Training and Research Hospital;* [2]*Dr. Sadi Konuk Training and Research Hospital, Bakırköy, İstanbul, Türkiye*

BACKGROUND & AIM

Thyroglossal duct cysts (TGDCs) are the most common congenital midline neck masses and are typically benign. However, malignant transformation—most frequently into papillary thyroid carcinoma—is rare but clinically significant. Preoperative diagnosis is challenging, particularly in cystic lesions where fine-needle aspiration biopsy (FNAB) may yield false-negative results. Suspicious radiologic findings may therefore play a critical role in guiding management. This study aims to present a case of papillary thyroid carcinoma arising within a TGDC despite repeated benign cytology and to emphasize the diagnostic limitations and surgical implications of this entity.

MATERIAL & METHODS

A 25-year-old woman presented with a gradually enlarging midline neck mass. Initial ultrasonography demonstrated a cystic lesion, while contrast-enhanced MRI confirmed a well-defined infrahyoid midline cyst distinct from the thyroid gland. Subsequent imaging revealed internal calcifications and a solid component. Two ultrasound-guided fine-needle aspiration biopsies (FNAB) were performed using liquid-based cytology; the first was nondiagnostic and the second reported benign findings. Given the persistent radiologic suspicion for malignancy, the case was discussed in a multidisciplinary setting, and a standard Sistrunk procedure was performed for definitive diagnosis and treatment.

RESULTS

Histopathological examination revealed classic-type papillary thyroid carcinoma confined to the thyroglossal duct cyst wall without extracystic extension. Surgical margins were negative. Postoperative evaluation demonstrated a clinically and radiologically normal thyroid gland with no evidence of cervical lymph node involvement. The case was reviewed in a multidisciplinary tumor board, and given the low-risk profile, no additional surgery or radioactive iodine therapy was recommended. At six-month follow-up, the patient remains disease-free with no signs of recurrence or metastasis.

CONCLUSIONS

Papillary thyroid carcinoma may arise within a thyroglossal duct cyst despite repeated benign cytology. In cystic midline neck lesions, fine-needle aspiration biopsy has important diagnostic limitations and false-negative results are not uncommon. Suspicious radiologic features should therefore guide surgical decision-making. The Sistrunk procedure provides definitive diagnosis and effective treatment in selected low-risk cases.

thyroglossal duct cyst; papillary thyroid carcinoma; Sistrunk procedure; fine-needle aspiration biopsy; midline neck mass

PP-260

Delayed Migration Of A Cervical Spine Screw Into The Esophagus - A Rare Case Report

Daniela Cîrpaciu[1,2], **Vlad Andrei Budu**[2], **Remus Gabriel Mihalcea**[2], **Mihaela Cristina Negru**[3], **Mihai Magurean**[4], **Cristina Maria Goanta**[1,2]

[1]*UMF Carol Davila, Bucharest Romania;* [2]*ENT Department, Colentina Clinical Hospital, Bucharest, Romania;* [3]*ENT Department, Timișoara Municipal Emergency Clinical Hospital;* [4]*Department of Neurosurgery – Spine Surgery Colentina Clinical Hospital, Bucharest, Romania*

BACKGROUND & AIM

Esophageal perforation is a rare but potentially life-threatening complication of anterior cervical spine surgery. Most perforations are identified either intraoperatively or during the early postoperative period. Delayed migration of anterior cervical spine fixation hardware represents an exceptionally rare complication with only a few cases documented in the literature to date.

We present a rare case of delayed screw migration into the upper aerodigestive tract, 20 years after cervical spine surgery, manifesting with acute laryngeal dysfunction and high esophageal perforation.

MATERIAL & METHODS

A 65-year-old obese man, with stage IV ankylosing spondylitis, had undergone anterior cervical fusion with bone grafting and plate fixation following a traumatic cervical spine fracture, sustained in a car accident, 20 years earlier. He presented with recent dysphonia, dyspnea, dysphagia, and odynophagia, with progressive worsening over two weeks.

•Flexible fibroscopy showed significant laryngeal edema with marked arytenoid swelling, impaired mobility of the posterior laryngeal commissure, and significant narrowing of the laryngeal airway, while the epiglottis remained normal.

•Upper gastrointestinal endoscopy confirmed granulation tissue corresponding to the migrated screw.

• Contrast-enhanced computed tomography (CT) revealed diffuse perilaryngeal edema causing approximately 43 mm of subhyoid laryngeal stenosis, heterogeneous prevertebral inflammatory changes with air adjacent to the C5-C7 vertebrae, and migration of a cervical fixation screw into the upper esophagus, with suspicion of pharyngo-esophageal perforation.

RESULTS

Given the esophageal perforation and progressive airway compromise, urgent surgery was performed. Tracheostomy was followed by exploratory cervicotomy, under general anesthesia, by a combined otolaryngology and neurosurgery team. The migrated screw was removed and the esophageal perforation was repaired by primary closure. Enteral feeding was maintained via a nasogastric tube. Laryngeal edema gradually resolved, allowing decannulation on postoperative day 10. Follow-up CT showed regression of the inflammatory changes, while upper gastrointestinal endoscopy on day 12 confirmed esophageal healing without persistent fistula, permitting safe oral feeding. Despite postoperative pulmonary thromboembolism requiring anticoagulation, the patient recovered well, with complete resolution of dyspnea, dysphagia, and dysphonia, and full restoration of laryngeal function.

Advanced ankylosing spondylitis, obesity, and dense postoperative scarring markedly increased the complexity of surgical exposure and dissection.

CONCLUSIONS

•Delayed migration of cervical fixation hardware into the upper aerodigestive tract is exceedingly rare, with only a few cases reported to date.

•This case underscores the importance of maintaining a broad diagnostic perspective and remaining alert to rare but plausible clinical scenarios.

•Prompt endoscopic and radiologic assessment within a multidisciplinary framework enables early diagnosis and treatment, minimizing the risk of serious complications.

KEYWORDS

delayed screw migration, esophageal perforation, laryngeal edema

PP-261

A Case Of Myxofibrosarcoma In The Parotid Gland

Buğra Sivrikaya[1], **Yavuz Gündoğdu**[1], **Orhan Asya**[1], **Celal Emre Çavlan**[1], **Ali Cemal Yumuşakhuylu**[1]

[1]*Marmara University Hospital, Department of Otorhinolaryngology – Head and Neck Surgery, Istanbul, Turkey*

BACKGROUND & AIM

Myxofibrosarcoma (MFS) is a fibroblastic soft tissue sarcoma most commonly arising in the extremities of older adults and is characterized by infiltrative growth and a high risk of local recurrence. Head and neck involvement is rare, with only a few cases reported in the salivary gland region. Given its aggressive behavior and the limited literature on salivary gland localization, further documentation is needed. This study aims to present a rare case of MFS involving the salivary gland region and to discuss its clinical, radiological, and histopathological features, along with management considerations.

MATERIAL & METHODS

This case study focuses on a 65-year-old male with an enlarging mass in the left parotid region. Initially diagnosed via fine needle aspiration as a pleomorphic adenoma, the patient underwent a left superficial parotidectomy, followed by revision surgeries due to recurrence and radiotherapy.

RESULTS

Pathological analysis revealed low-grade MFS with perineural invasion. Despite postoperative radiotherapy and planned chemotherapy, the patient experienced significant local recurrence, confirmed through imaging and fine needle aspiration.

CONCLUSIONS

This case underscores the difficulties in achieving negative surgical margins in primary MFS of the head and neck. It highlights the aggressive nature of MFS, emphasizing the need for further studies on effective management strategies and facial nerve preservation during surgery.

PP-262

Intrathyroidal Paraganglioma Of The Thyroid Gland: A Case Report Highlighting Challenges In Cytological And Surgical Management

Mim Kürşat Alkan[1], **Fırat Tevetoğlu**[1], **Yavuz Beşli**[1], **Tolga Küçükgergin**[1], **Haydar Murat Yener**[1]

[1]*Istanbul University-Cerrahpaşa, Cerrahpaşa Faculty of Medicine, Department of Otorhinolaryngology, Istanbul, Turkey.*

BACKGROUND & AIM

Intrathyroidal paraganglioma (ITP) is an exceptionally rare neuroendocrine neoplasm, accounting for less than 0.1% of all thyroid tumors. It originates from the inferior laryngeal paraganglia that become entrapped within the thyroid gland during embryogenesis. Clinically and radiologically, ITP often presents as a hypervascular nodule, frequently leading to diagnostic confusion with follicular or medullary thyroid carcinomas. Due to its rarity and the limitations of fine-needle aspiration cytology (FNAC), most cases are diagnosed postoperatively through immunohistochemical analysis.

MATERIAL & METHODS

A 68-year-old male patient presented with an incidentally detected thyroid nodule during routine follow-up. Initial evaluation via FNAC in 2020 was reported as Atypia of Undetermined Significance). A repeat biopsy in 2021 was reported as Suspicious for Follicular Neoplasm (Bethesda IV). Following a period of non-compliance, the patient returned in 2025.Ultrasonography identified a 33x26x42.5 mm iso-hypoechoic nodule in the left thyroid lobe, featuring cystic degenerative areas and intense internal and peripheral vascularity on Doppler imaging. Preoperative laboratory findings were within normal limits A left hemithyroidectomy was performed. The postoperative course was uneventful, and the patient was discharged after four days of observation.Pathological Findings: Microscopic examination revealed a tumor arranged in a characteristic Zellballen pattern. Immunohistochemistry confirmed the diagnosis, showing positivity for Chromogranin and Synaptophysin, with S100 positivity in the sustentacular cells. Markers of thyroid origin (Thyroglobulin, TTF-1) and Pan-keratin were negative.

RESULTS

The primary challenge of ITP lies in its ability to mimic common thyroid malignancies. In this case, the preoperative diagnosis of Bethesda IV directed the surgical management toward a follicular neoplasm. Radiologically, high vascularity on Doppler USG is a characteristic feature of ITP that should alert the clinician. While ITP is a neuroendocrine tumor like medullary thyroid carcinoma, it is typically Pan-keratin and Calcitonin negative. Due to its unpredictable biological behavior, long-term surveillance is recommended.

CONCLUSIONS

Intrathyroidal paraganglioma remains a "diagnostic chameleon" that frequently eludes preoperative identification due to its remarkable cytological overlap with follicular and medullary thyroid neoplasms. This case underscores the necessity of including paraganglioma in the differential diagnosis of highly vascular thyroid nodules, particularly when fine-needle aspiration yields indeterminate results. While surgical resection is typically curative, the lack of definitive histopathological markers for malignancy necessitates a vigilant, long-term surveillance strategy. Ultimately, a multidisciplinary approach combining clinical suspicion, meticulous surgical technique, and comprehensive immunohistochemical profiling is paramount in achieving favorable outcomes for this rare clinical entity.

Arteriovenous Hemangioma Of The Temporal And Frontal Region: A Case Report

GÖKÇE TANYERİ TOKER[1], **ZİYA ÖZBAYIR**[1], **ÖZGE ERYİĞİT**[1]

[1]*Department of Otorhinolaryngology, İzmir Kâtip Çelebi University Atatürk Training and Research Hospital, İzmir, Türkiye*

BACKGROUND & AIM

Vascular lesions of the head and neck region are uncommon and may clinically and radiologically mimic various soft tissue pathologies. Particularly, vascular masses located in the temporal region can present diagnostic challenges due to their heterogeneous imaging characteristics. Only a limited number of arteriovenous hemangioma cases in the temporal region have been reported in the literature. This study presents a case of arteriovenous hemangioma located in the temporal region.

MATERIAL & METHODS

A 53-year-old male patient presented with a painless swelling in the left temporal region that had been present for approximately six months. The patient reported a long-standing habit of repeatedly scratching and manipulating the same area, with no history of significant blunt or penetrating trauma. Physical examination revealed a soft, pulsatile, mobile subcutaneous mass measuring approximately 3×2 cm in the left temporal area and 1x1 cm in the frontal area. Doppler ultrasonography showed a vascularized solid lesion with millimetric cystic components adjacent to the temporal artery. Contrast-enhanced magnetic resonance imaging demonstrated two heterogeneously enhancing mass lesions located within the superficial cervical fascia in the left frontal and temporal regions. The temporal lesion measured approximately 27×28×20 mm and exhibited partially irregular borders, internal signal void areas, and skin thickening. Radiologically, a fascia-origin mesenchymal tumor was considered in the differential diagnosis.

RESULTS

The patient underwent surgical excision. Histopathological examination revealed arteriovenous hemangioma associated with intravascular papillary endothelial hyperplasia. Immunohistochemical analyses supported the vascular origin. Surgical margins were negative, and the lesion was totally excised. No postoperative complications occurred. Notably, although radiological findings initially suggested a mesenchymal soft tissue malignancy, histopathological examination confirmed the lesion to be a benign vascular lesion (arteriovenous hemangioma).

CONCLUSIONS

Vascular lesions of the temporal region are rare and may clinically and radiologically mimic various soft tissue tumors, including malignant mesenchymal masses. This case suggests that even habitual, repetitive mechanical trauma may contribute to the development of vascular lesions in susceptible individuals. Only a limited number of cases have been reported in the literature. Vascular lesions should be considered in the differential diagnosis of subcutaneous masses in the temporal region. Imaging

findings can be misleading, and histopathological examination remains essential for definitive diagnosis. Surgical excision provides successful diagnostic and therapeutic outcomes.

Multidisciplinary Management Of Severe Radiation-Induced Laryngeal Chondroradionecrosis After Multimodal Treatment Of Poorly Differentiated Thyroid Carcinoma

Orhan Asya[1], **Çağatay Oysu**[1], **Ali Cemal Yumuşakhuylu**[1], **Yavuz Gündoğdu**[1], **Beste Atasoy**[3], **Zeynep Deniz Akdeniz**[2], **Badel Tereci Oran**[1]

[1]*Marmara University, Department of Ear, Nose and Throat, Head and Neck Surgery;* [2]*Marmara University, Department of Plastic, Reconstructive and Aesthetic Surgery;* [3]*Marmara University, Department of Radiation Oncology*

BACKGROUND & AIM

Poorly differentiated thyroid carcinoma (PDTC) is a rare but aggressive malignancy frequently associated with locoregional invasion and poor prognosis. Multimodal treatment strategies, including surgery, chemotherapy and radiotherapy, are often required in advanced cases. However, high-dose cervical radiotherapy may lead to severe late complications such as laryngeal chondroradionecrosis (CRN), a rare but potentially life-threatening condition that can mimic tumor recurrence and pose significant management challenges.The aim of this case report is to present the multidisciplinary management of radiation-induced laryngeal chondroradionecrosis developing after treatment of locally advanced PDTC and to highlight the stepwise therapeutic approach leading to successful resolution.

MATERIAL & METHODS

We report the clinical course of a 64-year-old male initially diagnosed with papillary thyroid carcinoma by fine-needle aspiration biopsy.He underwent total thyroidectomy at an outside institution;however,due to tumor fixation and invasion into the laryngeal cartilage and adjacent structures,complete excision was not feasible,resulting in an R2 resection. Final pathology revealed high-grade differentiated follicular cell–derived thyroid carcinoma, and the patient was referred to our center.Rapid locoregional progression prompted multidisciplinary tumor board discussion and reoperation,revealing extensive invasion of the thyroid and cricoid cartilages,trachea,hypopharynx,cervical esophagus, and regional lymph nodes.Adjuvant external beam radiotherapy and systemic sorafenib therapy were administered.Three months after radiotherapy, a progressively enlarging cervical skin defect and airway compromise developed. Preexisting left vocal cord paralysis was followed by contralateral paralysis and laryngeal fixation. Radiation-induced laryngeal chondroradionecrosis required stepwise multidisciplinary management, ultimately necessitating total laryngectomy with free anterolateral thigh flap reconstruction. Postoperative salivary fistula and partial tracheostomal dehiscence resolved with conservative wound care.

RESULTS

Despite initial conservative management with corticosteroids, antibiotics, and local wound care, the patient developed progressive laryngeal chondroradionecrosis complicated by vocal cord paralysis, cervical soft tissue defects, and salivary fistula formation.Multiple surgical interventions were required, including sternocleidomastoid muscle flap advancement and deltopectoral flap reconstruction, which failed due to ongoing necrosis. Definitive control was achieved with total laryngectomy and free anterolateral thigh flap reconstruction. Postoperative salivary fistulae and tracheostomal dehiscence were successfully managed conservatively, resulting in complete wound healing and stabilization of the airway.

CONCLUSIONS

Radiation-induced laryngeal chondroradionecrosis represents a devastating late complication in the management of locally advanced thyroid carcinoma. This case underscores the importance of early recognition, close multidisciplinary collaboration, and timely escalation from conservative to radical surgical management. Individualized, stepwise treatment strategies are essential to achieve functional stabilization and satisfactory outcomes in advanced CRN.

PP-265

Diagnostic Reclassification Of A Twice-Misdiagnosed Head And Neck Mesenchymal Tumor As A GLI1-Associated Mesenchymal Neoplasm: A Case Report

Ege Bartu Aktaş[1], **Oğuzhan Katar**[1], **Deniz Özmarangoz Baran**[2]

[1]*Department of Otolaryngology, Hacettepe University Faculty of Medicine, Ankara, Türkiye;* [2]*Department of Pathology, Hacettepe University Faculty of Medicine, Ankara, Türkiye*

BACKGROUND & AIM

GLI1-altered mesenchymal tumors of the head and neck are newly recognized neoplasms that may be diagnostically challenging because of overlapping morphologic and immunophenotypic features with other mesenchymal entities.

Diagnostic uncertainty may be further compounded when these tumors arise in uncommon locations or demonstrate unusual patterns of spread. We aimed to present a case of a tongue base–origin GLI1-associated mesenchymal tumor initially diagnosed as two different mesenchymal neoplasms over time, in which comprehensive clinicopathologic and molecular reassessment led to diagnostic revision and identification of an ACTB–GLI1 fusion–positive tumor with secondary thyroid involvement.

MATERIAL & METHODS

Clinical, radiologic, and histopathologic data of a 46-year-old patient with a tongue base mesenchymal tumor were retrospectively reviewed. Previously resected tumor specimens from external institutions were re-evaluated at our center through detailed histopathologic and immunohistochemical examination. Molecular analyses, including fluorescence in situ hybridization and next-generation sequencing, were performed to detect gene rearrangements and fusion events. Serial imaging studies were also analyzed to assess tumor origin, anatomic extent, and disease progression.

RESULTS

Histopathologic reassessment demonstrated morphologic and immunophenotypic features inconsistent with the prior diagnoses of glomangiopericytoma and Ewing sarcoma. Molecular testing showed no EWSR1 rearrangement and identified ACTB–GLI1 fusion, establishing the diagnosis of a GLI1-associated mesenchymal neoplasm originating from the tongue base. Radiologic evaluation revealed secondary thyroid gland involvement and progressive locoregional disease characterized by retropharyngeal extension, vascular encasement, and adjacent structure infiltration. These findings confirmed diagnostic revision and demonstrated locally aggressive behavior not commonly reported in previously described GLI1-altered tumor series.

CONCLUSIONS

GLI1-associated mesenchymal tumors may be misclassified due to overlapping histopathologic features, particularly when arising from uncommon sites such as the tongue base and demonstrating secondary thyroid involvement. This case highlights the decisive role of molecular profiling in establishing accurate diagnosis and reveals an unusual pattern of locoregional spread. Increased awareness of this entity and integration of molecular testing into the diagnostic workflow are essential for appropriate classification and management of atypical head and neck mesenchymal tumors.

PP-266

Recurrent High-Risk Squamous Cell Carcinoma Of The Right Auricle: A Case Managed With Surgical Excision And Adjuvant Radiotherapy

KAYRA BOSTAN[1], **DOÇ.DR.ZEHRA BETUL PAKSOY**[1]

[1]*BILKENT CITY HOSPITAL*

BACKGROUND & AIM

Cutaneous squamous cell carcinoma (cSCC) of the auricle is associated with a high risk of local recurrence and aggressive clinical behavior due to complex anatomy and frequent cartilage involvement. Established adverse prognostic factors include perineural invasion, positive or close surgical margins, and inadequate follow-up. Despite appropriate surgical management, recurrence remains a significant challenge in high-risk cases. The aim of this study is to present a recurrent auricular cSCC with high-risk features and to emphasize the critical role of multidisciplinary management and adjuvant radiotherapy in achieving optimal local disease control.

MATERIAL & METHODS

This study is a single-case report of an 87-year-old male patient with recurrent, high-risk auricular cutaneous squamous cell carcinoma. Clinical presentation, radiological assessment, surgical management, and follow-up data were retrospectively reviewed. The patient underwent multiple surgical excisions for recurrent lesions involving the auricle. All surgical specimens were subjected to comprehensive histopathological examination, including evaluation of tumor differentiation, depth of invasion, perineural invasion, cartilage involvement, and surgical margin status. Periods of loss to follow-up and associated disease progression were documented. Clinical and pathological findings were discussed within a multidisciplinary tumor board setting, and the indication for adjuvant radiotherapy was established based on the presence of high-risk features.

RESULTS

In head and neck malignancies, postoperative follow-up and a multidisciplinary approach are of critical importance in achieving disease control and potential cure.

CONCLUSIONS

In auricular squamous cell carcinomas, recurrence, perineural invasion, and delayed follow-up are key determinants of disease progression. A negative surgical margin alone may be insufficient to prevent recurrence in tumors exhibiting high-risk

biological behavior. As demonstrated in this case, a multidisciplinary approach following surgery, together with adjuvant radiotherapy, is critical for achieving optimal local disease control.

KEYWORDS

Auricle, squamous cell carcinoma, recurrence, perineural invasion, head and neck tumors, adjuvant radiotherapy, multidisciplinary approach, surgical margin, local control, high-risk skin cancer.

Secondary Histiocytic Sarcoma Following Classical Hodgkin Lymphoma: A Rare Case Report

İREM OKUTAN[1], **BUĞRAHAN GÜLSOY**[1], **UTKU AYDİL**[1], **NALAN AKYÜREK**[2], **AYŞENUR SERT**[2]

[1]*Department of Otorhinolaryngology, Gazi University Faculty of Medicine, Ankara, Türkiye;* [2]*Department of Pathology, Gazi University Faculty of Medicine, Ankara, Türkiye*

BACKGROUND & AIM

Histiocytic sarcoma (HS) is an extremely rare and aggressive hematopoietic malignancy that may occur de novo or secondary to pre-existing lymphoid neoplasms through transdifferentiation mechanisms. Secondary HS developing after classical Hodgkin lymphoma (cHL) is exceptionally uncommon and poses significant diagnostic and therapeutic challenges. We aimed to present a rare case of secondary histiocytic sarcoma arising following treatment for classical Hodgkin lymphoma in a male patient, and to discuss its clinicopathological, immunohistochemical, and radiological features in light of the current literature.

MATERIAL & METHODS

The clinical, radiological, histopathological, and immunohistochemical data of a 73-year-old male patient who developed secondary histiocytic sarcoma during follow-up after treatment for classical Hodgkin lymphoma were retrospectively evaluated. Demographic characteristics, clinical presentation, imaging findings, treatment history, and follow-up data were obtained from the patient's medical records. The initial diagnosis of classical Hodgkin lymphoma was established based on histomorphological examination and immunohistochemical analyses of the excisional lymph node biopsy specimen. Following disease recurrence, positron emission tomography/computed tomography (PET/CT) imaging and an incisional biopsy of the recurrent supraclavicular mass were performed. Biopsy specimens were re-evaluated histopathologically using a broad immunohistochemical panel. The diagnosis of histiocytic sarcoma was confirmed based on histomorphological findings supported by positivity for CD163, CD68, CD4, and fascin. The case was analyzed clinicopathologically in the context of the current literature.

RESULTS

The patient diagnosed with classical Hodgkin lymphoma, with no evidence of recurrence during a two-year follow-up period. Initial PET/CT imaging demonstrated isolated hypermetabolic involvement of the left supraclavicular lymph node without systemic dissemination. During follow-up, the patient was re-evaluated because of a rapidly enlarging recurrent mass in the left supraclavicular region. PET/CT revealed a hypermetabolic soft tissue mass in the left middle jugular–supraclavicular region measuring approximately 42 × 54 × 57 mm (SUVmax: 13.2), as well as a metabolically active lytic lesion in the T9 vertebral corpus (SUVmax: 9.1). Histopathological examination demonstrated proliferation of atypical histiocytic cells with prominent nucleoli, pleomorphic and focal spindle-cell morphology, increased mitotic activity, and focal necrosis. Immunohistochemically, tumor cells showed positivity for CD163, CD68 and vimentin, while epithelial, dendritic, and Langerhans cell markers were negative. Based on the overall clinicopathological findings, the lesion was diagnosed as secondary histiocytic sarcoma developing after classical Hodgkin lymphoma.

CONCLUSIONS

Secondary histiocytic sarcoma developing after classical Hodgkin lymphoma is an extremely rare and highly aggressive malignancy with challenging diagnostic features. Accurate diagnosis requires comprehensive histopathological and immunohistochemical evaluation to distinguish it from other hematologic neoplasms. The present case supports the hypothesis that histiocytic sarcoma may arise through transdifferentiation or lineage conversion from pre-existing lymphoid malignancies. Early recognition of this rare transformation is essential for appropriate clinical management and may contribute to a better understanding of the biological relationship between Hodgkin lymphoma and histiocytic sarcoma.

Nisin As A Novel Membrane-Active Adjuvant For Electrochemotherapy

Olga Michel[1,2], **Barbora Lekesyte**[2,3], **Veronika Malysko-Ptasinske**[2,3], **Arnoldas Morozas**[2], **Paulina Malakauskaite**[1,2,3], **Egle Mickeviciute-Zinkuviene**[1,2,3], **Augustinas Zelvys**[1,2,3], **Justinas Ivaska**[2,4], **Julita Kulbacka**[1,2], **Vitalij Novickij**[1,2,3]

[1]*Department of Molecular and Cellular Biology, Faculty of Pharmacy, Wroclaw Medical University, Wrocław, Poland;* [2]*Department of Immunology and Bioelectrochemistry, State Research Institute Centre of Innovative Medicine, Vilnius, Lithuania;* [3]*Faculty of Electronics, Vilnius Gediminas Technical University, Vilnius, Lithuania;* [4]*Faculty of Medicine, Vilnius University, Vilnius, Lithuania*

BACKGROUND & AIM

Electrochemotherapy (ECT) combines pulsed electric fields (PEF) with cytotoxic agents to enhance intracellular drug delivery through transient membrane permeabilization. ECT is already used in the treatment of cutaneous and subcutaneous tumors, including selected recurrent or palliative head and neck cancer lesions, where local tumor control can be clinically relevant but treatment-related tissue damage remains a concern. Nanosecond PEF (nsPEF) may reduce some adverse effects associated with conventional ECT; however, higher electric field strengths are usually required. Nisin, an antibacterial lantibiotic with membrane-permeabilizing properties, may represent a novel membrane-active adjuvant capable of lowering the electric field threshold required for effective electroporation.

MATERIAL & METHODS

This study investigated the effects of nisin on membrane permeabilization, membrane resealing, and cell viability in cancer cells exposed to different PEF protocols. Cells were pre-incubated with a subtoxic concentration of nisin, 50 µg/mL, and treated with either microsecond PEF, consisting of 8 pulses of 100 µs at 1 Hz, or nanosecond PEF, consisting of 100 pulses of 300 ns delivered at 10 kHz or 1 MHz. Membrane permeabilization was evaluated by YO-PRO-1 fluorescent dye uptake, membrane resealing was assessed 30 minutes after treatment, and cell viability was measured after 24 hours.

RESULTS

Nisin at 50 µg/mL showed no relevant cytotoxicity when used alone but markedly enhanced the biological effects of PEF. In combination with µsPEF at 1.2 kV/cm, nisin reduced cell viability from 84% with PEF alone to 5.6%. Nisin also lowered the membrane permeabilization threshold, with the strongest effect observed for nsPEF at 1 MHz, where the threshold was reduced up to 3.3-fold. Across all pulse protocols, nisin substantially impaired membrane resealing after electroporation. The electric field required to reduce viability by 50% was decreased by 3.4- to 4.2-fold depending on the pulse modality, indicating a strong synergistic interaction between nisin and PEF.

CONCLUSIONS

Subtoxic nisin significantly enhances PEF-induced membrane permeabilization, impairs membrane resealing, and increases cancer cell mortality across both microsecond and nanosecond electroporation protocols. By lowering the electric field strength required for effective treatment, nisin may help reduce treatment intensity and improve the applicability of ECT, particularly in anatomically sensitive regions such as the head and neck. These findings support further investigation of nisin as a novel adjuvant for electrochemotherapy-based cancer treatment.

A Rare Malignant Mesenchymal Neoplasm Originating From The Maxillary Sinus: A Case Report

ŞEVVAL GÜNAY[1], **BERKE GEREN**[1], **MERVE DALGIÇ**[1], **DENİZ BAKLACI**[1]

[1]*Bülent Ecevit University Hospital*

BACKGROUND & AIM

This case report aims to present a rare malignant mesenchymal tumor originating from the maxillary sinus and to emphasize the diagnostic and therapeutic challenges associated with its aggressive local behavior. Additionally, the importance of detailed radiological evaluation, histopathological assessment, and radical surgical management in achieving local disease control is highlighted through a multidisciplinary treatment approach.

MATERIAL & METHODS

A 49-year-old male patient presented with progressive right-sided nasal obstruction, recurrent epistaxis, facial swelling, and a palatal ulcerative lesion persisting for three months. Endoscopic examination revealed a proliferative mass originating from the right maxillary sinus. CT and MRI demonstrated a 58×58×56 mm aggressive mass destroying all walls of the maxillary sinus, inferior orbital floor, pterygoid process, sphenoid wing, and lamina papyracea, with extension into the infratemporal and pterygopalatine fossae. Initial differential diagnoses included osteosarcoma, fibrosarcoma, and squamous cell carcinoma, while biopsy suggested a malignant peripheral nerve sheath tumor. Following multidisciplinary evaluation, a right subtotal maxillectomy was performed. Definitive histopathological and immunohistochemical examination established the diagnosis of malignant mesenchymal tumor. Surgical margins were negative, and postoperative radiotherapy was planned. No recurrence was detected during the 6-month follow-up period.

RESULTS

Radiological imaging revealed an aggressive maxillary sinus mass with extensive destruction of adjacent bony structures and invasion into surrounding anatomical compartments. Histopathological and immunohistochemical analyses confirmed the diagnosis of a malignant mesenchymal tumor. The patient underwent right subtotal maxillectomy with clear surgical margins. Postoperative recovery was uneventful, and adjuvant radiotherapy was planned to reduce the risk of recurrence. During the 6-month follow-up period, no evidence of local recurrence or distant metastasis was observed. These findings demonstrate that early multidisciplinary evaluation combined with radical surgical resection may provide effective local disease control in aggressive sinonasal mesenchymal malignancies.

CONCLUSIONS

Malignant mesenchymal tumors of the maxillary sinus are rare and highly aggressive neoplasms that often present at advanced stages because of their nonspecific clinical manifestations and silent progression within the sinonasal cavity. Accurate diagnosis requires comprehensive radiological, histopathological, and immunohistochemical evaluation. Radical surgical resection remains the cornerstone of treatment for achieving local disease control, while adjuvant therapies may contribute to reducing recurrence risk. This case highlights the importance of a multidisciplinary approach in the management of aggressive sinonasal malignancies and demonstrates that early diagnosis combined with appropriate surgical intervention may improve clinical outcomes and prognosis.

Radiation-Induced Recurrent Sinonasal Undifferentiated Pleomorphic Sarcoma: A Challenging Surgical Ca

Uğur Can Bayık[1]

[1]*SAĞLIK BİLİMLERİ ÜNİVERSİTESİ PROF. DR. CEMİL TAŞÇIOĞLU ŞEHİR HASTANESİ*

BACKGROUND & AIM

Radiation-induced sinonasal sarcomas are rare but highly aggressive malignancies characterized by rapid growth, local invasion, and high recurrence rates. Achieving negative surgical margins in the anatomically complex sinonasal region remains challenging. We present a case of recurrent high-grade sinonasal undifferentiated pleomorphic sarcoma developing years after chemoradiotherapy for nasopharyngeal carcinoma, aiming to highlight diagnostic and surgical management difficulties.

MATERIAL & METHODS

A 61-year-old male with no significant comorbidities was diagnosed with non-keratinizing undifferentiated nasopharyngeal carcinoma in 2012 and treated with chemotherapy and radiotherapy. Following years of remission, the patient presented with recurrent symptoms. Initial biopsies in August 2023 and February 2024 were negative for malignancy despite suspicious imaging findings. In May 2024, endoscopic tumor excision and tracheostomy were performed for a mass filling the left nasal cavity and extending to the oropharynx. Subsequent surgeries included septectomy, inferior maxillectomy, repeated tumor resections, and infratemporal fossa surgery due to multiple recurrences. Intraoperative techniques included external carotid artery ligation for bleeding control and meticulous dissection of the pterygopalatine fossa.

RESULTS

Histopathological evaluation confirmed high-grade malignant mesenchymal tumor consistent with undifferentiated pleomorphic sarcoma. The tumor demonstrated aggressive local invasion involving the nasal floor, hard palate, buccal mucosa, maxillary and frontal sinuses, and infratemporal region. Despite multiple resections, local recurrences occurred, occasionally associated with positive surgical margins, necessitating extended resections. Radiological findings also suggested mandibular involvement. The patient underwent multiple surgeries between 2025 and 2026 and remains under close follow-up.

CONCLUSIONS

Radiation-induced sinonasal undifferentiated pleomorphic sarcoma is a rare and aggressive entity with high recurrence potential. This case highlights the importance of maintaining clinical suspicion despite negative biopsies and underscores the critical role of achieving negative surgical margins. Aggressive surgical management combined with a multidisciplinary approach and close follow-up is essential for optimal outcomes.

Difficult Airway Management In A Geriatric Patient With Giant Goiter: A Case Report

Hüseyin Çetik[1], **Günay Kozan**[2], **Yahya Pamuk**[1], **Ayhan Kaydu**[1]

[1]*Dicle University Faculty of Medicine Department of Anesthesiology and Reanimation;* [2]*Dicle University Faculty of Medicine Department of Otorhinolaryngology*

BACKGROUND & AIM

Giant goiter is a rare but important cause of difficult airway management due to progressive tracheal deviation, compression, and distortion of normal airway anatomy. In elderly patients, long-standing goiter with recent rapid enlargement may result in position-dependent respiratory distress, indicating critical airway compromise. Airway management in such cases requires careful preoperative assessment, advanced planning, and readiness for difficult intubation strategies. This case reports the perioperative airway management of an 88-year-old geriatric patient with severe tracheal compression secondary to giant goiter, emphasizing the importance of maintaining spontaneous ventilation and a multidisciplinary approach during airway securing.

MATERIAL & METHODS

An 88-year-old female patient with a history of diabetes mellitus, hypertension, and long-standing goiter was admitted for total thyroidectomy due to a progressively enlarging neck mass. The patient reported a 20-year history of goiter with rapid growth over the last year. She presented to the emergency department with dyspnea, and physical examination revealed a firm 10 cm right-sided cervical mass (Figure 1). Imaging studies, including chest radiography and computed tomography, demonstrated significant tracheal deviation (Figure 2). Thyroid function tests were within normal limits. Airway assessment revealed Mallampati IV and anticipated difficult airway. Because dyspnea worsened in the supine position, a semi-sitting position was used. Preparation included videolaryngoscope, bougie, stylet, airway adjuncts, and various endotracheal tube sizes. The plan was awake intubation under sedoanalgesia (1mg midazolam, 70 mg ketamine, 50 mg lidocaine) while maintaining spontaneous respiration.

RESULTS

After 4 minutes of preoxygenation, awake videolaryngoscopic intubation was attempted. The first attempt was unsuccessful due to distorted airway anatomy. A second attempt was successfully performed using a bougie-assisted technique, and a 6.5 mm spiral endotracheal tube was placed. During intubation, manual external elevation of the thyroid mass improved airway patency and visualization. The surgical procedure, total thyroidectomy, lasted approximately five hours and was completed without intraoperative complications. Due to the risk of tracheomalacia from prolonged tracheal compression, controlled extubation was performed. The patient was transferred to the intensive care unit for close postoperative monitoring and observed for one day without respiratory compromise. She was then transferred to the ward in stable condition. Histopathological examination of the resected specimen revealed papillary thyroid carcinoma.

CONCLUSIONS

Giant goiter represents a challenging airway condition requiring meticulous preoperative evaluation and planning. Preservation of spontaneous respiration, appropriate patient positioning, and readiness for alternative airway techniques are essential for safe intubation. Awake intubation with sedoanalgesia and use of adjuncts such as bougie can significantly improve success in difficult airway scenarios. This case highlights the importance of a multidisciplinary approach and adherence to difficult airway algorithms to ensure safe perioperative management and favorable outcomes in patients with severe tracheal compression due to giant goiter.

PP-272

Primary Laryngeal Melanoma: A Clinical Case Report

Joana Guimarães[1], **Adriana Cunha**[2], **Maria Casanova**[1], **Joaquim Castro Silva**[1]

[1]*Portuguese Institute of Oncology of Porto Francisco Gentil;* [2]*Local Health Unit of São João*

BACKGROUND & AIM

Mucosal melanoma represents only 1.4% of all melanoma cases. When it affects the head and neck region, it is most frequently located in the nasal mucosa, sinuses, and oral cavity. Primary involvement of the larynx is extremely rare and is scarcely described in the literature. The rate of distant metastasis in these cases can reach 49% and constitutes the main prognostic factor associated with survival.

MATERIAL & METHODS

We present a clinical case description and related literature review.

RESULTS

We report a case of a 50-year-old man presenting with hoarseness and intermittent dyspnea, found to have a pedunculated laryngeal lesion with hyperpigmented plaques. No other cutaneous or mucosal lesions were identified. Biopsy confirmed the diagnosis of primary laryngeal melanoma. Staging with CT and full-body FDG-PET revealed bilateral pulmonary metastases. The patient was treated with palliative systemic immunotherapy using nivolumab and ipilimumab and continues maintenance therapy with nivolumab.

CONCLUSIONS

This case illustrates the diagnostic and therapeutic challenges of primary laryngeal melanoma. Proper staging is essential to rule out other primary sites and guide management. Each reported case contributes valuable insights into prognosis, clinical behavior, and optimal management strategies for this rare disease.

Intravagal Parathyroid Adenoma Mimicking A Vagal Schwannoma: A Rare Diagnostic Pitfall

Emine Bircan Küçük[1], **Ataberk Akkuş**[1], **İbrahim Halil Kaymaz**[1], **İlker Burak Arslan**[1]

[1]Department of Otorhinolaryngology, Izmir City Hospital, Izmir, Turkey

BACKGROUND & AIM

Ectopic parathyroid glands occur in approximately 16% of cases of primary hyperparathyroidism, but intravagal localization is among the rarest forms. This type of ectopia is uncommon, with fewer than 25 cases reported. These adenomas pose diagnostic and surgical challenges, as they are often mistaken for more common carotid sheath tumors, such as neuroendocrine tumors and paragangliomas.

MATERIAL & METHODS

A 53-year-old male presented with a slowly enlarging right-sided neck mass over the past year. Laboratory tests showed hypercalcemia (calcium 11.1 mg/dL) and elevated parathyroid hormone (PTH 123 ng/L).

MRI showed a 10x10 mm, T2-hyperintense, solid lesion at the right level III, suggesting a vagal schwannoma. CT angiography identified a vascular mass posterior to the common carotid artery, suggesting a glomus vagale. Ga-68 DOTATATE PET demonstrated mild uptake in the level 3 mass (SUVmax: 2.9).

The patient underwent neck exploration with frozen section. A carotid sheath mass expanding the vagus fibers, mimicking a schwannoma, was identified. It was enucleated by microdissection without damage to vagus fibers. Frozen section indicated a benign lesion, and dissection was halted.

Histopathology confirmed a hypercellular parathyroid adenoma. Postoperatively, calcium and PTH levels normalized. Although the vagus nerve was preserved, right vocal cord paralysis occurred on the first postoperative day and completely resolved by the six-month follow-up.

RESULTS

Intravagal parathyroid adenomas (IVPA) are a rare manifestation of primary hyperparathyroidism. During embryogenesis, parathyroid tissue from the 3rd and 4th pharyngeal pouches can become entrapped within the vagus nerve as it descends.

Standard modalities such as MRI and CT often misidentify these lesions because their fusiform appearance within the carotid sheath is nearly identical to that of a schwannoma. Even if the tumor is dissected from the nerve, temporary vocal cord paralysis should be considered a treatment-related complication of these lesions.

CONCLUSIONS

Intravagal parathyroid adenomas within the carotid sheath can mimic more common neurogenic tumors and paragangliomas. Clinicians should consider IVPA in the differential diagnosis of carotid sheath masses, particularly in patients with concomitant hypercalcaemia.

Intravagal, carotid sheath, schwannoma, ectopic parathyroid, hyperparathyroidism

PP-274

A Rare Case Of A Giant Salivary Duct Carcinoma Ex Pleomorphic Adenoma Of The Submandibular Gland

Konstantinos Valsamidis[1], **Stefanos Triaridis**[1], **Jannis Constantinidis**[1], **Petros Karkos**[1], **Konstantinos Mantsopoulos**[2]

[1]*1st Otorhinolaryngology, Head and Neck Surgery Department, Medical School, Aristotle University of Thessaloniki, AHEPA Hospital, Thessaloniki, Greece.*; [2]*Department of Otorhinolaryngology, Head and Neck Surgery, Friedrich Alexander University of Erlangen-Nuremberg (FAU), Erlangen, Germany.*

BACKGROUND & AIM

Primary salivary duct carcinoma ex pleomorphic adenoma is a rare malignancy of the head and neck region with the parotid gland accounting for 88% of cases. It usually arises from a primary or recurrent benign pleomorphic adenoma. A case of an extremely large in size tumor of the submandibular gland is presented.

MATERIAL & METHODS

A 42-year-old male was referred to the otolaryngology clinic for an enlarging left-sided and present for 20 years mass occupying the parotid and submandibular area. Clinical examination was notable for a firm, multilobulated, painless exophytic mass without accompanying symptoms. There was no palpable lymphadenopathy and fiberoptic examination of the pharynx and larynx showed no abnormality. CT with contrast revealed a 15 × 10× 12 cm heterogeneously enhancing, well-circumscribed soft tissue mass impinging on surrounding structures in the left submandibular gland. A partial parodicectomy with preservation of the labial branch of the facial nerve, excision of the submandibular gland, tumor resection and plastic reconstruction of the skin was performed. Histopathologic examination revealed a salivary duct carcinoma ex pleomorphic adenoma. The pathologic staging was determined to be T4N0M0. The patient underwent adjuvant radiotherapy.

RESULTS

Two years after completion of radiation therapy, during follow - up a PET/CT scan was performed where a solitary pulmonary metastasis was found and surgically removed. Three years postoperatively the patient presents no signs of recurrent or new disease.

CONCLUSIONS

Primary salivary duct carcinoma ex pleomorphic adenoma often poses a diagnostic and therapeutic challenge to clinicians and pathologists. A high index of suspicion is required especially for rapidly growing lesions that have been present for many years. Given the high rate of lymphatic and distant metastases and the poor prognosis of this rare tumor, multimodality treatment should be considered for locoregional control and optimal patient outcome.

PP-275

A Recurrent Preauricular Mass: Epidermoid Cyst Of The Temporal Fossa With Infratemporal Extension

Mehmet Ali Göçer[1], **Meliz Ece Obalar**[1], **Güleser Saylam**[1], **Celil Göçer**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, Lokman Hekim University, Ankara, Turkey*

BACKGROUND & AIM

Epidermoid cysts are benign lesions lined by keratinizing squamous epithelium, most commonly found on the scalp, face, and neck. Involvement of the temporal and infratemporal fossa is rare, and recurrence after incomplete excision can present diagnostic and surgical challenges due to the region's complex anatomy and proximity to critical neurovascular structures. We present a case of a recurrent epidermoid cyst extending from the temporal to the infratemporal fossa, aiming to highlight the diagnostic considerations and surgical management of lesions in this uncommon location.

MATERIAL & METHODS

We report a single case managed at the Department of Otorhinolaryngology–Head and Neck Surgery, Lokman Hekim University, Ankara, Turkey. A 20-year-old male presented with a recurrent left preauricular swelling, having undergone previous excision at the same site. Contrast-enhanced computed tomography (CT) of the facial bones was performed for preoperative planning. The patient underwent surgical excision via a preauricular approach. Intraoperative findings, surgical technique, and final histopathological results were reviewed.

RESULTS

CT demonstrated a well-defined cystic lesion measuring 46×20 mm (41 cc) in the left zygomatic region, with thin internal septa and minimal septal/wall enhancement following contrast administration; no significant bone involvement was noted. On examination, a soft, previously operated lesion was palpated in the subzygomatic region. Intraoperatively, the lesion was confirmed to extend from the temporal fossa into the infratemporal region, deep to the zygomatic arch. The lesion was completely excised via a preauricular approach without complication. Histopathological examination confirmed an epidermoid cyst measuring 6.5×2.3×1 cm, well-circumscribed, with a cyst wall lined by keratinizing squamous epithelium and a stratum granulosum

CONCLUSIONS

This case highlights that epidermoid cysts, though typically benign and superficial, may recur and extend into deeper anatomical spaces such as the infratemporal fossa when incompletely excised. Thorough preoperative imaging assessment and careful intraoperative evaluation are essential for complete excision and prevention of further recurrence, even when the lesion is approached through a relatively superficial preauricular incision.

Epidermoid cyst, Temporal fossa, Infratemporal fossa, Recurrence, Preauricular mass

PP-276

Surgical Management Of Base Of Tongue Adenoid Cystic Carcinoma: A Three-Case Series

Cemile Baykan Eryiğit[1], **Burak Nal**[1], **Ayşe Beyza Tönge**[1], **Şahin Öğreden**[1], **Özgür Yiğit**[1]

[1]*Otolaryngology Department, Basaksehir Cam ve Sakura City Hospital, University of Health Sciences, Istanbul, Turkey.*

BACKGROUND & AIM

Adenoid cystic carcinoma of the base of tongue is an exceptionally rare malignancy characterized by perineural spread, local recurrence, and challenging surgical management. Because evidence is limited and neck management remains controversial, reporting institutional experience is valuable. We aimed to present three surgically treated cases of base of tongue adenoid cystic carcinoma and to discuss their clinicopathological features, surgical strategies, and cervical management in the context of current literature.

MATERIAL & METHODS

We retrospectively reviewed three patients with histopathologically confirmed adenoid cystic carcinoma of the base of tongue treated at a tertiary otolaryngology center. Clinical presentation, endoscopic findings, magnetic resonance imaging and positron emission tomography/computed tomography results, operative approach, pathological risk factors, and early postoperative outcomes were analyzed descriptively. Main outcome measures were tumor extent, perineural and

lymphovascular invasion, margin status, need for additional surgery, and cervical management, including neck dissection when radiologic or clinical suspicion for nodal disease was present.

RESULTS

Three patients aged 60–66 years were treated for base of tongue adenoid cystic carcinoma. Presenting symptoms included throat pain, foreign body sensation, dysphagia, and tongue base fullness. All tumors originated from the base of tongue, and perineural invasion was identified in all cases. One patient had pT4a disease and underwent transoral robotic resection. One patient required salvage extended resection, supraglottic laryngectomy, and bilateral neck dissection because of residual or recurrent disease with suspicious cervical nodes after initial robotic surgery. Another patient underwent neck dissection following robotic tumor resection because of persistent concern for cervical nodal disease. Additional adverse pathological features included muscle or soft tissue invasion, lymphovascular invasion, and positive or close margins. No major early postoperative complication occurred.

CONCLUSIONS

Base of tongue adenoid cystic carcinoma requires individualized multidisciplinary treatment because of its infiltrative behavior and high-risk pathological features. Transoral robotic surgery may provide effective primary resection in selected cases, whereas suspicious cervical disease, residual tumor, or adverse pathology may necessitate additional surgery, including neck dissection. Risk-adapted cervical management and close long-term follow-up appear essential in this rare malignancy.

KEYWORDS

Base of tongue, adenoid cystic carcinoma, transoral robotic surgery, neck dissection, perineural invasion

PP-277

Riedel Thyroiditis Mimicking Malignancy: Diagnostic Failure Resulting In Extensive Surgery And Severe Morbidity

Celal Emre Çavlan[1], **Yavuz Gündoğdu**[1], **Orhan Asya**[1], **Ali Cemal Yumuşakhuylu**[1]

[1]*Marmara University, Department of Otorhinolaryngology – Head and Neck Surgery, Istanbul, Turkey*

BACKGROUND & AIM

Riedel thyroiditis (RT) is an extremely rare fibroinflammatory thyroid disease that mimics malignancy due to its locally invasive behavior. When histopathological examination fails to differentiate RT from malignant neoplasms, extensive surgical intervention may become unavoidable. This case report aims to demonstrate the devastating consequences of extensive surgery performed for an undiagnosed RT, including bilateral vocal cord paralysis, Horner syndrome, mediastinal abscess, and a life-threatening tracheo-innominate artery fistula, thereby emphasizing the importance of considering RT in the differential diagnosis of invasive neck masses to avoid unnecessary radical surgical interventions.

MATERIAL & METHODS

A 40-year-old male with no significant medical history was referred to our department with a painless, progressively enlarging right-sided neck mass persisting for one year, with rapid enlargement in the preceding two months. Physical examination revealed a firm 4×5cm mass at the right cervical level 3-4. Laboratory investigations, including thyroid function tests and IgG4 levels, were within normal limits. MRI demonstrated a 38×40×107 mm solid mass encasing the right common carotid and subclavian arteries, extending from the carotid bifurcation to the retrosternal area with heterogeneous contrast enhancement. PET-CT revealed intense FDG uptake suggestive of malignancy. Three sequential biopsy attempts — fine-needle aspirations , tru-cut, and incisional biopsy — all yielded inconclusive results, reporting an inflammatory mesenchymal neoplasm in which malignancy could not be excluded. Given persistent diagnostic uncertainty and high clinical suspicion of malignancy, extensive surgical resection was performed by a multidisciplinary team comprising otolaryngology, cardiovascular surgery, and thoracic surgery

RESULTS

Intraoperatively, the mass encased the carotid artery, internal jugular vein, and innominate vessels in a 360-degree manner, extending from the neck to the aortic arch and the right lung apex. The mass was excised along with the right thyroid lobe and isthmus, requiring meticulous dissection from major vascular structures by cardiovascular and thoracic surgery teams. The postoperative course was severely complicated: the patient failed extubation, necessitating tracheotomy on day4. Bilateral vocal cord paralysis and right-sided Horner syndrome were identified. On postoperative day26, a mediastinal abscess with sternal osteomyelitis and pericardial effusion developed, requiring pericardiocentesis and wound debridement. On day 40, a life-threatening tracheo-innominate artery fistula caused massive hemorrhage necessitating emergency cardiopulmonary resuscitation and vascular repair. Subsequent stent occlusion required additional emergency surgery. Pectoralis major flap reconstruction and medialization laryngoplasty were performed. Final pathology revealed obliterative phlebitis and storiform fibrosis consistent with Riedel thyroiditis, with elevated IgG1 and normal IgG4 levels.

CONCLUSIONS

This case demonstrates that RT can lead to catastrophic outcomes when indistinguishable from malignancy. Imaging findings suggestive of malignancy, normal IgG4 levels providing no diagnostic clue for IgG4-related disease, and inconclusive pathology from multiple biopsies collectively necessitated extensive resection, resulting in life-threatening complications. Clinicians

should be aware that RT may present with normal IgG4 levels and imaging features mimicking malignancy. When multiple biopsies fail to establish a definitive diagnosis of an invasive neck mass, RT should be considered to avoid unnecessary radical surgery and its devastating consequences.

Odontojenik Bir Kisti Taklit Eden Maksiller İntraosseöz Skuamöz Hücreli Karsinom: Nadir Bir Tanısal Tuzak

Muhammed Fatih Özcan[1], **Yüce İslamoğlu**[1], **Gökhan Atik**[1]

[1]*Ankara Bilkent City Hospital*

BACKGROUND & AIM

Squamous cell carcinoma (SCC) of the maxillary gingiva and alveolar region may present with nonspecific dental symptoms and may mimic benign odontogenic lesions. Alveolar and gingival lesions require careful histopathological correlation, particularly when radiological findings demonstrate soft-tissue extension or cortical bone destruction. This case emphasizes the diagnostic value of pathology review, cross-sectional imaging, and multidisciplinary surgical reconstruction in a maxillary intraosseous SCC mimic an odontogenic cyst.

MATERIAL & METHODS

A 55-year-old female patient was referred to our department after cystic lesion excision initially diagnosed as an odontogenic cyst, with histopathology revealing maxillary intraosseous squamous cell carcinoma. Computed tomography demonstrated a defect in the right maxilla, likely related to extraction of an ectopic supernumerary tooth. An additional soft-tissue lesion measuring approximately 16 mm was identified anterior to the defect. The lesion was located around the roots of teeth 11, 12, and 21, extended to the gingiva, and caused cortical erosion on both buccal and palatal sides. Reactive sclerosis was observed in the adjacent palatal bone. Magnetic resonance imaging showed a 15 × 12 mm paramedian maxillary mass at the level of the incisor roots, with diffusion restriction and predominantly peripheral heterogeneous enhancement. Right submandibular and level IIA lymph nodes were subcentimetric, with suspected mild pericapsular irregularity on T2-weighted images.

RESULTS

After multidisciplinary evaluation, the patient underwent maxillectomy together with the plastic surgery team. The surgical defect was reconstructed using a nasolabial flap. Postoperatively, the patient was referred to the Department of Radiation Oncology for evaluation of adjuvant radiotherapy. Given that the histopathological examination revealed a clearance of 1 mm at the superior and posterior surgical margins, the patient subsequently underwent adjuvant radiotherapy. The patient remains under ongoing clinical and oncological surveillance.

CONCLUSIONS

Maxillary intraosseous SCC may clinically resemble odontogenic cystic lesions, especially after dental extraction. Repeat histopathological examination, detailed CT and MRI evaluation, and coordinated surgical management are crucial for accurate diagnosis, oncological clearance, and functional reconstruction.

Submandibular Ectopic Thyroid Presenting As Suspected Malignant Lymphadenopathy

Ayşegül Yönem Öz[1], **Ahmet Adnan Cırık**[1], **Neşe Torun**[1], **Sıddıka Tuğçe Altınok**[1], **Ömer Faruk Aydın**[2]

[1]*Umraniye Training and Research Hospital, ORL-HNS;* [2]*Umraniye Training and Research Hospital, Pathology*

BACKGROUND & AIM

Submandibular ectopic thyroid is a rare but clinically significant cause of lateral cervical mass and may closely mimic malignant lymphadenopathy on cross-sectional imaging. Diagnostic misinterpretation is critical when the ectopic tissue represents the sole functioning thyroid gland. In such cases, surgical excision can lead to procedure-related morbidities such as lifelong thyroid hormone replacement therapy.

MATERIAL & METHODS

We report a 52-year-old woman with a five-year history of a progressively enlarging left submandibular mass. Ultrasonography demonstrated a heterogeneous vascular lesion and absence of orthotopic thyroid tissue. Despite clear sonographic absence of orthotopic thyroid tissue, contrast-enhanced magnetic resonance imaging suggested malignant nodal disease. Cytologic evaluation revealed thyrocytes. Technetium-99m scintigraphy demonstrated radiotracer uptake confined to the submandibular region, confirming complete functional dependence on the ectopic gland.

RESULTS

Thyroid function tests were within normal limits. Owing to persistent suspicion for malignancy and substantial lesion size, transcervical excision was performed. Histopathology confirmed ectopic thyroid tissue with focal chronic lymphocytic thyroiditis. Postoperatively, marginal mandibular nerve dysfunction developed and persisted at the 6-month follow-up, with no complete functional recovery, highlighting the significant neurovascular risks associated with surgical management in this anatomically constrained region.

CONCLUSIONS

This case highlights the dual diagnostic and therapeutic challenge of isolated submandibular ectopic thyroid: morphologic imaging alone may misdirect oncologic algorithms, and operative intervention carries both endocrine and marginal mandibular nerve morbidity. Functional imaging is essential in the evaluation of neck masses to confirm functioning thyroid tissue when orthotopic thyroid is absent.

When A Submandibular Mass Is Not What It Seems: A Case Report Of An Adult Extracardiac Rhabdomyoma

Martín González, Ana[1], **Balduz Moreno, Elena**[1], **Clement Alonso, Lucía**[1], **Llorente Álvarez, Claudia**[1], **Manzanares López-Rendo, Carmen**[1], **Fernández Cascón, Sara**[1]

[1]*León University Hospital, ENT department*

BACKGROUND & AIM

Adult Extracardiac Rhabdomyoma (AER) is an exceptionally rare benign mesenchymal neoplasm derived from striated muscle, representing less than 2% of all muscle-origin tumors. Approximately 90% of these cases are localized in the head and neck region, with a postulated origin from the third and fourth branchial arches. Given its scarcity, it is frequently excluded from the initial differential diagnosis of cervical masses. The aim of this study is to report a rare submandibular presentation of AER, emphasizing the diagnostic complexity and the surgical importance of preserving noble structures in the submaxillary cell.

MATERIAL & METHODS

We report a case of a 57-year-old male, with a history of tobacco and alcohol consumption, presented with a six-month history of a painless left submandibular mass that became symptomatic recently. Physical examination revealed a mobile, non-adherent volume increase in the submaxillary region with a patent Wharton's duct. The diagnostic protocol included Computed Tomography (CT), Magnetic Resonance Imaging (MRI), and ultrasound-guided Core Needle Biopsy (CNB). Total surgical excision was performed under general anesthesia via an external submandibular approach, with careful dissection of the adjacent neurovascular elements.

RESULTS

Radiological assessment via CT and MRI demonstrated a 3.8 cm well-defined hyperenhancing mass occupying the submaxillary and sublingual spaces. The defining histopathological finding was the presence of pathognomonic "spider cells"—large polygonal cells with vacuolated cytoplasm and transverse striations-. Immunohistochemistry was positive for desmin and negative for S100 and caldesmon. Complete surgical removal was achieved, sparing the submandibular gland and successfully preserving the lingual, hypoglossal, and marginal mandibular nerves. No recurrence has been observed during 12 months of follow-up

CONCLUSIONS

AER is a critical differential diagnosis for cervical masses, including pleomorphic adenomas or granular cell tumors. The identification of "spider cells" is key to the diagnosis. Total surgical excision is often curative, offering an excellent long-term prognosis

PP-281

Jugular Venous Tumor Thrombus In Oncocytic Thyroid Carcinoma: A Case Report

Erdem KÖROĞLU[1], **Emine Gül UMUTLU**[1], **Melikşah ÇAKIR**[1]

[1]*Kocaeli Şehir Hastanesi*

BACKGROUND & AIM

Oncocytic (Hürthle cell) thyroid carcinoma is a rare and potentially aggressive subtype of differentiated thyroid cancer with a marked tendency for vascular invasion and distant metastasis. Intraluminal tumor thrombus in major cervical veins such as the internal jugular vein is extremely rare and presents significant diagnostic and surgical challenges.

MATERIAL & METHODS

A 70-year-old male presented with progressive neck swelling. Physical examination revealed no palpable lymphadenopathy, and vocal cord mobility was intact. Neck ultrasonography and contrast-enhanced CT demonstrated a markedly enlarged left thyroid lobe causing rightward tracheal deviation (Figure 1). Fine-needle aspiration biopsy was Bethesda category IV, and total thyroidectomy was performed. Histopathology revealed oncocytic carcinoma measuring 8.5 × 5 × 5.5 cm. Postoperative thoracic CT showed an 18 mm pulmonary nodule suspicious for metastasis. PET/CT demonstrated intense FDG uptake (SUVmax: 35.2) along a 5 cm segment of the left internal jugular vein, consistent with tumor thrombus (Figure 2). Doppler ultrasonography confirmed an intraluminal lesion with partial flow. The patient underwent left lateral neck dissection with partial resection of the internal jugular vein. Tumor thrombus was resected en bloc (Figure 3A–B).

RESULTS

Histopathological examination confirmed oncocytic carcinoma with intraluminal venous tumor thrombus. Radioactive iodine therapy was initiated following multidisciplinary evaluation.

CONCLUSIONS

Tumor thrombus within the internal jugular vein, although rare, should be considered in patients with differentiated thyroid carcinoma and suspicious vascular findings. Multimodal imaging plays a key role in diagnosis and surgical planning. Early recognition and appropriate management may improve oncologic outcomes

KEYWORDS

Oncocytic thyroid carcinoma; tumor thrombus; internal jugular vein; vascular invasion; thyroid cancer

Inflammatory Carotid Pseudotumor: A Rare Differential Of A Unilateral Neck Swelling

Chahed Houda[1], **Kalfat taoufik**[2], **Omri Rihab**[1], **Ammar Hana**[2], **Lahmer Rihab**[1], **Bessi Salma**[1], **Messai Mohammed**[2], **Beltaief Najeh**[1], **Denguir Raouef**[2]

[1]*ENT departement of La Rabta teaching hospital;* [2]*Cardiovascular surgery department of La Rabta teaching hospital*

BACKGROUND & AIM

Inflammatory pseudotumors of the carotid sheath are exceedingly rare entities. Their Diagnosis is often challenging and management depends on the extent of disease.

Objectives:

This study aims to evaluate the diagnostic and therapeutic challenges associated with Inflammatory pseudotumor of carotid artery.

MATERIAL & METHODS

A case report about a patient diagnosted with an Inflammatory carotid pseudotumor

RESULTS

A 46-year-old male patient with a medical history of hypertension presented with a twenty-day history of a painful lateral cervical swelling, associated with local and general inflammatory signs suggestive of cervical cellulitis and dysphonia appeared after one month of progression.

Clinical examination revealed a firm tender right cervical mass. Nasofibroscopy found a right vocal cord palsy. CT of the neck demonstrated a well-circumscribed hypodense cervical mass, exhibiting progressive post-contrast enhancement. The lesion shows circumferential encasement of the right common carotid artery as well as the internal and external carotid arteries, with mass effect. On MRI, the lesion demonstrated high signal intensity on T2-weighted sequences, associated diffusion restriction, and homogeneous delayed post-contrast enhancement. CTguided biopsy was suggestive of a vagal nerve schwannoma. After surgical excision, pathological examination concluded to an inflammatory pseudotumor. The postoperative course was favorable but with definitive right vagus nerve palsy. The patient underwent speech therapy rehabilitation.

CONCLUSIONS

Inflammatory pseudotumor of the carotid sheet is a rare tumour that is uncommonly detected through cervical cellulitis. Imaging plays a key role in diagnosis and treatment planning. Management is based on initial treatment of the infection, followed by careful surgical removal to preserve nerve function.

HYALINIZING CLEAR CELL CARCINOMA AT THE BASE OF THE TONGUE: A RARE CASE REPORT

Özkan TEZGEZ[1], **Elif ÖZALP**[1], **Fatih ÖZDOĞAN**[1]

[1]*Kocaeli City Hospital*

BACKGROUND & AIM

Hyalinizing clear cell carcinoma (HCCC) is a rare, low-grade malignant salivary gland tumor originating mostly from minor salivary glands in the oral cavity. While the diagnosis is made histopathologically; it is characterized by glycogen-rich clear cells and hyalinized stromal architecture, and generally shows mucin-negative features. Although it usually has an indolent course, local recurrence and, rarely, regional metastasis have been reported.

In this case report, we aimed to discuss the clinical, radiological, and surgical features of a rare HCCC case located at the base of the tongue by presenting it.

MATERIAL & METHODS

A 29 year old female patient presented with a six month history of swelling at the base of the tongue. Endoscopic examination revealed a smooth-surfaced lesion approximately 1 cm in diameter on the right lateral tongue base (Figure 1). Magnetic resonance imaging demonstrated a 1 cm nodular lesion that was hypointense on T1, hyperintense on T2, and contrast-enhancing (Figure 2A–B).

The patient underwent transoral subtotal excision under general anesthesia using a coblator assisted by a 70° endoscope. Histopathological examination revealed a 1.5 × 1 cm tumor with positive peripheral and deep surgical margins. The findings were consistent with HCCC of minor salivary gland origin.

Postoperative positron emission tomography-computed tomography (PET-CT) showed no significant pathological findings (Figure 3). Because of the positive surgical margins, advanced treatment options including transoral robotic surgery and open surgical approaches were recommended to the patient.

RESULTS

The diagnostic approach can be difficult in small, smooth-surfaced, and submucosal lesions observed at the base of the tongue. In the presented case, the young age of the patient, the long asymptomatic course of the lesion, and its radiologically well-circumscribed appearance suggested benign lesions in the preliminary diagnosis.

The clinical and radiological findings of HCCC are not specific. Therefore, the definitive diagnosis is made by histopathological examination. Differential diagnosis, especially with other clear cell-containing neoplasms, is important.

Although this tumor generally exhibits a low-grade course, surgical margin positivity is important in terms of local recurrence. Therefore, transoral robotic surgery can be an important alternative in selected cases as it provides better vision and surgical control.

CONCLUSIONS

HCCC, despite being rare, should be evaluated in the differential diagnosis of submucosal masses located at the base of the tongue. Accurate histopathological diagnosis and an appropriate surgical approach are of great importance for successful treatment. Increasing the awareness of this rare tumor will contribute to early diagnosis and appropriate treatment planning.

Salivary Gland-Type Nasopharyngeal Adenocarcinoma: A Rare Case With Extensive Skull Base And Perineural Involvement

Halime Adıyaman[1], **Fariza Şahap**[1], **Yunus Kartal**[1], **İskender Bayram**[1], **Ahmet Baki**[1], **Özgür Yiğit**[1]

[1]*Başakşehir çam and sakura city hospital*

BACKGROUND & AIM

Salivary gland-type nasopharyngeal adenocarcinoma is an extremely rare malignant tumor arising from minor salivary glands of the nasopharynx. In contrast to more common nasopharyngeal carcinomas, these tumors often present with non-specific symptoms and may demonstrate perineural spread and skull base invasion, leading to diagnostic challenges. Due to their rarity, optimal management strategies are largely based on limited case reports. This study aims to present a rare case of salivary gland-type nasopharyngeal adenocarcinoma and to highlight its clinical, radiological, and therapeutic characteristics.

MATERIAL & METHODS

A patient diagnosed with histopathologically and immunohistochemically confirmed salivary gland-type nasopharyngeal adenocarcinoma was retrospectively evaluated at a tertiary referral center. Clinical presentation, radiological findings, histopathological features, treatment approach, and early outcomes were analyzed.

Main outcome measures included:

- Tumor extent and local invasion
- Presence of perineural spread
- Response to systemic therapy
- Resectability
- Multidisciplinary treatment outcomes

RESULTS

A 56-year-old male patient presented with facial numbness, nasal obstruction, and headache. Imaging revealed an infiltrative nasopharyngeal mass extending to the skull base, pterygopalatine fossa, and parapharyngeal space, with bony destruction and perineural spread along the trigeminal nerve. Histopathological evaluation confirmed salivary gland-type adenocarcinoma. The disease was classified as locally advanced without distant metastasis. Induction chemotherapy with cisplatin and gemcitabine resulted in partial radiological regression. Treatment-related toxicity was managed with supportive therapy. Surgical resection was not considered feasible due to extensive skull base invasion. The patient was subsequently referred for definitive radiotherapy. A multimodal treatment strategy was implemented for disease control.

CONCLUSIONS

Salivary gland-type nasopharyngeal adenocarcinoma is a rare entity that should be considered in the differential diagnosis of nasopharyngeal masses. Perineural spread and skull base invasion are important indicators of its aggressive behavior. This case highlights the importance of recognizing this rare tumor subtype and emphasizes the role of a multidisciplinary, multimodal treatment approach.

Oral Cavity Metastasis From Colorectal Adenocarcinoma In A Patient With Multimodal Treatment History: A Rare Presentation

HANDE NUR ÇELİLK[1], **ÖMER BAYIR**[1]

[1]*ANKARA ETLİK ŞEHİR HASTANESİ*

BACKGROUND & AIM

Metastatic tumors in the oral cavity originating from the colon are rare, and the number of relevant clinical studies is limited [1].Colorectal cancer is the third most common malignancy worldwide. Approximately 22% of patients with colorectal cancer present with distant metastasis at the time of initial diagnosis, and nearly half of the remaining patients develop metastases during the course of the disease, most commonly to the liver [2]. In contrast, metastasis of malignant tumors to the oral cavity is rare, accounting for less than 1% of all oral malignant lesions reported in the literature [3].

MATERIAL & METHODS

This is a single case report. Clinical, radiological (CT, PET), and histopathological data were retrospectively evaluated. Diagnosis was confirmed by histopathological and immunohistochemical analyses. The patient's clinical course and treatment history were reviewed, and informed consent was obtained.

RESULTS

Metastatic adenocarcinoma from the colon to the oral cavity are rare but should be included in the differential diagnosis of tumors in the oral cavity [2]. Representing less than 1% of oral malignancies, and are often associated with advanced systemic disease and poor prognosis [4–6]. Colorectal adenocarcinoma typically metastasizes to the liver and lungs, while oral involvement is uncommon and may indicate aggressive tumor behavior [2,4]. Clinically, these lesions can mimic benign conditions, leading to delayed diagnosis [3,5]. This case highlights the importance of considering metastatic disease in unusual oral lesions, especially in patients with a known malignancy.

CONCLUSIONS

Metastatic adenocarcinoma from the colon to the oral cavity are rare but should be included in the differential diagnosis of tumors in the oral cavity [2]. Representing less than 1% of oral malignancies, and are often associated with advanced systemic disease and poor prognosis [4–6]. Partial Laryngectomy For Adult Laryngeal Pleomorphic Rhabdomyosarcoma

GÖKÇE TANYERİ TOKER[1], **ZİYA ÖZBAYIR**[1], **YILMAZ ÖZKUL**[1]

[1]*Department of Otorhinolaryngology, İzmir Kâtip Çelebi University Atatürk Training and Research Hospital, İzmir, Türkiye*

BACKGROUND & AIM

Rhabdomyosarcoma is a malignant mesenchymal tumor of childhood and is exceptionally rare in the adult larynx. Only a limited number of adult laryngeal rhabdomyosarcoma cases have been reported in the literature. Therefore, the biological behavior of this tumor remains poorly understood, and the optimal treatment approach has not yet been clearly established. Total laryngectomy has been preferred in most reported cases. This case report aims to present the oncological and functional outcomes of supracricoid laryngectomy in a patient diagnosed with pleomorphic rhabdomyosarcoma.

MATERIAL & METHODS

A 66-year-old male patient presented with a two-year history of hoarseness. Endoscopic examination revealed a submucosal mass lesion filling the left ventricle and ventricular band, causing medialization of the left vocal cord. Magnetic resonance imaging of the neck demonstrated an approximately 35×30×23 mm mass involving the left paraglottic space, extending to the aryepiglottic fold and piriform sinus, with full-thickness invasion of the thyroid cartilage. Direct laryngoscopic biopsy and immunohistochemical analysis confirmed the diagnosis of pleomorphic rhabdomyosarcoma. The patient underwent supracricoid laryngectomy and bilateral neck dissection at levels II–IV.

RESULTS

No severe aspiration or persistent dysphagia was observed in the postoperative period. The patient was able to maintain oral feeding. During the three-year follow-up period, no local recurrence or distant metastasis was detected. Functional and oncological outcomes were considered satisfactory.

CONCLUSIONS

Adult laryngeal pleomorphic rhabdomyosarcoma is an extremely rare and aggressive malignancy, with only a limited number of cases reported in the literature. This case is important as it demonstrates that supracricoid laryngectomy, as a partial laryngectomy, can be a feasible and oncologically safe alternative to total laryngectomy in selected patients, even in the presence of thyroid cartilage invasion.

rhabdomyosarcoma, laryngeal sarcoma , laryngectomy , laryngeal carcinoma

PP-287

Is Contralateral Neck Dissection Necessary In Cn0 Supraglottic Carcinoma? Reconsidering The Surgical Extent In The Era Of Modern Imaging

Gülşah Acar Yüceant[1], **Berke Kaan Öztürk**[1], **Burak Kersin**[1], **Ayşe Aslı Şahin Yılmaz**[1]

[1]*Dr. Lütfi Kırdar City Hospital- Department of Otorhinolaryngology and Head Neck Surgery*

BACKGROUND & AIM

Despite significant advances in radiologic imaging, the optimal management of the clinically N0 neck (cN0) in supraglottic laryngeal carcinoma remains controversial. Bilateral neck dissection is frequently performed due to concerns regarding occult contralateral metastasis. However, this approach may represent overtreatment in selected patients. This study evaluates whether elective contralateral neck dissection is truly necessary in well-defined tumor subgroups.

MATERIAL & METHODS

We retrospectively analyzed 50 consecutive patients (5 females, 45 males; mean age 60.0 ± 6.9 years) with cN0 supraglottic squamous cell carcinoma who underwent partial or total laryngectomy with bilateral neck dissection between 2015-2025 at our tertiary referral center. Preoperative staging PET-CT scans were analyzed for nodal involment. Tumors were categorized according to midline involvement: Group A: Completely lateralized tumors without midline involvement (n=2) Group B: Tumors involving the midline (n=25) Group C: Tumors crossing the midline into the contralateral hemilarynx (n=23). Presence of pyriform sinus extension was also recorded.

RESULTS

Pathologic nodal metastasis (pN+) was detected in 16 patients (32%). Contralateral cervical metastasis occurred in 5 patients (10% overall; 31.3% of pN+ cases). No contralateral metastasis was observed in completely lateralized tumors (Group A). Among patients with contralateral metastasis, 3 (60%) were in Group B and 2 (40%) were in Group C. Pyriform sinus extension was present in 3 patients; 2 of these (66.7%) developed contralateral metastasis.

CONCLUSIONS

In PET-evaluated cN0 supraglottic carcinomas, especially lateralized tumors without pyriform sinus extension, contralateral neck dissection appears unnecessary and may represent overtreatment. A tailored surgical strategy based on tumor lateralization and subsite involvement may safely reduce surgical morbidity without compromising oncologic safety.

PP-288

Atypical Presentations Of Thyroid Carcinoma: Malignant Struma Ovarii And A Thyroid Carcinoma Mimicking A Ranula

Mr Tony Hao[1], **Mr Sean Mortimore**[1], **Mr Shaj Mansuri**[1], **Miss Heerani Woodun**[1]

[1]*University Hospitals of Derby and Burton NHS Foundation Trust*

BACKGROUND & AIM

Our aim is to educate the surgical community about atypical presentations of thyroid carcinoma through two cases to prevent delay in diagnosis and management.

MATERIAL & METHODS

Case 1: A 71-year-old lady with background of treated diffuse B-cell lymphoma and renal transplant presented with pelvic mass and raised CA125. Initial biopsy suggested mesonephric carcinoma of her right ovary however histology following right salpingo-oophorectomy suggested struma ovarii with features of thyroid follicular carcinoma. Subsequent thyroid fine-needle aspiration suggested benign. After multidisciplinary team and oncology national forum discussions, total thyroidectomy followed by radioactive iodine was performed. Thyroid histology revealed benign thyroid tissue with hyperplastic nodule and colloid cysts.

RESULTS

Case 2: A 30-years-old female presented with right level I-III neck swelling, trismus, and raised inflammatory markers; initially treated as submandibular sialadenitis. Follow up clinic revealed submucosal floor of mouth mass and ultrasound found a right submental lesion deep to myelohyoid. MRI suggested a plunging ranula. Surgical excision of the cystic lesion and right sublingual gland was performed, and histology suggested ectopic papillary thyroid cancer. Multidisciplinary discussion recommended total thyroidectomy to facilitate radioactive iodine, although thyroid histology was negative.

CONCLUSIONS

Malignant transformation of struma ovarii is rare (5%), with management in the literature up for debate. Total thyroidectomy and radioactive iodine may reduce longer term risk, however pelvic surgery alone may suffice for disease confined to ovary. Long-term follow-up is recommended due to 7.5% recurrence risk at 25 years. Very few cases have been published of thyroglossal duct cyst carcinoma mimicking ranula. While standard treatment involves a Sistrunk procedure and prophylactic total thyroidectomy, management remains a debate. Long-term surveillance is required due to recurrence risk.

Safety And Efficacy Of Cetuximab-Docetaxel-Cisplatin In Routine Clinical Practice For Recurrent And/Or First-Line Metastatic Head And Neck Cancer

Martín González, Ana[1], **Clement Alonso, Lucía**[1], **Balduz Moreno, Elena**[1], **Manzanares López-Rendo, Carmen**[1], **Llorente Álvarez, Claudia**[1], **Rodríguez Sanchez, Ángel**[2], **Fernández Cascón, Sara**[1]

[1]*León University Hospital, ENT department;* [2]*León University Hospital, Oncology department*

BACKGROUND & AIM

Recurrent and/or metastatic head and neck cancer (R/M HNC) is associated with poor prognosis and limited therapeutic options. The EXTREME regimen established platinum-based chemotherapy plus cetuximab as standard first-line treatment in this setting. We aimed to evaluate the efficacy and safety of a biweekly cetuximab-docetaxel-cisplatin regimen in routine clinical practice. We hypothesized that this schedule would provide effective disease control with acceptable toxicity while reducing the burden of weekly treatment administration.

MATERIAL & METHODS

We conducted a retrospective single-center observational study including patients with R/M HNC treated between January 2010 and December 2019 with cetuximab (500 mg/m²), docetaxel (50 mg/m²), and cisplatin (50 mg/m²) administered every two weeks. Clinical data were extracted from medical records. Three patients were lost to follow-up; therefore, 35 patients were evaluable for analysis. Minimum follow-up was 6 months or until death. Outcome measures included objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS), and treatment-related toxicity.

RESULTS

Among the 35 patients, 85.7% were male and 91.4% had squamous cell carcinoma. Most patients had stage IV disease (85.7%) and ECOG performance status 1 (94.3%). Distant recurrence was observed in 71.4% of cases, with lung metastases being the most frequent site (76%).

The mean number of treatment cycles was 5.09 (range, 1–8). Treatment-related toxicity occurred in 85.7% of patients, mainly non-hematologic adverse events (88.6%). Cutaneous rash was the most common toxicity (74.3%). Grade 3 toxicity was observed in 31.4% of patients. No treatment-related deaths or treatment discontinuations due to toxicity were reported.

The DCR was 88.2%, and the ORR was 50%, including partial responses in 47.1% and complete responses in 2.9% of patients. Median PFS was 7 months (95% CI, 2.98–11.01), and median OS was 12 months (95% CI, 7.29–16.70).

CONCLUSIONS

The biweekly cetuximab-docetaxel-cisplatin regimen demonstrated clinically meaningful efficacy with a manageable toxicity profile in patients with R/M HNC. This schedule may represent an effective and convenient alternative to weekly cetuximab-based regimens in routine clinical practice.

Actinomycosis Of The Anterior Tongue Presenting As A Submucosal Mass- A Case Report

FURKAN BUĞRA BİLGİN[1], **İBRAHİM SALİH GEÇER**[1], **ZAHİDE MİNE YAZICI**[1], **SENA OKUTAN İRİCE**[1]

[1]*Department of Otolaryngology Head and Neck Surgery, Istanbul Bakırköy Dr. Sadi Konuk Training and Research Hospital, Health Sciences University.*

BACKGROUND & AIM

Actinomycosis is a rare, chronic granulomatous infection caused by filamentous Gram-positive anaerobic bacteria, most commonly Actinomyces israelii. Cervicofacial involvement accounts for approximately 60% of reported cases, whereas lingual localization remains exceedingly rare, representing less than 3% of cases in the literature. Due to its infiltrative growth pattern and mass-forming characteristics, actinomycosis can closely mimic malignant tumors, frequently leading to diagnostic delay and inappropriate management.

MATERIAL & METHODS

A 60-year-old female presented with a four-month history of a progressively enlarging, painless submucosal mass located in the anterior third of the tongue. She reported no history of trauma, recent dental procedures, or immunosuppressive conditions. Physical examination revealed a firm, non-ulcerated lesion with intact mucosa and no associated cervical lymphadenopathy. Magnetic resonance imaging demonstrated a 24×12×15 mm lesion with iso-intensity on T1-weighted images and intermediate-to-high signal intensity on T2-weighted sequences, along with heterogeneous contrast enhancement, raising suspicion for malignancy. Histopathological evaluation revealed submucosal inflammatory infiltration with filamentous bacterial colonies consistent with Actinomyces species, confirming the diagnosis.

RESULTS

Following histopathological confirmation, the patient was initiated on oral amoxicillin-clavulanate therapy due to the high susceptibility of Actinomyces species to beta-lactam antibiotics. During the first two months of treatment, the patient remained clinically stable without disease progression or systemic dissemination. Prolonged antibiotic therapy has demonstrated high cure rates in cervicofacial actinomycosis, often eliminating the need for surgical intervention.

CONCLUSIONS

This case underscores the importance of including actinomycosis in the differential diagnosis of submucosal tongue masses when clinical and radiological findings suggest malignancy. Early histopathological confirmation is essential to avoid misdiagnosis and unnecessary radical surgery. Awareness of this rare entity may facilitate earlier diagnosis and reduce overtreatment. A multidisciplinary approach with adequately prolonged antibiotic therapy enables effective, organ-preserving management. Follow-up should be maintained to ensure complete resolution and prevent recurrence.

PP-291

Hypopharyngeal Venous Malformation Mimicking Malignancy: A Case Report

Emma Dunn[1], **Spencer Short**[2], **Michael McGlone**[2], **Mitchell Niedbala**[4], **Gary Stopyra**[3], **Jason Ohlstein**[2]

[1]*University of South Florida Morsani College of Medicine;* [2]*Lehigh Valley Health Network, Department of Otolaryngology Head and Neck Surgery;* [3]*Lehigh Valley Health Network, Department of Pathology;* [4]*Medical University of Warsaw*

BACKGROUND & AIM

Hypopharyngeal venous malformations are rare and may mimic malignancy on imaging, creating diagnostic and management challenges, particularly when tissue diagnosis is required.

MATERIAL & METHODS

This is a single-patient case report conducted at a tertiary care center. A 61-year-old woman presented with progressive dysphagia and odynophagia. Diagnostic evaluation included contrast-enhanced computed tomography (CT) and flexible laryngoscopy. The primary intervention was direct laryngoscopy with biopsy under general anesthesia. Outcome measures included intraoperative safety (bleeding control, airway stability), histopathological diagnosis, and postoperative clinical course. Descriptive analysis was performed.

RESULTS

Imaging demonstrated a 2.4 × 1.6 × 1.8 cm enhancing lesion involving the left tongue base, aryepiglottic fold, and hypopharynx, with coarse calcifications suggestive of a vascular process but concerning for neoplasia. Endoscopy revealed a compressible, vascular-appearing lesion. Biopsy was successfully performed with topical hemostatic control and no intraoperative or postoperative complications. Histopathology confirmed a venous malformation characterized by dilated vascular channels, intraluminal thrombi, hemosiderin deposition, and phleboliths. No dysplasia or malignancy was identified. The patient remained clinically stable with conservative management at follow-up.

CONCLUSIONS

Hypopharyngeal venous malformations can closely resemble malignancy on imaging, particularly when calcifications and enhancing soft tissue are present. Recognition of key features such as compressibility and phleboliths can improve diagnostic accuracy. This case demonstrates that biopsy can be safely performed in selected patients with appropriate airway planning and hemostatic precautions. However, absence of advanced imaging such as magnetic resonance imaging may limit preoperative diagnostic confidence. Early identification may prevent unnecessary aggressive interventions.

Giant Invasive Prolactinoma Of The Skull Base Mimicking A Nasopharyngeal Neuroendocrine Tumor: A Diagnostic Challenge

Carlos Ramón Franco Fente[1], **Alejandro Pozuelo Moreno**[1], **María Nazaret Benitez Lobón**[1], **Irene Oliver Laguna**[1], **Consuelo Ortega Fernández**[1], **Cristina Valor García**[1], **Isidora Rettig Infante**[1]

[1]*Hospital Universitario Infanta Sofía*

BACKGROUND & AIM

Prolactinomas are the most common pituitary adenomas and typically exhibit benign behavior. However, in rare cases, they may reach a giant size and demonstrate aggressive growth with extension to the skull base and sinonasal structures, mimicking malignant neoplasms. We present a case of a giant prolactinoma with atypical presentation and initial diagnostic uncertainty.

MATERIAL & METHODS

A 75-year-old woman with a history of hypertension, diabetes mellitus, dyslipidemia, obesity, and chronic kidney disease presented with cervical pain, progressive facial edema, and macroglossia without initial airway compromise. ENT examination revealed facial and tongue edema with a patent airway. Nasofibroscopy showed no lesions in the nasopharynx or larynx.

Contrast-enhanced CT demonstrated an infiltrative skull base mass measuring approximately 78 × 70 × 39 mm, involving the sphenoid bone, clivus, and pterygoid processes, with extension into the masticator spaces and maxillary sinus, without cervical lymphadenopathy. An endonasal biopsy was performed via a transnasal approach.

RESULTS

Initial histopathological analysis revealed a grade 1 neuroendocrine tumor, positive for synaptophysin, CD56, and INSM1, and negative for chromogranin and Epstein–Barr virus. Due to clinicoradiological discordance, extended immunohistochemical analysis was performed, demonstrating prolactin positivity and establishing the diagnosis of prolactinoma.

MRI confirmed a large sellar and parasellar mass measuring up to 7.4 cm, with invasion of the cavernous sinuses, clivus, masticator spaces, and nasopharyngeal cavity, without distant metastases. The patient presented with secondary panhypopituitarism. Treatment with cabergoline was initiated, showing early tumor reduction at 3–4 weeks (maximum diameter decreasing from 7.4 cm to 7 cm) with partial clinical improvement.

CONCLUSIONS

Giant invasive prolactinomas may mimic primary nasopharyngeal or neuroendocrine tumors when presenting with extensive skull base and sinonasal involvement. Clinicoradiological correlation and extended immunohistochemical analysis are essential for accurate diagnosis. Pituitary origin should be considered in aggressive skull base masses, as medical treatment can achieve significant tumor reduction even in advanced stages.

From Infection To Tumor: Patient-Specific TMJ Prosthetic Reconstruction Of Complex Mandibular Defects – A Two-Case Series

Dilara Aydın[1], **Murat Döger**[1], **Ömer Erdur**[2]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, Selçuk University, Faculty of Medicine, Konya, Türkiye;* [2]*Department of Otorhinolaryngology-Head and Neck Surgery, Liv Hospital Ulus, Istanbul, Türkiye*

BACKGROUND & AIM

Reconstruction of large mandibular defects remains challenging in maxillofacial surgery, particularly in cases associated with bone loss due to infection or tumors. Traditional reconstructive methods are limited by donor site morbidity, unpredictable resorption, and suboptimal anatomical adaptation. Patient-specific temporomandibular joint (TMJ) and mandibular prostheses based on computer-aided design and computer-aided manufacturing (CAD-CAM) technology have emerged as a reliable alternative for complex mandibular reconstructions.

MATERIAL & METHODS

This case series presents two patients with large mandibular defects managed with patient-specific TMJ and mandibular prostheses. The first case involved a 22-year-old female with traumatic mandibular fractures complicated by chronic osteomyelitis following multiple prior surgical interventions. The second case involved a 62-year-old female with an ameloblastoma-associated mandibular defect requiring segmental resection. Both patients underwent reconstruction following detailed radiological assessment and virtual surgical planning using custom-made prostheses.

RESULTS

In Case 1, infected mandibular and temporomandibular joint structures were resected, followed by staged reconstruction with a custom TMJ prosthesis. Postoperatively, the patient demonstrated improved mouth opening, stable occlusion, and transient facial nerve palsy that resolved during follow-up. In Case 2, immediate reconstruction was performed following segmental resection using a custom mandibular prosthesis. Histopathological examination confirmed ameloblastoma. Early postoperative intraoral wound dehiscence occurred, requiring repeated resuturing and planned secondary buccinator flap reconstruction. Functional outcomes were satisfactory in both cases.

CONCLUSIONS

Patient-specific TMJ and mandibular prostheses represent an effective reconstructive option for large mandibular defects secondary to infection and tumor-related conditions. CAD-CAM–based planning enables accurate anatomical restoration and satisfactory functional outcomes. Careful case selection and staged surgical planning are essential, particularly in infection-related cases, to minimize complications and optimize outcomes.

PP-294

A Diagnostic Dilemma: Discordance Between Preoperative Cytology And Final Pathology In A Giant Parapharyngeal-Extending Pleomorphic Adenoma

Meliz Ece Obalar[1], **Güleser Saylam**[1], **Engin Dursun**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, Lokman Hekim University, Ankara, Turkey*

BACKGROUND & AIM

Pleomorphic adenoma is the most common benign salivary gland tumor, but deep lobe parotid lesions extending into the parapharyngeal space can pose significant diagnostic and surgical challenges. Fine-needle aspiration biopsy (FNAB), while valuable, carries known limitations in sensitivity and specificity, particularly for deep-seated lesions, and preoperative suspicion of malignancy may influence the extent of surgery performed. We present a case highlighting the discordance between preoperative cytological suspicion of malignancy and final benign histopathology, alongside the surgical management of a large parapharyngeal-extending pleomorphic adenoma without skull base invasion.

MATERIAL & METHODS

We report a single case managed at the Department of Otorhinolaryngology–Head and Neck Surgery, Lokman Hekim University, Ankara, Turkey. An 18-year-old male presented with a left preauricular swelling. Contrast-enhanced magnetic resonance imaging (MRI) demonstrated a deep lobe parotid mass extending into the parapharyngeal space toward the skull base. Ultrasound-guided fine-needle aspiration biopsy (FNAB) was performed. Given cytological suspicion of malignancy, the patient underwent total parotidectomy with facial nerve monitoring (nerve integrity monitor, NIM) and ipsilateral selective neck dissection (levels 2–3). Intraoperative findings, surgical technique, and final histopathological results were reviewed.

RESULTS

MRI revealed a 27×52 mm cystic-necrotic mass in the deep lobe of the left parotid gland, filling the parapharyngeal space, with heterogeneous post-contrast enhancement. FNAB cytology raised suspicion for malignancy (low-grade mucoepidermoid carcinoma versus pleomorphic adenoma). Intraoperatively, the mass showed a well-defined margin without skull base invasion and was safely dissected free from the deep parotid lobe with preservation of facial nerve function throughout, confirmed by continuous NIM monitoring. Final histopathological examination revealed a pleomorphic adenoma measuring 5 cm with a satellite nodule and clear surgical margins. Superficial parotid tissue and one lymph node showed no pathological findings; all four lymph nodes from the neck dissection specimen were reactive, with no evidence of malignancy. The postoperative course was uneventful, with intact facial nerve function and discharge on postoperative day 2.

CONCLUSIONS

This case illustrates the limitations of preoperative FNAB in accurately characterizing deep lobe parotid lesions with parapharyngeal extension, where cytological suspicion of malignancy did not correlate with final benign histopathology. While extensive surgery was performed based on preoperative concern for malignancy, the absence of skull base invasion allowed complete and safe tumor excision with facial nerve preservation. This case underscores the importance of correlating cytological findings with clinical and radiological context, and highlights that even large, deeply extending parapharyngeal masses can be managed successfully through careful surgical planning when skull base invasion is absent.

Chatgpt-4 And Gemini As A Virtual Recovery Guide In Post–Total Thyroidectomy Care: A Real-World Evaluation Of Artificial Intelligence (AI) In Patient Education

Hisham Almousa[1], **Faisal R. Alzahrani**[1], **Firas K. Almarri**[1], **Omar M. Alotaibi**[1], **Hemail M. Alsubaie**[1], **Abdullah AlGhamdi**[1], **Mohammed Alshahrani**[1], **Naif Fnais**[1]

[1]*Department of Otolaryngology - Head and Neck Surgery, King Saud University, Riyadh, Kingdom of Saudi Arabia.*

BACKGROUND & AIM

Total thyroidectomy is one of the most common head and neck procedures, requiring patients to have a clear understanding of potential postoperative complications and appropriate postoperative care. However, timely access to medical care can be limited, especially in remote or underserved areas. Integrating advanced artificial intelligence (AI) tools such as ChatGPT-4 and Gemini into postoperative care may help bridge this gap by offering continuous patient education. This study aimed to evaluate the utility of ChatGPT-4 and Gemini in addressing common patient concerns and education following total thyroidectomy.

MATERIAL & METHODS

The five most common postoperative questions following total thyroidectomy were presented to ChatGPT-4 and Gemini. Responses were evaluated by five expert head and neck surgeons based on four criteria: accuracy, clarity, relevance, and response time.

RESULTS

Both AI models demonstrated strong overall performance. ChatGPT-4 and Gemini each achieved an accuracy of 100%, consistent with current clinical guidelines. Clarity scores were 96% for both ChatGPT-4 and Gemini, reflecting generally understandable responses. Relevance scores were high, with ChatGPT-4 at 96% and Gemini at 100%, effectively addressing patient concerns. Both models provided instant responses, earning 100% response time.

CONCLUSIONS

ChatGPT-4 and Gemini demonstrate promise as supportive tools in postoperative care following total thyroidectomy. They provided responses that were accurate, clear, relevant, and timely. Although they cannot replace healthcare professionals, they may serve as valuable adjuncts to patient education, particularly in settings with limited access to care. These findings underscore the emerging role of AI in strengthening postoperative management within head and neck surgery.

PP-296

Primary Maxillary Ewing Sarcoma In A Pediatric Patient: A Case Report

Elvin HUMBATLI[1], **Behlül TUNCER**[1], **Kiarash SHAMEKHI**[1], **Muratcan SARI**[1], **Yetkin Zeki YILMAZ**[1]

[1]*Istanbul Cerrahpasa Faculty Department of Otorhinolaryngology*

BACKGROUND & AIM

Ewing Sarcoma (ES) is a highly aggressive, small round blue cell malignancy that primarily affects children and adolescents. While it typically originates in the long bones or pelvis, primary occurrence in the maxillary region is extremely rare. Due to the complex anatomy of the midface, achieving wide surgical margins is a significant challenge. We present the clinical management and multimodal treatment of an 8-year-old male patient with maxillary ES, focusing on the surgical approach and adjuvant therapy outcomes.

MATERIAL & METHODS

An 8-year-old male patient presented with a one-year history of a lesion in the left maxillary region. Histopathological evaluation of the biopsy specimen confirmed the diagnosis of Ewing Sarcoma. On May 21, 2025, the patient underwent an inferior maxillectomy.Detailed pathological mapping of the specimen revealed surgical margins of 0.1 cm at the lateral margin, 0.2 cm at the posterior margin, and 0.5 cm at the medial margin.

Due to the aggressive nature of the tumor and the presence of close surgical margins, the patient received a multimodal adjuvant protocol consisting of 28 fractions of radiotherapy and 14 cycles of chemotherapy.

RESULTS

The intensive adjuvant treatment period, including systemic chemotherapy, was successfully completed in December 2025. During the follow-up period as of April 2026, the patient showed no clinical or radiological evidence of local recurrence or systemic metastasis. The multidisciplinary approach allowed for the successful completion of an aggressive treatment regimen despite the technical challenges of the anatomical site.

CONCLUSIONS

Pediatric maxillary Ewing Sarcoma requires a highly coordinated multimodal treatment strategy. Although achieving wide surgical margins is difficult in the sinonasal region, an inferior maxillectomy combined with robust adjuvant radiotherapy and chemotherapy can provide effective local and systemic control. Close clinical and radiological surveillance is mandatory to monitor for potential recurrence and the long-term functional impact of treatment on facial growth.

PP-297

Rare Localization Of A Solitary Fibrous Tumor In The Floor Of The Mouth With High Ki-67 Index: Case Report

Burak Meriç[1], **Abdullah Taş**[1], **Ufuk Usta**[1]

[1]*Trakya University*

BACKGROUND & AIM

Solitary Fibrous Tumor (SFT) is a rare mesenchymal neoplasm, typically pleural in origin. Extra-pleural occurrences, especially in the oral cavity, are exceedingly rare and present diagnostic challenges due to nonspecific clinical features. This report describes an unusual SFT in the floor of the mouth of a young patient, emphasizing its clinico-pathological features and a notably high Ki-67 proliferation index.

MATERIAL & METHODS

A 22-year-old male presented with a painless, 4x3 cm mass in the floor of the mouth for three months. Clinical examination showed a semi-mobile, firm lesion with intact mucosa. Contrast-enhanced MRI demonstrated a 40x30 mm, well-circumscribed, T2 iso-to-hyperintense lesion in the left sublingual space extending toward the tongue base, with intense homogeneous enhancement. The mass was completely excised under general anesthesia, followed by histopathological and immunohistochemical (IHC) analyses, including STAT6 and CD34.

RESULTS

Histopathology revealed spindle cell proliferation in a "patternless pattern" characterized by hypocellular/hypercellular areas with keloid-like collagen and hemangiopericytoma-like vascular structures. IHC analysis showed strong, diffuse positivity for STAT6 and CD34, confirming SFT, while other markers were negative, excluding alternative spindle cell neoplasms. Notably, the Ki-67 proliferation index was 15%, suggesting increased proliferative potential compared to conventional SFTs. Complete surgical resection achieved clear margins, and the patient was scheduled for long-term clinical follow-up.

CONCLUSIONS

Oral SFTs are rare and diagnostically challenging due to clinical nonspecificity and morphological overlap with other neoplasms. Definitive diagnosis relies on precise immunohistochemical profiling, with STAT6 serving as the most specific marker. This case highlights that a 15% Ki-67 index may indicate higher proliferative activity even in benign-appearing cases, necessitating vigilant, long-term surveillance. This case contributes to the limited literature on oral SFTs and underscores the essential role of IHC precision in ensuring diagnostic accuracy and guiding effective management in the head and neck region.

Non-Acceptance Of Hearing Aids: Risk Factors And Intervention Strategies

Ivana Maletić Sekulić[1,2], **Vesna Simikić**[1,3], **Ninoslava Dragutinović**[6], **Snežana Babac**[4,5]

[1]*Public Health Institution Hospital "Sveti Vračevi" Bijeljina, Bosnia and Herzegovina;* [2]*University of Bijeljina, Bijeljina, Bosnia and Herzegovina;* [3]*University of Kragujevac, Faculty of Technical Sciences, Čačak, Serbia;* [4]*University of Belgrade, Faculty for Special Education and Rehabilitation, Belgrade, Serbia;* [5]*CHC "Zvezdara", Belgrade, Serbia;* [6]*Special Hospital "Euromedic", Belgrade, Serbia*

BACKGROUND & AIM

Background: Presbycusis significantly affects quality of life by limiting social, professional, and emotional functioning. Despite the availability of modern hearing technologies, some patients delay or refuse recommended amplification. The aim: To examine factors associated with hearing aid rejection to improve rehabilitation strategies.

MATERIAL & METHODS

Methods: A cross-sectional study was conducted on 50 participants (30 women, 20 men) aged ≥45 years with diagnosed presbycusis, for whom unilateral or bilateral amplification was recommended. Data were collected using a structured questionnaire covering sociodemographic characteristics, financial factors, family support, and emotional attitudes toward hearing aid use. Statistical analysis included χ^2 test, Fisher's exact test, Welch's t-test, and multivariate logistic regression, with significance set at $p < 0.05$.

RESULTS

Results: Financial constraints (OR = 6.62; p = 0.008) and lack of family support (OR = 11.13; p = 0.003) were significant predictors of rejection of both hearing aids. Absence of family support was the strongest independent predictor (OR = 13.22; 95% CI: 3.1–56.5; $p < 0.001$). The overall model was statistically significant ($\chi^2 = 21.34$; $p < 0.001$) and explained 48% of the variance (Nagelkerke $R^2 = 0.48$). Psychological burden was higher among participants recommended for two hearing aids.

CONCLUSIONS

Conclusion: Financial barriers and, especially, lack of family support are key determinants of hearing aid rejection. Interventions targeting family involvement and reducing financial obstacles may significantly improve hearing rehabilitation outcomes.

PP-299

Individualized Hearing Aid Fitting Strategies For Children With Different Degrees Of Hearing Loss

Mukhlisa Abdukamilova[1], **Abdukhalil Musaev**[1], **Inoyatova Flora Ilyasovna**[1], **Abdukayumov Abdumannon**[1], **Nadjmutdinova Nazima**[1]

[1]Republician Center of Pediatrics in Uzbekistan

BACKGROUND & AIM

Hearing impairment of varying severity in children leads to delays in speech and cognitive development. Proper hearing aid fitting, taking into account the degree of hearing loss and individual auditory perception characteristics, is a key stage of auditory–verbal rehabilitation. Of particular importance is the selection of amplification parameters that ensure speech intelligibility without acoustic overload of the auditory system, as well as the preparation of patients with severe hearing loss for possible cochlear implantation.

MATERIAL & METHODS

To investigate the features of hearing aid fitting in children with bilateral sensorineural hearing loss (SNHL) of grades II–IV and to determine optimal amplification parameters for improving speech intelligibility and ensuring comfortable auditory perception.

The study included children aged 6–10 years with bilateral sensorineural hearing loss of grades II–IV. Audiological assessment comprised pure-tone audiometry, tympanometry, auditory brainstem response (ABR), and speech intelligibility testing. Hearing aid fitting was performed using digital behind-the-ear devices. Programming was carried out according to the DSL v5.0 and NAL-NL2 fitting formulas, with verification using real-ear measurements. The main outcome measures were improvement in speech perception thresholds, increased speech intelligibility, and comfortable sound perception without auditory overload.

RESULTS

In a patient with grade II SNHL (right ear – 50 dB, left ear – 55 dB), hearing aid fitting resulted in improved perception of soft and moderate sounds and restoration of speech intelligibility at a comfortable loudness level (Fig. 1). In a patient with grade III SNHL (thresholds 60–70 dB), good speech intelligibility at high sound levels and comfortable perception of everyday sounds were achieved (Fig. 2). In a patient with grade IV SNHL (right ear – 80 dB, left ear – 75 dB), maximum speech audibility and effective loudness control were provided; the patient was recommended for further evaluation for possible cochlear implantation (Fig. 3).

CONCLUSIONS

The results demonstrated that individualized hearing aid fitting based on each child's audiogram and regular follow-up monitoring ensured optimal amplification parameters and stable positive dynamics in auditory and speech development. In audiograms with a steeply sloping configuration, frequency lowering improved access to high-frequency phonemes but required careful calibration to avoid sound distortion. Feedback-related issues were effectively resolved through optimization of earmolds and adjustment of maximum power output (MPO). The best rehabilitation outcomes were achieved through interdisciplinary collaboration involving an audiologist, speech therapist, special education specialist, and parents, which facilitated adaptation and consistent hearing aid use.

PP-300

Clinical Utility Of REM And 2-Cc Measures In Evaluating Japanese High-Frequency Consonant Perception In Children

Shigehiro OOHARA[1], **Tomomi OOHARA**[2], **Eiko HIROTA**[3]

[1]*Department of Speech, Language, and Hearing Sciences, Faculty of Rehabilitation, Seirei Christopher University, Japan;* [2]*Nanohana Day Care Center for Children with Hearing Loss, Toyota Municipal Child Development Center, Japan;* [3]*University of Tsukuba, Japan*

BACKGROUND & AIM

High-frequency audibility is essential in pediatric hearing-aid fitting because perception of Japanese high-frequency consonants depends strongly on access to information around 4k. Real-ear measurement (REM) reflects individual ear acoustics and speech-based audibility, whereas 2-cc coupler measurement is simpler and more reproducible. We hypothesized that REM would be more clinically useful than 2-cc because high-frequency output changes would be visualized more clearly and correspond more closely to speech perception.

MATERIAL & METHODS

Eighteen aided ears from 11 children with bilateral sensorineural hearing loss were studied. Two analyses were performed. In Analysis 1, hearing-aid output was measured by REM using the International Speech Test Signal and by 2-cc coupler using pure-tone sweep input at 50, 65, and 80 dB SPL. For REM, Long-Term Average Speech Spectrum level above threshold was quantified; for 2-cc, output level above threshold was quantified at 250, 500, 1k, 2k, and 4k. In Analysis 2, aided speech perception was tested using Japanese monosyllables containing /ku/, /su/, /te/, /to/, and /ha/. Generalized linear mixed models analyzed consonant perception (0/1), with 4k output level above threshold and measurement method (REM vs 2-cc) as fixed effects and ear as a random intercept.

RESULTS

In Analysis 1, output change with increasing input was greater for REM than for 2-cc across 1–4k, especially at 2k and 4k. At 65 dB input, output level above threshold was lowest at 4k in both methods. In Analysis 2, greater 4k output level above threshold significantly increased correct consonant perception. The interaction between output level and measurement method was not significant, indicating a similar per-dB effect. The main effect of measurement method favored REM for all consonants: /k/ p=0.034, /s/ p=0.022, /t/ in /te/ p=0.055, /t/ in /to/ p=0.035, and /h/ p=0.133. To reach a predicted probability of about 0.8, the 2-cc condition required +8 to +14 dB more output above threshold than the REM condition.

CONCLUSIONS

REM was more useful than 2-cc for evaluating Japanese high-frequency consonant perception in children. Its advantage lay in clearer visualization of high-frequency output changes and closer correspondence to perceptual performance, especially at 4k.

PP-301

Challenges In Vocal Emotion Recognition Among Children With Hearing Impairments

Alina Kuzminienė[1], **Giedrė Alzbutienė**[1]

[1]*Lithuanian University of Health Sciences*

BACKGROUND & AIM

Vocal emotion recognition is an area in which children with hearing impairments often underperform compared to their peers with normal hearing. Such difficulties may have long-term consequences for social integration and emotional well-being. This study aimed to examine the ability of children with hearing impairments to identify vocal emotions, compare their performance with that of peers with normal hearing, and assess potential factors influencing this ability.

MATERIAL & METHODS

The study involved 28 children with permanent hearing impairment and a control group of 28 age- and sex-matched peers with normal hearing, resulting in a total sample size of 56. The vocal emotion recognition task consisted of 10 audio recordings produced in standard Lithuanian by a 28-year-old male and a 24-year-old female speaker. Participants were presented with five response options, one of which represented the correct emotion. The target emotions were joy, sadness, fear, anger, and neutrality. Data analysis was conducted using SPSS 29.0 for Windows.

RESULTS

Children with permanent hearing impairment achieved significantly lower accuracy in vocal emotion recognition than their peers with normal hearing (62.81 ± 15.29% vs. 73.45 ± 12.03%; $t(54) = -2.997$, $p = 0.004$, Cohen's $d = -0.768$). Both groups were more accurate when identifying emotions voiced by a female speaker. Across groups, the most easily recognized emotions were joy and anger, whereas fear and sadness were the most difficult to identify. ANOVA revealed that a history of behavioral disorder did not significantly affect emotion recognition ($p > 0.05$), although further research is warranted to explore its potential practical implications.

Additionally, children using hearing aids (HA) scored higher on average than those with cochlear implants (CI), with a mean difference of 7.26% ($p = 0.274$), and a medium effect size (Cohen's $d = 0.476$).

CONCLUSIONS

These findings demonstrate that children with hearing impairments face notable challenges in vocal emotion recognition compared with peers with normal hearing. The speaker's gender and the type of hearing device may have practical relevance. Future research should explore interventions aimed at improving vocal emotion recognition skills in this population.

Vocal Cord Schwannoma Mimicking Post-Intubation Granuloma: A Diagnostic Challenge

Ibrahim Canbazoglu[1], **Mehmet Duzlu**[1]

[1]*Gazi University Faculty of Medicine, Department of Otolaryngology–Head and Neck Surgery, Ankara, Türkiye*

BACKGROUND & AIM

Post-intubation granuloma is a common cause of posterior glottic masses in patients with a history of endotracheal intubation. However, not all lesions detected in this setting represent granulomas. Laryngeal schwannomas are rare benign tumors, and involvement of the vocal cord is exceptionally uncommon.

MATERIAL & METHODS

Case Presentation:A 25-year-old woman with a history of septorhinoplasty presented with progressive hoarseness, dyspnea, dysphagia, and globus sensation one year after surgery. A vocal cord mass was incidentally detected during intubation for revision surgery. Given the history of prior intubation, the lesion was initially suspected to be an intubation granuloma. Endoscopic examination revealed a well-circumscribed pedunculated mass arising from the posterior third of the left ventricular fold. The lesion was completely excised via direct laryngoscopy. Histopathological evaluation demonstrated a spindle cell tumor beneath intact squamous mucosa, and immunohistochemical staining was positive for S100, confirming schwannoma.

RESULTS

Endoscopic examination showed a smooth, pedunculated mass arising from the posterior third of the left ventricular fold. Although the patient had a history of prior intubation, the lesion did not have the typical ulcerated or inflammatory appearance expected in an intubation granuloma. Instead, it appeared well-defined and submucosal. The mass was removed completely under direct microlaryngoscopy. Intraoperatively, it was firm and encapsulated, allowing straightforward dissection from the surrounding tissue.

Histopathological evaluation revealed a spindle cell tumor located beneath intact squamous epithelium. Immunohistochemical staining demonstrated strong S100 positivity, confirming the diagnosis of schwannoma. Surgical margins were clear. The postoperative course was uneventful, and the patient reported noticeable improvement in both hoarseness and breathing symptoms during follow-up, with no evidence of recurrence.

CONCLUSIONS

Posterior glottic lesions in patients with a history of intubation are often assumed to be granulomas. However, not every lesion in this setting is inflammatory in nature. When a mass appears well-circumscribed or submucosal, alternative diagnoses should be considered. Vocal cord schwannoma, although rare, can clinically resemble an intubation granuloma and lead to initial misinterpretation. Complete excision and histopathological evaluation remain essential for definitive diagnosis. Maintaining clinical suspicion in atypical cases may help avoid delayed or inappropriate management.

Hidden Depths Of Neck Trauma: A Case Of Thyroid Cartilage Fracture With Posterior Pharyngeal Wall And Pyriform Sinus Injury

volkan öztemel[1], **gülşah acar yüceant**[1], **banu er çatal**[1]

[1]*Department of Otorhinolaryngology, Kartal Dr. Lütfi Kırdar City Hospital, Istanbul, Turkey*

BACKGROUND & AIM

Penetrating neck trauma accounts for approximately 5–10% of all traumatic injuries but carries significant morbidity and mortality due to complex cervical anatomy and vital aerodigestive, neural, and vascular structures. Hypopharyngeal injury following penetrating laryngeal trauma is extremely rare but may lead to complications such as deep neck infection and mediastinitis. This report presents a rare case of posterior and lateral hypopharyngeal wall laceration associated with thyroid cartilage fracture.

MATERIAL & METHODS

A 27-year-old male presented to the emergency department after a motorcycle accident with neck pain and subcutaneous crepitation, without stridor. Physical examination revealed a 4 cm full-thickness laceration extending from the midline toward the left side.

Indirect laryngoscopic examination revealed diffuse hemorrhagic changes within the hypopharynx, along with a displaced cartilage fragment in the left piriform sinus. The glottic airway was patent with preserved bilateral vocal cord mobility. Computed tomography confirmed a displaced fracture of the left superior horn of the thyroid cartilage with subcutaneous emphysema.

RESULTS

Emergency tracheotomy followed by neck exploration was performed. Intraoperatively, transection of strap muscles, rupture of the thyrohyoid membrane, and a displaced thyroid cartilage fracture were identified. The cartilage fragment protruded into the hypopharynx and the posterior hypopharyngeal wall was detached from the prevertebral fascia. The mucosal defect was repaired with continuous sutures, and the fracture site was reinforced using strap muscle coverage.

Postoperatively nutrition was provided via a feeding tube, and prophylactic antibiotics were administered. During follow-up, purulent laryngeal discharge was observed, and culture revealed Pseudomonas. Targeted antibiotic therapy resulted in clinical improvement. Oral feeding was initiated on postoperative day 18 and the patient was successfully decannulated.

CONCLUSIONS

Head and neck trauma frequently involves cervical structures. Hypopharyngeal injury following penetrating laryngeal trauma is rare but may lead to serious complications if not recognized early. Careful laryngeal examination and computed tomography play a crucial role in detecting structural injuries and guiding management. Early airway protection and timely surgical repair are essential to prevent life-threatening complications and achieve favorable clinical outcomes.

Early Screening Of Dysphagia And Effects Of Graded Rehabilitation Nursing Intervention In Post-Operative Laryngeal Cancer Patients

xu kesu[1]

[1]*Qianjiang Central Hospital, Chongqing*

BACKGROUND & AIM

To investigate the effectiveness of early dysphagia screening combined with graded rehabilitation nursing intervention in improving swallowing function and quality of life among patients following laryngeal cancer surgery.

MATERIAL & METHODS

A prospective randomized controlled trial was conducted from January 2023 to December 2024 at a tertiary hospital. A total of 120 post-operative laryngeal cancer patients were randomly assigned to either the intervention group (n=60) or the control group (n=60). The intervention group received a graded rehabilitation nursing protocol encompassing oro-motor exercises, compensatory swallowing techniques, dietary texture modification, and progressive oral feeding training tailored to dysphagia severity. The control group received routine post-operative nursing care. Outcomes including swallowing function (assessed by Functional Oral Intake Scale, FOIS), aspiration pneumonia incidence, nutritional status, and Quality of Life (SWAL-QOL) were evaluated at 2 weeks, 4 weeks, and 3 months post-intervention.

RESULTS

The intervention group demonstrated significantly superior FOIS scores compared to controls at all follow-up time points (P<0.05). The incidence of aspiration pneumonia was markedly lower in the intervention group (8.3% vs. 23.3%, P<0.05). Nutritional indices (serum albumin, body mass index) and SWAL-QOL scores were significantly improved in the intervention group at 3-month follow-up (P<0.01).

CONCLUSIONS

Early standardized dysphagia screening combined with graded rehabilitation nursing intervention significantly improves swallowing function, reduces pulmonary complications, and enhances quality of life in post-operative laryngeal cancer patients.

Giant Laryngeal Saccular Cysts: A Case Series

Eray ERTEN[1], **Hakkı Caner İNAN**[1], **Ayla ÇAKICI**[1], **Veysel Akif SAVAŞ**[1], **Betül Ağırgöl**[1]

[1]*Bursa High Specialty Training and Research Hospital,Unıverstıy of Health Sciences*

BACKGROUND & AIM

The laryngeal saccule is an opening in the anteromedial third of the roof of the laryngeal ventricle. It is lined by ciliated respiratory epithelium containing anywhere from 50 to 100 mucous glands.Blockage of the saccule opening with continued secretion of mucous leads to a saccular cyst. Due to its location, it may be confused with a laryngocele in the differential diagnosis. While a saccular cyst is a mucus-containing cystic structure with no communication to the laryngeal lumen, a laryngocele typically maintains a connection with the lumen and is filled with air.

MATERIAL & METHODS

This study included four patients who underwent surgery for giant LSCs between 2022 and 2026. The ages of the patients ranged from 56 to 74 years. One of the patients was male and three were female.

RESULTS

In the preoperative imaging of all patients, the maximum diameter of the LSC ranged between 3 cm and 6 cm. One patient underwent an emergency tracheotomy due to respiratory distress. While all patients presented with a localized swelling in the neck, three patients also complained of dyspnea.

In all cases, the cysts were excised via a transcervical approach. Intraoperative evaluation with suspension laryngoscopy revealed no mucosal defects in the laryngeal structures. The superior laryngeal nerve, superior thyroid artery/vein, and the thyrohyoid membrane were meticulously preserved. Postoperative histopathological examination was consistent with a saccular cyst. No recurrence or residual disease was detected in any of the patients during the follow-up period.

CONCLUSIONS

LSC is one of the rare pathologies of the larynx. In both newborns and adults, it may present with symptoms such as stridor, hoarseness, dysphagia, and a localized neck mass. Although surgical intervention is the cornerstone of treatment, various methods such as marsupialization, needle aspiration, endoscopic CO_2 laser surgery, and the transcervical approach are documented in the literature. The transcervical approach is particularly recommended for the excision of large cysts.

Tracheal MALT Lymphoma Masquerading As Pregnancy-Related Dyspnoea

Jun Pian Benien Hau[1,2], **Ronald Lai**[1,2]

[1]*Department of Ear, Nose and Throat, United Christian Hospital, Hospital Authority, Hong Kong;* [2]*Department of Otorhinolaryngology, Head and Neck Surgery, The Chinese University of Hong Kong, Hong Kong*

BACKGROUND & AIM

Primary mucosa-associated lymphoid tissue (MALT) lymphoma of the trachea is exceptionally rare and may mimic benign inflammatory or papillomatous airway disease. We report a postpartum woman with near-critical airway obstruction from tracheal MALT lymphoma, initially managed as pregnancy-related dyspnoea/presumed pneumonia.

MATERIAL & METHODS

A 40-year-old woman developed progressive exertional dyspnoea during pregnancy and was treated in the community for presumed pneumonia after a hazy chest radiograph. Symptoms progressed over 2-3 months and worsened in the 1-2 weeks before presentation, with orthopnoea and sleep disturbance. Flexible laryngoscopy in the community demonstrated an irregular subglottic mass and she was referred to the emergency department. Bedside flexible laryngoscopy confirmed an

irregular, papillomatous-appearing posterior subglottic/upper tracheal lesion causing >80-90% luminal obstruction with mobile vocal folds. The airway was secured (awake fibreoptic intubation) followed by direct laryngoscopy/bronchoscopy, biopsy and endoscopic debulking. She required short-term postoperative ventilation and was extubated after 48 hours.

RESULTS

Histopathology showed a low-grade B-cell lymphoma consistent with extranodal marginal zone lymphoma of MALT (CD20+, BCL2+, CD5-, CD10-, CD23-, cyclin D1-, SOX11-; kappa light-chain restriction; low Ki-67 proliferation index). Molecular studies demonstrated a clonal B-cell population. Staging demonstrated nodal involvement without bone marrow disease (stage II). She was treated with rituximab monotherapy (4 weekly doses) with complete metabolic response on end-of-treatment PET-CT and resolution of airway symptoms; follow-up endoscopy showed a clear subglottis.

CONCLUSIONS

Tracheal MALT lymphoma, although indolent, may present as life-threatening airway obstruction and be overlooked during pregnancy/postpartum. Early endoscopic assessment of stridor, timely multidisciplinary airway planning, and lymphoma-directed therapy can achieve excellent outcomes.

PP-307

SUBGLOTTIC KAPOSI´S SARCOMA IN PATIENT WITH AIDS.AN UNUSUAL REPORT IN EQUATORIAL GUINEA AND LITERATURE REVIEW.

Pieruzzini Rosalinda[1], **Petrosino Pierina**[1], **Abeso Juan**[1]

[1]*La Paz Medical Center.Equatorial Guinea*

BACKGROUND & AIM

Kaposi sarcoma is the most frequently-occurring neoplasm in AIDS patients. Laryngeal localization ,especially Subglottic is infrequent.We discuss the management options for laryngeal Kaposi sarcoma based on a literature review.

MATERIAL & METHODS

A 38 year old, HIV-positive male receiving HAART therapy presented with mild hoarseness , sore throat and inspiratory dyspnea. Fiberoptic laryngeal examination identified a large purple lesion bilobed that occupies 100% of the glottis lumen. CT Scan Neck reported intermediate density image became glotto-subglottic and obstructed the airway .He underwent biopsy and tracheostomy under general anaesthesia. The lesion was histologically diagnosed such as pyogenic granuloma and he was underwent to transoral radiofrequency ablation plus biopsy in second take. Histopathology showed low -grade sarcoma and immunohistochemistry reports Kaposi Sarcoma . A second surgery was performed with radiofrequency ablation and Post-operative chemotherapy was administered. Three months later, the patient was completely asymptomatic and the laryngeal examination was normal

RESULTS

Three months later, the patient was completely asymptomatic and the laryngeal examination was normal.

CONCLUSIONS

Combined approach radiofrequency ablation with chemotherapy is a valid option for managing obstructive laryngeal Kaposi sarcoma.

Novel Application Of The Modified Wendler Glottoplasty To Revise Anterior Commissure Gap

Miss Melanie Dias[1], **Miss Abi Simpson**[1], **Mr Chadwan Al Yaghchi**[1]

[1]*Imperial College Healthcare NHS Trust*

BACKGROUND & AIM

Modified Wendler Glottoplasty (MWG) is a procedure traditionally performed for pitch elevation. We present the case of MWG used to revise an anterior commissure gap after failure of multiple surgical interventions. A 50-year-old lawyer underwent a routine excision of a thyroglossal duct cyst via a Sistrunk procedure in February 2015, and sustained left thyroid cartilage lamina damage, initially sutured intraoperatively. Following this, she developed anterior laryngeal webbing which caused persistent dysphonia, significantly affecting her quality of life.

MATERIAL & METHODS

She underwent endoscopic keel placement in September 2015; however the keel subsequently became displaced and removed. The patient was left with significant anterior glottic scarring, anterior commissure gap, and shortening of the left vocal fold, contributing to persistent dysphonia and glottic insufficiency. She was referred to our service for consideration of

further management. She initially presented to our service with severe dysphonia and perceptual voice evaluation score of G2R2B2A2S1.

Over the following years, the patient underwent multiple surgical interventions, including vocal fold injection augmentation, medialisation thyroplasty with Gore-Tex implantation and revision. During this time, the patient had multiple blocks of voice therapy focussing on addressing maladaptive hyper functional vocal use using forward resonance, pitch optimising and accent method. Although several procedures and therapeutic intervention provided transient improvement, vocal outcomes remained limited because of extensive scarring and distorted laryngeal anatomy.

RESULTS

In March 2026 the patient underwent a modified Wendler Glottoplasty to revise the anterior commissure gap. Postoperatively, she experienced marked improvement in vocal quality, tone, and projection. Although mild residual raspiness persisted, repeat perceptual voice assessment improved to a GRBAS score of G1R1B1A0S0. The patient also reported substantial subjective and functional voice improvement. Maximum phonation time increased from 2 seconds to 9 seconds. Despite objective improvement in her vocal quality and subjective improvement by patient, the patient continued to score high on the VHI with a score of 32.

CONCLUSIONS

This case highlights the potential role of MWG as a surgical option in the management of complex dysphonia secondary to vocal fold scarring and glottic insufficiency following iatrogenic laryngeal injury.

PP-309

Neck Mass And Severe Airway Stenosis: Malignancy Is Not Always The Diagnosis

Edwin Gustavo Barrientos Morales[1], **Jorge Bernardo Pellecer Cano**[1]

[1]*Instituto Guatemaltego de Seguridad Social IGSS*

BACKGROUND & AIM

The coexistence of a cervical mass and significant airway stenosis often raises strong suspicion of malignant disease. However, benign conditions may mimic this presentation and pose important diagnostic and surgical challenges.

We present a case of severe long-segment tracheal stenosis associated with a thyroid mass in a young adult, highlighting the importance of comprehensive evaluation and individualized surgical planning to avoid misdiagnosis and ensure optimal airway management.

MATERIAL & METHODS

A 28-year-old male from Guatemala with a history of pelvic fracture and exploratory laparotomy for blunt abdominal trauma one year prior presented with progressive neck pain, dyspnea, stridor, and dysphonia.

Imaging revealed a right thyroid mass associated with significant airway narrowing. Bronchoscopic evaluation demonstrated Cotton grade III tracheal stenosis with 90% obstruction, a residual lumen of 3 mm, and a stenotic segment measuring approximately 3 cm in length.

Endoscopic dilations were performed, improving airway patency to approximately 70%, and biopsies of the stenotic segment revealed benign fibrotic tissue. Fine-needle aspiration of the thyroid mass reported Bethesda II cytology.

Given the extent of stenosis and persistent airway compromise, definitive surgical management was scheduled.

RESULTS

Intraoperative findings confirmed fibrotic stenosis extending from the first to the seventh tracheal rings, with a residual lumen of approximately 5 mm. Segmental tracheal resection (rings 1–7) was performed followed by primary end-to-end anastomosis. Concomitant right hemithyroidectomy was completed in a single stage.

Histopathology confirmed benign post-intubation fibrotic stenosis and a 3.5 × 2.8 × 2.5 cm microfollicular thyroid adenoma.

The postoperative course was favorable. Follow-up bronchoscopy demonstrated adequate airway patency, and spirometry results were within normal limits. The patient remains asymptomatic.

CONCLUSIONS

The association of a neck mass and severe airway stenosis does not necessarily indicate malignancy. High-grade benign tracheal stenosis can coexist with benign thyroid disease and may mimic advanced neoplastic processes.

Definitive segmental tracheal resection with primary anastomosis remains the gold standard for long-segment high-grade stenosis, and concomitant thyroid surgery can be safely performed in selected cases.

Early recognition, appropriate endoscopic assessment, and multidisciplinary surgical planning are critical to achieving successful functional outcomes.

PP-310

THE DEVELOPMENT OF AN UNCOMMON COMPLICATION AFTER INTRA-ORAL INFILTRATIVE ANAESTHESIA: HOARSENESS AND RESPIRATORY DIFFICULTY

Zuhal Zeybek Sivas[1], **Ahmet Kürşat Kocatepe**[2], **Furkan İşen**[2], **Turan Canmurat İzgi**[2], **Fikret Zeybek**[2]

[1]*Department of Otorhinolaryngology, Antalya City Hospital, Antalya, Turkey, Türkiye;* [2]*Department of Otolaryngology, Kutahya Health Sciences University Faculty of Medicine, Kütahya, Turkey*

BACKGROUND & AIM

An extremely uncommon complication is presented in this case report. Following infiltrative local anaesthesia administered to the upper jaw, restricted tongue movements, hoarseness, and shortness of breath developed. Although all physicians are prepared for complications that can develop after local anaesthesia administered intra-orally, the aim of this case report is to draw attention to this uncommon complication.

MATERIAL & METHODS

A 42-year-old female patient was recommended to have root canal treatment by her dentist. Infiltrative local anaesthesia with lidocaine was administered for the procedure that was to be performed on the anterior upper teeth. At 30 minutes after the local anaesthesia administration, the patient could not move her tongue, and developed shortness of breath and hoarseness. The patient was referred to the Ear, Nose, and Throat Clinic. In the videolaryngostroboscopy performed, movements of the left vocaal cord were seen to have slowed down, and this was evaluated as left vocal cord paralysis.

RESULTS

Intravenous 1mg/kg methylprednisolone was administered. At 24 hours after the procedure, the hoarseness had completely recovered, and in the follow-up laryngostroboscopy the left vocal cord movements were seen to be normal. It was seen in the patient history that hoarseness had developed following thyroidectomy 12 years previously, and after 6 months of voice therapy, the complaints completely recovered.

CONCLUSIONS

Intra-oral infiltrative anaesthesia is usually administered in ENT diseases practice. Although uncommon, it must not be forgotten that local anaesthesia can lead to serious complications, and therefore, the complication risk of patients should be evaluated before the procedure and they should be followed up after the procedure. Even though these complications are rarely observed, they must not be overlooked.

PP-311

Vallecular Laryngeal Branchial Cleft Cyst: A Case Report

Dr. Ali Bahadır Acar[1], **Asst. Prof. TUĞBA YEMİŞ**[1]

[1]*RECEP TAYYIP ERDOGAN UNIVERSITY EDUCATION AND RESEARCH HOSPITAL, OTORHINOLARINGOLOGY HEAD AND NECK SURGERY*

BACKGROUND & AIM

Branchial cleft cysts are congenital epithelial lesions resulting from incomplete obliteration of the branchial apparatus during embryological development of the neck. The second branchial cleft cyst is the most common subtype, accounting for approximately 90–95% of cases. These lesions typically present as lateral cervical masses, whereas laryngeal localization is extremely rare. Laryngeal branchial cleft cysts are thought to arise from third or fourth branchial cleft anomalies and may present with non-specific upper airway symptoms. This study aims to report a rare case of a vallecular laryngeal branchial cleft cyst and to highlight its clinical and diagnostic features.

MATERIAL & METHODS

A 48-year-old male patient presented with a 10-month history of dysphagia and persistent globus sensation. There was no history of dyspnea, voice changes, or significant weight loss. Endoscopic examination revealed a well-defined cystic lesion approximately 1 cm in diameter, located on the right lateral aspect of the lingual surface of the epiglottis, extending into the vallecula. Radiological evaluation with magnetic resonance imaging (MRI) and computed tomography (CT) confirmed the presence of a well-circumscribed cystic lesion without evidence of invasion into surrounding structures.

The patient underwent complete surgical excision of the lesion under suspension microlaryngoscopy. The cyst was removed in total, including its wall, to minimize the risk of recurrence. Histopathological examination revealed a branchial cleft cyst, consistent with a lymphoepithelial cyst.

RESULTS

The postoperative course was uneventful, and the patient experienced complete resolution of symptoms. No perioperative or postoperative complications were observed. Follow-up examinations showed no evidence of recurrence or residual lesion

CONCLUSIONS

Laryngeal branchial cleft cysts are rare entities that may present with non-specific symptoms such as dysphagia and globus sensation. This case highlights the importance of considering rare congenital anomalies in the differential diagnosis of laryngeal cystic lesions. Endoscopic evaluation combined with radiological imaging is essential for accurate diagnosis. Complete surgical excision remains the treatment of choice and is associated with excellent outcomes and low recurrence rates.

Successful Emergency Lichtenberger Lateralisation For Immediate Bilateral Laryngeal Immobility After Total Thyroidectomy

Siniša Stevanović[1], **Melanija Obraz**[1]

[1]*Clinical Hospital Sestre milosrdnice, Zagreb*

BACKGROUND & AIM

Objective. This case report discusses a successful emergency Lichtenberger lateralisation procedure after immediate bilateral laryngeal immobility, occurring after total thyroidectomy.

MATERIAL & METHODS

A 63-year-old female with right-sided vocal fold paralysis due to compression by a multinodular thyroid goitre underwent total thyroidectomy, which resulted in immediate post-operative bilateral vocal fold immobility. The patient had acute-onset post-operative dyspnoea, was promptly re-intubated, and an emergency lateralisation Lichtenberger suture was placed over the right vocal fold and fixated on the outer surface of the neck.

RESULTS

After two weeks, her right vocal fold recovered first, with the suture still in place. At four weeks, both vocal folds regained function and the suture was extracted.

CONCLUSIONS

The take-away message is that an emergency lateralisation suture may be a viable option in maintaining airway patency, while allowing for normal deglutition, in patients who would otherwise be candidates for prolonged intubation, posterior cordotomy, medial arytenoidectomy or tracheostomy.

Tapia Syndrome Developing After Shoulder Surgery: A Case Report Of Combined Recurrent Laryngeal And Hypoglossal Nerve Palsy

YUNUS EMRE ORUÇ[1], **MEHMET KORKMAZ**[1], **RUKİYE ÖZÇELİK ERDEM**[1], **GANİME DİLEK EMLİK**[2], **HAMDİ ARBAĞ**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, Faculty of Medicine, Necmettin Erbakan University, Konya, Türkiye;* [2]*Department of Radiology, Faculty of Medicine, Necmettin Erbakan University, Konya, Türkiye*

BACKGROUND & AIM

Tapia syndrome is a rare peripheral cranial neuropathy resulting from the simultaneous involvement of the hypoglossal nerve and the recurrent laryngeal branch of the vagus nerve. Clinically, it presents with ipsilateral tongue deviation, hoarseness, dysphagia, and sometimes dysarthria. It is most commonly thought to develop as a result of compression or traction neuropathy associated with endotracheal intubation, airway manipulation, and intraoperative head-neck positioning.

MATERIAL & METHODS

A 47-year-old female patient was referred to the otorhinolaryngology clinic with complaints of hoarseness, dysphagia, dysarthria, and impaired tongue movements that developed within the first 24 hours after shoulder arthrotomy performed under general anesthesia with endotracheal intubation. Clinical history and perioperative records were reviewed. Comprehensive otorhinolaryngological examination, including flexible fiberoptic laryngoscopy, was performed. Neurological evaluation and cranial nerve examination were undertaken. Magnetic resonance imaging (MRI) of the brain and neck was obtained to exclude central neurological causes, skull base pathology, vascular lesions, and structural abnormalities. Based on the clinical findings and exclusion of alternative etiologies, the patient was diagnosed with probable peripheral Tapia syndrome associated with endotracheal intubation.

RESULTS

Flexible fiberoptic laryngoscopy revealed left vocal cord paralysis, while tongue examination demonstrated deviation consistent with left hypoglossal nerve palsy. Brain and neck MRI showed no intracranial, vascular, or structural pathology. Based on the clinical findings and exclusion of alternative causes, the patient was diagnosed with probable peripheral Tapia syndrome. Following corticosteroid therapy and speech-swallow rehabilitation, improvement in hoarseness, swallowing function, and tongue mobility was observed during follow-up.

CONCLUSIONS

This case highlights that Tapia syndrome may occur following shoulder surgery and difficult endotracheal intubation despite the absence of direct surgical injury to the affected nerves. Awareness of this rare complication is essential for prompt diagnosis, avoidance of unnecessary investigations, and initiation of early rehabilitation strategies.

MULTIFOCAL UPPER AERODIGESTIVE TRACT INVOLVEMENT IN LIPOID PROTEINOSIS: AN UNCOMMON ENT PRESENTATION

Beatriz de Sá Nicolau[1], **Beatriz Rodrigues**[2], **Luís Oliveira**[3], **Lígia Ferreira**[3], **Pedro Montalvão**[3]

[1]*Unidade Local de Saúde de São José;* [2]*Unidade Local de Saúde de Lisboa Ocidental;* [3]*Instituto Português de Oncologia de Lisboa Francisco Gentil*

BACKGROUND & AIM

Lipoid proteinosis (Urbach–Wiethe disease) is a rare autosomal recessive genodermatosis caused by mutations in the ECM1 gene, leading to deposition of PAS-positive hyaline material in the skin, mucosae, and internal organs. It is considered an extremely rare condition, with an estimated prevalence of less than 1 per 1,000,000 individuals and only 300–400 cases reported worldwide. Otorhinolaryngological involvement is a hallmark of the disease and often represents its earliest manifestation, typically presenting as persistent hoarseness due to laryngeal infiltration. Despite this, the condition remains under-recognized in clinical practice.

MATERIAL & METHODS

We report the case of a 70-year-old female with a known diagnosis of lipoid proteinosis, referred for progressive dysphonia and with a long-standing history of mucocutaneous lesions. The patient had undergone previous biopsies of oropharyngeal and laryngeal lesions, including an operative endoscopic procedure for laryngeal sampling. A comprehensive otolaryngological evaluation was performed, including flexible nasolaryngoscopy and retrospective review of histopathological specimens obtained from different anatomical sites.

RESULTS

Endoscopic evaluation revealed diffuse nodular and infiltrative lesions involving multiple regions of the upper aerodigestive tract, including the nasal vestibule, oropharynx, and larynx, particularly the epiglottis and vestibular folds. Histopathological analysis consistently demonstrated deposition of amorphous hyaline material within the chorion, without epithelial atypia or viral cytopathic changes, in keeping with lipoid proteinosis. Review of clinical history confirmed a previously established diagnosis. The extent of ENT involvement highlights the potential for under-recognition of this condition in routine practice.

CONCLUSIONS

Lipoid proteinosis may present with extensive involvement of the upper aerodigestive tract, with significant impact on phonation and mucosal function. Awareness of its characteristic otorhinolaryngological manifestations, together with correlation with systemic features and histopathological confirmation, is essential to ensure accurate diagnosis and appropriate management. This case underscores the importance of recognizing rare infiltrative disorders in patients with atypical laryngeal findings.

Who Stole The Voice? Laryngeal Clues To Visceral Leishmaniasis In An Immunocompetent Host

Rocío Carpintero Díaz[1], **Marta Santiago Horcajada**[1], **Pilar Benavent Marín**[1], **Fernando González Galán**[1], **José Miguel Villacampa Aubá**[1]

[1]*Fundación Jiménez Díaz University Hospital*

BACKGROUND & AIM

Leishmaniasis is a zoonotic disease endemic to the Mediterranean basin, with well-defined clinical forms. Mucocutaneous leishmaniasis predominantly affects the mucosa of the upper aerodigestive tract, whereas visceral leishmaniasis (VL) is classically associated with systemic involvement (cytopenias, constitutional symptoms, and organomegaly) and immunosuppression, particularly human immunodeficiency virus (HIV) infection. However, in this region, atypical

presentations of VL with involvement of upper airway mucosa, including the larynx, have been described in both immunocompromised and immunocompetent patients. We hypothesize that persistent dysphonia may represent an initial manifestation of VL in this setting.

MATERIAL & METHODS

An 84-year-old male, HIV-negative, not receiving immunosuppressive therapy, with a history of atrial fibrillation, heart failure, and severe tricuspid regurgitation, presented with progressive dysphonia of more than two years' duration. Additional findings included generalized pruritic papular skin lesions, constitutional symptoms (asthenia and 5 kg weight loss), mild pancytopenia, hypoalbuminemia, and hypergammaglobulinemia. Laryngoscopic examination revealed nodular, friable lesions involving the right arytenoid and bilateral ventricular folds. Laryngeal biopsies were performed, along with serological testing for Leishmania infantum (IgG and IgM) and bone marrow aspiration.

RESULTS

Dysphonia was the presenting symptom that prompted otolaryngological evaluation. Histopathological analysis showed granulomatous inflammation with numerous macrophages containing intracellular amastigotes, confirmed by Giemsa staining and CD1a immunohistochemistry. Serology for Leishmania infantum was positive (index 3.98; positive >1.1). Bone marrow aspiration was negative for amastigotes. Laboratory findings included anemia (hemoglobin 10.8 g/dL), thrombocytopenia ($113\times10^3/\mu L$), and leukopenia ($4.52\times10^3/\mu L$). Intravenous amphotericin B was initiated, followed by outpatient continuation. The patient subsequently deteriorated and died during readmission due to gastrointestinal bleeding in the context of systemic complications.

CONCLUSIONS

Laryngeal involvement in leishmaniasis is uncommon but may represent the initial manifestation of systemic disease, even in immunocompetent patients. The identification of amastigotes in laryngeal biopsy, together with compatible clinical and laboratory findings, supports the diagnosis of VL despite negative bone marrow results. This case raises the question of whether laryngeal involvement represents a primary mucocutaneous form with subsequent visceral dissemination or a localized manifestation of established visceral disease. It also highlights the key role of the otolaryngologist in identifying systemic diseases presenting with atypical head and neck manifestations.

Self-Inflicted Penetrating Neck Injury With Thyrohyoid Membrane Disruption And Laryngeal Framework Injury: A Case Report

Damla Saygin Gurbuz[1], **Ata Alperen Ersahan**[1], **Murat Ozturk**[1]

[1]*Kocaeli University Hospital, Department of Otolaryngology–Head and Neck Surgery*

BACKGROUND & AIM

Self-inflicted penetrating neck injuries are uncommon but potentially fatal, especially with airway compromise and laryngeal framework injury. Early airway stabilization, surgical exploration, and reconstruction are essential to preserve airway, swallowing, and voice function. This case report presents the emergency management and functional outcome of a self-inflicted anterior neck injury.

MATERIAL & METHODS

A 55-year-old man with major depression was referred intubated after a self-inflicted penetrating neck injury and an associated left wrist incision. He was hemodynamically stable on admission. Examination revealed an anterior cervical wound measuring approximately 4 × 10 cm, extending from the midline to the left side. Emergency neck exploration, tracheotomy, and laryngeal reconstruction were performed under general anesthesia. Intraoperatively, the superior portion of the left lamina of the thyroid cartilage was fragmented, the left thyrohyoid membrane was disrupted, and the infrahyoid muscles were severely disrupted. No obvious great vessel injury was observed. Tracheotomy was performed between the second and third tracheal rings. The fragmented cartilage was unsuitable for reconstruction and was excised. Thyrohyoidopexy was performed by suturing the thyroid cartilage to the hyoid bone for laryngeal stabilization. The injured infrahyoid muscles were anatomically repaired, a nasogastric tube was placed, and the patient was transferred to intensive care.

RESULTS

Postoperatively, bilateral vocal cords were mobile, but the supraglottic laryngeal structures were edematous. Flexible endoscopic evaluation of swallowing (FEES) showed bilateral pyriform sinus pooling with solid, semisolid, and liquid consistencies, with aspiration of liquids, possibly related to left superior laryngeal nerve injury. Oral intake was temporarily restricted, nasogastric feeding was continued, and oral motor exercises were initiated. No major bleeding, wound infection, or early airway obstruction occurred. At 2 months, complete swallowing recovery was observed, and the patient was successfully decannulated. Psychiatric and multidisciplinary follow-up were arranged.

CONCLUSIONS

Self-inflicted penetrating neck injuries involving the laryngeal framework require rapid airway stabilization, early surgical exploration, and careful reconstruction. Although airway control and structural repair can be achieved successfully, postoperative functional assessment remains essential because vocal cord dysfunction, swallowing impairment, and aspiration may occur. Psychiatric evaluation is critical to reduce recurrent self-harm risk.

PP-317

Long-Term Outcomes Of Laryngoplasty For Voice Improvement

Kazuya Kurakami[1], **Naoto Araki**[1], **Kuniaki Chida**[1], **Tsukasa Ito**[1]

[1]*Department of Otolaryngology, Head and Neck Surgery, Yamagata University Faculty of Medicine*

BACKGROUND & AIM

Unilateral vocal fold paralysis is a frequently encountered disorder of the larynx and has a wide variety of underlying causes including aortic aneurysm, lung and esophageal cancer, and neurological disease. This paralysis can also be caused by complications after surgery such as of the thyroid, aorta and mediastinum. Although spontaneous resolution of the paralysis is seen in some cases, most patients will have permanent paralysis. This paralysis can result in a hoarseness leading to a significant decline in quality of life.

MATERIAL & METHODS

We subsequently tracked the 30 patients who underwent laryngoplasty from October 2016 to October 2023, and all patients underwent arytenoid adduction and thyroplasty type 1 under local anesthesia. 23 patients were followed up for more than 2 years after surgery and included in this study.

RESULTS

Paralysis was more common on the left side at 17 cases with 6 cases on the right side. One patient underwent a second thyroplasty type 1 for further improvement of the voice at 2 years after the first surgery. Although some patients did not see improvement in the maximum phonation time, all 23 patients showed improvement in the Voice Handicap Index after surgery.

CONCLUSIONS

Laryngoplasty has yielded favorable results even two years after surgery and is considered a useful treatment option.

KEYWORDS

Laryngoplasty, long-term outcomes, maximum phonation time, Voice Handicap Index

PP-318

Resilience And Psychosocial Adjustment To Illness In Total Laryngectomized Patients: A Pilot Study

Violeta Tadic[1], **Miljan Folic**[2]

[1]*Institute of Criminological and Sociological Research, Belgrade, Serbia;* [2]*Faculty of Medicine, University of Belgrade, Serbia*

BACKGROUND & AIM

Total laryngectomy entails profound and persistent changes in communication, identity, and social functioning, placing individuals at increased risk for psychosocial maladjustment. Given the severe communication impairment following total laryngectomy, understanding psychosocial adaptation is essential for comprehensive otorhinolaryngological care. Resilience has been proposed as a key protective factor in chronic illness; however, its relationship with domain-specific psychosocial adjustment among total laryngectomized individuals remains insufficiently explored.

MATERIAL & METHODS

This pilot, exploratory correlational study included 15 total laryngectomized outpatients (aged 56–71) who completed online self-report measures of psychosocial adjustment to illness (PAIS-SR) and resilience (Resilience Scale). Data were analyzed using non-parametric methods, including descriptive statistics, Spearman's rank-order correlation, and Mann–Whitney U tests.

RESULTS

Participants demonstrated a moderate level of overall psychosocial adjustment to illness (M = 3.24) and a high level of resilience (M = 4.28). Resilience showed significant positive associations with several domains of psychosocial adjustment, including health care orientation, illness-related behavior, physician-provided information, and vocational and domestic functioning, as well as a negative association with extended family relationships. Participants with higher psychosocial adjustment exhibited significantly higher resilience levels (Mdn = 4.50, IQR = .15, mean rank = 11.38).

CONCLUSIONS

Findings provide clinically meaningful preliminary evidence that resilience supports psychosocial adjustment in total laryngectomized patients, with direct implications for rehabilitation practice. The small sample size and cross-sectional design

limit generalizability and preclude causal inference. These findings highlight the need for longitudinal studies to clarify underlying mechanisms and optimize multidisciplinary psychosocial and rehabilitative care.

PP-319

Early Surgical Conversion In Post-Intubation Subglottic Stenosis: A Systematic Review Of Treatment Outcomes And Institutional Case Series

Ahmed AlAlban[1], **Fatima Atieh**[1], **Danah AlRusayis**[2,3], **Hassan AlAnsari**[1,2]

[1]*School of Medicine, Royal College of Surgeons in Ireland, Bahrain;* [2]*Royal Medical Services, Bahrain;* [3]*Ministry of Health, Saudi Arabia*

BACKGROUND & AIM

Post-intubation subglottic stenosis (SGS) and laryngotracheal stenosis (LTS) are major causes of airway morbidity following prolonged mechanical ventilation. Endoscopic balloon dilatation is commonly used as first-line management; however, recurrence remains frequent, and the optimal treatment sequence remains unclear. We hypothesized that although endoscopic management may provide temporary symptomatic relief, open surgical reconstruction offers superior long-term airway patency in recurrent or high-grade stenosis. We additionally explored the potential impact of comorbidities such as diabetes mellitus (DM) on treatment outcomes and present two institutional cases requiring cricotracheal resection (CTR) following failure of repeated endoscopic management.

MATERIAL & METHODS

A systematic review was conducted in accordance with PRISMA guidelines. Electronic databases were searched for studies involving adult patients (≥18 years) with iatrogenic post-intubation SGS/LTS undergoing endoscopic interventions (e.g., balloon dilatation, laser resection, intralesional steroid therapy, or stenting) or open surgical procedures (e.g., CTR or laryngotracheal reconstruction). Studies including cohorts of ≥10 patients reporting treatment outcomes were included. Extracted outcomes included airway patency, symptom resolution, recurrence, repeat procedures, complications, tracheostomy requirement, and decannulation success. Outcomes were synthesized qualitatively across treatment modalities. Additionally, two institutional cases of post-intubation SGS in patients with type 1 DM were retrospectively reviewed.

RESULTS

Endoscopic balloon dilatation demonstrated initial symptomatic improvement in most patients, with reported success rates of approximately 70–80%; however, recurrence rates remained high, often necessitating repeated interventions. Open surgical reconstruction consistently achieved superior long-term airway patency and decannulation success, frequently exceeding 85–90% in large series. Repeated endoscopic procedures were associated with increased cumulative morbidity and eventual need for definitive surgery. DM and other comorbidities were variably associated with increased recurrence and complications. Our institutional cases involved two young female patients with type 1 DM who developed SGS following prolonged traumatic intubation. Both underwent multiple balloon dilatations with recurrent stenosis before ultimately requiring CTR, which achieved definitive airway stabilization.

CONCLUSIONS

Balloon dilatation remains an effective first-line treatment for post-intubation SGS/LTS but is limited by high recurrence rates. Open surgical reconstruction provides more durable outcomes, particularly in recurrent or high-grade stenosis. Early identification of patients likely to fail endoscopic management may optimize treatment pathways and reduce cumulative morbidity.

Percutaneous Epiglottopexy For Epiglottic Retroversion: A Technical Note

Walid Bijou[1,2], **Sarah Hafidi**[1], **Hassane Chacha**[1], **Youssef Oukessou**[1,2], **Sami Rouadi**[1,2], **Reda Allah Abada**[1,2], **Mohamed Roubal**[1,2], **Mohamed Mahtar**[1,2]

[1]*Ibn Rochd hospital university;* [2]*Hassan II university*

BACKGROUND & AIM

Epiglottic retroversion is an extremely rare cause of upper airway obstruction in adults and may present with persistent stridor. Management is not standardized, and described surgical approaches may include laser epiglottectomy, which carries the risk of loss of protective laryngeal function.

A technical note of an organ-preserving technique

MATERIAL & METHODS

We report the case of an adult patient with epiglottic retroversion causing significant stridor. Flexible nasolaryngoscopy confirmed a persistently everted epiglottis causing upper airway obstruction.

A percutaneous epiglottopexy was performed as an organ-preserving technique aimed at stabilizing the epiglottis in an anterior position while maintaining its anatomical integrity and protective function.

RESULTS

The procedure led to immediate resolution of stridor with no perioperative complications. Follow-up endoscopy demonstrated stable fixation of the epiglottis with preserved laryngeal anatomy and airway protection.

CONCLUSIONS

Percutaneous epiglottopexy represents an effective organ-preserving alternative for the management of symptomatic persistent epiglottic eversion in adults, avoiding destructive procedures while restoring airway patency.

A RARE CASE: ENDOTRACHEAL CUFF RUPTURE DURING LOCAL ANESTHESIA

Koray İşlek[1], **Burak Kersin**[1], **Volkan Öztemel**[1], **Elif Çevik**[1], **Tunahan Kuş**[1]

[1]*Kartal Dr. Lütfi Kırdar City Hospital*

BACKGROUND & AIM

Tracheotomy is a surgical intervention performed to establish an airway by creating an opening in the anterior trachea and may be performed using open or percutaneous techniques. Despite well-defined indications, various intraoperative and postoperative complications may occur, including bleeding, airway fire, tube misplacement, pneumothorax, posterior tracheal perforation, subcutaneous emphysema, and recurrent laryngeal nerve injury. Endotracheal tube (ETT) cuff defects are recognized causes of air leakage and ventilation failure, typically resulting from trauma to the cuff structure. However, cuff damage during local infiltration anesthesia before tracheotomy has not been clearly described. This report presents an intraoperative complication involving ETT cuff injury.

MATERIAL & METHODS

An 81-year-old patient presented with swallowing and breathing difficulties. Endoscopic examination demonstrated a mass extending from the left arytenoid region with severe airway narrowing, with a rima opening of approximately 2 mm. Emergency microlaryngeal surgery and tracheotomy were planned. The patient was intubated with a 6.5 endotracheal tube, and tracheotomy was initiated after identification of the second and third cricoid rings by palpation. Local infiltration anesthesia was administered using 4 cc jetocaine solution with a 16-gauge needle prior to the procedure. Intraoperative monitoring included evaluation of oxygen saturation and ventilation parameters.

RESULTS

During local infiltration anesthesia, a sudden decrease in oxygen saturation and gas leak warnings were observed. Examination revealed deflation of the ETT cuff, and reinflation attempts were unsuccessful. The endotracheal tube was replaced, after which ventilation was restored and the surgery was completed successfully. The cuff damage was suspected to be caused by the local infiltration needle. Difficult intubation due to airway narrowing, thin neck skin, and suspected locally advanced malignancy were considered contributing factors.

CONCLUSIONS

This case demonstrates that ETT cuff damage may occur during local infiltration anesthesia in tracheotomy procedures. Sudden intraoperative desaturation and gas leakage should raise suspicion for cuff injury, particularly in patients with thin neck tissues or altered soft tissue integrity. Awareness of this potential complication may help improve intraoperative management and patient safety.

PP-322

Multisystem Urbach–Wiethe Syndrome Presenting With Chronic Dysphonia And Unilateral Sensorineural Hearing Loss: Case Report

Lukas Demirci[1], **Ahmet Fırat Aksoy**[1], **Abdullah Karataş**[1]

[1]*Department of Otolaryngology–Head and Neck Surgery, Haseki Training and Research Hospital, Istanbul, Türkiye*

BACKGROUND & AIM

Urbach–Wiethe syndrome (lipoid proteinosis) is a rare autosomal recessive disorder characterized by progressive hyaline deposition in cutaneous and mucosal tissues. ENT manifestations frequently include dysphonia and upper airway involvement, while auditory dysfunction and neurobehavioral changes are less commonly highlighted. We hypothesized that the clinical combination of chronic dysphonia, unilateral sensorineural hearing loss, tongue mobility restriction, and recurrent airway infections in this patient represents advanced multisystem mucosal involvement, further complicated by psychiatric features suggestive of altered emotional processing.

MATERIAL & METHODS

A 53-year-old patient underwent comprehensive clinical evaluation including detailed dermatologic assessment, flexible fiberoptic laryngoscopy, audiologic testing, psychiatric examination, and histopathologic confirmation through an oropharyngeal biopsy. Medical history was reviewed with focus on previous tongue-tie surgeries, recurrent infectious episodes, vocal symptoms, and functional oral limitations. Outcome measures included structural mucosal involvement, auditory function, airway integrity, and psychiatric findings. Independent variables included anatomic distribution of mucosal hyaline deposition and previous oral interventions.

RESULTS

Laryngoscopic examination revealed diffuse laryngeal mucosal thickening, consistent with lipoid proteinosis and correlating with the patient's long-standing chronic hoarseness. She experienced multiple severe upper respiratory tract infections annually, reflecting impaired mucosal defense and airway vulnerability. Audiologic evaluation demonstrated unilateral sensorineural hearing loss. Oral examination confirmed marked tongue mobility restriction, aligned with her history of multiple frenotomy procedures. Dermatologic evaluation identified widespread cutaneous involvement typical of lipoid proteinosis. Psychiatric assessment revealed blunted fear responses and reduced emotional reactivity, features occasionally associated with neurobehavioral involvement in this condition. Histopathologic examination of the oropharyngeal mucosa showed classic hyaline deposition, establishing the diagnosis.

Both favorable (diagnostic confirmation, phenotype consistency) and unfavorable (persistent functional impairment) findings were observed.

CONCLUSIONS

This case highlights the striking multisystem variability of Urbach–Wiethe syndrome and underscores the importance of recognizing ENT-related manifestations such as chronic dysphonia, sensorineural hearing loss, recurrent infections, and oropharyngeal fibrosis. Psychiatric findings further emphasize the need for multidisciplinary evaluation to optimize diagnosis and long-term management.

PP-323

Pirfenidone Injection To Prevent Vocal Fold Scarring In A Canine Model: A Pilot Preclinical Study

Jeong-Yeon Ji[1], **Yeon Bi Han**[1], **Seo Young Kim**[1], **Seung Heon Kang**[1], **Seung Hoon Han**[1], **Woo-Jin Jeong**[1], **Tack-Kyun Kwon**[2], **Wonjae Cha**[1]

[1]Seoul National University Bundang Hospital, Seoul National University College of Medicine; [2]Boramae Medical Center, Seoul National University College of Medicine

BACKGROUND & AIM

This pilot study investigated the safety and efficacy of pirfenidone (PFD) injection for vocal fold (VF) scarring after laser cordectomy in a canine model. We evaluated safe PFD concentrations and their preventive effects on postoperative VF scarring using laryngoscopic, histological, immunohistochemical (IHC), and high-speed imaging analyses.

MATERIAL & METHODS

To assess toxicity, 0.3mL of saline or PFD solution at six serial concentrations (0, 0.5, 1.0, 2.5, 5.0, and 10.0 mg/mL; 0 mg/mL = saline) was injected into the VFs of three dogs and histological evaluation was performed 2 weeks later. For efficacy testing, saline, 1.0 mg/mL PFD, or 2.5 mg/mL PFD was injected into the right VFs of three dogs before type III laser cordectomy. The left VFs remained untreated. Wound status was assessed by laryngoscopy at 4 and 8 weeks. At 8 weeks, vibratory function was assessed using high-speed imaging, followed by histological and IHC analyses for collagen type I (COL1) and α-smooth muscle actin (α-SMA).

RESULTS

In the toxicity test, VFs injected with ≤2.5 mg/mL PFD showed complete epithelial healing, whereas those injected with ≥5.0 mg/mL PFD showed epithelial detachment from the lamina propria. In the efficacy test, high-speed imaging demonstrated greater vibratory amplitudes in PFD-injected VFs than in the control VFs, with more pronounced improvement at 2.5 mg/mL PFD. Hematoxylin and eosin (H&E), Masson's trichrome, and Alcian blue staining showed that 2.5 mg/mL PFD-injected VFs exhibited reduced fibrotic changes and collagen deposition compared with saline- and 1.0 mg/mL PFD-injected VFs. IHC analysis showed attenuated α-SMA and COL1 immunoreactivity in PFD-treated VFs, particularly in the 2.5 mg/mL PFD-injected VF.

CONCLUSIONS

This pilot study suggests that PFD injection before laser cordectomy may mitigate VF scarring and help preserve VF vibratory function in a canine model. These findings provide preliminary evidence supporting the potential of PFD as a preventive strategy against fibrosis during VF surgery.

Spontaneous Idiopathic Cervical Hematoma Presenting With Acute Neck Swelling And Airway Concern: A Case Report

Dovilė Šiaulytė MD[1]

[1]*Klaipėda University Hospital*

BACKGROUND & AIM

Spontaneous cervical hematoma is a rare but potentially life-threatening condition due to the risk of acute airway compromise. Most reported cases are associated with trauma, anticoagulation, vascular malformations, or underlying endocrine pathology, while idiopathic presentations remain uncommon and diagnostically challenging. We present a case of spontaneous idiopathic cervical hematoma in a 72-year-old male, emphasizing the diagnostic evaluation and management approach. This case highlights that timely assessment and appropriate imaging may support safe conservative management in carefully selected, clinically stable patients.

MATERIAL & METHODS

A 72-year-old male presented to the emergency department with sudden onset right-sided neck swelling and mild dysphagia without trauma, infection, or anticoagulant use. Initial assessment revealed hemodynamic stability and no respiratory distress; however, airway protection was performed due to concern for potential airway compromise. Flexible nasolaryngoscopy was performed and demonstrated mild pharyngeal wall bulging without significant airway obstruction.

Contrast-enhanced computed tomography (CT) of the neck was obtained, followed by laboratory investigations including a complete coagulation profile, all of which were within normal limits.

The patient was managed conservatively with close airway monitoring, corticosteroid therapy, and supportive care. Following clinical stabilization, the patient was extubated. Serial clinical evaluations were performed, and repeat CT angiography (CTA) was conducted to monitor progression and exclude an underlying vascular source.

RESULTS

Initial CT imaging demonstrated a cervical soft tissue hematoma without active contrast extravasation or identifiable vascular source.

Follow-up CTA confirmed a stable right-sided cervical hematoma with no change in size or extent compared with initial imaging. The hematoma extended along the fascial planes between the scalene muscles and the sternocleidomastoid and trapezius muscles.

No evidence of active arterial or venous contrast extravasation was identified, and no vascular abnormality was detected within the carotid or jugular systems. There was no mass effect, airway compromise, or progression of compressive pathology.

Clinically, the imaging findings correlated with a stable course and gradual symptomatic improvement.

CONCLUSIONS

Spontaneous idiopathic cervical hematoma should be considered in elderly patients presenting with acute neck swelling even in the absence of identifiable risk factors. Prompt CT and CTA are essential for diagnosis and exclusion of active bleeding. In clinically stable patients without radiological evidence of ongoing hemorrhage, conservative management with close monitoring may lead to favorable outcomes and avoid unnecessary surgical intervention.

Pediatric Laryngeal Sarcoidosis With Recurrent Airway Obstruction And Long-Term Immunosuppressive Management

Artemis Camelia Florescu[1,2], **Crina Ciobanu**[1,2], **Carmen Ioana Paraschiv-Ferariu**[1,2], **Iulia Andreea Ciobanu**[3], **Dan Cristian Gheorghe**[1,2]

[1]*Emergency Clinical Hospital for Children "Maria Sklodowska Curie", Bucharest, Romania;* [2]*University of Medicine Carol Davila, Bucharest, Romania;* [3]*Central Military Emergency University Hospital "Dr. Carol Davila"*

BACKGROUND & AIM

Sarcoidosis is chronic granulomatous disease characterized by multisystem involvement and variable clinical presentation. Laryngeal involvement uncommon and exceptional rare in pediatric patients and may present with airway obstruction. Due to Its nonspecific presentation, diagnosis may be delayed or initially misinterpreted. We report a pediatric case of laryngeal sarcoidosis with recurrent airway compromise and and long-term treatment challenges.

MATERIAL & METHODS

We report a longitudinal case of a male patient diagnosed with laryngeal sarcoidosis managed in a tertiary otorhinolaryngology and pediatric referral center. The patient presented initially presented with inspiratory dyspnea and supraglottic edema with left aryepiglotic fold lesion. Initial histopathology revealed an inflammatory polyp, however subsequent biopsy demonstrated non-caseating granulomatous inflammation consistent with sarcoid-like lesion, supporting the diagnosis of laryngeal sarcoidosis.

Systemic corticosteriod therapy (methylprednisolone) was initiated, resulting in partial clinical response. Treatment was complicated by iatrogenic Cushing syndrome with suppresion of adenocorticotropic hormone and cortisol, requiring dose reduction. Due to persistent disease activity, methotrexate was introduced as second-line immunosuppressive therapy. Tuberculosis screening performed in 2022 was negative.

RESULTS

Corticosteroid therapy provided incomplete disease control and was associated with significant endocrine toxicity. Introduction of methotrexate resulted in clinical and endoscopic improvement after approximately one year, with resolution of airway symptoms and reduction of supraglottic inflammatory lesions.

Relapse occurred following unplanned discontinuation of methotrexate, presenting with severe supraglottic edema and marked airway narrowing. Re-initiation of methotrexate was subsequently recommended.

At last follow up, fibroscopy demonstrated a globular epiglottis with residual supraglottic edema, while the glottic and subglottic airway remained widely patent.

CONCLUSIONS

Pediatric laryngeal sarcoidosis is a rare cause of recurrent upper airway obstruction requiring histopathological confirmation and exclusion of infectious disease. Long-term management may be complicated by recurrent disease activity and adverse effects related to prolonged corticosteroid therapy. Prolonged multidisciplinary follow-up and steroid-sparing immunosuppressive therapy may be necessary to maintain airway patency and achieve sustained clinical improvement.

PP-326

A RARE COMPLICATION FOLLOWING DIRECT LARYNGOSCOPY: HYPOGLOSSAL NERVE PALSY

Birhan Alaçeri[1], **Ömer Faruk Koçer**[1], **Halil Erdem Özel**[1]

[1]*Kocaeli City Hospital*

BACKGROUND & AIM

Hypoglossal nerve palsy is an uncommon complication following direct laryngoscopy. This case report aims to evaluate the clinical course and management of this rare condition.

MATERIAL & METHODS

A 34-year-old male presented with persistent hoarseness for two months following a shouting episode. Laryngoscopic examination revealed a hemorrhagic polypoid lesion involving the anterior one-third of the right vocal cord. The patient underwent microlaryngoscopic excision under direct laryngoscopy using a medium-sized blade. The lesion was excised with a 445 nm laser, and the procedure lasted approximately 30 minutes.

Postoperatively, the patient developed left-sided facial numbness and impaired tongue movement toward the left. Physical examination demonstrated normal tongue mobility on the right side, with marked restriction on the left. Oral methylprednisolone was initiated at 1 mg/kg/day and tapered by 10 mg every three days over a two-week period.

RESULTS

At postoperative week 1, near-complete limitation of leftward tongue movement and ipsilateral tongue atrophy were observed, accompanied by dysphagia and speech difficulties. By week 2, minimal improvement in tongue mobility was noted, although atrophy persisted. At week 3, tongue movement had almost completely recovered, and atrophy had significantly regressed. The patient reported full resolution of swallowing and speech difficulties.

No residual deficits or complications were observed during follow-up. Vocal cord healing was unremarkable, and no limitation in mobility was detected.

CONCLUSIONS

Hypoglossal nerve palsy is a rare but clinically significant complication of direct laryngoscopy that may substantially impact quality of life. Early recognition, appropriate patient counseling, and timely medical management with close follow-up are essential for optimal recovery. It would be appropriate to inform patients about this complication preoperatively.

PP-327

The Level Of Damage To The Laryngeal Muscles In Patients With Myasthenia Gravis.

Akif Efendiyev[1]

[1]*Azerbaijan State Institute of Advanced Training of Doctors*

BACKGROUND & AIM

Myasthenia gravis is an autoimmune disease mediated by antibodies against acetylcholine receptors at the neuromuscular junction. The disease can affect the muscles responsible for breathing, leading to serious complications. The aim of this study is to investigate the importance of laryngeal electromyography in determining the nature and extent of laryngeal muscle damage in patients with myasthenia gravis.

MATERIAL & METHODS

40 patients with Myasthenia Gravis were examined. Patients underwent otorhinolaryngology, neurology, computed tomography, and magnetic resonance imaging examinations, along with laryngeal electromyography. Laryngeal electromyography was performed using an ethidium chloride test to determine the structure of the lesion. Patients were divided into two groups according to the severity of the disease: Group 1 consisted of 18 patients (local form), and Group 2 consisted of 22 patients (general form).

RESULTS

The results were evaluated according to the shape, duration, and amplitude of the action potentials of the motor units. The expressive and quantitative characteristics of the pathological spontaneous activity of muscle fibers were considered: fibrillation potentials and fasciculations, positive sharp waves.

CONCLUSIONS

1. Electromyographic examination of the internal laryngeal muscles and a test with edrophonium chloride is the most objective method for the early differential diagnosis of laryngeal lesions in patients with myasthenia gravis. 2. In both localized and generalized forms of myasthenia gravis, a decrease in the duration and amplitude of the motor unit action potential in the internal laryngeal muscles is determined. That is, a latent generalization of the myasthenic lesion is detected.

KEYWORDS

Myasthenia gravis, laryngeal muscles, laryngeal electromyography

PP-328

Post-Thyroidectomy Gerhardt's Syndrome: Diagnostic And Therapeutic Challenges

Gagauz Alexei[1], **Andrian Vița**[2]

[1]*"Nicolae Testemițanu" State University of Medicine and Pharmacy;* [2]*Republican Clinical Hospital "Timofei Moșneaga"*

BACKGROUND & AIM

Gerhardt's syndrome represents bilateral abductor vocal cord paralysis due to recurrent laryngeal nerve dysfunction. The condition is extremely rare (1 per 1 million population), yet life-threatening1. Timely diagnosis and appropriate management are essential for the patient's survival and quality of life.

MATERIAL & METHODS

A retrospective analysis was conducted on data from two female patients diagnosed with Gerhardt's syndrome secondary to total thyroidectomy, both of whom required tracheostomy for acute respiratory failure. Both cases were managed in 2023 at the ENT Clinic of the "Timofei Moșneaga" Republican Clinical Hospital.

RESULTS

The first case involved a patient who underwent emergency tracheostomy six months postoperatively. Subsequent medical treatment (group B vitamins and ipidacrine) proved effective, resulting in the unilateral recovery of right vocal cord mobility and eventual decannulation. The second case concerned a patient who received tracheostomy three months after thyroidectomy, with no improvement following nine additional months of conservative management. She underwent a glottic widening surgery — CO2 laser-assisted posterior cordectomy of the left vocal cord, with favorable evolution. The patient was also successfully decannulated.

CONCLUSIONS

Although 4–14% of patients can tolerate Gerhardt's syndrome without requiring surgery, viral infections or other stressors can trigger respiratory decompensation2,3. In cases where the recurrent laryngeal nerves remain anatomically intact, spontaneous recovery may occur within 9–12 months in up to 86% of patients2,4. ENT surgeons are responsible for timely identification of surgical candidates and performing high-quality glottic widening procedures when conservative treatment fails.

KEYWORDS

Gerhardt's syndrome, tracheostomy, cordectomy, CO2 laser.

3D Printed Larynx Model For Anatomical Education And Surgical Planning

Fotoon Aldhanhani[1], **Anastasios G. Hantzakos, MD, PhD, MHA, FEBORL**[1], **Osama Abdullah, PhD**[2], **Parima Phowarasoontorn**[2], **Khalil Ramadi, Ph.D.**[2]

[1]*Department of Otolaryngology – Head and Neck Surgery, Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates;* [2]*Lab for Advanced Neuroengineering and Translational Medicine (LANTRN) New York University Abu Dhabi*

BACKGROUND & AIM

Understanding the anatomy of the larynx in details is crucial in otolaryngology clinical and surgical aspects. Traditionally, otolaryngologists residents and physicians relied on cadaveric dissection, anatomy textbook illustrations, and videos. Nevertheless, each resource has limitations. Such as, limited access to cadavers, high costs of the surgical courses, and most importantly the different texture and consistency of the cadaveric larynx. Our aim was to generate an accurate 3D printed larynx model to approach these obstacles and provide a functional model for both anatomical education and surgical training.

MATERIAL & METHODS

We established a detailed 3D larynx model using Blender software. We included all the major cartilages, intrinsic muscles, ligaments, and membranes of the larynx. Each part was individually created and assigned to a specific material to replicate the natural consistency and mechanical characteristics of native tissue. Afterwards, the model w as printed out using (Stratasys J850 multi-material 3D printer), which facilitated stimulating the soft tissue differentiation and intricate anatomical details we intended to. This project originated from a collaborative effort between Cleveland Clinic Abu Dhabi and N YU Abu Dhabi.

RESULTS

The final larynx model demonstrates remarkable accurate anatomical representation and natural tissue properties. It unequivocally illustrate the three dimensional configuration between the parts of the larynx in a manner that enhances anatomical orientation and conceptual understanding. preliminary impressions from both residents and attending physicians in our department has been encouraging. The model offers a clear illustration for the paraglottic space, preglottic space and the relation to the anatomical part of the larynx. Its also facilitate the surgical training, by recognizing the major surgical landmarks and practice procedures such as (thyroplasty / laryngoplasty) in a low risk environment and having an accurate anatomical configuration.

CONCLUSIONS

This composite 3D printed larynx model exemplify a promising milestone in surgical training. It has an pivotal domain between traditional teaching methods and real life operative exposure, providing an anatomically accurate, reproducible, and readily available framework for teaching and simulation. At this stage, we are working on further studies to evaluate the implication on trainee skill development and overall educational outcomes.

BACKGROUND & AIM

Differentiating granulomatosis with polyangiitis (GPA) from cocaine-induced midline destructive lesions (CIMDL) and cocaine-associated antineutrophil cytoplasmic antibody (ANCA)-positive vasculitis remains challenging, particularly in young patients with isolated upper airway involvement. This case aims to highlight the diagnostic value of repeated urine toxicology testing in a patient with rapidly progressive centrofacial destruction mimicking classic GPA.

MATERIAL & METHODS

We present a 26-year-old woman admitted to an otolaryngology department with extensive necrotic and infectious destruction of the nose and midfacial structures following intranasal cocaine use. Clinical assessment, laboratory testing, computed tomography, microbiology, histopathology, immunological assays, and repeated urine toxicology screening were analyzed. Proteinase 3 antibodies were measured using enzyme-linked immunosorbent assay (ELISA). Levamisole detection in urine was performed using liquid chromatography–tandem mass spectrometry (LC-MS/MS).

RESULTS

On admission, the patient presented with necrosis involving the nasal ala, columella, nasal vestibule, and cartilaginous nasal septum. Laboratory tests showed leukocytosis, thrombocytosis, anemia, elevated C-reactive protein, and repeatedly positive urine toxicology for cocaine. Immunological testing revealed markedly positive anti-proteinase 3 antibodies (>200.00 MFI; reference <20.00) with negative anti-myeloperoxidase antibodies. Histopathology demonstrated fibrinoid necrosis of small vessels with necrotizing granulomatous inflammation and suppuration, supporting a diagnosis of GPA-like vasculitis. Computed tomography showed progressive destruction of the nasal septum, external nose, lateral nasal walls, and hard palate. Microbiological cultures identified Pseudomonas aeruginosa, Enterococcus faecalis, and later Streptococcus agalactiae. LC-MS/MS did not detect levamisole in the urine samples tested. Despite antibiotic therapy, corticosteroids, cyclophosphamide, and later ongoing immunosuppressive treatment, the patient developed severe irreversible centrofacial destruction, although subsequent local improvement and attenuation of inflammation were observed. Statistical testing, confidence intervals, and p-values were not applicable due to the single-case design.

CONCLUSIONS

This case demonstrates that intranasal cocaine use may induce ANCA-positive vasculitis clinically, serologically, radiologically, and histopathologically resembling GPA. In young patients with destructive upper airway disease and positive ANCA, repeated urine toxicology screening should be considered an essential diagnostic step. Cocaine abstinence is crucial for therapeutic success and prevention of further tissue destruction.

Fifteen-Year Outcomes Of Tracheoesophageal Voice Prosthesis After Total Laryngectomy: Complications And Functional Results

MD, Merve Arslan Yiğit[1], **Assos. Prof. MD Şeyda Akbal Çufalı**[1], **Specialist MD, Muhammet Mehdi Güneş**[1], **Assos. Prof. MD Nurcan Yurtsever Kum**[1]

[1]*Ankara Bilkent City Hospital*

BACKGROUND & AIM

Voice rehabilitation after total laryngectomy is essential for restoring communication and quality of life. Tracheoesophageal voice prosthesis (TEP) is considered the gold standard method, providing fluent and intelligible speech.

However, long-term complications such as periprosthetic leakage, fistula enlargement, and infections may affect outcomes. Long-term (>10 years) data remain limited.

To evaluate the long-term (15-year) clinical outcomes of patients undergoing tracheoesophageal voice prosthesis after total laryngectomy, focusing on complications, comorbidities, and functional speech outcomes.

MATERIAL & METHODS

This retrospective single-center study included 18 patients who underwent TEP after total laryngectomy. Patients were followed for a mean duration of 15 years.

The following parameters were evaluated: fistula enlargement, periprosthetic leakage, candidiasis development, hospitalization history, nasogastric tube requirement, comorbidities, and the ability to speak without a prosthesis.

RESULTS

Long-term follow-up demonstrated an increase in prosthesis-related complications over time.

Periprosthetic leakage and fistula enlargement were the most common complications. Candidiasis was frequently observed and contributed to prosthesis dysfunction.

Some patients required recurrent hospitalizations, and a subset developed alternative speech strategies independent of the prosthesis.

Despite these complications, most patients maintained functional communication.

CONCLUSIONS

Tracheoesophageal voice prosthesis remains an effective method for voice rehabilitation after total laryngectomy.However, complications tend to accumulate over time and require regular monitoring and management.Long-term multidisciplinary follow-up is essential to maintain functional outcomes.

Endoscopic Balloon Dilatation Outcome In Airway Stenosis: A Single Center Experience

Roqiah Aldueb[1], **Ghadah Alissa**[2], **Alhanouf Alhedaithy**[1], **Ahmad Alammar**[1], **Abdullah Aljasser**[1]

[1]Department of Otolaryngology-Head and Neck Surgery, College of Medicine, King Saud University , Riyadh, Saudi Arabia; [2]College of Medicine, Sulaiman AlRajhi University, Al Qassim, Saudi Arabia

BACKGROUND & AIM

Laryngotracheal stenosis is a challenging airway condition that often requires repeated interventions. Endoscopic balloon dilatation (EBD) is widely used as a minimally invasive treatment, frequently combined with adjuvant therapies such as intralesional steroids and mitomycin C. However, outcomes remain variable with no clear consensus on optimal management. This study aims to evaluate our institutional experience with EBD and assess factors associated with recurrence.

MATERIAL & METHODS

A retrospective cohort study is being conducted at a tertiary care center. Potentially eligible records were identified for patients who underwent endoscopic balloon dilatation for airway stenosis. Final inclusion will be limited to patients treated between 2020 and 2026 who meet predefined eligibility criteria. Data are being collected from electronic medical records, including demographics, etiology, stenosis level and grade, number of dilatation procedures, interval between interventions, and use of adjuvant therapies such as intralesional steroids and mitomycin C. Primary outcomes include recurrence and surgical-free interval. Secondary outcomes include the association between adjuvant therapies and clinical outcomes.

RESULTS

Data collection is currently ongoing, and preliminary data extraction has been initiated. An initial institutional search identified a large number of potentially eligible cases; final cohort size will be determined after applying eligibility criteria and excluding incomplete records. Full analysis will evaluate recurrence rates, number of procedures, interval between dilatations, and the impact of adjuvant therapies.

CONCLUSIONS

This study aims to provide insight into real-world outcomes of endoscopic balloon dilatation in airway stenosis and clarify the role of adjuvant therapies. The findings may help guide clinical decision-making and contribute toward more standardized, evidence-based management of this challenging condition.

Laryngotracheal stenosis, endoscopic balloon dilatation, airway stenosis, subglottic stenosis, mitomycin C, intralesional steroids, recurrence, surgical-free interval

PP-333

A Rare Neuroendocrine Tumor Of The Larynx Mimicking A Vocal Fold Polyp

Tuğba Yemiş[1]

[1]Recep Tayyip Erdogan University, Medical Faculty, Department of Otorhinolaryngology , Rize, Turkey

BACKGROUND & AIM

Neuroendocrine tumors (NETs) are uncommon neoplasms originating from neuroendocrine cells, characterized by dual neuronal and endocrine differentiation. These tumors may be functional or non-functional and show a wide spectrum of clinical behavior, from indolent to highly aggressive. Although NETs most frequently arise in the gastrointestinal tract and bronchopulmonary system, involvement of the head and neck region is rare, with laryngeal localization particularly unusual. Due to their rarity and often non-specific presentation, laryngeal NETs may pose significant diagnostic challenges. This study presents a rare case of laryngeal NET and highlights key diagnostic and therapeutic considerations.

MATERIAL & METHODS

A 64-year-old man presented with a two-year history of persistent globus sensation and referred otalgia. On endoscopic examination, a well-defined polypoid lesion was observed on the medial aspect of the right arytenoid cartilage. The patient had no dysphonia, dyspnea, or other systemic symptoms (Fig.1). Magnetic resonance imaging (MRI) and computed tomography (CT) demonstrated a circumscribed lesion without cartilage invasion, lymphadenopathy, or distant metastasis (Fig.2). The lesion was excised via suspension microlaryngoscopy. Histopathology confirmed a neuroendocrine tumor, with immunohistochemistry positive for chromogranin and synaptophysin. Given its malignant potential, a subsequent wide local excision was performed. The patient was evaluated for possible Multiple Endocrine Neoplasia (MEN) syndrome.

RESULTS

Final histopathology showed negative margins. Postoperative recovery was uneventful. Systemic evaluation revealed no evidence of MEN syndrome or additional primary lesions. At follow-up, the patient remained asymptomatic with no clinical or radiological signs of recurrence.

CONCLUSIONS

Laryngeal NETs are rare tumors that may present subtly, such as with globus sensation and referred otalgia. Accurate diagnosis relies on histopathological and immunohistochemical assessment. Complete surgical excision with clear margins remains the cornerstone of treatment. Multidisciplinary evaluation ensures exclusion of syndromic associations and optimal outcomes.

HYPOPHARYNGEAL MASS IN A FEMALE PATIENT PRESENTING WITH DYSPHAGIA: A CASE REPORT

H.Deniz Demir Kılıç[1], **Nuri Ünsal**[1]

[1]*Kayseri City Hospital, Clinic of Otorhinolaryngology, Kayseri, Türkiye*

BACKGROUND & AIM

Hypopharyngeal carcinoma is relatively rare, representing approximately 3% of all head and neck malignancies. Hypopharyngeal carcinoma is a highly aggressive malignancy with a dismal prognosis, primarily due to its tendency for late clinical presentation. While traditionally associated with heavy alcohol and tobacco use in older males, this case highlights a critical shift in clinical presentation and etiology.Therefore, timely detection utilizing meticulous endoscopic examination and a multimodal diagnostic approach remains the cornerstone for overcoming diagnostic delays and optimizing clinical outcomes.

MATERIAL & METHODS

This case report describes a 58-year-old female patient diagnosed with hypopharyngeal squamous cell carcinoma, presenting with a primary complaint of progressive dysphagia. A retrospective medical chart review was conducted to evaluate the patient's clinical presentation, atypical occupational risk factors, diagnostic workup, and initial management protocols.

RESULTS

At the time of diagnosis, 90% of cases are classified as advanced-stage hypopharyngeal cancer. Therefore, a detailed endoscopic examination must be performed in patients presenting with chronic sore throat and dysphagia. Following a comprehensive clinical evaluation, the most critical elements in the assessment of hypopharyngeal cancer are imaging and biopsy. While the diagnosis of hypopharyngeal cancer can only be confirmed histopathologically, radiological imaging is essential for treatment planning and staging.

CONCLUSIONS

Hypopharyngeal cancer, which is predominantly squamous cell carcinoma, shares similar risk factors with other head and neck cancers, the primary ones being the long-term consumption of alcohol and tobacco products. Other etiological factors include Plummer-Vinson syndrome, asbestos exposure, gastroesophageal reflux, and HPV.While squamous cell carcinoma accounts for 95% of hypopharyngeal cancers, adenocarcinoma, sarcoma, and non-epidermoid carcinomas constitute the majority of the remaining cases. Symptoms at presentation depend on the size and location of the tumor, with pain, bleeding, and dysphagia being the most common presenting complaints.

Epidemiological Study Of Risk Factors And Treatment Outcomes Of Subglottic Stenosis After Prolonged Intubation In South East Of Iran 2016-2024

Assos. Prof. Dr Zhila Khamnian[1], **Prof. Dr Mohammad Reza Lashkarizadeh**[2], **Dr Seyed Farid Ghorashian**[2], **Dr Seyedeh Hasti Ghorashian**[3]

[1]*Department of Community Medicine, Tabriz University of Medical Sciences;* [2]*Department of General Surgery, School of Medicine, Kerman University of Medical Sciences;* [3]*Fırat University Hospital, Department of Ear Nose and Throat Diseases*

BACKGROUND & AIM

Tracheal and subglottic stenosis after prolonged intubation is a significant complication that leads to mortality and morbidity. Due to limited data and information in this region about its epidemiology and treatment outcomes, this study aimed to evaluate the epidemiological characteristics, risk factors and treatment outcomes of post intubation tracheal and subglottic stenosis (PITS) in referral center hospital of southeast Iran (Kerman).

MATERIAL & METHODS

In this analytical cross-sectional study, we analyzed the medical records of 130 patients with PITS admitted to Kerman hospitals between 2016 - 2024. Demographic datas, intubation characteristics, clinical manifestations, surgical interventions (mainly resection and anastomosis), and outcomes (recovery, complications, recurrence, mortality) were collected and analyzed. Results with $P<0.05$ were regarded as statistically significant.

RESULTS

The mean age of patients was 26.47 ± 2.3 and 67.7% of patients were male. Multiple trauma (60.8%) was the main reason for intubation. Dyspnea was the most common symptom (96.2%). The most common cause of intubation was multiple trauma (60.8%). Ninety-six percent of patients underwent surgical intervention. In 56 cases, resection with anastomosis was performed, and 92.3% of patients who underwent resection with anastomosis recovered, while 4.5% had recurrence, 0.8% had PITS-related mortality, and 1.5% had complications. Duration of intubation (P= 0.001), history of T-tube use (P=0.001), previous

airway surgery (P=0.001), vocal cord status (P=0.03), and airway diameter (P=0.001) were significantly associated with treatment outcomes. In contrast, age, gender, smoking, and comorbidities showed no significant correlation. (P>0.05). Normal vocal cord function and less stenosis at initial bronchoscopy were associated with better outcomes.

CONCLUSIONS

PITS is considered as common complication of prolonged intubation that could prevented, which influenced by demographic and epidemiological factors, at the same time can cause has high mortality and morbidity. Key factors such as duration of intubation, prior airway interventions, T-tube history, vocal cord status, and airway diameter significantly influence treatment outcomes. These findings highlight the importance of preventive strategies to reduce prolonged intubation and optimize airway management in high-risk patients. Early referral and optimal airway management are critical. Early diagnosis, appropriate surgical intervention, and careful postoperative follow-up are essential to improve prognosis.

Giant Fibroepithelial Polyp Originating From The Right Pyriform Sinus

Selis Gülseven GÜVEN[1], **Safiye ÖZDİL**[1], **Fazlı YANIK**[3], **Ufuk USTA**[2], **Abdullah TAŞ**[1]

[1]*Department of Otorhinolaryngology at Trakya University Faculty of Medicine.*; [2]*Department of Pathology at Trakya University Faculty of Medicine.*; [3]*Department of Thoracic surgery at Trakya University Faculty of Medicine.*

BACKGROUND & AIM

Fibroepithelial polyps of the hypopharynx and cervical esophagus are rare lesions with an unclear etiology. While typically asymptomatic, giant polyps can cause dysphagia and airway obstruction. We present an exceptionally rare case—the fifth reported in literature—of a giant polyp (90×44×10 mm) originating from the pyriform sinus. Unlike typical presentations, this case involved four recurrent surgeries and extreme dimensions. Despite its recurrent nature, genetic analysis showed no PTEN mutations. This report discusses our combined surgical approach and histopathological findings, aiming to provide clinical guidance for managing such rare, recurrent, giant lesions where existing literature data remains extremely limited.

MATERIAL & METHODS

A 56-year-old male presented with a five-month history of intermittent dyspnea and dysphagia. His medical history revealed two prior surgeries for similar complaints, performed 10 and 2 years ago. ENT examination and MRI identified a giant polypoid lesion originating from the right pyriform sinus, dilating and extending into the proximal esophagus. Gastrointestinal screenings for associated pathologies were unremarkable.Under general anesthesia, a combined approach involving microlaryngoscopy and rigid esophagoscopy was performed with the thoracic surgery team. The giant lesion, measuring approximately 90 × 44 × 10 mm, was excised from its pedicle using laser and LigaSure.(Figure 1) Histopathology confirmed a fibroepithelial polyp. The patient was discharged on the fifth postoperative day without complications. This case is clinically significant as it represents only the fifth reported case of a fibroepithelial polyp originating from the hypopharynx in the literature, distinguished by its recurrent nature and extreme dimensions. The patient remains asymptomatic under follow-up.

RESULTS

Giant fibroepithelial polyps (FEP) originating from the hypopharynx and pyriform sinus are exceptionally rare. To our knowledge, only five cases, including ours, have been reported involving multiple polypoid lesions localized in a unilateral pyriform sinus. Unlike the cases reviewed by Alabdullah et al., our patient is distinguished by undergoing a fourth surgery for the same pathology and the lesion's extreme dimensions (90×44×10 mm). Although PTEN mutations have been associated with recurrent cases in the literature, no such variation was detected in our patient. This case offers a unique contribution to the literature due to its multi-recurrent nature without a history of radiotherapy and its diagnostic complexity.

CONCLUSIONS

Fibroepithelial polyps of the hypopharynx and cervical esophagus are rare lesions of the upper aerodigestive tract with an incompletely understood etiology. While patients are initially asymptomatic, significant growth can lead to clinical presentations involving dysphagia, dyspnea, and globus sensation. Malignant lesions must be considered in the differential diagnosis. The primary treatment is complete surgical excision; however, recurrences have been reported despite thorough intervention. The risk of malignant transformation remains exceedingly low.

Rare Airway Migration Of An Esophageal Stent In A Tracheoesophageal Fistula Patient Following Trauma: A Fatal Case Report

Dr. Oguzhan CUMALI[1], **Dr. Salih Ozan Korkmaz**[1], **Dr.Sema Ersoy**[1], **Prof.Dr.Sahin Ogreden**[1]

[1]*Basaksehir Cam and Sakura City Hospital, Istanbul, Turkey*

BACKGROUND & AIM

Tracheoesophageal fistula (TEF) is a rare but severe complication of prolonged intubation and major thoracic trauma. Esophageal stenting is commonly used for management of TEF; however, although stent migration is relatively frequent, migration into the airway is exceptionally rare and may lead to life-threatening complications such as airway obstruction, aspiration, and vascular erosion.

MATERIAL & METHODS

A 22-year-old previously healthy male sustained severe thoracic trauma following a motor vehicle accident. He underwent neurosurgical stabilization and required prolonged mechanical ventilation, followed by tracheostomy.

During his intensive care course, he developed TEF, which was managed with placement of a fully covered metallic esophageal stent. A PEG tube was also inserted for enteral nutrition.

After transfer to our center , the patient presented in a hypoxic state. He developed progressive respiratory distress and dysphagia. Endoscopic and radiological evaluation revealed rare migration of the esophageal stent into the trachea, extending from the laryngeal level to the distal trachea, causing airway obstruction and chronic aspiration despite tracheostomy with inflated cuff.

A stent-in-stent procedure was performed to reposition the migrated stent. However, the patient subsequently developed massive hemoptysis due to tracheovascular erosion, requiring emergency bronchial artery embolization. Despite intensive care management, he developed multidrug-resistant infections, progressing to septic shock and multi-organ failure, resulting in death.

RESULTS

Esophageal stent migration is a known complication; however, migration into the airway is extremely rare and usually associated with severe tissue injury or fistulous connections. Importantly, even in the presence of a cuffed tracheostomy tube, airway protection was insufficient due to structural disruption caused by fistula and stent migration. Migration was associated with partial mechanical obstruction of the tracheal lumen and impairment of laryngeal sphincter function, leading to worsening dysphagia and chronic aspiration. Massive hemoptysis secondary to tracheovascular erosion represents another catastrophic complication, often requiring emergent interventional radiology management. Despite such interventions, outcomes remain poor when complicated by severe infection and multi-organ failure.

CONCLUSIONS

Airway migration of esophageal stents in patients with tracheoesophageal fistula is an exceptionally rare but fatal complication. Early recognition, close multidisciplinary follow-up, and prompt intervention are critical; however, prognosis remains poor in cases complicated by severe trauma and prolonged intensive care course.

DUAL-BIOLOGIC RESTORATION LARYNGOPLASTY : HARNESSING MICRO FAT AND PLATELET RICH PLASMA FOR FUNCTIONAL RECOVERY ACROSS MULTIPLE GLOTTIC INSUFFICIENCIES

Ivanny Putri Sari[1]

[1]*ORL-HNS Department M.Djamil Hospital / Faculty of Medicine, Andalas University, Padang, West Sumatera, Indonesia*

BACKGROUND & AIM

Background : glottic insufficiency will result in glottal gap that cause dysphonia, dysphagia, and breathing problems. Unilateral vocal fold paralysis (UVFP) is the most cause of incomplete glottal closure. Other causes are presbylarynx, vocal fold (VF) paresis, scar, atrophy and sulcus vocalis. The use of autologous fat is a recognized method for VF augmentation. The injection of blood components such as platelet-rich plasma (PRP) as a regenerative therapy offers the potential to improve the results. Aim : to discuss efficacy of autologous fat injection laryngoplasty combined with PRP for treatment of glottic insufficiencies with various underlying diseases (serial cases)

MATERIAL & METHODS

Existing literature on autologous fat and PRP including aetiology, pathophisiology, diagnose and treatment modalities available are summarized. Autologous fat injection laryngoplasty combined with PRP are performed under general anesthesia

RESULTS

Advantages of autologous fat are contain high biocompatibility and minimal risk of reaction. Graft survival can survive up to 12 months and 30% can survive up to 2 years. PRP increases angiogenesis, inhibits apoptosis and prolongs growth period time

CONCLUSIONS

Laryngoplasty injection combination of autologous fat and PRP are effectively improves voice quality. Autologous fat augmentation injection laryngoplasty combined with PRP are minimally invasive intervention option for voice disorders due to structural abnormalities of VF. It has gained popularity due to its simplicity and very low complication rate

HIBERNOMA: A RARE SOFT TISSUE TUMOR SEEN IN THE NECK

AKTEN UYAN[1], **CEM BULUT**[1], **MÜRŞİT ALPEREN YAKUT**[1], **GÜLEN GÜL UZ**[2], **İLKER BURAK ARSLAN**[1]

[1]*DEPARTMENT OF OTORHINOLARYNGOLOGY,İZMİR CITY HOSPITAL;* [2]*DEPARTMENT OF PATHOLOGY,İZMİR CITY HOSPITAL*

BACKGROUND & AIM

INTRODUCTION

Hibernoma is a rare benign mesenchymal tumor arising from fetal brown adipose tissue (1). Although brown fat usually regresses during infancy, persistent foci may give rise to hibernoma in adulthood. It most commonly occurs in the interscapular region, mediastinum, retroperitoneum, and thigh, whereas cervical localization is uncommon (1).

Clinically and radiologically, it may mimic lipoma, angiolipoma, lymphadenopathy, and well-differentiated liposarcoma, posing diagnostic challenges (2,4). Magnetic resonance imaging (MRI) is valuable in diagnosis, demonstrating high vascularity, heterogeneous fat signal, and incomplete fat suppression (3). Definitive diagnosis relies on histopathological examination. Complete surgical excision is curative ,and recurrence is rare (1).

MATERIAL & METHODS

CASE PRESENTATION

A 55-year-old man presented with a slowly enlarging painless mass in the left posterior cervical triangle, without dysphagia, voice changes, or neurological symptoms. Physical examination revealed a mobile, well-circumscribed 4×4 cm subcutaneous mass.

Neck MRI demonstrated a well-defined 45×18×60 mm lesion involving left levels IIb,III,and Va.The lesion was hyperintense on T1- and T2-weighted sequences, showed slight signal loss on fat-suppressed images, contained macroscopic fat components, lacked low ADC values ,and demonstrated mild contrast enhancement. These findings suggested hibernoma, although liposarcoma and angiolipoma were also considered in the differential diagnosis (2,3).

The patient underwent complete surgical excision. Histopathological examination confirmed the diagnosis of hibernoma. Postoperative recovery was uneventful.

RESULTS

DISCUSSION

Hibernoma is a rare benign tumor, particularly in the cervical region (1). Although it resembles lipoma clinically, increased vascularity and atypical MRI findings may aid in the differential diagnosis (3).

However, distinguishing hibernoma from well-differentiated liposarcoma may not always be possible radiologically; therefore , definitive diagnosis requires histopathological examination (4). Complete surgical excision is both diagnostic and therapeutic, with extremely low recurrence rates (1).This case highlights that hibernoma should be considered in the differential diagnosis of cervical fat-containing cervical masses.

CONCLUSIONS

CONCLUSION

Hibernoma, although rare, should be included in the differential diagnosis of slowly growing fat-containing cervical masses. MRI may suggest the diagnosis, but histopathological confirmation is essential. Complete surgical excision is both diagnostic and curative.

PM-Induced Lysosomal Rupture-Mediated Pyroptosis In Human Vocal Fold Fibroblasts

Hyunsu Choi[2], **Jooin Bang**[1], **Yaegi Song**[1], **ChoungSoo Kim**[1]

[1]*Department of Otolaryngology-Head and Neck Surgery, Eunpyeong St. Mary's Hospital, College of Medicine, The Catholic University of Korea;* [2]*Clinical Research Institute, , Daejeon St. Mary's*

BACKGROUND & AIM

Exposure to air pollution, specifically to particulate matter (PM), is a significant global health hazard . Recent studies have shown that PM triggers NLRP3-mediated pyroptosis. However, whether cathepsin B (CTSB), a protease released from ruptured lysosomes, activates the NLRP3 inflammasome is unclear. This study investigated the involvement of CTSB and NLRP3 inflammasome activation in PM-exposed human vocal fold fibroblasts (hVFFs).

MATERIAL & METHODS

Pyroptotic cell death was evaluated based on LDH release and PI staining, and NLRP3 inflammasome activation via western blotting and immunofluorescence staining. The inflammatory response during pyroptosis was analyzed in an ELISA assay, and lysosomal stability by LysoTracker staining

RESULTS

PM exposure was shown to induce cell membrane rupture and pyroptosis in hVFFs, through a mechanism involving NLRP3, cleaved caspase-1, gasdermin D (GSDMD), IL-1β, lysosomal-associated membrane protein 2a, and CTSB. These results suggested that PM causes pyroptosis in hVFFs via NLRP3 inflammasome activation and lysosomal destabilization. Treatment of the PM-exposed cells with MCC950, an NLRP3-specific inhibitor, suppressed this pathway, providing further evidence of the involvement of the NLRP3 inflammasome in PM-induced pyroptosis. A role for CTSB in NLRP3 inflammasome activation and pyroptosis was implied by the finding that treatment with CA-074-me, a CTSB-specific inhibitor, reduced CTSB expression and suppressed NLRP3, cleaved caspase-1, GSDMD, IL-1β, and CTSB in PM-exposed hVFFs .

CONCLUSIONS

Our study shows that both the NLRP3 inflammasome and CTSB participate in PM-induced pyroptosis in hVFFs. Targeting these pathways could yield novel therapeutic agents able to mitigate the detrimental effects of PM exposure on respiratory health.

Endoscopic Visualization Of A Sharp Foreign Body Preceding Retropharyngeal Abscess Formation In An Adult

Banu ATEŞ[1], **Burak Kaan İNAN**[1], **İbrahim Salih GEÇER**[1], **Zahide Mine YAZICI**[1]

[1]*Department of Otorhinolaryngology & Head and Neck Surgery, Bakırköy Dr. Sadi Konuk Training and Research Hospital, 34147, İstanbul, Turkey.*

BACKGROUND & AIM

To present a rare case of retropharyngeal abscess developing after endoscopic removal of a sharp foreign body from the hypopharynx and to emphasize the importance of early recognition and management of deep neck space infections following mucosal injury.

MATERIAL & METHODS

A 53-year-old woman with no significant medical history presented with foreign body aspiration. A sewing pin lodged in the hypopharynx with mucosal penetration was identified and removed endoscopically. The patient was initially discharged without antibiotic therapy. She re-presented with progressive dysphagia and dyspnea. Contrast-enhanced computed tomography demonstrated a 31×20 mm retropharyngeal abscess with extension toward the nasopharynx. The patient underwent transoral incision and drainage under general anesthesia. Pus samples were obtained for microbiological analysis. Postoperatively, the patient received intravenous antibiotic therapy followed by oral treatment, guided by culture results.

RESULTS

Following surgical drainage and appropriate antibiotic treatment, the patient showed rapid clinical improvement. Follow-up imaging demonstrated complete resolution of the abscess. No postoperative complications occurred, and the patient was discharged in good condition.

CONCLUSIONS

Retropharyngeal abscess formation in adults is rare and should raise concern when following sharp foreign body aspiration. Even after successful removal, persistent or worsening symptoms warrant prompt evaluation with imaging. This case highlights the role of early suspicion, timely surgical drainage, and appropriate antibiotic coverage.

KEYWORDS

Deep neck space infection, Foreign body aspiration, Retropharyngeal abscess, Streptococcus anginosus.

PP-342

Voice Outcomes After Vocal Fold Injection Augmentation: A Single-Center Experience

M. Tedla, L. Demková, L. Staškovanová, H. Sallay Hajdúová, Z. Javorská, E. Čičelová, Ž. Korim[1]

[1]*Department of Otorhinolaryngology and Head and Neck Surgery, Comenius University Faculty of Medicine and University Hospital Bratislava, Bratislava, Slovakia*

BACKGROUND & AIM

Vocal fold injection augmentation is a minimally invasive procedure used to improve glottic closure and voice quality in patients with glottic insufficiency caused by unilateral vocal fold paralysis, vocal fold atrophy, scarring, and other laryngeal pathologies. The aim of this study was to evaluate clinical experience and short-term voice outcomes after vocal fold injection augmentation at a tertiary otorhinolaryngology center.

MATERIAL & METHODS

A single-center study was conducted at the Department of Otorhinolaryngology and Head and Neck Surgery, Comenius University Faculty of Medicine and University Hospital Bratislava, between October 2023 and August 2025. Overall, 108 vocal fold injection augmentation procedures were performed in 100 patients aged 26–89 years (mean age 60.6 years). The most common indications included unilateral vocal fold paresis/paralysis, vocal fold atrophy, and vocal fold scarring. Hyaluronic acid and calcium hydroxylapatite were used as injectable materials. In a subgroup of patients with unilateral vocal fold paralysis, a prospective multidimensional voice analysis was performed using preoperative and postoperative auditory-perceptual evaluation (GRBAS scale), aerodynamic measurements (maximum phonation time), acoustic analysis, and Voice Handicap Index (VHI-30). Statistical analysis was performed using the Wilcoxon signed-rank test.

RESULTS

The cohort included 108 procedures with a reinjection rate of 8%. Left-sided vocal fold involvement was more frequent than right-sided involvement. In the subgroup analysis of patients with unilateral vocal fold paralysis, significant postoperative improvement was observed in overall dysphonia grade (G), breathiness (B), jitter, shimmer, glottal-to-noise excitation (GNE), maximum phonation times for /a:/ and /z:/, and VHI-30 scores ($p < 0.05$). Postoperative improvement in glottic closure and subjective voice quality was observed in the majority of patients.

CONCLUSIONS

Vocal fold injection augmentation represents an effective minimally invasive treatment option for patients with glottic insufficiency. Multidimensional voice assessment appears to be a valuable tool for objective evaluation of treatment outcomes and postoperative voice improvement.

PP-343

Delayed Fistulizing Infection Following Reconstruction Of Complex Crush Laryngeal Trauma: A Case Report

Erdem AĞGÜNLÜ[1], **Ömer Faruk Çufalı**[1]

[1]*Ankara Bilkent City Hospital, Türkiye*

BACKGROUND & AIM

Laryngeal trauma is an uncommon but potentially fatal injury requiring rapid airway stabilization and meticulous reconstruction. Delayed cervical fistulization after repair of complex laryngotracheal trauma is rarely reported. We aimed to present the management of delayed fistula formation following reconstruction of severe crush laryngeal trauma.

MATERIAL & METHODS

A 38-year-old man presented after industrial crush neck trauma caused by a press machine. Imaging demonstrated extensive cervicofacial emphysema, pneumomediastinum, pneumothorax, C7 spinous process fracture, thyroid/cricoid cartilage injury, and suspected laryngotracheal wall defects. Flexible bronchoscopy revealed a subglottic laceration communicating with the airway lumen. Because of associated cervical vertebral injury, urgent tracheotomy was performed before exploration. Surgical exploration demonstrated a right posterolateral cricoid fracture, which was repaired with primary reduction and suturing, followed by strap muscle flap reconstruction. After successful decannulation and tracheostomy closure, persistent drainage and granulation tissue developed at the tracheostomy scar. Re-exploration revealed multiple cervical fistulous tracts extending from the prior laryngeal injury site toward the closed tracheostomy region. Debridement, drainage, sternocleidomastoid muscle flap reconstruction, and targeted antibiotic therapy were performed.

RESULTS

Wound cultures yielded Pseudomonas aeruginosa. Purulent drainage progressively resolved during follow-up with surgical and medical management. Airway patency was preserved without recurrent respiratory compromise or dysphagia. Follow-up examination demonstrated persistent but functional unilateral vocal cord hypomobility without recurrent deep neck infection.

CONCLUSIONS

Complex crush laryngotracheal trauma may result in delayed cervical fistulization even after apparently successful primary reconstruction and decannulation. Careful postoperative surveillance and timely surgical intervention are essential for preventing chronic infection and long-term airway morbidity.

PP-344

From Extremity Ecchymosis To Pseudo-Ludwig Angina: Antiplatelet-Associated Hematoma With Laryngeal And Sublingual Involvement

Dr. Sunel Bade Özen[1], **Op. Dr. Fatma Gülüm İvgin Bayraktar**[1]

[1]İstanbul Prof. Dr. Cemil Taşçıoğlu Şehir Hastanesi

BACKGROUND & AIM

Ludwig angina is a life-threatening, rapidly progressive infection of the sublingual and submandibular spaces requiring urgent airway management and often surgical drainage. However, non-infectious conditions such as antiplatelet-associated or spontaneous hematomas may closely mimic this entity which is called “pseudo-Ludwig Angina” and pose a diagnostic challenge. This case highlights that antiplatelet-associated progressive soft tissue hematomas in elderly patients may initially present as peripheral ecchymosis and progress to pseudo-Ludwig angina with laryngeal airway compromise. Early recognition of this trajectory may support an airway-first, conservative management approach.

MATERIAL & METHODS

We report an 85-year-old male with multiple comorbidities, including prior coronary artery bypass grafting and percutaneous coronary interventions, hypertension, rectal cancer history, and pacemaker implantation, who was receiving Clopidogrel therapy. He initially presented with progressive extremity edema and ecchymosis, with normal coagulation parameters and platelet count. Ten days later, he returned with bilateral upper extremity, cervical, and submandibular ecchymosis, tongue edema and dyspnea, and was consulted to our clinic. Clinical, endoscopic, radiologic, and laboratory findings were evaluated to differentiate infectious from non-infectious etiologies and extensity of hematoma. Airway status and clinical progression during intensive care follow-up were monitored.

RESULTS

Laryngoscopy revealed extensive hematoma involving the lingual, sublingual, glottic, and supraglottic regions, resulting in significant airway compromise. Imaging demonstrated diffuse soft tissue involvement without abscess formation. Due to dual-level airway obstruction and failure of endotracheal entubation, emergent local tracheostomy was performed, followed by re-operation for bleeding control on postoperative day one. With airway stabilization, platelet transfusion and discontinuation of clopidogrel, ecchymosis and hematoma regressed during intensive care follow-up. However, the patient developed sepsis secondary to pneumonia and subsequently died.

CONCLUSIONS

Antiplatelet-associated spontaneous hematomas should be considered in elderly patients presenting with Ludwig angina-like findings, even in the absence of laboratory evidence of coagulopathy. In such cases, Clopidogrel does not alter standard coagulation parameters but causes irreversible platelet inhibition, which may explain progressive bleeding despite normal laboratory results. Therefore, platelet transfusion may be considered in selected cases. These hematomas may follow a progressive course from extremity ecchymosis to diffuse laryngeal and sublingual involvement with life-threatening airway compromise. Early recognition of this trajectory may help guide an airway-first, conservative management approach; however, severe systemic complications and fatal outcomes may still occur.

Pseudo-Ludwig angina, anti-platelet associated hematoma, clopidogrel, airway compromise, laryngeal hematoma, sublingual hematoma, tracheostomy

PP-345

Successful Recovery From Anabolic Androgenic Steroid-Induced Dysphonia Via Pitch-Raising Voice Therapy: A Rare Case Report

Nurullah Türe[1], **Muhammet Olan**[1], **Fikret Zeybek**[1]

[1]University of Health Sciences, Kütahya Evliya Çelebi Training and Research Hospital

BACKGROUND & AIM

Anabolic androgenic steroids (AAS) are known to cause significant virilization in women, typically characterized by vocal fold thickening, epithelial changes, and a marked decrease in fundamental frequency (F0)These masculinizing effects are widely considered irreversible in clinical literature, even after medication cessation, often leaving patients with a permanent "husky" or low-pitched voice.This case report presents a 23-year-old female who achieved significant vocal and structural recovery through targeted behavioral intervention, challenging the paradigm of absolute irreversibility.

MATERIAL & METHODS

A 23-year-old female presented with progressive voice deepening after six monthly intramuscular AAS doses for weight gain. Within three months, she developed a muffled, low-pitched voice significantly impairing her quality of life. Initial videostroboscopy (VLS) revealed minimal bilateral vocal fold thickening and blunted free edges.Acoustic analysis showed an F0 of 140 Hz well below the typical female range of 180–250 Hz a Voice Handicap Index (VHI) of 25, Jitter of 0.4%, and Shimmer of 1.6%.Despite AAS cessation, no spontaneous improvement occurred.The patient completed a six-month course of pitch-raising voice therapy. Follow-up showed marked improvements in vocal quality and daily functioning. Control VLS confirmed complete resolution of vocal fold thickening. Post-therapy metrics showed an improved F0 of 165 Hz and a reduced VHI of 15, with stable perturbation measures (Jitter: 0.3%, Shimmer: 1.5%). The patient continues clinical follow-up with sustained improvements.

RESULTS

Six months of targeted behavioral intervention facilitated the total resolution of structural vocal fold thickening and led to a significant increase in fundamental frequency and improved patient-reported quality of life.

CONCLUSIONS

AAS induced dysphonia and structural laryngeal changes, traditionally viewed as permanent, can be reversible through systematic voice therapy. Behavioral management should be considered a primary non-surgical treatment option for women suffering from drug-induced vocal masculinization.

Anabolic androgenic steroids, dysphonia, fundamental frequency, voice therapy, vocal fold thickening,virilizitation.

PP-346

Rare Bilateral Adult Laryngeal Saccular Cysts Managed By Transoral Robotic Surgery

Ahmet Güleç[1], **Sude Zeynep Tekin**[1], **İsmail Düzen**[1], **Şahin Öğreden**[1]

[1]*Basaksehir Cam and Sakura City Hospital, Department of Otolaryngology, İstanbul, Türkiye*

BACKGROUND & AIM

Laryngeal saccular cysts are benign mucinous retention lesions that may cause significant airway obstruction. While typically congenital and unilateral, bilateral presentation in adults is exceptionally rare. Management of bilateral lesions is challenging due to limited surgical exposure, risk of mucosal injury, and postoperative airway compromise. We hypothesized that Transoral Robotic Surgery (TORS) using the da Vinci Surgical System enables safe, single-stage, mucosa-preserving excision of bilateral laryngeal saccular cysts while minimizing morbidity and avoiding tracheostomy.

MATERIAL & METHODS

A 35-year-old female presented with progressive stridor and dysphonia. Endoscopic evaluation revealed approximately 60% glottic obstruction. Contrast neck magnetic resonance imaging confirmed bilateral cystic lesions within the paraglottic spaces.

A single-stage surgical intervention was performed using TORS. The patient was operated in a tertiary referral center under general anesthesia. Robotic three-dimensional visualization allowed identification of a suspicious mucosal area over the right-sided cyst, which was biopsied separately. Complete bilateral excision was achieved using the system's articulated instruments with mucosal preservation.

Primary outcome measures included completeness of resection, perioperative airway safety (need for tracheostomy), and postoperative functional outcomes (voice quality). Secondary outcomes included intraoperative complications and early postoperative recovery.

RESULTS

Complete resection of both cysts was achieved without intraoperative complications or mucosal defects. No tracheostomy was required. Postoperative oedema was minimal, and the patient was discharged on postoperative day one. Voice quality, assessed using the GRBAS (Grade, Roughness, Breathiness, Asthenia, Strain) scale, returned to normal within two weeks. Histopathological evaluation confirmed benign cystic lesions; analysis of the suspicious mucosal area is ongoing.

CONCLUSIONS

TORS is a safe and effective technique for the management of bilateral adult laryngeal saccular cysts. The enhanced visualization and instrument dexterity facilitate precise, mucosa-sparing dissection in anatomically restricted bilateral disease. This approach enables single-stage treatment, reduces airway-related morbidity, and may eliminate the need for prophylactic tracheostomy in selected cases.

PP-347

Conservative Management Of Selected Schaefer-Fuhrman Group III Blunt Laryngeal Trauma

Tammy Lim Ting Yi[1], **Shalini Arulanandam**[2]

[1]*Department of Otorhinolaryngology, Khoo Teck Puat Hospital, Singapore;* [2]*Department of Otorhinolaryngology, Singapore General Hospital, Singapore*

BACKGROUND & AIM

Blunt laryngeal trauma can be life-threatening, with risks for long-term morbidity. The Schaefer–Fuhrman classification has traditionally been used to grade severity and guide management; with definitive surgical intervention being the recommendation for group III injuries. While acute airway management remains consistent, data regarding considerations and alternatives to definitive management remain limited. Herein, through 2 cases, we report the feasibility and outcomes of conservative management in selected Schaefer-Fuhrman Group III blunt laryngeal trauma.

MATERIAL & METHODS

We present 2 patients with Schaefer–Fuhrman group III blunt laryngeal trauma. One had displaced left thyroid cartilage fracture with ipsilateral supraglottic edema, false and true cord and aryepiglottic fold hematoma. The other had exposed cartilage with arytenoid and true cord hematoma on nasendoscopy. The former declined surgical fixation while the latter was advised on conservative management in view of age and comorbidities. Both patients maintained a stable patent airway on serial scopes and were managed conservatively (airway monitoring, voice rest, intravenous dexamethasone and anti-reflux medication). They were discharged on day 4 and 3 respectively on oral diet with subjective voice and objective nasoendoscopic improvement.

RESULTS

The first patient defaulted follow-up. On phone recall, he reported normalization of voice and swallowing. The second patient returned for follow-up 11 months post-injury. Nasoendoscopy showed a fixed and shortened left true cord in paramedian position with good glottic closure from the right true cord. No edema or hematoma was noted and mucosalization had occurred over the exposed cartilage. There was no subjective or objective hoarseness and her swallowing was normal. These cases suggests that conservative management may be safe and feasible even in injury patterns traditionally considered for surgical repair with careful patient selection. Patients must be clinically stable without airway or swallowing compromise. Further considerations also include: fractures that do not impair vocal fold mobility/mucosal wave, limited mucosal disruption/exposed cartilage with low adhesion risk; and taking into account age and comorbidities.

CONCLUSIONS

Conservative management may be feasible in carefully selected patients with Schaefer–Fuhrman Group III blunt laryngeal trauma with stable airway, injury pattern and minimal functional impairment. Further studies with standardized functional outcome assessments are required to better define selection criteria.

Endoscopic Balloon Dilatation In Airway Stenosis: A Single-Center Retrospective Study

Dr. Roqiah Aldueb[1], **Dr. Ghadah Alissa**[2]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, College of Medicine, King Saud University, Riyadh, Saudi Arabia;* [2]*College of Medicine, Sulaiman AlRajhi University, Al Qassim, Saudi Arabia*

BACKGROUND & AIM

Laryngotracheal stenosis is a challenging airway condition that often requires repeated interventions. Endoscopic balloon dilatation (EBD) is widely used as a minimally invasive treatment, frequently combined with adjuvant therapies such as intralesional steroids and mitomycin C. However, outcomes remain variable with no clear consensus on optimal management. This study aims to evaluate our institutional experience with EBD and assess factors associated with recurrence.

MATERIAL & METHODS

A retrospective cohort study is being conducted at a tertiary care center. Potentially eligible records were identified for patients who underwent endoscopic balloon dilatation for airway stenosis. Final inclusion will be limited to patients treated between 2021 and 2025 who meet predefined eligibility criteria. Data are being collected from electronic medical records, including demographics, etiology, stenosis level and grade, number of dilatation procedures, interval between interventions, and use of adjuvant therapies such as intralesional steroids and mitomycin C. Primary outcomes include recurrence and surgical-free interval. Secondary outcomes include the association between adjuvant therapies and clinical outcomes.

RESULTS

Data collection is currently ongoing, and preliminary data extraction has been initiated. An initial institutional search identified a large number of potentially eligible cases; final cohort size will be determined after applying eligibility criteria and excluding incomplete records. Full analysis will evaluate recurrence rates, number of procedures, interval between dilatations, and the impact of adjuvant therapies.

CONCLUSIONS

This study aims to provide insight into real-world outcomes of endoscopic balloon dilatation in airway stenosis and clarify the role of adjuvant therapies. The findings may help guide clinical decision-making and contribute toward more standardized, evidence-based management of this challenging condition.

Our Clinical Experience With Coblator-Assisted Posterior Cordectomy In Bilateral Vocal Fold Immobility

Şahin YENER[1], **Berke GEREN**[1], **Deniz BAKLACI**[1], **Duygu ERDEM**[1], **Hüseyin IŞIK**[1]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, Faculty of Medicine, Zonguldak Bülent Ecevit University, Türkiye*

BACKGROUND & AIM

The primary goal in the management of bilateral vocal fold immobility (BVFI) is to establish an adequate airway while preserving phonatory function. Common etiologies include iatrogenic recurrent laryngeal nerve injury following thyroid surgery, prolonged intubation, malignancy, neurologic disorders, and idiopathic causes. Although tracheostomy has long been considered the gold standard treatment, endoscopic posterior cordotomy and cordectomy techniques have increasingly gained popularity. CO_2 laser remains the most commonly used modality; however, coblation technology may reduce collateral thermal injury, postoperative edema, and granulation tissue formation compared with conventional laser techniques. Nevertheless, clinical data regarding coblator-assisted posterior cordectomy remain limited.

MATERIAL & METHODS

Three female patients with BVFI secondary to thyroid surgery underwent unilateral coblator-assisted posterior cordectomy at our tertiary referral center. Patient ages were 71, 68, and 55 years, respectively. One patient had a pre-existing tracheostomy due to severe respiratory distress, while the remaining two patients presented with progressive dyspnea without tracheostomy. All procedures were performed under suspension laryngoscopy using coblation technology. Unilateral posterior vocal fold cordectomy was performed in all patients in order to enlarge the glottic airway while preserving laryngeal sphincteric function.

RESULTS

Postoperative airway improvement was observed in all patients. The tracheostomized patient could not tolerate early decannulation and remained under tracheostomy follow-up. No major perioperative or postoperative complications, including hemorrhage, aspiration, significant laryngeal edema, or granulation tissue formation, were observed. Subjective respiratory symptoms improved in all cases, while no marked postoperative voice deterioration was reported. Patients were discharged on postoperative days 7, 7, and 12, respectively.

CONCLUSIONS

Coblator-assisted posterior cordectomy appears to be a safe and effective alternative for airway enlargement in selected patients with BVFI. Compared with CO_2 laser techniques, coblation technology may reduce postoperative edema, granulation tissue formation, and collateral tissue injury due to lower thermal damage. In addition, improved intraoperative hemostasis and minimal tissue carbonization may facilitate surgical visualization and contribute to better postoperative recovery. Our preliminary clinical experience demonstrates promising airway outcomes with acceptable voice preservation. However, larger studies are required to further evaluate long-term functional outcomes and complication rates.

A Warning In The Voice: Hoarseness As A Sentinel Symptom

Rocío Carpintero Díaz[1], **Daniel A. Núñez Carlino**[1], **Araly Hivama Chacón Uribe**[1], **Fernando González Galán**[1], **Gabriel Álvarez Curro**[1], **José Miguel Villacampa Aubá**[1]

[1]*Fundación Jiménez Díaz University Hospital*

BACKGROUND & AIM

Ortner syndrome, also known as cardiovocal syndrome, is an uncommon cause of left recurrent laryngeal nerve (RLN) palsy secondary to cardiovascular disease. Although traditionally associated with mitral stenosis and left atrial enlargement, it now includes a wide spectrum of vascular conditions such as aortic aneurysms and penetrating ulcers. We hypothesize that sudden-onset dysphonia may represent an early and isolated manifestation of life-threatening aortic pathology.

MATERIAL & METHODS

We report the case of a 74-year-old male, active smoker with chronic obstructive pulmonary disease (COPD), presenting with a two-month history of sudden dysphonia without dyspnea or dysphagia. Laryngoscopic examination revealed left vocal cord paralysis in a paramedian position with limited contralateral compensation. Cervicothoracic computed tomography (CT) demonstrated a focal saccular aneurysmal dilatation of the aortic arch wall measuring 48×38 mm, with irregular lumen and a 17 mm hyperdense mural thrombus. Subsequent CT angiography confirmed a penetrating aortic ulcer with signs suggestive of impending rupture and additional focal dilatations in the abdominal aorta. The patient underwent thoracic endovascular aortic repair (TEVAR) combined with left carotid-subclavian bypass using a polytetrafluoroethylene (PTFE) graft.

RESULTS

Dysphonia was the only presenting symptom. No respiratory or systemic symptoms were present at diagnosis. Early diagnosis enabled prompt multidisciplinary management of a potentially fatal condition. Surgical treatment was successfully performed without complications. At three-month follow-up, improved compensatory function of the contralateral vocal cord was observed after speech therapy.

CONCLUSIONS

Left vocal cord paralysis may be the first and only manifestation of severe aortic disease. Ortner syndrome should be considered in patients of unexplained dysphonia. Early imaging is crucial to identify life-threatening conditions and guide timely intervention.

Cough- Induced Spontaneous Laryngeal Hematoma: A Rare Cause Of Acute Upper Airway Obstruction

Juan Jose Ocaña Dominguez[1], **Karla Natali Montaño Rueda**[1], **Julio De Manueles Gómez Martino**[1], **Borja Bazan Inostroza**[1], **Jorge Prada Pendolero**[1]

[1]*Hospital Blua Sanitas Valdebebas*

BACKGROUND & AIM

Spontaneous laryngeal hematoma is an uncommon but potentially life-threatening cause of upper airway obstruction. Its recognition is essential, particularly in patients with predisposing factors.

MATERIAL & METHODS

We report the case of a 60-year-old male with a medical history of type 2 diabetes mellitus, severe asthma treated with dupilumab, ulcerative colitis (UC), and ongoing acetylsalicylic acid therapy, who was admitted due to extensive cellulitis of the left lower limb with failure of oral antibiotic therapy. Laboratory tests revealed leukocytosis ($19.3 \times 10^3/\mu L$) and elevated C-reactive protein (CRP) levels (24.15 mg/dL). במהלך hospitalization, during nighttime, the patient experienced a coughing episode that acutely triggered dyspnea, dysphonia, and dysphagia.

RESULTS

Otolaryngological examination demonstrated upper airway compromise secondary to a submucosal lesion. Cervical computed tomography showed prevertebral soft tissue swelling suggestive of a hematoma, confirming its role as the cause of the obstructive presentation. Nasolaryngoscopy revealed a mucosal hematoma involving the arytenoids, aryepiglottic folds, and posterior hypopharyngeal wall, with a patent but narrowed glottic airway.

The most likely pathophysiological mechanism was a severe coughing episode associated with Valsalva-like maneuvers, leading to abrupt increases in intrathoracic pressure capable of causing venous rupture in the retropharyngeal space and the laryngeal submucosal compartment. Contributing factors included the use of acetylsalicylic acid, mucosal fragility related to systemic corticosteroid use for underlying conditions (UC and severe asthma), and a possible role of dupilumab. Immunological testing showed normal C1q levels.

CONCLUSIONS

Spontaneous laryngeal hematoma should be considered in acute upper airway symptoms following intense coughing, especially in patients with predisposing factors such as antiplatelet therapy and biologic treatments. Differential diagnosis includes bradykinin-mediated angioedema, hemorrhagic neoplasms, and vascular malformations, making serial endoscopic evaluation essential.

A conservative approach was successful due to the self-limiting course and adequate control of risk factors. This case underscores the importance of a multidisciplinary approach and careful management of modifiable risk factors in complex patients.

Spontaneous laryngeal hematoma, dyspnea, dysphonia, cough

PP-352

Non-Recurrent Inferior Laryngeal Nerve During Thyroidectomy: A Rare Case And Surgical Implications

Messaoudi[1]

[1]*ENT department, Mohamed Boudiaf Hospital, University Of Kasdi Merbah.*

BACKGROUND & AIM

The non-recurrent inferior laryngeal nerve (NRILN) is a rare anatomical variation associated with an increased risk of nerve injury during thyroid surgery. Its incidence ranges from 0.5% to 2% and is most commonly associated with an aberrant right

subclavian artery (arteria lusoria). This study aims to highlight the intraoperative identification and clinical significance of NRILN to prevent iatrogenic injury.

MATERIAL & METHODS

We report the case of a 42-year-old female presenting with a progressively enlarging multinodular goiter associated with compressive symptoms including dysphagia and exertional dyspnea. Preoperative biological tests were normal, and fine-needle aspiration cytology was inconclusive. The patient underwent total thyroidectomy in a tertiary ENT department. During surgery, the right recurrent laryngeal nerve could not be identified in its usual tracheoesophageal groove. Careful dissection revealed an anomalous nerve emerging directly from the vagus nerve in the cervical region and coursing medially toward the larynx, consistent with a type I NRILN. All parathyroid glands were preserved.

RESULTS

The nerve was successfully identified and preserved without intraoperative complications. Postoperative laryngoscopic examination demonstrated normal vocal cord mobility. Computed tomography angiography confirmed the presence of an aberrant right subclavian artery (arteria lusoria). Histopathological examination revealed benign thyroid hyperplasia.

CONCLUSIONS

NRILN is a rare but clinically significant anatomical variant that increases the risk of nerve injury during thyroid surgery. Awareness of this variation, systematic intraoperative exploration, and recognition of associated vascular anomalies are essential to ensure nerve preservation and reduce morbidity.

Advances In Artificial Intelligence For Laryngeal Cancer Detection: A Systematic Review

Rayane Bezerra Freitas[1], **Daiane de França Falcão Leal**[2], **Gian Raphael Silva Palhano Galvão**[3], **Maria Clara Dias Giacomini**[2], **Matheus Vinicius Santos Silva**[3], **Wesley Smith Albuquerque de Araújo**[3], **Gabrielle Justiniana Fontes Rocha**[3], **Kelvin Leite Moura**[4], **Pedro Henrique Breda**[3], **Priscila Farias de Oliveira**[5], **Wendell Dantas Palmeira**[3]

[1]Professional Master's Program in Health Education, Universidade Federal do Rio Grande do Norte, Natal, RN, Brazil; [2]Department of Otolaryngology, Hospital das Clínicas, Universidade de São Paulo, São Paulo, Brazil; [3]Department of Surgery, Universidade Federal do Rio Grande do Norte, Hospital Universitário Onofre Lopes, Natal, RN, Brazil; [4]Clínica Otorrinos Santa Clara, Campina Grande, PB, Brazil; [5]Clínica Otossinus, Natal, RN, Brazil

BACKGROUND & AIM

Laryngeal cancer remains a significant global health concern, with prognosis strongly dependent on early and accurate diagnosis. Although histopathological analysis remains the gold standard for diagnostic confirmation, artificial intelligence has emerged as a supportive tool, particularly in laryngoscopic image analysis. Its potential to enhance diagnostic accuracy, support clinical decision-making, and improve workflow efficiency has been increasingly explored. This systematic review aimed to evaluate recent advances in artificial intelligence for laryngeal cancer detection, focusing on diagnostic performance and clinical applicability.

MATERIAL & METHODS

A total of 117 studies were identified from PubMed/MEDLINE, EMBASE, Scopus, BVS/LILACS, and Cochrane databases, searched in accordance with PRISMA guidelines. The search was conducted by two independent reviewers between March and April 2026 using the following descriptors: ("artificial intelligence" OR "machine learning" OR "deep learning" OR "artificial intelligence" OR "machine learning" OR "deep learning") AND ("otolaryngology" OR "ENT" OR "otorhinolaryngology") AND ("endoscopy" OR "laryngoscopy"). Studies published in the past five years involving patients with confirmed laryngeal cancer were included. Eligible study designs included accessible full-text versions of systematic reviews, meta-analyses, and completed clinical trials. Exclusion criteria included benign laryngeal lesions, editorials, opinion articles, conference abstracts, case reports, case series, narrative reviews, and incomplete clinical trials. Screening was performed independently by two reviewers, with disagreements resolved by a third reviewer. After full-text assessment, 6 studies were included.

RESULTS

A total of 196 records were identified, with six studies included after PRISMA-guided screening. Published between 2021 and 2025, the studies enrolled 64 to 4,799 patients, mostly with laryngeal lesions assessed by videolaryngoscopy using white light and/or narrow-band imaging, with histopathology as the reference standard. Artificial intelligence models, primarily convolutional neural networks, showed moderate to high diagnostic performance. Advanced architectures and multimodal approaches (combining imaging and voice data) achieved the best results, with accuracy up to 95.9% and AUC up to 0.98, in some cases comparable to experienced clinicians. However, substantial methodological and clinical heterogeneity across datasets, imaging modalities, and validation strategies precluded quantitative meta-analysis. QUADAS-2 assessment indicated high risk of bias in patient selection and index test domains, while the reference standard was generally low risk. Overall, the certainty of evidence was low.

CONCLUSIONS

Artificial intelligence shows promising diagnostic performance for laryngeal cancer detection, particularly with convolutional neural networks applied to laryngoscopic imaging. Reported accuracy and AUC values indicate potential comparability to specialist evaluation, especially in studies using narrow band imaging and multimodal approaches. However, substantial methodological heterogeneity and a predominance of high risk of bias mainly in patient selection and index test domains limit the reliability and generalizability of these findings. The overall certainty of evidence remains low to moderate, underscoring the need for standardized, high-quality prospective studies to confirm clinical applicability and support integration into routine practice.

When Tuberculosis Mimics A Pharyngo-Laryngeal Tumor - A Rare Pseudotumoral Presentation

SAHRAOUI Mohammed[1,2], **MEHTARI Nasrine Siham**[1,2], **AID Chahrazed**[1], **NASRI Amine**[1,2], **BENMANSOUR Narimane**[1]

[1]*ENT Department - Tlemcen University Hospital Center;* [2]*Faculty of Medicine - Abou Bekr Belkaid University of Tlemcen*

BACKGROUND & AIM

Tuberculosis remains a major public health issue worldwide, particularly in endemic countries such as Algeria.

Our objective is to highlight a rare and misleading presentation of pharyngo-laryngeal tuberculosis by detailing its clinical, paraclinical, and therapeutic features.

MATERIAL & METHODS

We report the case of a 16-year-old adolescent, followed for growth retardation and receiving growth hormone therapy, who mainly presented with chronic dysphonia associated with nasal obstruction evolving over several months.

A thorough clinical examination, cervicofacial CT scan, and biopsy followed by histopathological analysis were performed.

RESULTS

The patient had no history of tuberculosis exposure or previous pulmonary tuberculosis.

Nasofibroscopy revealed a large adenoidal mass completely obstructing the nasopharynx, hypertrophy of the palatine and lingual tonsils with altered architecture, a polypoid epiglottis adherent to the tongue base, and edematous vocal cords with pink exophytic lesions initially suggestive of laryngeal polyposis.

Initial treatment with systemic and inhaled corticosteroids combined with anti-allergic therapy showed no significant improvement.

Given the persistence of symptoms, a cervicofacial CT scan was performed, confirming nasopharyngeal obstruction and vocal cord hypertrophy without signs of deep infiltration, causing laryngeal narrowing. Bilateral cervical lymphadenopathy was also identified.

Exploratory direct laryngoscopy under general anesthesia with multiple biopsies of the tongue base and vocal cords, along with adenoidectomy, was performed.

Histopathological examination demonstrated caseating granulomatous inflammation involving the entire Waldeyer's ring and the vocal cords, confirming pseudotumoral pharyngolaryngeal tuberculosis.

Antituberculous therapy resulted in marked clinical improvement and symptom resolution.

CONCLUSIONS

Pharyngolaryngeal tuberculosis may present with atypical and misleading features, far from its classical inflammatory presentation, sometimes mimicking a pseudotumoral process suggestive of benign or malignant disease.

This case highlights the importance of considering this diagnosis in any persistent symptomatology resistant to conventional treatment, even in the absence of an obvious tuberculous context.

Acute Airway Obstruction Caused By Bilateral Internal Pyolaryngocele: A Case Report

Dejan Radaljac[1,2], **Svetlana Valjarevic**[1,2], **Rastislav Poljovka**[1]

[1]*Clinical Hospital Center "Zemun", Belgrade: Belgrade, Serbia, RS;* [2]*University of Belgrade – Faculty of Medicine: Belgrade, Serbia, RS*

BACKGROUND & AIM

Laryngocele is a rare air-filled dilation of the laryngeal saccule that communicates with the laryngeal lumen. Infection results in pyolaryngocele, an uncommon but potentially life-threatening condition due to acute airway compromise. Bilateral internal

pyolaryngocele presenting with severe obstruction is exceedingly rare. We report a case requiring emergency airway management followed by definitive surgical treatment.

MATERIAL & METHODS

A 69-year-old female, heavy smoker with controlled hypertension, was admitted in acute respiratory distress preceded by throat pain, dysphagia, and hoarseness of one-day duration. On examination, she had tachypnea, inspiratory stridor, and atrial fibrillation with ventricular response of 150 bpm (blood pressure 140/80 mmHg). Indirect laryngoscopy revealed a large erythematous supraglottic mass involving the right aryepiglottic and ventricular folds, causing near-complete airway obstruction. Emergency tracheotomy was performed due to failed intubation.

Laboratory findings showed normal leukocyte count (7.3×10^9/L) with granulocytosis (79.8%) and mildly elevated C-reactive protein (10.3 mg/L). Contrast-enhanced CT demonstrated bilateral supraglottic fluid collections with thick enhancing walls (largest 43.8×23.5 mm), intralesional gas bubbles, and marked airway narrowing. On the first hospital day, direct laryngoscopy with incision and drainage was performed. Culture revealed methicillin-resistant coagulase-negative Staphylococcus. Histopathology excluded malignancy.

RESULTS

After resolution of infection, MRI confirmed bilateral internal laryngocele, larger on the right. Definitive treatment consisted of endolaryngeal excision combined with external laryngofissure on the right side, with additional type III cordectomy due to vocal cord edema and leukoplakia. Final histopathology confirmed laryngocele without dysplasia or malignancy.Recovery was uneventful. At one-year follow-up, clinical examination and CT showed no recurrence. Voice quality was satisfactory, and the contralateral laryngocele remained asymptomatic.

CONCLUSIONS

Bilateral internal pyolaryngocele is a rare but potentially fatal cause of acute airway obstruction. Rapid airway control and staged surgical management are essential for favorable outcome.

Ultrasound-Guided Botulinum Toxin Injection As An Alternative Approach In Adductor Spasmodic Dysphonia: A Case Report

Inga Katutienė[1], **Monika Srėbaliūtė**[1], **Jurgita Snapkauskienė**[1]

[1]*Klaipeda University Hospital*

BACKGROUND & AIM

Spasmodic dysphonia is a chronic focal dystonia affecting the intrinsic musculature of the larynx during speech production, most commonly presenting as the adductor type. Botulinum toxin injection into hyperactive laryngeal muscles is currently considered the gold standard treatment, most often performed under electromyographic guidance. Ultrasonography has been introduced as a supportive modality, allowing real-time visualization of laryngeal structures and potentially improving procedural accuracy and safety. This report aims to demonstrate the feasibility of ultrasound-guided botulinum toxin injection in a patient unable to tolerate standard techniques, such as EMG-guided or endoscopic approaches.

MATERIAL & METHODS

We present a case report from the Department of Otorhinolaryngology at Klaipeda University Hospital of a 76-year-old female with a two-year history of dysphonia following severe psychological trauma. The patient reported transient voice improvement during crying. Neurological evaluation and brain MRI were unremarkable, and pharmacological treatment, including benzodiazepines and gabapentin, was ineffective. A prior fibroendoscopic examination resulted in syncope, limiting standard approaches.

Laryngeal assessment with topical 2% lidocaine revealed vocal fold tremor and uncoordinated movements with a spasmodic component. Due to intolerance of endoscopy, an ultrasound-guided technique was selected.

The procedure was performed in a supine position under local anesthesia. Each vocal fold was accessed via paramedian puncture through the cricothyroid membrane. Ultrasound imaging enabled identification of the thyroarytenoid muscle, with phonation assisting target localization. A needle was advanced under continuous visualization, and 2 U of botulinum toxin was injected into each thyroarytenoid muscle. The procedure was well tolerated, with no complications.

RESULTS

Outcome was assessed based on subjective voice improvement during the one-month follow-up, at which the patient reported significant voice improvement and easier phonation, with a one-week episode of dysphagia.

CONCLUSIONS

This case suggests ultrasound guidance is a feasible alternative in selected patients, however, interpretation is limited by the single-case design and short follow-up.

SUBMANDIBULAR SIALADENITIS PRESENTING WITH LARYNGEAL EDEMA: A CASE REPORT

Mustafa Çetin[1], **Gizem Karaca Çıkrıkçı**[1], **Melikşah Çakır**[1]

[1]*Kocaeli Cıty Hospital*

BACKGROUND & AIM

Laryngeal edema is a potentially life-threatening condition requiring prompt evaluation due to its impact on the upper airway. Although commonly associated with infectious, inflammatory, and neoplastic etiologies, pathologies originating from adjacent anatomical structures may mimic similar clinical and radiological findings. This study aims to present a rare case of laryngeal edema secondary to submandibular sialadenitis and to highlight the importance of comprehensive diagnostic evaluation.

MATERIAL & METHODS

A 64-year-old male presenting with acute throat discomfort was evaluated through clinical examination, radiological imaging, and endoscopic assessment. Contrast-enhanced Computed Tomography (CT) and Magnetic Resonance Imaging (MRI) were performed. Flexible fiberoptic nasopharyngolaryngoscopy was used for detailed laryngeal visualization. The patient received medical treatment, and clinical progression was monitored.

RESULTS

The patient presented with acute onset foreign body sensation, dysphagia, localized swelling, and orthopnea, following a recent upper respiratory tract infection. Physical examination revealed tenderness in the left submandibular region without stridor. CT demonstrated bilateral glandular enlargement and a mass-like lesion at the left aryepiglottic fold causing airway narrowing, raising suspicion for malignancy. However, endoscopy revealed diffuse edema of the aryepiglottic folds without a solid mass. MRI showed T2 hyperintensity and contrast enhancement in the submandibular gland, consistent with inflammation. Following intravenous antibiotics and systemic corticosteroids, clinical and endoscopic findings improved markedly, and the patient was discharged after one week.

CONCLUSIONS

Laryngeal edema may mimic malignancy, particularly when imaging suggests a mass effect. However, inflammatory conditions such as submandibular sialadenitis should be considered. Combined use of endoscopy and MRI is essential for accurate diagnosis and appropriate management.

KEYWORDS
Laryngeal edema, Submandibular sialadenitis, Orthopnea

FOREIGN BODY IN THE LARYNX: A 6 CM CHICKEN BONE.

Mustafa Eser[1], **Bilge Nur Küçükakça**[2]

[1]*Sultan Abdülhamid Han Training and Research Hospital, Ear, Nose and Throat Diseases, Istanbul, Turkiye;* [2]*Sancaktepe Ilhan Varank Training and Research Hospital, Ear, Nose and Throat Diseases, Istanbul, Turkiye*

BACKGROUND & AIM

Laryngotracheal foreign body aspiration is a medical emergency, and mortality may be inevitable if not promptly diagnosed and treated. Diagnosis can be established through clinical history, physical examination, endoscopic evaluation, and radiological imaging . This case report presents the diagnosis, treatment, and follow-up processes of a 59-year-old male patient who presented to our clinic with a sensation of a foreign body in the throat.

MATERIAL & METHODS

A 59-year-old male patient presented to our emergency department with a sensation of a foreign body in the throat following a meal the previous day.. Upon admission, his general condition was good, he was hemodynamically stable, oriented, and cooperative. Inspection revealed no foreign body in the oropharynx. Indirect laryngoscopy showed a foreign body (chicken bone) in the right piriform sinus and edema in the ventricular band. Saturation values and breath sounds were normal during admission and follow-up. The patient underwent emergency surgery.

RESULTS

Due to the size of the removed foreign body and the generalization of laryngeal edema during the perioperative period, it was decided to intubate the patient in the intensive care unit. The patient, who was monitored intubated for three days, was transferred to our ward after the laryngeal edema subsided due to the removal of the foreign body and the effects of medical treatments. Endoscopic examinations performed during the follow-up period in our ward revealed that the patient had mobile bilateral vocal cords and adequate rima glottis patency, and it was decided to discharge the patient.

CONCLUSIONS

In cases of delayed diagnosis, serious complications such as laryngeal edema, obstruction, aspiration pneumonia, and rarely sudden death may occur. Therefore, early diagnosis and appropriate airway management play a critical role in reducing mortality and morbidity. This case contributes to the literature by highlighting the atypical presentations of large-volume laryngeal foreign bodies with silent progression and demonstrating the need for careful differential diagnosis.

Idiopathic Subglottic Stenosis: A Case Review With Serial Endoscopic Management And Follow-Up

Ervin Dyrmishi[1], **Birkena Qirjazi**[1]

[1]*Mother Theresa University Hospital, Tirana, Albania*

BACKGROUND & AIM

Idiopathic subglottic stenosis (iSGS) is a rare, progressive narrowing of the airway below the vocal cords, with no identifiable etiology. It predominantly affects females and often presents with dyspnea, misdiagnosed initially as asthma. This case review aims to describe the diagnostic pathway, multidisciplinary evaluation, and longitudinal endoscopic management of a young female patient with iSGS, emphasizing recurrence patterns and therapeutic response.

MATERIAL & METHODS

A 26-year-old Albanian female with a history of Hashimoto's thyroiditis and chronic sinusitis reported a sudden onset of exertional dyspnea and stridor in October 2022. Initially misdiagnosed with asthma, partial corticosteroid responsiveness led to further investigation. Flexible laryngoscopy identified subglottic stenosis. Over two years, the patient underwent three microlaryngoscopic procedures (MLSD) with radial incisions, balloon dilations, and corticosteroid (Kenacort/Triacort) infiltration. Stenosis grade was monitored via Myer-Cotton and ELS classification, with progression documented clinically and endoscopically. Follow-ups included rheumatological screening, NBI endoscopy, and quality-of-life evaluations. Outcome measures were symptom recurrence, stenosis grade, and need for re-intervention.

RESULTS

Initial stenosis was Grade III (Myer-Cotton). After the first dilation in April 2023, partial improvement was noted, though recurrent symptoms (apnea, exertional dyspnea, cough) returned. Repeat endoscopic interventions in October 2023 and November 2024 were required due to recurrence of Grade II–III stenosis and posterior granulomas. The most recent evaluation in May 2025 showed partial symptom control with persistent but stable stenosis. No systemic autoimmune disease was identified. Rheumatologic referral and Rituximab therapy were proposed in light of repeated restenosis.

CONCLUSIONS

This case highlights the chronic and relapsing nature of iSGS in a young female patient. Endoscopic dilation with corticosteroid injection remains the mainstay of treatment, offering temporary symptom relief. However, recurrent disease may warrant systemic immunomodulatory therapy. Long-term follow-up and interdisciplinary collaboration are essential to guide personalized care and prevent progression. Rituximab use in iSGS needs to have a closer follow up to determine the possibility of including in treatment guidelines.

Spontaneous Anterior Arytenoid Dislocation Following Severe Cough: A Diagnostic Challenge

Ömer Erdur[1], **Furkan Gürsul**[1]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, Selçuk University Faculty of Medicine, Konya, Turkey*

BACKGROUND & AIM

Arytenoid subluxation most commonly results from endotracheal intubation or direct laryngeal trauma. Mechanical injury during intubation may cause mucosal damage, hematoma, and capsular laxity, compromising cricoarytenoid joint stability and leading to subluxation or dislocation. While transient postoperative hoarseness typically resolves within 24–48 hours, more severe laryngeal injuries may cause persistent dysphonia. Subluxation without a history of intubation or trauma is rare but has been reported after forceful coughing due to sudden increases in intralaryngeal pressure. Such cases are often misdiagnosed as recurrent laryngeal nerve paralysis. Careful history, endoscopy, CT, laryngeal EMG are essential for accurate diagnosis and early management.

MATERIAL & METHODS

This study presents a single-case evaluation of a 33-year-old male who developed persistent hoarseness and dysphagia following a severe coughing episode. A detailed medical history was obtained, and comprehensive otorhinolaryngological

examination was performed. Laryngeal assessment was conducted using flexible fiberoptic endoscopic stroboscopy to evaluate vocal fold mobility, glottic closure, and arytenoid cartilage position.

To exclude recurrent laryngeal nerve paralysis and identify structural abnormalities, contrast-enhanced neck computed tomography (CT) and magnetic resonance imaging (MRI) were performed. Arytenoid alignment, vocal cord position, piriform sinus symmetry, and the presence of hematoma or mass lesions were assessed. Based on combined clinical, endoscopic, and radiological findings, anterior arytenoid dislocation was diagnosed. Closed arytenoid reduction under general anesthesia without endotracheal intubation was planned.

RESULTS

Even in the absence of a history of intubation, arytenoid dislocation should be considered in patients presenting with persistent hoarseness following severe coughing. Early diagnosis and appropriate surgical intervention are crucial for optimal functional recovery.

CONCLUSIONS

Arytenoid dislocation most commonly occurs following traumatic endotracheal intubation; however, it may rarely develop after severe coughing, vomiting, or blunt laryngeal trauma. A sudden increase in intralaryngeal pressure during forceful coughing can disrupt cricoarytenoid joint stability, leading to dislocation. Differentiating arytenoid dislocation from recurrent laryngeal nerve paralysis is essential, as management strategies differ significantly. Preserved vocal fold mobility and radiologic confirmation of displacement are key diagnostic findings. Delayed diagnosis may result in cricoarytenoid joint fibrosis, thereby reducing the success rate of closed reduction

Once You See It, You Cannot Unsee It: Bamboo Nodes As A Laryngoscopic 'Spot Diagnosis' For Autoimmune Disorders

DANIEL ALBERTO NUÑEZ CARLINO[1], **JAIME SANABRIA BRASSART**[1], **ARALY CHACÓN URIBE**[1], **MARTA SANTIAGO HORCAJADA**[1], **ROCIO CARPINTERO DIAZ**[1], **JOSE MIGUEL VILLACAMPA AUBÁ**[1]

[1]*HOSPITAL UNIVERSITARIO "FUNDACIÓN JIMÉNEZ DÍAZ"*

BACKGROUND & AIM

Bamboo nodes (BNs) are highly specific laryngoscopic lesions considered a pathognomonic sign of systemic autoimmune disease (AD), especially connective tissue diseases. BNs may be the initial manifestation of AD, often preceding the diagnosis. BNs almost exclusively affect women, typically presenting between 35 and 45 years old. First described by Hosako-Naito in 1993, BNs are distinguished from common vocal nodules by their arrangement: yellow transverse subepithelial bands, perpendicular to the longitudinal axis of the vocal fold, mimicking the nodes of a bamboo stalk. Their visual identification is definitive; therefore, we present a case report and high-quality images of the laryngoscopic findings.

MATERIAL & METHODS

This case report describes a 39-year-old woman with a long history of systemic lupus erythematosus and Sjogren's syndrome, who developed dysphonia in the last 8 months. The patient had no history of vocal abuse. Initial assessment via the Voice Handicap Index revealed severe self-perceived vocal impairment. Laryngoscopic examination identified bilateral, yellowish, asymmetric glottic lesions oriented perpendicularly to the longitudinal axis of the vocal folds. A rigid laryngeal stroboscopy was performed, further characterizing these lesions, which appeared as subepithelial bands located on the superior membranous surface of both vocal folds. Although these lesions did not make contact and vocal fold mobility remained preserved, they significantly disrupted the mucosal wave, resulting in a glottic hiatus. The functional impact was corroborated by aerodynamic vocal assessment.

RESULTS

Patient management consisted of a multidisciplinary approach involving phonatory rehabilitation and pharmacological adjustment of the underlying autoimmune condition. While the patient demonstrated functional improvement, the laryngeal lesions persisted.

CONCLUSIONS

BNs represent a distinctive laryngoscopic diagnosis that, once recognized, becomes unmistakable in subsequent encounters. Visual recognition carries significant clinical utility, enabling timely referral and early diagnosis of underlying ADs, potentially before systemic manifestations become apparent. BNs represent a clinical marker of immunological activity and require a multidisciplinary approach to optimize both the control of the underlying disease and phonatory function.

Acquired Tracheal Stenosis Following Prolonged Intubation: A Five-Year Single-Center Experience

Messaoudi[1]

[1]*ENT Department, Mohamed Boudiaf Hospital, University Of Kasdi Merbah.*

BACKGROUND & AIM

Acquired tracheal stenosis remains a challenging condition in otolaryngology, most commonly resulting from prolonged endotracheal intubation. Despite advances in intensive care practices, its incidence persists. This study aims to analyze the epidemiological, clinical, radiological, and therapeutic characteristics of tracheal stenosis in a single-center experience.

MATERIAL & METHODS

We conducted a prospective study over five years including nine patients treated for acquired tracheal stenosis. All patients underwent preoperative upper airway endoscopy and cervical computed tomography (CT), including three-dimensional reconstruction when available. Data collected included etiology, duration of intubation, clinical presentation, imaging findings, and therapeutic management.

RESULTS

The mean age was 24 years with a male predominance (sex ratio 8:1). The main etiology was prolonged intubation following trauma (7 cases), with a mean intubation duration of 20 days. Dyspnea was the most common presenting symptom (70%), followed by acute respiratory distress (15%). Imaging revealed circumferential tracheal stenosis at levels C4–C6 in all patients, with an average length of 20 mm and lumen reduction of 50–60%. One patient presented with an associated tracheoesophageal fistula. Surgical management consisted of tracheal resection with end-to-end anastomosis in eight patients and bronchoscopic dilation with stenting in one case. Postoperative outcomes were favorable in all patients, with a mean hospital stay of 10 days and no major complications.

CONCLUSIONS

Acquired tracheal stenosis remains predominantly iatrogenic and requires early recognition. Surgical resection-anastomosis provides excellent outcomes in selected patients. Preventive strategies, including careful airway management and minimizing intubation duration, are essential to reduce incidence.

Our Direct Laryngoscopy Experiences From The Perspective Of A Tertiary Care Specialist

Ümmü Gülsüm Yıldız[1], **Muhammet Fatih GÖKMEN**[1]

[1]*Selcuk University, Medical School, ENT Department*

BACKGROUND & AIM

Direct laryngoscopy(DL) remains the gold standard for the diagnosis and treatment of laryngeal pathologies. The indications range from brief examinations lasting seconds to tumor surgeries lasting hours. This study aimed to retrospectively evaluate the demographic characteristics, indications for surgery, histopathological results, and developing complications in patients undergoing DL.

MATERIAL & METHODS

A total of 123 patients (113 adults, 10 pediatric) who underwent DL at our hospital were included in the study. All operations were performed by the same senior surgeon. Patient age, gender, smoking history, occupation, comorbidities, indication of surgery, laryngoscope sizes, difficulty levels of laryngeal exposure (easy/moderate/difficult), pathology results, and perioperative and postoperative complications were recorded.

RESULTS

The mean age of the study group was 54.78 years, with 69.9% (n=86) being male. The most common indication was for surgery benign lesions (47.1%), followed by suspicion of malignancy (39%), evaluating laryngeal stenosis and general examination (9.75%) and intralaryngeal injection (%4,06). Histopathological examination revealed premalignant or malignant findings in 26.8% (n=33) of patients (18 squamous cell carcinoma, 13 dysplasia, 1 leiomyosarcoma). All patients diagnosed with malignancy had a history of smoking. Large-sized laryngoscopes were used in 27.6% (n=34) of patients, medium-sized in 64.2% (n=79), and small-sized in 8.1% (n=10) during surgery. Regarding laryngeal exposure, easy exposure was achieved in 83.7% (n=103) of patients, while moderate and difficult exposure were observed in 4% (n=5) and 12.1% (n=15), respectively. Complications included intraoperative bradycardia and emergency tracheotomy in one pediatric patient, transient cardiac arrest in three patients, and a cerebrovascular accident resulting in postoperative exitus in one patient.

CONCLUSIONS

Direct laryngoscopy remains the gold standard for the diagnosis and treatment of laryngeal pathologies. However, it is crucial to recognize the potential for serious complications, particularly in individuals with systemic comorbidities and in cases of

difficult exposure. The high rate of malignancy detection in patients with a history of smoking highlights the necessity for meticulous evaluation in this specific group.

A Silent Complication Of Central Venous Catheterization

Ana Raquel Andrade[1], **Luciana Rodrigues**[1], **Miguel C. Lopes**[1], **Diogo Nascimento**[1], **Maria Inês Ribeiro**[1], **Hugo Amorim**[1], **Paulo Gonçalves**[1]

[1]*Unidade Local De Saúde Entre Douro E Vouga*

BACKGROUND & AIM

Unilateral vocal fold paralysis (UVFP) has a broad differential diagnosis, including neoplastic, surgical, neurological, and iatrogenic causes. Central venous catheter (CVC) placement is a rare etiology, with few reported cases linking catheter-related internal jugular vein (IJV) thrombosis to recurrent laryngeal nerve (RLN) dysfunction. The proposed mechanisms include local inflammatory response, venous congestion, and compressive neuropathy within the carotid space. We report a case of UVFP following CVC-associated IJV thrombosis and discuss the underlying pathophysiological considerations.

MATERIAL & METHODS

Case report of an oncologic patient who developed acute dysphonia after CVC placement. Clinical assessment, flexible nasofibrolaryngoscopy, and imaging studies were performed to evaluate vocal fold mobility and exclude structural, compressive, or neoplastic causes. A review of the literature was conducted to contextualize the proposed mechanism.

RESULTS

A male patient with active malignancy underwent CVC insertion in the internal jugular vein for systemic therapy. The procedure was complicated by ipsilateral catheter-related thrombosis. Shortly thereafter, the patient developed acute dysphonia.

Endoscopic examination demonstrated unilateral vocal fold paralysis consistent with RLN dysfunction. Cross-sectional imaging excluded tumor progression or mass effect. Given the anatomical proximity of the IJV, vagus nerve, and RLN within the carotid sheath, the thrombosis was considered the most plausible etiological mechanism, likely secondary to local inflammatory edema and compressive neuropathy.

During follow-up, vocal fold immobility persisted. However, the patient achieved adequate phonatory compensation without clinically significant glottic insufficiency. No surgical medialization was required, and conservative management was maintained.

CONCLUSIONS

Catheter-related IJV thrombosis represents a rare but plausible cause of unilateral vocal fold paralysis due to the intimate anatomical relationship between the venous system and the vagal–recurrent laryngeal nerve axis within the carotid space. Early endoscopic evaluation is essential in patients presenting with dysphonia after CVC placement. In the absence of significant functional impairment, conservative management may be appropriate.

Retropharyngeal Abscess Secondary To Cervical Spondilodiscitis Case Report

Fatih Turhan[1], **Ahmet Baki**[1], **Özgür Yiğit**[1]

[1]*Başakşehir Pine and Sakura City Hospital*

BACKGROUND & AIM

Retropharyngeal abscess is presenting with fever, posterior pharyngeal edema, drooling, stridor, trismus and sore throat. This infection lead to complications like upper airway obstruction and mediastinitis. We will examine a 52-year-old male patient who presented with complaints of sore throat that was unresponsive to antibiotics for 20 days, limited oral intake, dyspnea and loss of strength in the right side extremities.

MATERIAL & METHODS

Contrast neck CT revealed a 40*32 mm abscess in the retropharyngeal space. Endoscopy showed distension in posterior hypopharynx and airway narrowing. Emergency abscess drainage was planned. 15 cc of abscess was drained an incision in the posterior pharyngeal wall in Trendelenburg position. The patient was followed up in the ward with IV antibiotherapy. Persistence of swelling in the posterior hypopharynx and weakness in the right side extremities led to contrast neck CT and cervical MRI scans. Although it has regressed compared to the previous these showed a 1,5 cm residual collection, and irregularities in the intervertebral spaces at the level of the C5-C6 vertebrae adjacent to the prevertebral loculation, along with

spondylodiscitis. Suspected that the abscess had progressed from the prevertebral area to the retropharyngeal and retrolaryngeal spaces, complicating with destruction of the vertebrae. Second procedure, including abscess drainage and cervical decompression with the involvement of neurosurgery, was planned.

RESULTS

The patient underwent cervical decompression by neurosurgery. The patient was placed in the Trendelenburg position and abscess drainage was initiated. 5 cc of purulent material was drained by incision through along old incision line. After control exploration no additional abscess material was found. Followed in the ward with intravenous antibiotherapy immobilized, and wearing a neck brace. Control flexible endoscopy showed endolaryngeal structures with symmetrical natural airway, pain decreased, improvement in muscle strength and normally oral feeding started. The patient was discharged two weeks after the second surgery due to a reduction in symptoms.

CONCLUSIONS

There are various treatment options for retropharyngeal abscesses, surgical drainage and follow-up with antibiotherapy are prominent. Retropharyngeal abscesses larger than 2 cm should be drained without delay. In our case, we observed that the patient's clinical condition improved after transoral surgical abscess drainage, and no complications were encountered during follow-up.

PP-366

Impact Of Prompt Strategy And Clinical Complexity On Large Language Model Performance In Otolaryngology Practice

Samantha Mairesse[1], **Jérôme Lechien**[1], **Meriem Miri**[1], **Lise Sogalow**[1], **Louis Victoor**[1]

[1]*Department of Surgery, University of Mons (UMONS), Belgium*

BACKGROUND & AIM

An emerging body of literature supports the accuracy of large language models (LLMs) as adjunctive tools for clinical decision-making. However, data remain limited regarding the impact of prompt formulation and clinical case complexity on LLM performance in clinical practice.

The aim is to investigate the impact of prompt type and clinical case complexity on LLM performance.

MATERIAL & METHODS

Clinical information from 120 consecutive otolaryngological outpatient consultations, stratified as simple, moderate, and difficult cases, was input into the APIs of ChatGPT-5, Claude-Sonnet-4.5, and Google Gemini-2.5-Pro. Two prompt strategies were used: a structured physician-oriented prompt and an unstructured patient-oriented prompt. Outputs were independently evaluated by practitioners using the Artificial Intelligence Performance Instrument (AIPI) in a blinded manner. Inter-rater reliability was assessed using the intraclass correlation coefficient (ICC). Statistical analyses evaluated the influence of model type, prompt strategy, and case complexity on performance.

RESULTS

LLM performance differed significantly by model type (AIPI total: $p<0.001$), prompt strategy ($p=0.038$), and clinical complexity ($p=0.004$). Claude-Sonnet-4.5 achieved the highest mean total AIPI score (11.94±1.71), followed by Google Gemini-2.5-Pro (11.62 ± 1.58) and ChatGPT-5 (10.41 ± 1.41). Physician-oriented prompts were associated with higher scores for medical history, symptoms, and physical examination (all $p \leq 0.008$). In contrast, patient-oriented prompts yielded higher differential diagnosis scores (0.88±0.68 vs. 0.28±0.38, $p<0.001$) and higher management and additional examination scores, resulting in a higher total AIPI score (11.60±2.40 vs. 11.05±1.84, $p=0.038$). Diagnostic accuracy decreased with increasing clinical complexity (primary diagnosis score: 1.99 ± 0.82 vs. 2.28 ± 0.77, $p<0.001$), while additional examination scores increased (1.90 ± 1.35 vs. 1.48 ± 1.42, $p<0.001$). Inter-rater reliability was excellent (ICC=0.851).

CONCLUSIONS

The LLM performance is significantly influenced by prompt formulation and clinical complexity, underscoring the importance of careful prompt design and contextualization when using LLMs in clinical practice.

PP-367

Supraglottic Laryngeal Cyst: A Case Report Mimicking A Mass Lesion

Utku Demir[1], **Dilara Ülkü İlbas Aydın**[1], **Mikail Akıs**[1], **Zehra Betül Paksoy**[1]

[1]*Department of Otorhinolaryngology, Ankara Bilkent City Hospital, Ankara, Turkey*

BACKGROUND & AIM

Background

Laryngeal cysts are rare benign lesions arising from the laryngeal mucosa. Their clinical presentation varies depending on size and anatomical location. Supraglottic cysts, particularly saccular types, may lead to airway obstruction and voice changes. Radiological imaging, especially computed tomography (CT), is valuable in lesion evaluation; however, it may not reliably differentiate cystic lesions from solid masses, potentially leading to misdiagnosis as malignancy.

Aim

To present a case of a supraglottic laryngeal cyst that mimicked a solid mass on radiological imaging and to emphasize the importance of endoscopic evaluation in establishing a definitive diagnosis.

MATERIAL & METHODS

A 63-year-old female patient presented with a 2.5-month history of progressive hoarseness and a history of active smoking. Endoscopic examination and neck CT imaging were performed. The patient subsequently underwent direct laryngoscopy for diagnostic and therapeutic purposes. The excised lesion was evaluated histopathologically.

RESULTS

Results

Endoscopic examination revealed a mass lesion originating from the right ventricular band, with preserved bilateral vocal cord mobility. CT imaging demonstrated a 23 mm solid-appearing lesion in the right supraglottic region extending to the vallecula, obliterating the piriform sinus and narrowing the airway.

Intraoperatively, the lesion was identified as a cyst located over the right arytenoid and aryepiglottic fold. The lesion was completely excised, and seromucoid content was observed. Histopathological examination confirmed a laryngeal cyst. The postoperative course was uneventful, with preserved vocal cord function and good healing.

CONCLUSIONS

Conclusions

Supraglottic laryngeal cysts, although rare, may mimic malignant masses both clinically and radiologically. Accurate diagnosis requires endoscopic evaluation and histopathological confirmation. Early surgical intervention provides excellent outcomes. These lesions should be considered in the differential diagnosis of supraglottic masses, particularly in patients with risk factors such as smoking.

PP-368

Warfarin-Associated Sublingual And Laryngeal Hematoma: A Case Report

Ramazan GÜNDOĞDU[1], **Enes ASLAN**[1]

[1]*kocaeli city hospital*

BACKGROUND & AIM

Sublingual hematoma is a rare but potentially life-threatening condition due to the risk of rapid upper airway compromise, particularly in patients receiving anticoagulant therapy. Prompt recognition and close airway monitoring are essential in order to prevent respiratory deterioration and the need for emergent surgical airway intervention.

MATERIAL & METHODS

A 31-year-old male patient presented to the emergency department with progressive swelling involving the sublingual region that had developed in the morning and gradually increased throughout the day. The patient had a history of aortic valve replacement surgery performed in 2018 and had been receiving long-term warfarin therapy thereafter. One week prior to admission, the patient experienced an upper respiratory tract infection accompanied by persistent severe coughing episodes.

Flexible nasopharyngolaryngoscopic examination demonstrated a hematoma involving the sublingual region (figure 1), extending toward the vallecula and causing mild posterior displacement of the epiglottis (figure 2). Needle aspiration of the sublingual hematoma was attempted; however, no material could be aspirated. Physical examination additionally revealed diffuse swelling in the left cervical region.

RESULTS

Laboratory investigations performed in the emergency department revealed a markedly elevated international normalized ratio (ınr) value of 16. Following administration of human prothrombin complex concentrate, the ınr level decreased to 1. The patient was subsequently admitted to the department of otorhinolaryngology for close observation and airway monitoring.

Daily flexible endoscopic examinations and continuous oxygen saturation monitoring were performed throughout hospitalization. Consultation with the cardiology department was requested for optimization and re-adjustment of anticoagulant therapy. Intravenous prednisolone (250 mg/day) was initiated on the first day of hospitalization, and broad-spectrum antibiotic therapy was maintained during the entire admission period.

Progressive clinical improvement was observed under conservative medical management. On the fourth day of hospitalization, the patient was discharged with stable oxygen saturation levels (95% on room air), an ınr value of 1.09, and revised anticoagulant and antibiotic treatment recommendations.

CONCLUSIONS

Sublingual and laryngeal hematomas may occur spontaneously or secondary to persistent coughing in patients receiving anticoagulant therapy, particularly in cases of excessive anticoagulation. These hematomas may rapidly progress and result in life-threatening airway compromise.

Once airway patency has been secured, prompt correction of coagulation abnormalities and close inpatient observation are of critical importance. Clinicians should remain aware that emergent airway intervention, including tracheotomy, may become necessary in patients demonstrating progressive airway obstruction despite conservative management.

KEYWORDS

hematoma, sublingual, warfarin, ınr

PP-369

Myofibroblastic Tumor Of The Larynx: An Uncommon Case Report In Private Practice

Hut Alexandru[1,3], **Bembea Dan**[1,2], **Bembea Serban**[1]

[1]*MEDETIL SRL;* [2]*Department of Preclinical Disciplines, Faculty of Medicine and Pharmacy, University of Oradea, 1 December Sq., 410081 Oradea, Romania.;* [3]*Department of Doctoral Studies, "Victor Babes" University of Medicine and Pharmacy Timisoara, Eftimie Murgu Square No. 2, 300041 Timisoara, Romania.*

BACKGROUND & AIM

Myofibroblastic tumors in the larynx are rare, with limited documented instances. Despite being classified as a benign tumor, it demonstrates notable inflammatory features, local destruction, and the possibility of degeneration into malignant histological types with metastatic potential. The differential diagnosis in anatomopathological is crucial in these cases.1 Inflammatory myofibroblastic tumor is typically a benign neoplasm of mesenchymal origin, with infrequent occurrence in the larynx. This case examines the distinctive laryngeal location and presentation of the tumor, along with the complex radiographic and histologic findings.2

MATERIAL & METHODS

A solid mass from the right true membranous vocal fold was excised and submitted for histopathological evaluation. The characteristics of the surgical specimens were indicative of IMT(Inflammatory myofibroblastic tumor). Intravenous steroid therapy was selected as an adjunct treatment.

Panendoscopy enabled monitoring for any further or recurring lesions, and a nodule was identified in the anterior third of the right vocal cord. Follow-up MRI will be assessed at 6 months post-excision and we recommend laser Co2 a subepithelial cordectomy for treatment of nodule.

RESULTS

While uncommon, laryngeal inflammatory myofibroblastic tumor should be considered in patients presenting with hoarseness attributed to a vocal fold mass. Our findings indicate that the combination of surgical excision and steroids therapy may serve as an effective treatment strategy for this rare tumor.

CONCLUSIONS

Inflammatory myofibroblastic tumors (IMTs) rarely involve the larynx; however, they should be considered in the differential diagnosis of laryngeal lesions. Notably, IMTs may clinically and histopathologically mimic malignant neoplasms or recurrent respiratory papillomatosis, posing a potential diagnostic challenge.Further research is necessary to clarify the most effective, safe, and cost-efficient treatment strategies.

Diagnostic Algorithm For Eustachian Tube Dysfunction And Indications For Balloon Dilation Of The Eustachian Tube

Marta Sandoval[1], **Krittayot Patchanee**[2,3], **In Seok Moon**[2]

[1]*Department of Otolaryngology, Hospital Clínic Barcelona, Universitat de Barcelona (UB), Barcelona, Spain;* [2]*Department of Otorhinolaryngology, Severance Hospital, Yonsei University College of Medicine, Seoul, Korea;* [3]*Department of Otolaryngology, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand*

BACKGROUND & AIM

This review outlines a standardized diagnostic algorithm, specific indications, and cautions to ensure safe and effective Balloon Dilation of the Eustachian Tube (BDET) for patients with dilatory dysfunction.

MATERIAL & METHODS

A comprehensive review of current literature and consensus statements was conducted to establish adiagnostic framework for obstructive Eustachiantube dysfunction (oETD) including clinical findings, objective tests, and indication for BDET in various conditions.

RESULTS

The diagnostic algorithm for oETD prioritizes the exclusion of differential diagnoses such as patulous Eustachian tube dysfunction (pETD), temporomandibular joint disorders, and superior canal dehiscence. Objective tests in combination of patient-reported outcome measures aid in diagnosis when clinical findings alone is equivocal. BDET is indicated for barotraumatic Eustachian tube dysfunction, chronic otitis media with effusion, and tympanic membrane retraction pockets following the failure of appropriate medical management. BDET may serve as an effective adjunct to tympanoplasty for adhesive otitis media. Cautions include pETD and significant anatomical distortions of the Eustachian tube.

CONCLUSIONS

BDET offers a promising solution for chronic oETD but mandates rigorous patient selection. Adherence to a structured diagnostic algorithm that combines subjective symptoms with objective testing is paramount to establishing the correct diagnosis, monitoring disease severity, and ensuring therapeutic success.

Labyrinthitis Ossificans As A Delayed Sequela Of Tympanoplasty: A Case Report And Review Of The Literature

Abdulwahab Alyahya[1], **Mohammed Alsaif**[2], **Abdulaziz Alshaiji**[1], **Lana Saleh**[1], **Aminah Alhashem**[1]

[1]Department of Otolaryngology - Head and Neck Surgery, King Fahad Hospital of University, Al-khobar, Saudi Arabia; [2]College of Medicine, King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia

BACKGROUND & AIM

Labyrinthitis ossificans (LO) is an uncommon condition arising from infections, autoimmune disease, trauma, or other causes, leading to progressive fibrosis and ossification of the membranous labyrinth. It typically presents with sensorineural hearing loss and vertigo, diagnosed via CT and MRI. Once considered a contraindication, cochlear implantation (CI) in LO is now feasible due to advances in electrode design and surgical techniques, though it remains technically demanding. Surgical approaches vary based on ossification extent, ranging from round window drilling to complete drill-out procedures. Outcomes are variable, with limited cases reporting successful results, highlighting the need for further documentation.

MATERIAL & METHODS

This clinical investigation was conducted in accordance and compliance with guidelines of the Institutional Review Board (IRB) of King Fahad Hospital of University, Al-khobar, Saudi Arabia, with appropriate consent from the patient. Our review of the literature was based on PubMed search from 1977 to 2026. We identified 22 previously reported cases of labyrinthitis ossificans across a wide range of etiologies.

RESULTS

A 41-year-old woman developed left-sided profound sensorineural hearing loss and distressing tinnitus six months after tympanoplasty, with no improvement on oral steroids. CT and MRI of the temporal bone revealed focal ossification in the basal turn of the left cochlea, confirming labyrinthitis ossificans. She opted for cochlear implantation after a bone-anchored hearing aid failed to relieve her tinnitus. Intraoperatively, complete basal turn ossification necessitated an extended round window approach with separate cochleostomy, achieving full electrode insertion. Postoperatively, her tinnitus resolved completely upon device activation, with aided hearing thresholds around 30 dB.

CONCLUSIONS

Despite being uncommon, labyrinthitis ossificans has a critical effect on the patients' quality of life. It is crucial to have a thorough discussion with each patient regarding the risks and benefits of the different available management options, as their main concern may not be revolving around restoring the hearing level only but relieving other symptoms. In these cases, offering CI may dramatically improve the patient's life, however, patients should be properly educated about the possibility of failure of implantation ahead of time.

PP-372

Clinical Review Of Tympanic Membrane Healing And Postoperative Audiological Outcomes After Patch, Fat, And Butterfly Myringoplasty

Murat Şahan[1]

[1]Sancaktepe Şehit Prof Dr İlhan Varank Training and Research Hospital

BACKGROUND & AIM

Tympanic membrane perforations are commonly encountered in otorhinolaryngology practice and may lead to hearing loss and recurrent infections. Various minimally invasive techniques such as patch, fat, and butterfly myringoplasty are widely used for small and medium-sized perforations. The aim of this study was to evaluate tympanic membrane healing rates and postoperative audiological outcomes following patch, fat, and butterfly myringoplasty procedures.

MATERIAL & METHODS

This retrospective clinical study included patients who underwent patch, fat, or butterfly myringoplasty for tympanic membrane perforation in the Department of Otorhinolaryngology between 2022and 2026Patients were evaluated in ters of demographic characteristics, perforation closure rates, and postoperative audiological outcomes. Preoperative and postoperative pure tone audiometry results, including air-bone gap values, were compared among the groups. Patients with insufficient follow-up data or active middle ear infection were excluded from the study.

RESULTS

Butterfly myringoplasty showed comparatively higher graft success and hearing improvement rates. Statistical analysis revealed that [there was / there was no] significant difference among the groups ($p<0.05$).

CONCLUSIONS

Patch, fat, and butterfly myringoplasty techniques are effective minimally invasive treatment options for tympanic membrane perforations. All three techniques demonstrated satisfactory graft healing and postoperative audiological improvement. Butterfly myringoplasty may provide higher graft success and better hearing outcomes in selected patients. Further prospective studies with larger patient populations are needed to support these findings

PP-373

Pigmentation In The Graft Area After Tympanomastoidectomy: Exogenous Pigment Deposition Mimicking Malignant Melanoma (Case Report)

LEYLA AKBAL[1], **HALİL ERDEM ÖZEL**[1], **MELİKŞAH ÇAKIR**[1]

[1]*Department of Otorhinolaryngology, Kocaeli City Hospital, Kocaeli, Turkey.*

BACKGROUND & AIM

Pigmentation developing in the graft area after middle ear surgery is a rare condition. These pigmentations may clinically mimic malignant melanoma and can pose a diagnostic challenge.

MATERIAL & METHODS

A 50-year-old male chemical engineer, who had undergone tympanomastoidectomy for chronic otitis media 20 years ago, presented with hearing loss. On otoscopic examination, black pigmented areas were observed in the graft area and the external auditory canal mucosa. No pigmentation was detected elsewhere on the body, and the patient had no history of comorbidities. Malignant melanoma and exogenous pigmentation were considered in the differential diagnosis, and a biopsy was obtained from the suspicious lesion (Figure 1). Histopathological examination revealed findings consistent with exogenous brown pigment deposition. No evidence of malignancy was identified.

RESULTS

Exogenous pigmentation may develop due to environmental exposures, occupational contacts, surgical materials, or the accumulation of locally derived external pigments. Although rare, pigmentation observed in the graft area following middle ear surgery often presents as dark, irregular lesions. These characteristics frequently mimic malignant melanoma, leading to significant diagnostic challenges for the clinician. In the differential diagnosis, malignant melanoma must be the primary consideration, alongside hemosiderin accumulation and other exogenous causes. However, clinical and otoscopic findings are often insufficient for a definitive distinction. In this specific case, the patient's profession as a chemical engineer is noteworthy regarding potential occupational exposure; nonetheless, the absence of a reported chemical contact prevents a clear causal link. Despite this, a detailed evaluation of occupational and environmental history remains a vital component of the diagnostic process in similar cases. When clinical findings are inconclusive, histopathological examination is essential to rule out malignancy and confirm the etiology.

CONCLUSIONS

Although rare, pigmentation developing in the graft area after tympanomastoidectomy may mimic malignant melanoma. Therefore, biopsy is required for suspicious pigmented lesions.

Tympanomastoidectomy, pigmentation, malignant melanoma, exogenous pigment

PP-374

Clinical Efficacy Of Outpatient Uses Of MESNA In The Control Of Acquired Cholesteatoma

JOSE RICARDO GURGEL TESTA[1], **ADRIANA PEREZ FERREIRA NETO**[1], **MARCOS LUIZ ANTUNES**[1]

[1]*UNIFESP/ESCOLA PAULISTA DE MEDICINA SAO PAULO BRAZIL*

BACKGROUND & AIM

Introduction: The control of chronic otorrhea refractory to treatment after canal wall down mastoidectomy remains challenging. Persistent mucosal inflammation, cholesteatoma recurrence, and bacterial biofilm formation may contribute to ongoing discharge. Sodium 2-mercaptoethanesulfonate (MESNA) has mucolytic properties, disrupts keratin disulfide bonds, and may act against biofilms, suggesting potential therapeutic benefit.

Objective: To evaluate the outpatient use of topical MESNA for chronic otorrhea in patients previously submitted to canal wall down mastoidectomy for middle ear cholesteatoma, and to assess its audiological safety and in vitro effect on bacterial biofilm formation.

MATERIAL & METHODS

Methods: A randomized, double-blind, placebo-controlled clinical trial was conducted at the Otology Outpatient Clinic of UNIFESP. Patients were assigned to either the MESNA or control group. The MESNA group received 100% MESNA applied to the mastoid cavity for 10 minutes, while the control group received 0.9% saline solution. The primary outcome was a standardized otoscopic evaluation grading cavity status according to purulent secretion and debris. Audiological safety was assessed by comparing pure-tone averages (500, 1000, 2000, and 3000 Hz) for air and bone conduction before and after treatment. The in vitro effect on biofilm formation was analyzed using microtiter plates with optical density measurement.

RESULTS

Results: Thirty-five patients were included (18 MESNA; 17 control). The MESNA group showed clinical improvement in otorrhea and reduction in debris; however, no statistically significant superiority over saline was observed. Mean bone conduction thresholds did not differ between groups. In vitro analysis demonstrated no significant inhibitory effect of MESNA on biofilm formation.

CONCLUSIONS

Conclusion: Outpatient topical use of 100% MESNA did not show superiority over saline in controlling chronic otorrhea and debris after canal wall down mastoidectomy, nor did it inhibit biofilm formation in vitro. However, this is the first clinical trial evaluating outpatient MESNA use and confirming audiological safety at 100% concentration. Larger studies are needed to validate these findings.

Cochlear Fistula Without Cholesteatoma An Exceptionally Rare Complication Of Chronic Otitis Media

Anıl Akgün[1], **Mahmut Demirtaş**[1], **Mert Gök**[1]

[1]*Department of Otorhinolaryngology, Aydın Adnan Menderes University Faculty of Medicine, Aydın, Turkey*

BACKGROUND & AIM

Cochlear fistulas are rare complications of chronic otitis media (COM), typically associated with cholesteatoma. Bone erosion in non-cholesteatomatous COM is extremely rare. This report aims to present an unusual case of advanced cochlear destruction and an anthrocutaneous fistula in a patient with chronic inflammation but no evidence of cholesteatoma, emphasizing the destructive potential of long-term non-cholesteatomatous infection.

MATERIAL & METHODS

A 62-year-old male with a lifelong history of right-sided otorrhea and progressive hearing loss presented with a retroauricular skin retraction pouch. Audiometry revealed ipsilateral total hearing loss ($104/49$ dB). Temporal bone CT showed widespread soft tissue density in the middle ear and mastoid, along with dehiscence in the cochlear basal turn and the tympanic segment of the facial nerve. The patient underwent a right tympanomastoidectomy. Intraoperatively, the skin retraction pouch was found to extend to the mastoid antrum. Extensive erosion of the promontory, round window niche, and cochlear scalae was observed.

RESULTS

Despite advanced cochlear destruction, no perilymph or endolymph leakage was observed intraoperatively, and the patient had no preoperative or postoperative vertigo. The exposed cochlear segments and facial nerve dehiscence were covered with a temporal fascia graft. Histopathological examination confirmed granulation tissue and chronic inflammation, with no evidence of cholesteatoma. The postoperative course was uneventful without any facial paralysis or vestibular symptoms. Radical mastoidectomy provided effective infection control and prevented further complications in the non-functional ear.

CONCLUSIONS

Advanced cochlear destruction and spontaneous anthrocutaneous fistulas can develop in non-cholesteatomatous COM due to chronic inflammatory processes. In cases of long-term unilateral otorrhea and retroauricular skin changes, inner ear erosions should be suspected even if imaging does not suggest cholesteatoma. Radical mastoidectomy with fascia grafting is a reliable surgical approach for managing such extensive destruction in ears without residual hearing.

PP-376

Angiomatous Meningioma Mimicking Serous Otitis Media: A Rare Clinical Entity And Diagnostic Pitfall

Muhammet Yıldız[1], **Nuray Ensari**[1], **Tolga Gediz**[2], **Dinç Süren**[3]

[1]*Antalya Training and Research Hospital, Department of Otorhinolaryngology;* [2]*Antalya Training and Research Hospital, Department of Neurosurgery;* [3]*Antalya Training and Research Hospital, Department of Pathology*

BACKGROUND & AIM

Angiomatous meningioma is a rare histological variant of meningioma characterized by prominent vascularity. Due to its atypical locations or secondary compressive effects, it can occasionally masquerade as benign otological conditions. This case aims to highlight the potential for intracranial space-occupying lesions to mimic common otolaryngological disorders and emphasize the importance of early advanced imaging.

MATERIAL & METHODS

We present the case of a 48-year-old female with a two-year history of progressive, unilateral right-sided hearing loss, non-pulsatile tinnitus, and a persistent sensation of ipsilateral aural fullness. Over the preceding 12 months, the clinical course was further complicated by a significant exacerbation of episodic vertigo and the onset of intermittent, non-specific headaches. Initial management targeted suspected right-sided serous otitis media (SOM) and Eustachian tube dysfunction. Following the failure of successive courses of broad-spectrum oral antibiotics and corticosteroid therapy, alongside the onset of neurological/vestibular symptoms, advanced diagnostic imaging via contrast-enhanced cranial MRI was performed, followed by surgical resection and histopathological analysis.

RESULTS

Contrast-enhanced cranial MRI revealed a large, extra-axial mass along the right trigeminal nerve, extending from the prepontine cistern into Meckel's cave and the anteromedial temporal lobe. The lesion exerted a significant mass effect, compressing the adjacent pons, cavernous sinus, and Eustachian tube, with associated right temporal vasogenic edema. Following surgical resection, histopathological examination definitively confirmed the diagnosis of an angiomatous meningioma (WHO Grade I).

CONCLUSIONS

Angiomatous meningioma should be considered in the differential diagnosis of unilateral, treatment-resistant serous otitis media accompanied by progressive neurological or otological symptoms. Early advanced imaging is paramount to prevent diagnostic delay and minimize cranial nerve morbidity.

PP-377

Inner Ear Dysplasia As A Cause Of Recurrent Meningitis : Diagnostic Challenge

Hajar Al Marshoudi[1]

[1]*Oman Medical specialty Board, Oman*

BACKGROUND & AIM

Recurrent meningitis is rare but serious complication of congenital inner ear malformations. These malformations can result in direct communication between the subarachnoid space and the middle or inner ear, providing a pathway for pathogens to enter CSF. Such malformations are often associated with hearing loss, vestibular dysfunction, and increased susceptibility to meningitis. This case report describes a 10-year-old girl presented with recurrent meningitis and progressive unilateral hearing loss. High-resolution CT showed incomplete partition type 1 and CSF leak. The patient recovered well after surgical treatment, and the symptoms did not recur after one year follow-up.

MATERIAL & METHODS

This is a case report, so no special methods used.

RESULTS

A previously well 10-year-old girl had failed left-sided otoacoustic emissions on newborn hearing screening. She was later found to have left-sided sensorineural hearing loss following recurrent admission for meningitis. To further investigate the hearing loss, the patient had pure tone audiometry and acoustic immittance audiometry. The results indicated profound sensorineural hearing loss in the left ear. High-resolution computed tomography was performed, which revealed an incomplete partition type 1 (IP-1) as per Levent Sennaroğlu classification, and noted the presence of opacification in the middle ear. Given the findings of a CSF leak, inner ear malformation, and episodes of recurrent meningitis surgical intervention was decided. Exploratory tympanotomy was performed. Intra-op findings showed footplate was pushed out by a cyst, and a CSF leak was observed. The superstructure stapes were removed along with cyst. The defect was covered with multiple layers, which successfully stopped the CSF leak.

CONCLUSIONS

Recurrent meningitis associated with inner ear malformations presents a complex challenge for both diagnosis and treatment. Early recognition of the underlying malformation through imaging and prompt surgical intervention to repair the anatomical defect are key to preventing further episodes of meningitis. This case highlights the critical role of a multidisciplinary approach in managing recurrent meningitis associated with inner ear malformations, which is essential for optimizing patient outcomes and enhancing quality of life.

Attic Reconstruction Techniques In Cholesteatoma Surgery: A Comparative Analysis Of Cartilage Versus Bone Pate

Mohammad Ibrahim Mousa Al alawneh[1]

[1]*Department of Otolaryngology surgery school of Medicine, Jordan University of Science and Technology*

BACKGROUND & AIM

Background: Cholesteatoma surgery involves canal wall down (CWD) and canal wall up (CWU) mastoidectomy. CWU is associated with higher cholesteatoma recurrence, often linked to attic retraction pockets. Attic reconstruction with cartilage or bone pate lacks comparative evidence.

Aims/objectives: To compare the effectiveness of cartilage and bone pate in attic reconstruction during CWU mastoidectomy for cholesteatoma.

MATERIAL & METHODS

We conducted a retrospective study at King Abdullah University Hospital (KAUH) in Jordan, analyzing surgeries performed from 2011 to 2021. Patients who underwent CWU mastoidectomy with attic reconstruction using tragal cartilage with perichondrium or bone pate were included

RESULTS

Of 48 patients analyzed, 26 had cartilage graft attic reconstruction, and 22 received bone pate. Recurrent cholesteatoma occurred in 19.23% of the cartilage group but none in the bone pate group ($p = .001$). Ear discharge was observed in 19.23% of the cartilage group and 18.18% of the bone pate group, while tympanic membrane perforations and external auditory canal cholesteatoma were more prevalent in the cartilage group.

CONCLUSIONS

Our study indicates that bone pate results in significantly lower cholesteatoma recurrence than cartilage grafting in CWU mastoidectomy attic reconstruction. Bone pate offers stability and favorable long-term outcomes for outer attic wall repair.

Whiplash-Unmasked Superior Canal Dehiscence Syndrome: Immediate Symptoms And The Diagnostic Role Of A 4 Khz Ovemp Response

Antigoni Ktisti[1], **Eleftherios Papathanasiou**[2], **Andreas Anagiotos**[3]

[1]*Donna Health Care;* [2]*The Cyprus Institute of Neurology and Genetics;* [3]*Nicosia General Hospital*

BACKGROUND & AIM

Superior Semicircular Canal Dehiscence Syndrome (SSCD) may become clinically manifest following trauma in predisposed individuals with an underlying osseous defect. However, immediate symptom onset after whiplash is not typically recognized as a distinct clinical presentation. High-frequency (4 kHz) oVEMP responses may offer increased specificity for third-window pathology, although they are not yet routinely incorporated into diagnostic protocols. We present a case of SSCD with immediate symptom onset after whiplash, highlighting the diagnostic value of a reproducible 4 kHz oVEMP response.

MATERIAL & METHODS

A 34-year-old female with no prior otologic history presented after a road traffic accident involving a whiplash mechanism. She reported immediate onset of right-sided pulsatile tinnitus, hyperacusis, sound-induced dizziness with occasional vertigo, aural fullness, and imbalance. Otoscopic examination, laboratory investigations, and fundoscopy were unremarkable. Pure tone audiometry showed normal thresholds, with reduced uncomfortable loudness levels on the right (85 vs 115 dB HL) and supranormal low-frequency bone conduction (-5 dB HL at 0.25 kHz). MRI/MRA excluded retrocochlear and vascular pathology. High-resolution CT (0.6 mm) suggested focal absence of the bony roof over a 1 mm segment of the right superior semicircular canal dome, without evidence of fracture or middle ear/mastoid opacification. oVEMP testing showed increased amplitudes with 500 Hz stimulation and a reproducible response at 4 kHz on the right.

RESULTS

Symptoms progressed after returning to work, with sound-induced vertigo triggered by low-frequency environmental noise. Findings were consistent with third-window pathology, and the patient was referred for otoneurologic evaluation and consideration of superior canal occlusion.

CONCLUSIONS

Whiplash may unmask subclinical SSCD with immediate symptom onset, potentially acting as a second hit in predisposed individuals. This differs from its traditional link to cervicogenic dizziness. Pulsatile tinnitus may be a prominent presenting feature. A reproducible 4 kHz oVEMP response supports the diagnosis and may offer increased specificity compared to conventional low-frequency stimulation.

Diagnostic And Therapeutic Management Of Three Cases Of Otogenic Meningitis Within 60 Days. Coincidence Or Epidemic Wave.

Tzavara Evgeneia[1], **Karamali Maria**[1], **Nikolopoulou Efstathia**[1], **Christiana Stavrou**[1], **Pantos Pavlos**[1], **Papacharalampous Georgios**[1], **Chrysovergis Aristeidis**[1]

[1]*ENT Department,"Elpis" General Hospital of Athens*

BACKGROUND & AIM

Meningitis is a rare but life-threatening complication of otitis media. Spread of infection occurs either by bone erosion or via progressive thrombophlebitis of small venules. Despite modern antibiotic therapy, it remains associated with significant morbidity and mortality. In our study we present three cases of otogenic meningitis that occurred within a 60-day period, raising the question of coincidence or epidemic trend.

MATERIAL & METHODS

Case presentation: Three male patients presented at the emergency department complaining of high fever, otalgia ,otorrhea and headache. Otoscopy revealed swelling and hyperemia of the Tympanic Membrane. Kernig and Brudzinski signs were positive. Contrast enhanced CT-scan showed no abnormalities from the brain or the sigmoid sinus. Lumbar puncture revealed elevated white blood cells. CSF culture confirmed Streptococcus pneumoniae infection. Management included myringotomy and administration of intravenous antibiotics (Ceftriaxone). All patients showed rapid clinical and radiological improvement. Follow-up confirmed complete recovery in all patients without evidence of relapse or residual intracranial disease.

RESULTS

Otogenic meningitis remains a major clinical challenge. Early recognition, accurate diagnosis, and administration of appropriate antibiotic therapy are crucial for patient's survival.

CONCLUSIONS

High fever and altered consciousness in patients with otitis media along with extra clinical signs from CNS should prompt immediate evaluation for possible meningitis. The clustering of cases within a short timeframe highlights the importance of clinical vigilance and epidemiological monitoring.

PP-381

Dermal Non-Langerhans Cell Histiocytosis Presenting As An External Auditory Canal Obstructing Mass In An Infant: A Case Report

Sedef Nur Kahriman[1], **Merve Doğan**[1], **Aybike Taşkın**[1], **İlker Akyıldız**[1]

[1]*Ankara Etlik City Hospital*

BACKGROUND & AIM

Histiocytic disorders are rare in pediatric patients and may present with a wide range of clinical manifestations. Non-Langerhans cell histiocytosis typically involves the skin, while involvement of the external auditory canal (EAC) is extremely uncommon. This study aims to present a rare case of dermal non-Langerhans cell histiocytosis presenting as a mass causing complete obstruction of the EAC in an infant and to highlight its diagnostic and therapeutic approach.

MATERIAL & METHODS

A 13-month-old female patient presented with a mass in the right external auditory canal. Otoscopic examination revealed a cystic lesion completely obstructing the canal. Temporal bone computed tomography (CT) demonstrated a soft tissue lesion confined to the EAC without bony erosion or middle ear involvement. The patient underwent complete excisional biopsy under general anesthesia. Histopathological and immunohistochemical analyses were performed.

RESULTS

Histopathological examination showed dermal infiltration by foamy histiocytes, multinucleated giant cells, and inflammatory cells. Immunohistochemical staining revealed S100 positivity, CD1a and Langerin negativity, and a low Ki-67 proliferation index. The findings were consistent with dermal non-Langerhans cell histiocytosis, most compatible with juvenile xanthogranuloma. The lesion was completely excised, and no complications were observed.

CONCLUSIONS

Non-Langerhans cell histiocytosis should be considered in the differential diagnosis of external auditory canal masses in infants. Imaging is essential to evaluate lesion extent, while histopathological examination is required for definitive diagnosis. Complete surgical excision provides both diagnosis and treatment in such cases.

PP-382

Spontaneous Intracranial Hypotension Mimicking Ménière's Disease And Multiple Sclerosis Relapse

Arda Yavuz[1], **Ömer Faruk Birkent**[1], **Müzeyyen Doğan**[1], **İlhan Topaloğlu**[1]

[1]*Yeditepe University Faculty of Medicine, Department of Otorhinolaryngology, Istanbul, Turkey*

BACKGROUND & AIM

Spontaneous intracranial hypotension (SIH) is an underrecognized condition resulting from cerebrospinal fluid (CSF) volume depletion, classically presenting with orthostatic headache. However, audiovestibular symptoms such as vertigo, tinnitus, and subjective hearing loss may predominate, mimicking both peripheral and central vestibular disorders. This diagnostic challenge becomes more complex in patients with underlying neurological diseases. This study aims to present a case of SIH presenting with acute audiovestibular symptoms, mimicking both Ménière's disease and multiple sclerosis (MS) relapse, and to emphasize key diagnostic considerations.

MATERIAL & METHODS

A 40-year-old female patient with a known diagnosis of MS and a previously identified vestibular schwannoma presented with acute-onset neck pain followed by vertigo, right-sided tinnitus, and subjective hearing loss. Clinical evaluation included otorhinolaryngological examination, pure-tone audiometry, speech discrimination testing, and vestibular assessment. Cranial magnetic resonance imaging (MRI) was performed to evaluate possible neurological causes.

RESULTS

MRI revealed no new demyelinating lesions suggestive of MS relapse but demonstrated findings consistent with decreased CSF pressure. Audiological and vestibular evaluations were within normal limits. Based on clinical and radiological findings, SIH was considered. The patient was managed conservatively with bed rest, hydration, and caffeine intake. Due to the potential risk of MS relapse, systemic corticosteroid therapy was also administered. At 5-day follow-up, the patient showed significant clinical improvement, with stable audiological findings.

CONCLUSIONS

SIH should be considered in the differential diagnosis of acute audiovestibular symptoms, particularly when orthostatic features are present. Clinical improvement following corticosteroid therapy does not reliably differentiate SIH from MS relapse or Ménière's disease. This case highlights the importance of integrating clinical, radiological, and audiovestibular findings and underscores the need for a multidisciplinary approach in patients presenting with overlapping neurological and otological symptoms.

Prevalence Of Endolymphatic Hydrops In Patients Evaluated By Gadolinium-Enhanced Inner Ear MRI

Haruka Nakabayashi[1], **Mei Sakamoto**[1], **Junko Tsuda**[1], **Makoto Hashimoto**[1], **Kazuma Sugahara**[1]

[1]*Department of Otolaryngology–Head and Neck Surgery, Yamaguchi University Hospital, Yamaguchi, Japan*

BACKGROUND & AIM

Endolymphatic hydrops was previously established as the principal pathological substrate of Ménière's disease, and its diagnosis was historically based on clinical findings and physiological examinations. With the advent of Gadolinium-enhanced inner ear MRI, in vivo visualization of endolymphatic hydrops became feasible. We initiated Gadolinium-enhanced inner ear MRI in 2018. The aim of this study is to evaluate the prevalence of endolymphatic hydrops in our institution.

MATERIAL & METHODS

The participants included 123 patients who underwent Gadolinium-enhanced inner ear MRI treated in the Department of Otolaryngology, Yamaguchi University Hospital, Japan between January 1, 2018, and March 31, 2023.They were clinically diagnosed with Ménière's disease, atypical Ménière's disease, delayed endolymphatic hydrops (DEH), vertigo disorder, or acute sensorineural hearing loss. Four hours after intravenous administration of gadoteridol, MRI was performed using a 3T scanner (MAGNETOM Prisma 3T, Siemens Healthcare GmbH, Erlangen, Germany). Endolymphatic hydrops was assessed according to the criteria proposed by Nakashima et al., and the endolymphatic space in the cochlea and vestibule was graded as significant, mild, or none.

RESULTS

The positive rate of endolymphatic hydrops in definite Ménière's disease cases in our institution was 80%. For other conditions, the positive rates were approximately 50% for atypical Ménière's disease and 100% for delayed endolymphatic hydrops. The association between the duration of Ménière's disease and the positive rate was considered. However, no clear relationship

was observed between the time from the first Ménière's disease attack to MRI examination and the presence of hydrops (t(22)=1.20，p=0.24).

CONCLUSIONS

Gadolinium-enhanced inner ear MRI is useful for the definitive diagnosis of Ménière's disease. In addition, more than half of the cases with atypical Ménière's disease or DEH also showed positive findings. These results suggest that Gadolinium-enhanced inner ear MRI can serve as a valuable tool in clinical practice. Further research is needed to determine whether endolymphatic hydrops in Ménière's disease represents a progressive or reversible change.

Evaluation Of Tinnitus In Patients Undergoing Tympanoplasty In A Tertiary Hospital

Kelvin Leite Moura[1], **Priscila Farias de Oliveira**[2], **Rayane Bezerra Freitas**[3], **Pedro Henrique Breda**[3], **Wendell Dantas Palmeira**[3], **Daiane França de Falcão Leal**[3], **Gabrielle Justiniana Fontes Rocha**[3], **Damácio Soares Paiva**[3], **Lidiane Maria de Brito Macedo Ferreira**[3]

[1]Clínica Otorrinos Santa Clara, Campina Grande, PB, Brazil; [2]Clínica Otossinus, Natal, RN, Brazil; [3]Department of Surgery, Universidade Federal do Rio Grande do Norte, Natal, RN, Brazil

BACKGROUND & AIM

Tinnitus is a frequent complaint among patients with chronic otitis media (COM). Tympanoplasty is indicated for selected cases of non-cholesteatomatous COM since it aims to reconstruct the tympanic membrane, restore sound protection to the round window, and reestablish sound conduction mechanisms, thereby improving hearing. Improvement in tinnitus after tympanoplasty is traditionally attributed to postoperative auditory gain, representing a classical model of the relationship between hearing and tinnitus perception. This study aimed to evaluate the impact of tympanoplasty on postoperative tinnitus outcomes in patients with non-cholesteatomatous COM.

MATERIAL & METHODS

This observational, prospective, and analytical field study was conducted between January and December 2023. Patients undergoing tympanoplasty were evaluated using a questionnaire to assess tinnitus characteristics in the pre- and postoperative periods. Audiometric findings and tinnitus intensity were analyzed, and frequency distribution tables were constructed according to postoperative tinnitus presence and severity. The most frequently used surgical technique was the retroauricular medial approach with temporalis muscle fascia graft (80%), followed by the endaural technique. Statistical analysis included Fisher's exact test, with significance set at $\alpha = 0.05$.

RESULTS

A total of 33 tympanoplasties were performed in 25 patients, 80% female and 20% male, with a mean age of 44 years (range: 20–76). Previous otologic surgery was reported by 40% of patients. Preoperatively, tinnitus was intermittent in 80% and constant in 20% of cases. Mixed hearing loss was identified in 44% of patients, predominantly mild to moderate. Audiometric evaluation also demonstrated conductive hearing loss in an average of 28% of patients. Tinnitus intensity was classified as moderate in 84%, mild in 8%, and severe in 8%. Fisher's exact test demonstrated a significant association between previous surgery and persistence of postoperative tinnitus. The mean Visual Analog Scale score decreased from 4.8 preoperatively to 2.2 postoperatively, with complete tinnitus resolution reported by 36% of patients.

CONCLUSIONS

Tinnitus is highly prevalent in patients with COM, and tympanoplasty was associated with a significant reduction in tinnitus intensity, likely related to postoperative hearing improvement. Long-term prospective studies are recommended to assess the durability of these outcomes and identify factors influencing surgical success.

PP-385

POSTOPERATIVE MASTOID CAVITY OBLITERATION USING A POSTERIOR AURICULAR MUSCLE FLAP

Valdas Bernotas[1], **Žygimantas Tverskis**[1]

[1]Klaipeda University Hospital. Eye, head and neck surgery clinic. Ear, Nose, and Throat Diseases Department

BACKGROUND & AIM

Introduction

Canal wall down mastoidectomy (CWDM) remains an effective surgical approach for the management of middle ear cholesteatoma. However, postoperative mastoid cavity – related complications continue to represent a significant clinical challenge. Chronic otorrhea, recurrent infections, and the need for frequent cavity care adversely affect long-term outcomes and patients' quality of life.

Mastoid cavity obliteration using vascularized tissue has been increasingly advocated to improve cavity stability, promote epithelialization, and optimize postoperative results.

Aim: To evaluate the clinical outcomes of mastoid cavity obliteration using a posterior auricular muscle flap following canal wall down mastoidectomy.

MATERIAL & METHODS

A clinical observational study was conducted including 18 patients who underwent canal wall down mastoidectomy with simultaneous mastoid cavity obliteration using a posterior auricular muscle flap in 2025. All procedures were performed as single – stage surgeries by the same otologic surgeon at the Department of Otorhinolaryngology, Clinic of Eye, Head and Neck Surgery, Klaipeda University Hospital.

Postoperative follow – up was performed after removal of ear packing at 4 weeks and subsequently at 8 and 12 weeks postoperatively. Clinical outcomes were assessed based on the presence of otorrhea, granulation tissue, and the degree of epithelialization of the mastoid cavity.

RESULTS

At 4 weeks postoperatively, all patients (18/18, 100%) exhibited otorrhea, with no evidence of granulation tissue or epithelialization. By 8 weeks, clinical improvement was observed, with otorrhea persisting in 11 patients (61.1%) and granulation tissue present in 7 patients (38.9%); however, complete epithelialization was not achieved in any case.

At 12 weeks, outcomes further improved, with only 2 patients (11.1%) demonstrating minimal residual otorrhea and 2 patients (11.1%) showing granulation tissue, while complete epithelialization of the postoperative mastoid cavity was achieved in 14 patients (77.8%).

Overall, mastoid cavity obliteration using a posterior auricular muscle flap resulted in progressive cavity stabilization, a marked reduction in cavity volume, and facilitation of postoperative management. The majority of patients achieved a dry, stable, and well – epithelialized cavity, with a substantially reduced need for routine cavity care. No major flap – related complications, including flap necrosis or wound healing disturbances, were observed.

CONCLUSIONS

Mastoid cavity obliteration using a posterior auricular muscle flap represents a safe, reliable, and effective adjunct to canal wall down mastoidectomy. The technique promotes durable cavity stabilization, accelerates epithelialization, and significantly reduces postoperative cavity-related complications, thereby facilitating long-term cavity management.

These findings support its role as a valuable surgical option in the management of cholesteatoma. Further studies with larger cohorts and extended follow – up are warranted to validate these outcomes and to better define its place in contemporary otologic practice.

Peripheral Facial Nerve Palsy Secondary To Chronic Otitis Media: A Case Report

Furkan ADLUĞ[1], **Arda TETİK**[1], **Burak Mustafa TAŞ**[1], **Süheyla KANDEMİR**[1], **Ziya ŞENCAN**[1], **Ela CÖMERT**[1], **Nuray BAYAR MULUK**[1]

[1]*Kırıkkale University Faculty of Medicine, Department of Otorhinolaryngology*

BACKGROUND & AIM

Chronic Otitis Media (COM) is a persistent inflammation of the middle ear and mastoid air cells lasting ≥3 months, with or without tympanic membrane perforation. It is a rare but serious cause of facial nerve paralysis, accounting for about 0.16–5.8% of cases. Early surgical decompression is the treatment of choice; pathological tissue is removed and the facial nerve canal is decompressed.

In this case report, we aimed to present the clinical findings and management of a patient with long-standing bilateral chronic otitis media complicated by left-sided peripheral facial nerve palsy.

MATERIAL & METHODS

A 65-year-old female presented with a long-standing history of intermittent bilateral greenish otorrhea. Her symptoms had progressively worsened over the preceding 2–3 weeks despite medical treatment. Two days prior to presentation, she developed left-sided facial weakness consistent with peripheral facial nerve palsy.

On otoscopic examination, bilateral tympanic membrane perforations were identified. Purulent otorrhea was noted in the left external auditory canal. The patient was found to have left-sided Grade IV peripheral facial nerve palsy.

Temporal bone CT (Computed Tomography) imaging was performed. The study demonstrated complete loss of aeration within the left mastoid air cell system with marked trabecular sclerosis. Diffuse soft-tissue density was present involving both the mastoid cavity and middle ear cleft. Dehiscence of the tympanic segment of the left facial nerve was identified, together with a bony defect of the facial nerve canal.

RESULTS

Emergency surgical intervention was recommended for the patient. The preliminary diagnosis was peripheral facial nerve palsy secondary to chronic otitis media.Under appropriate operating room conditions, a vascular flap was elevated from the external auditory canal extending posteriorly. A tympanomeatal flap was elevated. Malposition of the malleus, incus, and stapes was noted. A postauricular sulcus incision was then performed. A left mastoidectomy was carried out. Cholesteatoma tissue was removed from the antrum. A cartilage graft was harvested from the left tragus, and a left tympanoplasty was performed.

CONCLUSIONS

The development of peripheral facial nerve palsy in patients with chronic otitis media is an indication for emergency surgical intervention. Temporal bone CT is an indispensable tool for demonstrating facial nerve dehiscence and mastoid pathology.

Tympanic Paraganglioma Mimicking Chronic Otitis Media: A Diagnostic Pitfall

Dilara Ülkü İlbaş Aydın[1], **İrem Yalabık Aydoğdu**[1], **Ömer Faruk Çufalı**[1], **Mehmet Ali Çetin**[1]

[1]*Ankara Bilkent City Hospital*

BACKGROUND & AIM

Tympanic paraganglioma, also known as glomus tympanicum, is the most common primary neoplasm of the middle ear and arises from paraganglionic tissue associated with the tympanic branch of the glossopharyngeal nerve (Jacobson's nerve). It usually presents with pulsatile tinnitus, conductive hearing loss, or a retrotympanic vascular mass. Rarely, it may mimic chronic otitis media with inflammatory polyp or granulation tissue, causing delayed diagnosis and unexpected intraoperative bleeding. We present a case initially interpreted as chronic otitis media with an external auditory canal polyp.

MATERIAL & METHODS

A 47-year-old female patient presented with a 6-month history of persistent right-sided suppurative otorrhea, otalgia, and hearing loss unresponsive to medical treatment. Otoscopic examination showed suppurative discharge and a smooth-surfaced, nonpulsatile, non-vascular-appearing mass occluding the right external auditory canal. The lesion was considered compatible with inflammatory polyp or granulation tissue secondary to chronic otitis media. Bilateral facial nerve motor function was intact. Preoperative imaging findings were also interpreted as consistent with chronic otitis media. Surgical exploration and histopathological examination were performed for definitive diagnosis.

RESULTS

During the initial surgery, an unexpectedly hemorrhagic mass was encountered. Because of marked bleeding and suspicion of a vascular lesion, complete excision was not attempted; multiple biopsy specimens were obtained, and the procedure was terminated. Histopathology was consistent with paraganglioma. The patient subsequently underwent revision tympanomastoidectomy. For improved exposure, temporary en bloc osteotomy of the posterior bony external auditory canal wall was performed. After tumor excision, the canal wall was repositioned and reconstructed, and ossicular chain reconstruction was performed. The tumor involved the middle ear and mastoid antrum and was classified as Fisch type B and Glasscock–Jackson type IV. Postoperative otoscopy showed no recurrent canal mass, and magnetic resonance imaging (MRI) revealed no clear residual or recurrent disease.

CONCLUSIONS

Tympanic paraganglioma may rarely present as a nonpulsatile, non-vascular-appearing external auditory canal mass associated with suppurative otorrhea, otalgia and hearing loss, mimicking chronic otitis media. Vascular middle ear tumors should remain in the differential diagnosis of persistent canal polyps or granulation tissue, especially when unresponsive to treatment. Awareness of this atypical presentation and staged surgery after histopathological confirmation may improve safety and disease control.

APOE Genotype And Hearing Loss In A Taiwanese Population

Ting-Ting Yen[1,5], **Kai-Hsiang Shih**[1], **Chiann-Yi Hsu**[3], **Ting-Gang Chang**[2,4]

[1]*Department of Otolaryngology, Taichung Veterans General Hospital, Taichung, Taiwan;* [2]*Department of psychiatry, Taichung Veterans General Hospital, Taichung, Taiwan;* [3]*Biostatistics Task Force,Taichung Veterans GeneralHospital, Taichung, Taiwan;* [4]*College of Medicine, National Chung Hsing University, Taichung , Taiwan;* [5]*School of Medicine, National Yang Ming Chiao Tung University, Taipei , Taiwan*

BACKGROUND & AIM

Age-related hearing loss is a prevalent condition in aging populations and exhibits substantial inter-individual variability. Apolipoprotein E (APOE), a key genetic factor involved in neurodegeneration, has been implicated in hearing outcomes;

however, previous findings remain inconsistent and rarely consider genotype-specific or frequency-specific effects.This study aimed to investigate the association between APOE genotypes and hearing outcomes, and to determine whether these associations are genotype-dependent and frequency-specific.

MATERIAL & METHODS

A total of 827 participants were included. Hearing outcomes, including pure-tone thresholds (0.25–8 kHz), pure-tone average, and hearing loss severity, were compared across APOE genotypes (e2e2, e2e3, e2e4, e3e4, e4e4). Within each genotype, hearing outcomes were further compared between APOE-positive and APOE-negative groups.

RESULTS

In the overall cohort, significant differences across APOE genotypes were observed at the 2 kHz threshold in the right ear. Genotype-stratified analyses revealed significant associations between APOE status and specific frequency thresholds as well as hearing loss severity in the e2e3 and e3e4 genotypes, whereas no significant associations were observed in the e2e2 and e4e4 genotypes. Notably, significant findings were frequency-specific rather than reflected in overall pure-tone averages.

CONCLUSIONS

These findings demonstrate that the association between APOE and hearing outcomes is both genotype-dependent and frequency-specific. This nuanced effect may explain inconsistencies in prior studies and supports the potential role of APOE in hearing loss risk stratification during aging.

Endoscopy Guided Eustachian Tube Balloon Dilation In Patients With Eustaschian Tube Dysfunction: Our Experience

Ieridou Fotini[1], **Ilias Karakitsos**[1], **Sofia Anastasiadou**[1], **Konstantinos Valsamidis**[1], **Petros Karkos**[1], **George Psillas**[1]

[1]*1st Otorhinolaryngology, Head and Neck Surgery Department, Medical School, Aristotle University of Thessaloniki, AHEPA Hospital, Thessaloniki, Greece.*

BACKGROUND & AIM

Eustachian tube dysfunction (ETD) is a common clinical entity but its treatment is still challenging to Otorhinolaryngologists. Symptoms of chronic obstructive ETD include aural fullness, tinnitus, hearing loss and otalgia. The aim of this study was to evaluate the effect of transnasal endoscopic balloon dilatation of the eustachian tube in patients with ETD.

MATERIAL & METHODS

This is a retrospective observational study that included thirteen consecutive patients aged between 27 and 56 years who were identified with the diagnosis of ETD resistant to adequate medical therapy. They all underwent tympanometry, pure tone audiometry and tubomanometry preoperatively. Additionally they all completed the ETDQ7 questionnaire (Eustachian Tube Dysfunction Questionnaire -7) for the evaluation of ETD related symptoms. The transnasal endoscopic procedure was performed to dilate the cartilaginous part of the eustachian tube with a balloon catheter. All patients were post-operatively assessed in 1st, 2nd and 8th week after the procedure

RESULTS

Balloon dilation of the eustachian tube was performed in all cases. Seven patients underwent balloon dilation unilaterally and in six participants the surgery was performed bilaterally. All patients reported subjective improvement of the ETD related symptoms based on the ETDQ7 scores (Table 1). Additionally the objective measurements of the eustachian tube function with the use of tubomanometry were significantly improved. There were no peri- or postoperastive complications noticed in this study

CONCLUSIONS

Balloon dilation of the eustachian tube appears to be a feasible, safe and minimally invasive procedure and a promising alternative method to restore middle ear ventilation in patients with chronic ETD.

Results Of School-Age Hearing Screening Among First-Grade Primary School Students In Karabuk Province

serhat ekemen[1]

[1]*Karabuk University Faculty of Medicine*

BACKGROUND & AIM

Of this study is to present the results of hearing screenings conducted on first-grade primary school students living in Karabük province between 2022 and 2026.

MATERIAL & METHODS

Method: Between 2022 and 2026, a total of 9171 first-grade primary school students underwent hearing screening tests. Four referral reasons were indicated in the screening test. Parents of the students completed the questionnaire shown in Table 1. A total of 174 students who failed the hearing screening were re-evaluated at the ENT outpatient clinic of Karabük Training and Research Hospital. Whether the students had hearing loss was assessed using pure-tone audiometry, pediatric audiometry, tympanometry, OAE, and BERA. Examinations were performed by a single physician assigned to this task. Impaired cerumen was detected and aspirated in 21 students. Hearing was found to be normal in 121 students. Hearing loss was detected in 30 students.

RESULTS

25 Hearing loss was defined as being above a certain dB level. The average values obtained separately for the right and left ears at 500Hz, 1000Hz, 2000Hz, and 4000Hz frequencies were as follows: right ear 34.8, 33.5, 28.8, 36.1; left ear 30.6, 28.5, 24.8, 28.6 In our study, the distribution of hearing loss in 30 students was as follows: 32 students had conductive hearing loss, 4 students had mixed hearing loss, and 1 student had sensorineural hearing loss (SNHL). BERA was administered to 5 students who were unable to cooperate with the test. All students (100%) with conductive hearing loss had effusion. Otitis. The media reported that 0.4% of primary school students had hearing loss.

CONCLUSIONS

This rate is lower than the screening tests conducted in Turkey. This is attributed to the early detection of children with hearing loss through newborn hearing screening tests conducted at our hospital."

PP-391

A Novel Microsurgical Instrument For Malleus Skeletonization And Middle Ear Dissection: The 21-Gauge Syringe Needle Technique

Dr Hasret KAYA[1], **Dr Melikşah ÇAKIR**[1], **Prof Dr Selahattin GENÇ**[1]

[1]*Kocaeli City Hospital, Department of Otorhinolaryngology*

BACKGROUND & AIM

Malleus skeletonization and dissection of soft tissues adherent to the stapes are critical and technically demanding steps in middle ear surgery. Avoiding trauma to the ossicular chain, particularly the stapes, is essential for optimal hearing outcomes and inner ear safety.Conventional techniques include sharp picks, fine microscissors, and lasers. However, picks may concentrate force at a single point, increasing the risk of ossicular injury or luxation; microscissors can limit visualization in narrow spaces; and lasers may not always be available due to cost and equipment requirements.This study presents an affordable and widely available technique using a modified 21-gauge syringe needle.

MATERIAL & METHODS

A standard 21-gauge green syringe needle is firmly mounted onto the handle of an ear pick or a similar microsurgical instrument, creating a microdissection tool. The sharp tip and lateral edges allow it to function like a mini-blade with controlled, saw-like back-and-forth movements.

Malleus Skeletonization: A periosteal incision is made along the manubrium of the malleus. The sharp lateral surfaces enable atraumatic separation of soft tissues from the bony surface with minimal mechanical force.

Stapes Dissection: Soft tissues adherent to the stapes are excised by applying minimal force to the stapes head, preserving its mobility while reducing transmission of traumatic force to the footplate.

Chorda Tympani: Adherent tissues over the nerve are removed without traction or thermal injury.

The disposable nature of the needle ensures consistently sharp cutting edges for each case.

RESULTS

The technique was successfully applied in three different cases involving malleus skeletonization, stapes head dissection, and chorda tympani clearance. Dissections performed with the modified 21-gauge tip were observed to be controlled, safe, and highly sharp. No intraoperative complications such as ossicular chain injury, stapes subluxation, footplate trauma, or unexpected bleeding were encountered in any case. The method was found to be practical, reproducible, and to improve overall surgical comfort, providing enhanced precision in delicate middle ear dissection steps.

CONCLUSIONS

Uncontrolled force during dissection around the malleus and stapes may cause ossicular chain damage or stapes subluxation.Conventional sharp picks often require greater pushing and pulling force due to their limited cutting surface, whereas the modified syringe needle reduces this force requirement with its sharp edges.However, it is designed for soft tissue

dissection and is not suitable for bone work.Its lower rigidity compared to steel picks may lead to bending; therefore, it should be used for cutting rather than leverage.Secure fixation to the instrument handle is essential.This modification reduces force transmission and enhances surgical safety with low cost and wide availability

Non Surgical Treatment Of Otosclerosis : A Systematic Review

Maria Korodima[1], **Georgios Grivas**[2], **Alexandros Chatzakis**[2], **Eugenia Maria Domuta**[3]

[1]*ENT Department, Sismanogleio General Hospital, Athens, Greece;* [2]*ENT Department, Pammakaristos Hospital, Athens, Greece;* [3]*Faculty of Medicine and Pharmacy, University of Oradea,Romania;* [4]*Faculty of Medicine and Pharmacy, University of Oradea,Romania*

BACKGROUND & AIM

Otosclerosis is a primary osteodystrophy of the otic capsule characterized by abnormal bone remodeling that leads to progressive conductive or mixed hearing loss. Although stapedotomy remains the standard surgical treatment, non-surgical management is increasingly important in patients who are not surgical candidates, refuse surgery, or present with early-stage disease. The aim of this systematic review was to evaluate the effectiveness and safety of non-surgical treatment modalities for otosclerosis, with emphasis on hearing outcomes and disease progression.

MATERIAL & METHODS

A systematic review of the literature was conducted according to PRISMA guidelines. Electronic databases including PubMed, Scopus, and Cochrane Library were searched for studies published between 2000 and 2025 using the keywords “otosclerosis,” “non-surgical treatment,” “medical therapy,” “hearing aids,” “sodium fluoride,” and “bisphosphonates.” Randomized controlled trials, cohort studies, and observational studies evaluating conservative management were included. Data regarding patient demographics, treatment modality, audiological outcomes, symptom control, and adverse effects were extracted and analyzed qualitatively.

RESULTS

A total of 27 studies involving approximately 2,100 patients met the inclusion criteria. Hearing aids were consistently shown to provide significant functional hearing improvement and quality-of-life benefits in patients with conductive and mixed hearing loss. Sodium fluoride therapy demonstrated potential stabilization of sensorineural hearing deterioration in selected patients, although evidence quality was moderate. Bisphosphonates, particularly third-generation agents, showed promising results in reducing cochlear otosclerosis progression and vestibular symptoms; however, available studies were limited by small sample sizes and heterogeneous methodologies. Overall, non-surgical therapies were well tolerated, with minimal serious adverse effects reported.

CONCLUSIONS

Non-surgical treatment represents an effective and safe alternative or adjunct in the management of otosclerosis, especially for patients unsuitable for surgery. Hearing amplification remains the cornerstone of conservative management, while medical therapies such as sodium fluoride and bisphosphonates may offer disease stabilization in selected cases. Further high-quality randomized studies are required to establish standardized treatment protocols and long-term efficacy.

Langerhans Cell Histiocytosis In The Mastoid Bone Mimicking Cholesteatoma Adjacent To The Facial Nerve, Posterior Semicircular Canal And Sigmoid Sinus

Şilan Fidan, Berna Kayacılar, Emre Ocak[1]

[1]*Department of Otorhinolaryngology, Ankara University Faculty of Medicine, Ankara, Turkey*

BACKGROUND & AIM

Langerhans Cell Histiocytosis is a rare clonal proliferative disorder characterized by pathological accumulation of Langerhans cells. The annual incidence is approximately 5–6 cases per million in children and 1–2 cases per million in adults. Temporal bone involvement occurs in nearly 15–25% of cases, whereas mastoid involvement in adults is particularly rare. Temporal bone lesions may clinically and radiologically mimic chronic otomastoiditis or cholesteatoma. We aimed to present a rare adult case of mastoid Langerhans cell histiocytosis initially suspected to be cholesteatoma.

MATERIAL & METHODS

A 40 year old male patient presented with otologic complaints and underwent audiological and radiological evaluation. Pure-tone audiometry demonstrated bilateral hearing thresholds within normal limits with a mild conductive component on the left side. Tympanometric findings were compatible with middle ear dysfunction. Contrast-enhanced temporal magnetic resonance imaging revealed a 14×16 mm peripherally enhancing lesion within the left mastoid cells, initially interpreted as

cholesteatoma. Temporal bone computed tomography demonstrated a destructive lytic lesion measuring approximately 20×10 mm adjacent to the jugular foramen in the left mastoid segment. Cortical bone destruction with loss of clear separation from the intracranial compartment was observed. The lesion was closely associated with the mastoid segment of the facial nerve canal, sigmoid sinus, and posterior fossa dura. Mastoid exploration and surgical excision were performed. Histopathological examination established the diagnosis of Langerhans cell histiocytosis.

RESULTS

Intraoperatively, the lesion was found to extend within the mastoid cavity in close proximity to the facial nerve canal, posterior semicircular canal, sigmoid sinus and posterior fossa dural plate. Although preoperative radiological findings strongly suggested cholesteatoma, definitive diagnosis was achieved histopathologically. No postoperative facial nerve deficit or major intracranial complication occurred. Audiological findings remained stable during postoperative follow-up.

CONCLUSIONS

Temporal bone Langerhans cell histiocytosis is particularly rare in adults and should be considered in the differential diagnosis of destructive mastoid lesions mimicking cholesteatoma. Detailed preoperative imaging evaluation of the relationship between the lesion and adjacent structures such as the facial nerve, sigmoid sinus, and posterior fossa dura is essential for minimizing surgical morbidity. Histopathological examination remains the gold standard for definitive diagnosis.

Xenograft In Transcanal Endoscopic Tympanoplasty

Ning-Chia Chang[1], **Chen-Yu Chien**[2]

[1]*Department of Otorhinolaryngology Head and Neck Surgery, Kaohsiung Municipal Siaogang Hospital, Kaohsiung Medical University;* [2]*Department of Otorhinolaryngology Head and Neck Surgery, Kaohsiung Medical University Hospital, Kaohsiung Medical University;* [3]*Department of Otorhinolaryngology Head and Neck Surgery, School of Medicine, College of Medicine, Kaohsiung Medical University*

BACKGROUND & AIM

Transcanal endoscopic tympanoplasty is the main stream of operation in the repairment of tympanic membrane perforation. The tympanoplasty procedure often requires a membraneous graft for patching the perforation. The aim of the present study is to evaluate the healing condition by using xenograft in transcanal endoscopic tympanoplasty.

MATERIAL & METHODS

This study is a retrospective review of charts of the patients who received transcanal endoscopic tympanoplasy for chronic otits media. The membraneous graft for patching the tympanic perforation was either autograft (tragus perichondrium or temporalis muscle fascia) or xenograft (Biodesign; porcine small intestinal mucosa product). The completely healing rate, partial closure rate, and the operation time comsumed were analyzed and compared between the autograft and the xengraft. The possible factors relating to partial closure were also analyzed.

RESULTS

During the period between January 1st, 2022 to December 31st, 2025, 206 transcanal endoscopic tympanoplasty procedures were performed on 197 patients (120 females, 77 males). The comletely healing rates were 94.4% for autografts and 79.7% for xenografts. The partial colsure rates were 4.2% for autografts and 14.3% for xenografts. The average operation time were 80±24 minutes for autografts and 64±25 minutes for xenografts. The original perforation size was the primary factor that might result in partial closure. With the ROC curve analysis, the area under the curve was 0.750. At the cutoff point of 37.50% perforation, the sensitivity and specificity of partial closure for xengraft use 0.737 and 0.623, respectively.

CONCLUSIONS

Xengraft of porcine small intestinal mucosa product gave a satisfactory healing rate in transcanal endoscopic tympanoplasty. The use of xenograft may save about 16 minutes operation time and prevent an addition al wound from the harvest of grafts. The porcine small intestinal mucosa product is a good choice of graft in endoscopic tympanoplast surgeries.

PP-395

From Hearing Loss To Genetic Diagnosis: A Family Case Of Mohr–Tranebjaerg Syndrome

Sofia Carvalho[1], **Rita Carvalho**[1], **Ana Silva**[1], **João Lino**[1], **Miguel Coutinho**[1]

[1]*ULS Santo António*

BACKGROUND & AIM

Mohr–Tranebjaerg syndrome (MTS), also known as Deafness–Dystonia–Optic Neuronopathy (DDON) syndrome, is a rare X-linked recessive neurodegenerative disorder that predominantly affects males. It is caused by pathogenic variants in the TIMM8A gene, which encodes a mitochondrial protein involved in inner membrane protein import, leading to progressive

neurological dysfunction. The condition typically presents in early childhood with sensorineural hearing loss, often the first and most prominent feature. As the disease progresses, patients may develop dystonia, spasticity, optic atrophy, peripheral neuropathy, cognitive decline, and psychiatric manifestations.

MATERIAL & METHODS

Case report of a family with four diagnosed cases of Mohr–Tranebjaerg syndrome (MTS)

RESULTS

We describe a family with four male cases of Mohr–Tranebjaerg syndrome (MTS): three siblings and one maternal uncle.

Two monozygotic twins were referred to consultation at 3 years old due to global developmental delay, especially in the language area, unilateral strabismus and ataxia. Neonatal otoacoustic emissions were present, but auditory brainstem responses showed absence of waveforms at all tested intensities.

Their older brother was referred for evaluation due to speech delay at 4 years old. After irregular attendance at medical appointments, he was diagnosed with postlingual progressive bilateral sensorineural hearing loss at 9 years old.

Family history revealed a maternal uncle with a history of childhood-onset sensorineural deafness. At age 18 presented early onset dementia and at 28 years old developed dysmetria, limb hyperreflexia, dystonia and spasticity.

Genetic testing, including mitochondrial DNA sequencing, confirmed hemizygosity for a pathogenic variant in TIMM8A, establishing the diagnosis of X-linked MTS in this family.

CONCLUSIONS

In Mohr–Tranebjaerg syndrome (MTS), deafness is often the first manifestation and may be overlooked, delaying recognition of the underlying disorder. Thereby genetic testing and counseling are essential due to the high recurrence risk and the potential severity of the condition, enabling informed reproductive decisions and early intervention for affected children.

Mohr–Tranebjaerg syndrome (MTS), sensorineural hearing loss, genetic testing

PP-396

Impact Of A Hearing Screening Intervention On Noise-Induced Hearing Loss Awareness And Protective Practices Among Quarry Workers: A 12-Months Follow-Up Study

NOOR DINA HASHIM[1], **ROSNAH ISMAIL**[2], **WAN FAZLINA WAN HASHIM**[3], **FATIMAH SAZARI**[3], **FARAH LIANA LOKMAN**[1]

[1]Department of Otorhinolaryngology–Head and Neck Surgery, Faculty of Medicine, Universiti Kebangsaan Malaysia; [2]Department of Community Health, Faculty of Medicine, Hospital Canselor Tuanku Muhriz Universiti Kebangsaan Malaysia; [3]Audiology Unit, Department of Rehabilitation, Hospital Canselor Tuanku Muhriz Universiti Kebangsaan Malaysia

BACKGROUND & AIM

Noise-induced hearing loss (NIHL) remains a preventable yet highly prevalent occupational hazard among quarry workers exposed to hazardous noise levels. Despite established effective hearing conservation strategies, sustained behavioral compliance remains a persistent challenge. The aim of this study is to determine the short- and long-term impact on knowledge, attitudes and practices (KAP) related to NIHL over 12-months following a hearing conservation initiative.

MATERIAL & METHODS

A quasi-experimental study was conducted at a quarry site. The intervention included targeted hearing health educational sessions, information on hearing protection and ear examinations. A validated KAP questionnaire was administered at baseline (pre-intervention), immediately post-intervention and at 6- and 12-months. Trends in KAP scores were analyzed to evaluate immediate gains and sustainability of impact.

RESULTS

The intervention produced significant and sustained improvements in knowledge and attitudes towards hearing conservation throughout follow-up assessments. However, while protective practices immediately post-intervention, adherence declined over time, highlighting a gap between awareness and sustained behavioral change. Despite risk perception, consistent use of hearing protection remained suboptimal at 12 months.

CONCLUSIONS

Although educational interventions improved knowledge and attitudes toward NIHL, sustained behavioral change in hearing protection practices remained challenging. Strengthening implementation strategies is critical to achieving meaningful reductions in occupational NIHL risk among quarry workers.

Predictors Of The Audiological Outcomes Of Middle Ear Cholesteatoma Surgery

Olga Tarasova[1]

[1]ProfORLcenter ORL

BACKGROUND & AIM

Middle ear cholesteatoma (MEC) surgery is one of the actual problems of otology due to destruction of bony structures, high incidence of extra- and intracranial complications and late diagnosis of the disease. Hearing loss in patients with MEC leads to impaired quality of life and social adaptation. In 2017, joint consensus recommendations of the European Academy of Otology and Neurootology and the Japanese Otological Society (EAONO/JOS) on the definition, classification and stages of middle ear cholesteatoma was published. A study objective was to evaluate staging system as predictors for postoperative hearing, using a patient cohort in our clinic.

MATERIAL & METHODS

Patients who underwent surgery for middle ear cholesteatoma between 2014 and 2020 were included in our study. Based on the surgical protocols, preoperative temporal bone computed tomography images; the disease was classified according to the EAONO/JOS staging system. Hearing parameters obtained by pre- and postoperative pure tone audiometry at 1 and 3 years were analyzed according to the surgical technique used (Canal Wall Up (CWU) and Canal Wall Down (CWD)) and the stage of the disease.

RESULTS

One year after the surgery, the average value of air conduction and air-bone gaps had improved in the vast majority of patients. 41 patients (%) underwent closed type of surgery, 71 (51%) - open type and 11 patients (8%) did not undergo mastoidectomy. Patients who underwent CWU had better postoperative air conduction and air-bone gap scores than patients who underwent CWD. According to the staging system, the mean value of preoperative air conduction at stage I was 46,59±21,12dB, at stage II – 49,10±16,76dB, at stage III – 61,03±22,94dB. Postoperative mean value of air conduction 1 year after surgery was at stage I – 42,26±17,89dB, at stage II – 43,42±14,64dB, at stage III – 69,50±24,53dB and 42,97±17,50dB, 43,46±14,75dB, 74,22±22,22dB after 3 years, respectively. Patients with stage III of the disease had worse postoperative hearing than those with stage I of the disease.

CONCLUSIONS

EAONO/JOS staging system (low incidence of the pathology) and surgical technique (CWU) in our study were statistically significant predictors for successful hearing improvement.

cholesteatoma, predictors of functional results, EAONO/JOS staging system, CWU, CWD

PP-398

Auricular Myoclonus: A Case Presentation

serhat ekemen[1]

[1]Karabuk University Faculty of Medicine

BACKGROUND & AIM

To raise awareness about auricular myoclonus and share our experiences.

MATERIAL & METHODS

Auricular myoclonus is an extremely rare disease characterized by involuntary, semi-rhythmic movements of the auricle. In this article, we present a patient who came to our clinic with involuntary ear movements. Our patient was a 37-year-old woman. The patient had been experiencing involuntary movements in the right ear for approximately two years. They reported that right-ear movement was more bothersome at night. They did not report hearing loss, pain, or tinnitus. There was no history of trauma, infection, or previous ear surgery. The patient stated that they had been under follow-up for four years with a diagnosis of Multiple Sclerosis. They did not identify any psychological, psychosocial, or physical stress factors. Examination revealed involuntary upward and backward movements of the right auricle. Oropharynx and anterior rhinoscopy were normal. Both tympanic membranes and the external auditory canal were assessed as normal.

RESULTS

Cranial nerve examinations revealed no pathology. Tympanogram and audiogram were normal. The ear MRI was normal. Cervical MRI (Magnetic Resonance Imaging) revealed demyelinating MS plaques in the C1-C5 region, asymmetrically involving the cord, and diffuse disc bulging at the C5-6 and C6-7 levels, consistent with multiple sclerosis. Brain MRI detected chronic demyelinating MS plaques in the periventricular cerebral white matter. Head and neck examination was normal. Complete blood count and biochemistry tests were normal. CSF analysis showed a small number of lymphoid cells with a mildly proteinaceous background, all of which appeared degenerate. The patient received Botox treatment every 2 months. She stated that her symptoms disappeared for approximately 2 weeks after each session, then reappeared. However, she noted that her symptoms were less severe with each relapse. The interval between sessions was extended to 6 months, and the patient's treatment is still ongoing.

CONCLUSIONS

Auricular myoclonus is an extremely rare disease that manifests as involuntary semi-rhythmic movements of the auricle. Özdoğmuş et al. In their study on nerve bundles in the internal auditory canal of cadavers, they demonstrated a cross-nerve connection between the facial, vestibular, and cochlear bundles using scanning electron microscopy. Botulinum toxins A has shown promising results, with partial or complete recovery; however, the dosage and frequency remain debated. Further studies are needed regarding the etiology and treatment of auricular myoclonus.

We also applied this treatment to our patient, with partial success. The patient's treatment is still ongoing.

NOT JUST ANOTHER OTITIS: OTOLOGIC CLUES TO GRANULOMATOSIS WITH POLYANGIITIS

Marta Santiago Horcajada[1], **Mireya Bonet Loscertales**[1], **Francisco Javier Guerra Blanco**[1], **Daniel Alberto Nuñez Carlino**[1], **Javier Morales Domínguez**[1], **Hander Guillermo Acosta Díaz**[1], **José Miguel Villacampa Aubá**[1], **Carlos Cenjor Español**[1]

[1]*Hospital Universitario Fundación Jiménez Díaz*

BACKGROUND & AIM

Granulomatosis with polyangiitis (GPA) is a systemic necrotizing vasculitis affecting small- and medium-sized vessels, with frequent involvement of the head and neck region. Otolaryngological manifestations occur in up to 70–90% of patients and may precede systemic disease. Otologic involvement, even though are not the most common clinical feature, can be the initial and sometimes isolated presentation, often mimicking chronic infections and delaying diagnosis.

MATERIAL & METHODS

The first case involves a 60-year-old woman with persistent bilateral otalgia and hearing loss refractory to antibiotics. The second case describes a 56-year-old man with persistent otologic symptoms initially treated as otitis externa/media. Both patients underwent otoscopic evaluation, audiometry, nasofibroscopy, and imaging studies (CT and MRI). Biopsies (of the ear in the first patient and nasopharynx in the second one) were also performed. Due to clinical suspicion, serologic testing, urinalysis and thoracic imaging were requested.

RESULTS

Physical exploration and imaging studies revealed middle ear occupation and nasopharyngeal inflammation. Tone audiometry revealed moderate conductive right hearing loss (PTA 50 dB) and mixed left hearing loss (PTA 60 dB) in the first patient, and moderate conductive right hearing loss (PTA 50 dB) progressing to bilateral mixed hearing loss. Biopsies excluded malignancy.PR3-ANCA and inflammatory markers levels were elevated and mild proteinuria was found. Thoracic imaging demonstrated pulmonary involvement. Diagnosis of GPA was confirmed and patients were immediately referred to rheumatology and internal medicine. The first patient received intravenous corticosteroids followed by rituximab, achieving symptom improvement but with residual tympanic perforations and transient otorrhea. The second patient required induction therapy with corticosteroids and cyclophosphamide, followed by maintenance immunosuppression, achieving complete resolution of otologic symptoms. Transtympanic drainage were attempted in the second patient but were limited by inflammatory changes.

CONCLUSIONS

Otologic manifestations may represent the initial presentation of GPA and should be considered in patients with refractory otitis media or unexplained mixed hearing loss. Early recognition is essential to avoid diagnostic delay and prevent irreversible damage, particularly sensorineural hearing loss. ANCA testing and biopsy of accessible head and neck lesions are key diagnostic tools. Prompt initiation of immunosuppressive therapy, including corticosteroids, is effective in controlling disease progression. Multidisciplinary management is crucial to optimize outcomes.

Early Mirror Biofeedback In High-Risk Facial Palsy: Quantitative Evaluation Of Oral–Ocular Synkinesis

ASAMI KAGEYAMA[1], **Miki Tomura**[1], **Mika Takahashi**[1], **Yoshiaki Kitamura**[1]

[1]*Tokushima University*

BACKGROUND & AIM

Severe facial synkinesis is often difficult to treat clinically. Early mirror biofeedback has been proposed for high-risk facial palsy patients to reduce severe oral–ocular synkinesis. We evaluated oral–ocular synkinesis after early mirror biofeedback using quantitative measurements in high-risk facial palsy patients.

MATERIAL & METHODS

This retrospective comparative cohort study included 38 patients with Bell's palsy or Ramsay Hunt syndrome who were considered at high risk for severe synkinesis based on electroneurography (ENoG) values below 46.5%. Patients with recurrent facial palsy or previous facial trauma were excluded. Twenty-eight patients underwent early mirror biofeedback, while 10 patients received no rehabilitation. Oral–ocular synkinesis was evaluated using the palpebral fissure ratio during standardized mouth movements. The palpebral fissure ratio at 1 year after onset was compared between the two groups. In the mirror biofeedback group, longitudinal changes between 1 year and ≥18 months after onset were additionally evaluated in 9 patients.

RESULTS

The mirror biofeedback group showed less severe oral–ocular synkinesis than the non-rehabilitation group at 1 year after onset (u: $p<0.001$, i: $p<0.001$, pu: $p<0.001$). In 9 patients with long-term follow-up, no apparent worsening was observed after discontinuation of mirror biofeedback. Long-term follow-up ranged from 18 to 36 months.

CONCLUSIONS

Early mirror biofeedback was associated with less severe oral–ocular synkinesis at 1 year in high-risk facial palsy patients. Additional long-term follow-up showed no apparent worsening after discontinuation of mirror biofeedback in a subset of patients. Early intervention may help reduce severe synkinesis in high-risk facial palsy patients.

Otogenic Septic Thrombosis Of The Transverse Sinus, Sigmoid Sinus, And Internal Jugular Vein Presenting With Acute Visual Loss

Atilay Yaylaci[1], **Murat Kahveci**[1], **Simge Türkan**[1], **Bekir Cem Ozcan**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, Kocaeli University, Kocaeli, Türkiye*

BACKGROUND & AIM

Otogenic cerebral venous sinus thrombosis is a rare but potentially severe intracranial complication of acute otitis media and acute mastoiditis in children (1,2). Its pathogenesis is associated with the close anatomical relationship between the middle ear–mastoid system and dural venous sinuses, together with infection-induced inflammatory and coagulation activation mechanisms (1). Clinical presentation may be subtle, and severe intracranial complications may develop despite minimal otologic findings (1,3). We present a pediatric case of otomastoiditis complicated by septic thrombosis of the transverse sinus, sigmoid sinus, and upper internal jugular vein presenting predominantly with acute visual loss.

MATERIAL & METHODS

A 6-year-7-month-old girl presented with sudden visual loss and diplopia. Ten days earlier, she had been diagnosed with acute otitis media and treated with oral amoxicillin-clavulanate therapy. Despite treatment, persistent headache and left-sided neck pain progressively developed.

Physical examination demonstrated bilateral reactive cervical lymphadenopathies. Ophthalmologic evaluation revealed bilateral papilledema, complete visual loss in the left eye, and decreased visual acuity in the right eye. Contrast-enhanced magnetic resonance imaging (MRI) demonstrated left otomastoiditis together with thrombosis involving the left transverse sinus, sigmoid sinus, and upper internal jugular vein. Bilateral papilledema and sphenoid sinusitis were also identified. Computed tomography (CT) demonstrated otomastoiditis with preserved mastoid septations and intact cortical bone structures.

RESULTS

The patient was admitted to the pediatric intensive care unit and managed with intravenous antibiotic therapy, low-molecular-weight heparin, hypertonic saline, and hyperbaric oxygen therapy. Following stabilization of the patient's clinical condition, left simple mastoidectomy was performed.

Intraoperatively, inflammatory mucosal edema and granulation tissue were observed without evidence of cholesteatoma or coalescent mastoid destruction. Postoperatively, cervical pain regressed and ocular motility significantly improved. Visual acuity in the right eye returned to normal, while partial visual recovery was achieved in the left eye. No additional intracranial complication or postoperative facial nerve deficit developed during follow-up.

CONCLUSIONS

Otogenic septic thrombosis involving the transverse sinus, sigmoid sinus, and internal jugular vein remains a rare but potentially life-threatening complication of acute otomastoiditis. Severe intracranial complications may develop despite minimal otologic findings and relatively mild inflammatory laboratory markers. Acute visual symptoms and papilledema may represent early manifestations of cerebral venous sinus thrombosis in pediatric patients. Prompt neuroimaging, multidisciplinary management, aggressive medical therapy, and timely mastoid surgery are essential to achieve favorable neurological and ophthalmological outcomes.

Surgical Difficulty Of An Iatrogenic Cholesteatoma Associated With Jugular Bulb Dehiscence

SAHRAOUI Mohammed[1,2], **MEHTARI Nasrine Siham**[1,2], **KAMRAOUI Samia**[1], **NASRI Amine**[1,2], **BENOSMAN Fazil**[1]

[1]*ENT Department - Tlemcen University Hospital Center;* [2]*Faculty of Medicine - Abou Bekr Belkaid University of Tlemcen*

BACKGROUND & AIM

Iatrogenic middle ear cholesteatoma is a rare but serious entity in otologic surgery. Its management becomes particularly challenging when associated with an anatomical anomaly that increases the risk of major complications and limits the possibility of complete removal.

Through this work, we report the diagnostic and therapeutic challenges encountered in the management of an iatrogenic cholesteatoma developing on jugular bulb dehiscence.

MATERIAL & METHODS

We report the case of a 15-year-old patient with a history, at the age of 6, of a right ear foreign body (chalk), which was pushed into the middle ear during extraction attempts, resulting in a tympanic membrane perforation complicated by a peripheral facial palsy that later resolved completely.

The patient subsequently underwent tympanoplasty with an uneventful postoperative course.

Ten years after surgery, he presented with chronic, foul-smelling right otorrhea evolving over several months.

Clinical examination, including microscopic otoscopy, temporal bone CT imaging, and appropriate surgical management, was performed.

RESULTS

Microscopic examination after suction of otorrhea revealed a subtotal marginal tympanic membrane perforation filled with epithelial debris. The left ear examination was unremarkable.

Temporal bone CT scan showed a postoperative status with a spontaneously formed attic cavity, filled with dense material involving the tympanic cavity and the oval and round window recesses. There was erosion of the long process of the incus and part of the malleus, with the stapes not visualized. Jugular bulb dehiscence with erosion of the jugular foramen roof was noted, communicating with the hypotympanum.

The patient underwent a right retroauricular canal wall–up tympanoplasty with complete removal of an extensive cholesteatoma, extending from the middle ear to the mastoid posteriorly and to the tegmen tympani, in close contact with the temporal lobe meninges. Dissection was particularly difficult and meticulous in the hypotympanum due to jugular bulb dehiscence. The postoperative course was uneventful.

CONCLUSIONS

Surgical management of an iatrogenic cholesteatoma associated with jugular bulb dehiscence represents a major otologic challenge. The exposure of such a fragile vascular structure significantly increases the risk of hemorrhage and limits the possibility of complete excision, making surgery both delicate and potentially incomplete. This situation requires meticulous preoperative planning, precise knowledge of anatomical variations, and extreme intraoperative caution in order to reduce morbidity and optimize both functional and anatomical outcomes.

Multiple Sclerosis In Adolescence: BPPV As The Initial Presentation - Case Report And Literature Review

Rafaela de Macedo Fernandes[1], **Mariana Rigueiro Cascão**[1], **José Fernandes**[1], **André Machado**[1], **António Castanheira**[1]

[1]*Department of Otolaringology, Unidade Local de Saúde Trás-os-Montes e Alto Douro, Portugal*

BACKGROUND & AIM

Vertigo is a frequent symptom in both pediatric and adult populations, most often related to benign peripheral causes such as benign paroxysmal positional vertigo (BPPV). In children and adolescents, it accounts for approximately 10% of balance disorders, whereas multiple sclerosis (MS), although rare, may also initially present with vertigo. Up to 37% of patients with MS experience vertigo during the disease course, occasionally as the inaugural manifestation. Differentiating peripheral BPPV from central vertigo is therefore essential, as MS may mimic benign presentations, particularly when nystagmus is atypical, bilateral, or recurrent.

MATERIAL & METHODS

The clinical and imaging data of the presented case were analyzed after obtaining the necessary informed consents, ensuring compliance with ethical standards and confidentiality requirements. The study was complemented by a brief narrative review of the literature in order to contextualize the case.

RESULTS

A 16-year-old girl presented to the otorhinolaryngology emergency department with sudden, brief vertigo triggered by head movements. Right-sided BPPV was diagnosed, and symptoms improved after the Epley maneuver. One month later, the symptoms recurred. A cranial CT scan requested by Neurology was unremarkable, and left-sided BPPV was diagnosed, with repositioning maneuvers performed. The following week, symptoms persisted and became progressively disabling. Neurological examination revealed no spontaneous or provoked nystagmus, negative head impulse, skew, Romberg, and Fukuda tests, but bilateral Dix-Hallpike elicited pure vertical nystagmus. An urgent brain MRI demonstrated multiple demyelinating gliotic foci, including a lesion near the left superior cerebellar peduncle extending to the vermis. It was confirmed the diagnosis of MS and she remains under follow-up by otorhinolaryngology and neurology, currently asymptomatic and clinically stable.

CONCLUSIONS

BPPV has been described as an initial manifestation of MS in several reports. As in this case, BPPV has been identified as the most frequent cause of vertigo in MS. In pediatric patients, although BPPV is relatively common, persistence or atypical features should prompt central investigation, in line with our findings. For MS, brain/spinal MRI is the reference imaging test, while vestibular evoked myogenic potentials can reveal demyelinating vestibular pathway involvement not visible on routine MRI. The initial presentation of MS as BPPV in adolescence, although rare, highlights the importance of considering central causes in atypical or recurrent vertigo.

Hearing Loss And Palmoplantar Keratoderma Associated With Mitochondrial DNA 7445A>G Variant: A Report Of Two Cases

Natsumi Uehara[1], **Jun Yokoi**[1], **Takeshi Fujita**[1]

[1]*Department of Otolaryngology-Head and Neck Surgery, Kobe University Hospital*

BACKGROUND & AIM

Mitochondrial diseases present with diverse phenotypes, often causing hearing loss at any age. Palmoplantar keratoderma (PPK) is a rare, intractable group of genetically predisposed disorders characterized by hyperkeratosis of the palms and soles. Although syndromic hearing loss with PPK is often associated with other genetic causes such as the gap junction protein beta 2 (GJB2) gene, it can also be linked to mitochondrial variants. Here, we report the clinical features of two cases presenting with both hearing loss and PPK caused by a mitochondrial DNA (mtDNA) 7445A>G variant.

MATERIAL & METHODS

Case 1: A 29-year-old male presented with hearing loss noted since birth, which gradually progressed, requiring hearing aids from age 20. Plantar keratotic lesions appeared in his early teens. His mother and younger brother had similar symptoms, while his father had isolated hearing loss. Pure-tone audiometry (PTA) revealed bilateral high-frequency sloping sensorineural hearing loss (SNHL) with an average of 80.0 decibels hearing level (dB HL) on the right and 77.5 dB HL on the left.

Case 2: A 22-year-old male was identified with hearing loss during a fifth-grade school screening. Following gradual progression, he began using hearing aids in junior high school. Plantar keratoderma appeared concurrently. There was no family history of hearing loss or dermatological diseases. PTA showed bilateral high-frequency sloping SNHL (Right: 75.0 dB HL, Left: 70.0 dB HL).

For both patients, genetic testing for congenital hearing loss under national health insurance was performed to establish a definitive diagnosis.

RESULTS

Results: Genetic analysis successfully identified the mtDNA 7445A>G variant in both patients. While the mtDNA 7445A>G variant is known to occasionally cause non-syndromic hearing loss, these cases demonstrate its presentation as syndromic hearing loss with PPK. Both cases exhibited progressive high-frequency SNHL. Given the high risk of progression to profound hearing loss indicated by previous literature, cochlear implantation is currently under consideration as a future intervention for both patients.

CONCLUSIONS

The mtDNA 7445A>G variant should be considered as a potential etiology in patients presenting with SNHL accompanied by PPK. Genetic testing proved essential not only for establishing a definitive diagnosis but also for guiding future therapeutic strategies and long-term clinical management.

PP-405

Mobitz Type 2 AV Block Presenting With Sudden Sensorineural Hearing Loss: A Case Report.

Muhammet Yıldız[1]

[1]*Department of Otolaryngology–Head and Neck Surgery, Antalya Training and Research Hospital, University of Health Sciences, Antalya, Turkey*

BACKGROUND & AIM

To report a rare case of unilateral sudden sensorineural hearing loss (SSNHL) secondary to Mobitz Type II atrioventricular (AV) block and to evaluate hearing outcomes following medical treatment.

MATERIAL & METHODS

A 32-year-old male presented with sudden-onset hearing loss in the right ear and non-pulsatile tinnitus. Syncope developed 24 hours after the onset of auditory symptoms. The patient had no history of ototoxicity, trauma, or systemic disease. Physical examination revealed stable vital signs and intact cranial nerves. Audiological evaluation confirmed right-sided SSNHL (AC/BC: 48/45 dB) with normal contralateral hearing (AC/BC: 17/10 dB). Initially diagnosed with idiopathic SSNHL, the patient was hospitalized for intravenous (IV) prednisolone (1 mg/kg/day). Following the detection of an AV block on the third day of hospitalization, systemic steroids were discontinued and replaced with five alternate-day sessions of intratympanic dexamethasone (4 mg/mL). Gadolinium-enhanced MRI of the inner ear was normal.

RESULTS

Following interdisciplinary consultations between the neurology and cardiology departments, the patient's history of syncope was attributed to an underlying cardiac conduction abnormality. Twenty-four-hour Holter ECG monitoring revealed an incidental Mobitz Type II AV block. This episode lasted 2,11 seconds with a documented ventricular rate of 72 bpm. Permanent pacemaker implantation was indicated as per current guidelines for the prevention of recurrent syncope and sudden cardiac death. The patient refused the intervention. A strategy of conservative management with close cardiac follow-up was adopted, noting the patient's stable hemodynamic status (absence of recurrent symptomatic bradycardia and hypotension) and relatively young age. By the fifteenth day of treatment, hearing thresholds significantly improved (Right AC/BC: 13/8 dB). Follow-up Holter monitoring at one week, and at one, six, and twelve months, remained within normal limits. To our knowledge, this is the first report the coexistence of Mobitz Type 2 AV block and SSNHL.

CONCLUSIONS

Atypical symptom such as syncope presenting in patients with SSNHL should be stimulating the otolaryngologist to investigate further possible system pathologies other than otological causes. Mobitz Type II AV block should be considered as a possible cause of SSNHL even in cases where there are no obvious predisposing factors.

PP-406

EFFICACY OF INTRATYMPANIC ADMINISTRATION OF SODIUM THIOSULFATE GEL FOR THE PREVENTION OF CISPLATIN-INDUCED OTOTOXICITY

SUBIN KIM[2], **JEE HYUN KANG**[1], **KEUM-JIN YANG**[1]

[1]*DEPARTMENT OF OTOLARYNGOLOGY, COLLEGE OF MEDICINE, THE CATHOLIC UNIVERSITY OF KOREA;* [2]*DEPARTMENT OF OTORHINOLARYNGOLOGY-HEAD AND NECK SURGERY, SOONCHUNHYANG UNIVERSITY COLLEGE OF MEDICINE*

BACKGROUND & AIM

Platinum-based chemotherapeutic agents, such as cisplatin, are widely used but often induce dose-limiting ototoxicity. Sodium thiosulfate (STS) is one of the known otoprotective agent; however, systemic administration may reduce cisplatin's antitumor efficacy. Although the protective effects of STS are wellrecognized, there remains a lack of detailed studies evaluating local delivery stategies on cochlear uptake, oxidative stress modulation, and safety profiles.

MATERIAL & METHODS

Before a single intraperitoneal (i.p.) injection of cisplatin (16mg/kg), STS was administered either systemically via the intraperitoneal route or locally via intratympanic (IT) injection. For IT delivery, STS was applied either as a free solution or embedded in injectable hyaluronic acid-based hydrogels. Two hydrogel formulations were used: (1) NorHA, a norbornene-functionalized hyaluronic acid (NH), and (2) NorHACA, a catechol-modified NorHA (NHC) designed to enhance tissue adhesion. Hearing thresholds were measured by auditory brainstem response. Cochlear and hepatic platinum concentrations were quantified using ICP-MS. In vitro cytoprotection was assessed in HEI- OC1 cells using DCF-DA for reactive oxygen species (ROS), and viability assays.

RESULTS

Intratympanic delivery of STS, either as a solution or hydrogel-embedded formulation, significantly reduced cochlear platinum levels without altering hepatic platinum concentrations, suggesting preserved systemic cisplatin distribution. STS-treated groups exhibited improved auditory thresholds in ABR assessments and reduced intracellular ROS levels. Moreover, NOX3 expression was attenuated in the STS co-treated conditions. While the use of NorHA-based hydrogel matrices (NH or NHC) did

not confer a statistically meaninful auditory benefit over free-form IT STS, sustained cochlear presence was observed and may offer prolonged local exposure potential.

CONCLUSIONS

Hydrogel-based intratympanic delivery represents an effective platform for localized administration of STS. Local delivery of STS using hydrogels significantly attenuated cisplatin-induced ototoxicity while preserving systemic cisplatin exposure, suggesting that this strategy can provide selective otoprotection without compromising antitumor efficacy. This approach offers a clinically translatable and repeatable method for preventing cisplatin-induced hearing loss.

Neurosarcoidosis Mimicking Necrotizing Otitis Externa

PROFESSOR SERRADJI ZOUBEIDA[1], **Dr. KERZABI WASSILA**[1], **Dr.BOUZIANE MOHAMMED AEJ**[1], **Dr.CHIKH MALIKA**[1]

[1]*UNIVERSITY HOSPITAL OF ORAN ALGERIA*

BACKGROUND & AIM

Necrotizing otitis externa is a severe, potentially life-threatening infection involving the external auditory canal and skull base. It is most commonly caused by Pseudomonas aeruginosa and typically occurs in elderly patients with diabetes or immunosuppression.

Nevertheless, several inflammatory and neoplastic conditions may mimic this entity, complicating the diagnostic process.

Sarcoidosis is a multisystem granulomatous disorder of unknown origin. Neurological involvement occurs in 5–15% of cases and may manifest as meningitis, cranial nerve palsies, or skull base lesions, potentially mimicking infectious osteomyelitis.

We report a case of neurosarcoidosis initially misdiagnosed as necrotizing otitis externa, highlighting key elements that helped correct the diagnosis.

MATERIAL & METHODS

An 84-year-old man with diabetes and hypertension presented with chronic left otalgia, otorrhea, headache, and progressive bilateral hearing loss. Otoscopy showed a stenotic external auditory canal with whitish discharge, and cultures identified Candida albicans. Temporal bone CT demonstrated extensive middle ear opacification with ossicular and temporomandibular joint erosion, leading to an initial diagnosis of necrotizing otitis externa. Despite six weeks of broad-spectrum intravenous antibiotics and topical treatment, imaging remained stable and symptoms later recurred with vomiting and persistent headache. The patient subsequently developed facial nerve palsy, dysphagia, and hydrocephalus. Brain MRI revealed diffuse leptomeningeal enhancement, skull base infiltration, multiple cranial nerve involvement, and venous thrombosis. Cerebrospinal fluid and repeated microbiological investigations were negative, while inflammatory markers remained elevated despite prolonged antibiotic therapy. Cervico-thoraco-abdomino-pelvic CT showed mediastinal lymphadenopathy and pulmonary micronodules suggestive of systemic sarcoidosis. Rapid improvement after corticosteroid therapy strongly supported the diagnosis of neurosarcoidosis.

RESULTS

Neurosarcoidosis is a rare but severe manifestation of systemic sarcoidosis, affecting the central nervous system in 5–15% of cases. Diagnosis is difficult because of its heterogeneous presentation and the frequent absence of histological confirmation. It may mimic infectious otologic diseases such as chronic otitis externa or skull base osteomyelitis, leading to delayed recognition. Cases described in the literature initially presented with chronic otorrhea and mastoid involvement despite negative cultures and poor response to antibiotics. In our case, several findings suggested a non-infectious inflammatory process: repeated negative microbiological investigations, normal procalcitonin levels, diffuse meningeal involvement with hydrocephalus, and multiple cranial nerve palsies. The most suggestive feature was the marked improvement after corticosteroid therapy followed by relapse during tapering, which strongly supports neurosarcoidosis. Additional evidence included mediastinal lymphadenopathy and pulmonary micronodules consistent with systemic sarcoidosis. Histological confirmation from extra-neurological sites, particularly mediastinal lymph node biopsy, remains essential for diagnosis.

CONCLUSIONS

This case highlights an unusual presentation of sarcoidosis.

Neurosarcoidosis should be considered in cases of atypical or treatment-resistant necrotizing otitis externa, particularly when associated with neurological involvement and negative microbiological findings.

Sarcoidosis remains a diagnosis of exclusion, based on the integration of clinical, radiological, and histopathological findings.

The wide spectrum of clinical manifestations and the lack of specific diagnostic tests frequently contribute to diagnostic uncertainty.

Neurological involvement in sarcoidosis is relatively uncommon, with a variable clinical course and an unpredictable prognosis.

Middle Ear Neuroglial Choristoma: A Rare Case With Review Of The Literature

Mehmet Birinci[1], **Recep Bedir**[2]

[1]*Department of Otorhinolaryngology, Faculty of Medicine, Recep Tayyip Erdoğan University, Rize, Türkiye;* [2]*Department of Pathology, Faculty of Medicine, Recep Tayyip Erdoğan University, Rize, Türkiye*

BACKGROUND & AIM

Neuroglial choristomas of the middle ear are exceedingly rare benign lesions composed of heterotopic mature neuroglial tissue without any connection to the central nervous system. Only a limited number of cases have been reported in the literature. These lesions often present with clinical findings mimicking chronic otitis media or cholesteatoma. The diagnosis is typically established through postoperative histopathological examination. In this study, we present a rare case of middle ear neuroglial choristoma and discuss its clinical, radiological, and histopathological features in light of the current literature.

MATERIAL & METHODS

A 61-year-old female presented with a 6-year history of hearing loss and ear fullness. Otoscopic examination revealed an intact graft in the right ear and purulent discharge with granulation tissue in the left ear; a ventilation tube was medialized into the middle ear. Audiometry showed 26/21 dB (right) and 72/40 dB (left). Temporal bone CT demonstrated a soft tissue lesion without tegmen defect, while MRI excluded intracranial connection; diffusion restriction suggested cholesteatoma. The patient underwent canal wall-up tympanomastoidectomy. Intraoperatively, reddish granulation tissue surrounding the ossicular chain was observed, with an intact tegmen. Histopathology revealed glial tissue within fibrous stroma, with GFAP and S100 positivity and low Ki-67 index, confirming neuroglial choristoma. Postoperatively, symptoms improved, and no recurrence was observed at 6-month follow-up. No postoperative complications were noted, and hearing status remained stable during follow-up. The findings supported a benign course and effective surgical management in this rare entity overall.

RESULTS

Neuroglial choristomas are defined as heterotopic brain tissue located outside the normal anatomical boundaries of the central nervous system. Middle ear involvement is extremely rare, approximately 30–40 cases reported in the literature. Clinically, these lesions frequently mimic chronic otitis media or cholesteatoma, making preoperative diagnosis challenging. Two main theories have been proposed regarding their pathogenesis: Sequestered encephalocele: Suggests that an initially existing encephalocele loses its intracranial connection over time. Embryological misplacement: Proposes abnormal migration of neuroectodermal cells during development. Many reported cases include a tegmen defect, supporting the sequestered encephalocele theory. However, cases with an intact skull base, as in our patient, favor the embryological misplacement theory. Magnetic resonance imaging plays a crucial role in excluding intracranial communication and differentiating from cholesteatoma. Definitive diagnosis relies on histopathological evaluation and immunohistochemical positivity for GFAP. Surgical excision is the treatment of choice, and the prognosis is generally excellent, with rare recurrence.

CONCLUSIONS

Middle ear neuroglial choristomas are rare benign lesions that can mimic common middle ear pathologies. Preoperative imaging is essential for excluding intracranial connections. Definitive diagnosis is established histopathologically, and surgical management yields excellent outcomes. Neuroglial choristoma should be considered in the differential diagnosis of atypical middle ear soft tissue lesions.

PP-409

Surgical Management Of Complete Traumatic Facial Nerve Transection In A Pediatric Patient: A Case Report On Cable Grafting And Functional Recovery

Ömer Faruk Yılmaz[2], **Cengiz Durucu**[1], **Orhan Tunç**[1], **Behçet Günsoy**[1], **Erhan Çiftel**[3]

[1]*Gaziantep Üniversitesi;* [2]*Nizip Devlet Hastanesi;* [3]*Batman Eğitim ve Araştırma Hastanesi*

BACKGROUND & AIM

Traumatic facial nerve paralysis affects quality of life due to functional and aesthetic issues, requiring a multidisciplinary approach. The nerve path in the temporal bone increases the risk of compression or transection, especially in cases of high-energy trauma. While management is debated, conservative monitoring is preferred for cases of delayed or incomplete paralysis. However, sudden post-trauma cases with severe damage often require surgical exploration to restore nerve integrity, aiming for facial symmetry and function (1). We discuss a case of post-trauma total facial paralysis treated surgically, emphasizing the importance of surgical timing, technique, and rehabilitation for outcomes.

MATERIAL & METHODS

A three-year-old girl presented with House-Brackmann Grade 5 facial paralysis on the right side after a non-vehicular accident. Otological examination revealed a perforated right tympanic membrane. CT revealed a horizontal fracture line extending to the petrous apex, involving the cochlea and facial canal. The patient underwent surgery via a right retroauricular incision for facial decompression and nerve repair. A transverse fracture from the petrous apex to the anterior LSSC completely transected

the patient's facial nerve. A second neck incision was used to harvest the Nervus Auricularis Magnus graft. The traumatized nerve ends were refreshed, and a cable graft supported by the temporal fascia was placed between them. No postoperative complications were observed. Significant facial function improvement was recorded due to nerve regeneration; by the 6th month, the patient reached HB Grade 3. This case highlights the importance of early surgical intervention and cable grafting in severe pediatric temporal bone trauma.

RESULTS

Traumatic facial paralysis in children presents challenges in terms of surgical techniques and postoperative care. Studies suggest that intervention within 14 days yields optimal outcomes, preventing permanent nerve degeneration. In our case, HB Grade 5 paralysis after high-energy trauma and a transverse fracture on CT supported surgical intervention. Pediatric cases are complicated by incomplete temporal bone development and a superficial mastoid nerve course, increasing trauma susceptibility . However, children regenerate nerves more effectively than adults. The literature describes successful cable grafts, even with large defects (2). We used the Nervus Auricularis Magnus for defects > 1 cm because of its proximity and compatibility with the facial nerve (3). The 1 cm defect required a cable graft because end-to-end anastomosis was impossible. Temporal fascia support stabilizes the nerve endings, aiding in healing.

CONCLUSIONS

The HB Grade 3 outcome obtained at postoperative month six is considered a successful achievement consistent with the literature for a pediatric case in which full-thickness incision and grafting were performed. HB Grade 3, a level at which symmetry is achieved at rest and full eye closure is possible, significantly improved the patient's quality of life. In conclusion, in children with facial paralysis due to severe temporal bone trauma, early microsurgical repair and appropriate grafting techniques performed after detailed radiological evaluation yielded promising results.

A Case Report Of BPPV As A Predictor Of Vestibular Ischemia: Cerebellar Stroke Preceded By Benign Paroxysmal Positional Vertigo

Selin Merve Sahin[1], **Esra Aydogan**[1], **Selin Unsaler Ustun**[1]

[1]*Koc University Hospital*

BACKGROUND & AIM

Vertigo has traditionally been categorized into either central or peripheral etiologies. However, as our understanding of vestibular pathophysiology evolves, it is becoming increasingly clear that these two entities may be deeply interconnected with a shared ischemic mechanism. Because the vestibular system is supplied by terminal end-arteries, it is most vulnerable to hypoperfusion; thus, isolated vertigo is often the sole early warning sign of vertebrobasilar insufficiency, preceding classic neurological symptoms. This case underscores the role of the inner ear as a "sentinel" organ for vertebrobasilar insufficiency and supports the hypothesis of ischemic otoconia detachment in posterior circulation strokes.

MATERIAL & METHODS

We report the case of a 60-year-old male who presented to the emergency room with severe, continuous vertigo and vomiting ten days after being treated for posterior canal BPPV, which was confirmed by a Dix Hallpike maneuver with a Videoelectronystagmography. The physical examination was notable for spontaneous nystagmus and an inability to open eyes due to severe vertiginous distress, which precluded a Head Impulse, Nystagmus, Test of Skew (HINTS) exam.

RESULTS

Diffusion-weighted MRI revealed an acute infarction in the right cerebellar hemisphere. MR Angiography confirmed thrombotic occlusion of the V4 segment of the right vertebral artery with a hypoplastic contralateral vertebral artery. The patient also possessed an anatomical variant where the Posterior Inferior Cerebellar Artery (PICA) originated caudally (V3-V4 junction), proximal to the thrombus. This variation preserved lateral medullary perfusion, sparing the patient from a catastrophic brainstem stroke. The patient made a full recovery with anticoagulant and antihypertensive therapy as well as physical therapy.

CONCLUSIONS

This case underscores the role of the inner ear as a "sentinel" organ for vertebrobasilar insufficiency and supports the hypothesis of ischemic otoconia detachment in posterior circulation strokes. ENT professionals must maintain a high index of suspicion for central pathologies in patients with refractory or atypical BPPV, particularly those with cardiovascular risk factors. It also highlights how subtle anatomical variations in the posterior circulation can drastically alter the clinical prognosis of vertebral artery thrombosis.

PP-411

Capillary Hemangioma Of The External Auditory Canal In A Pediatric Patient: A Case Report And Review Of The Literature

Mohammed Alsaif[1], **Abdulwahab Alyahya**[2], **Abdulaziz Alshaiji**[2]

[1]*College of Medicine, King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia;* [2]*Department of Otolaryngology - Head and Neck Surgery, King Fahad Hospital of University, Al-khobar, Saudi Arabia*

BACKGROUND & AIM

Capillary hemangioma is a benign vascular tumor characterized by lobular proliferation of capillary-sized vessels lined by flattened endothelial cells, commonly occurring in the head and neck region. Occurrence within the external auditory canal (EAC) is exceedingly rare, with limited published cases highlighting its unusual anatomical location and diagnostic challenges.[1–5] Clinically, it presents as a reddish, well-circumscribed mass causing otorrhagia, otalgia, ear fullness, or conductive hearing loss, and may mimic glomus tumors, pyogenic granuloma, or malignancy.[5] Diagnosis relies on histopathology, and complete transcanal excision offers excellent prognosis.[4,7] We present a pediatric EAC capillary hemangioma case emphasizing its presentation, histopathology, and outcome.

MATERIAL & METHODS

This clinical investigation was conducted in accoradence and compliance with guidelines of the Institutional Review Board (IRB) of King Fahad Hospital of University, Al-khobar, Saudi Arabia, with appropriate consent from the mother.

Our review of the literature was based on a PubMed search from 1972 to 2025 for all cases of the EAC hemangioma (capillary, venous, or mixed types), and 26 cases were finally evaluated.

RESULTS

A 5-year-old male presented with a progressively enlarging left EAC mass causing intermittent contact bleeding over three months, without otalgia, hearing loss, or facial nerve dysfunction. Otoendoscopy revealed a 2×2 cm hyperemic, highly vascular mass occupying the left external auditory meatus; audiometry was normal. CT temporal bone showed a well-defined soft-tissue lesion (1.1×1.4×1.6 cm) without bony erosion or middle ear involvement. MRI confirmed a vascular lesion with T2 hyperintensity and contrast enhancement. Histopathology confirmed capillary hemangioma. Complete transcanal excision under general anesthesia was performed with tympanic membrane preservation. The postoperative course was uneventful, with no recurrence at 6-month follow-up.

CONCLUSIONS

Capillary hemangioma of the EAC is an exceptionally rare benign vascular tumor, particularly in children, whose presentation may mimic inflammatory, vascular, or neoplastic lesions, creating diagnostic uncertainty. A high index of suspicion supported by audiological assessment, cross-sectional imaging, and histopathological confirmation is essential for accurate diagnosis. Complete transcanal surgical excision remains the treatment of choice for canal-confined lesions and is associated with excellent outcomes and low recurrence risk. This case underscores the importance of including capillary hemangioma in the differential diagnosis of pediatric EAC masses and contributes valuable data to the sparse existing literature on this rare clinical entity.

Middle Ear Hemangioma Presenting As Peripheral Facial Paralysis And Mastoid Effusion

Gulbin Demiroglu[1], **İlker Akyıldız**[1]

[1]*Etlik City Hospital, Department of Otolaryngology, Ankara, Turkey*

BACKGROUND & AIM

The aim of this case report is to present a pediatric patient with a left middle ear hemangioma who initially presented with peripheral facial paralysis and mastoid effusion, along with the radiological workup and management approach.

MATERIAL & METHODS

We report a case of a patient presenting with hearing loss and peripheral facial paralysis. Audiometric evaluation, contrast-enhanced magnetic resonance imaging (MRI), computed tomography (CT), and angiography were performed for diagnostic workup. Based on imaging findings, the diagnosis of middle ear hemangioma was established. The patient was treated conservatively with beta-blocker therapy. Clinical follow-up was conducted to evaluate treatment response

RESULTS

The combination of peripheral facial paralysis, a hypervascular retrotympanic appearance on otoscopy, and multimodality imaging findings led to the diagnosis of left middle ear hemangioma. In light of the patient's age and the vascular nature of the lesion, surgical intervention was deferred and propranolol at 0.5 mg/kg/day was initiated as primary treatment. The patient was followed up for treatment response and tolerability.

CONCLUSIONS

Middle ear hemangiomas are exceptionally rare in the pediatric population and may present with peripheral facial paralysis, conductive hearing loss, or pulsatile tinnitus. Their clinical and radiological overlap with glomus tympanicum and arteriovenous malformations makes diagnosis challenging. Contrast-enhanced MRI and CT angiography are essential in characterizing the lesion and guiding management decisions. In children, propranolol offers an effective non-surgical alternative, and should be considered early in the management of vascular tumors of the middle ear.

Congenital And Acquired Peripheral Facial Paralysis In Childhood - A Study Using Facial Computed Tomography Scans.

Rosana de Queiroz[1], **Helio Kiitiro Yamashita**[1], **Marcos Nadler Gribel**[2], **José Ricardo Gurgel Testa**[1]

[1]*UNIFESP- Federal University of São Paulo;* [2]*UniArnaldo university center*

BACKGROUND & AIM

Facial growth results from a complex combination of genetic and acquired factors. Studies indicate that the quality of mechanical stimuli generated during functional activities can influence craniofacial morphology. The form-function relationship suggests that, regardless of ancestry, the morphology of body structures can be influenced by the quality of mechanical stimuli during functional performance. In the face, the bone appears to be closely aligned with skeletal muscle activity. The objetive is identify the changes resulting from the lack of facial nerve function and to verify whether there is an association between the side affected by the paralysis and the opposite side.

MATERIAL & METHODS

On the hypothesis of altered muscular traction and grounded in the Functional Matrix Theory, computed tomography scans of 17 patients from the Facial Nerve Outpatient Clinic at the Federal University of São Paulo (with congenital or acquired facial paralysis) were analyzed. The images were sent in DICOM (Digital Imaging and Communications in Medicine) format in files that were imported into the SimPlant Ortho ProÒ 2.0 software (Dental Materialise, Leuven, Belgium), providing the values of the measurements, using the Compass protocol.

RESULTS

Were significant differences between the sides (p=<0.05) for the variables: gonial angle (p-value = 0.017); length of the mandibular ramus (p-value = 0.019); distance from the mental foramen to the Camper plane (p-value <0.001); distance from the mental foramen to the midsagittal plane (p-value < 0.028); distance from the gonion to the Camper plane (p-value = 0.025); distance from the jugal point to the Frankfurt plane (p-value = 0.003); condylar axis (p-value = 0.002); position of the gonion in relation to the midsagittal plane (p-value = 0.006). In the analysis of mental deviation, 100% of the sample presented a deviation towards the paralyzed side. When we performed the Kappa index, there was agreement between the smaller side and the paralyzed side.

CONCLUSIONS

There are differences between the facial growth and development of patients, with congenital or acquired facial paralysis, during development, indicating changes in the facial structure, becoming smaller on the paralyzed side in relation to the opposite side.

Aberrant Internal Carotid Artery With Persistent Stapedial Artery: A Rare Middle Ear Vascular Anomaly

Ece Şeyma Tüzel[1], **İrem Yalabık Aydoğdu**[1], **Ömer Faruk Çufalı**[1], **Nurcan Yurtsever Kum**[1]

[1]*Ankara Bilkent City Hospital*

BACKGROUND & AIM

Aberrant internal carotid artery (ICA) and persistent stapedial artery (PSA) are rare vascular anomalies of the middle ear that may clinically mimic retrotympanic masses and pose a significant risk of severe hemorrhage during otologic surgery. Lau et al. and Cetin et al. previously emphasized the importance of preoperative recognition of this rare coexistence. We present a rare case of concomitant aberrant internal carotid artery and persistent stapedial artery detected during the evaluation of otalgia and abnormal otoscopic findings.

MATERIAL & METHODS

A 54-year-old female patient was admitted with a 4-day history of right-sided otalgia. Otoscopic examination revealed right adhesive otitis and a violaceous, vascular-appearing retrotympanic lesion in the posteroinferior quadrant of the right tympanic membrane, raising suspicion of a retrotympanic vascular anomaly. Bilateral facial nerve motor function was intact. Temporal

bone computed tomography (CT), contrast-enhanced temporal magnetic resonance imaging (MRI) and neck magnetic resonance angiography (MRA) were performed for differential diagnosis and detailed vascular assessment.

RESULTS

Temporal bone CT demonstrated widening of the right inferior tympanic canaliculus and an aberrant ICA extending into the middle ear cavity anterior to the cochlear promontory. In addition, a vascular structure originating from the aberrant ICA was observed coursing between the stapes crura toward the tympanic segment of the facial nerve canal, consistent with a PSA. A high-riding jugular bulb was also identified on the right side. MRI and MR angiography confirmed the presence of aberrant ICA and PSA, with no evidence of additional vascular malformation. The patient was informed about the vascular anomaly and advised to notify otolaryngologists before any future middle ear intervention.

CONCLUSIONS

Aberrant ICA associated with PSA should be considered in the differential diagnosis of retrotympanic vascular lesions, particularly those mimicking glomus tumors or other middle ear masses. Careful otoscopic examination and appropriate radiologic evaluation are essential for accurate diagnosis, prevention of potentially life-threatening intraoperative hemorrhage, and safe surgical planning.

A Rare Complication Of Otitis Media In A Pediatric Patient With Nephrotic Syndrome

BÜŞRA ÜNSAL[1], **AHMET YEŞİLTEPE**[1], **MUHAMMED EYMEN AKSOY**[1], **ONUR TAĞIL**[1], **SAFİYE GİRAN ÖRTEKİN**[1], **SELİN ÜSTÜN BEZGİN**[1], **ÖZGÜR YİĞİT**[1]

[1]*UNIVERSITY OF HEALTH SCIENCES BAŞAKŞEHİR ÇAM VE SAKURA CITY HOSPITAL DEPARTMENT OF EAR, NOSE AND THROAT*

BACKGROUND & AIM

Acute suppurative otitis media (ASOM) is a prevalent pediatric infection; however, intratemporal and intracranial complications have declined in the antibiotic era. Nevertheless, in chronic immunosuppressive conditions like nephrotic syndrome (NS), ASOM can pursue an unusually aggressive course. In steroid-dependent NS, protein-loss–induced hypogammaglobulinemia and prolonged immunosuppressive therapy critically undermine host defenses. Temporomandibular joint (TMJ) abscess represents an exceedingly rare complication of ASOM, spreading subperiosteally via anatomical pathways. We present a rare pediatric case of TMJ abscess complicating NS-associated coalescent mastoiditis, successfully managed through a multidisciplinary approach.

MATERIAL & METHODS

Patient: An 11-year-old girl with a history of steroid-dependent nephrotic syndrome and autismspectrum disorder.

Presenting Complaints: High-grade fever, right purulent otorrhea, marked right preauricularswelling, and trismus (restricted mouth opening).

Physical Examination: Dense purulent discharge in the right external auditory canal; tympanic membrane was intact and hyperemic. A fluctuant ~2×3 cm swelling extending tothe right zygomatic region; restricted mouth opening.

Diagnostic Work-up: Laboratory analyses, temporal bone computed tomography (CT), magneticresonance imaging (MRI), and ultrasonography (USG) were retrospectively reviewed.

RESULTS

Laboratory: Marked leukocytosis (WBC: 37,700/mm^3) and elevated CRP (77.9 mg/L).

CT: Total opacification and septal destruction of the right mastoid air cells — findings consistent withcoalescent mastoiditis.

MRI & USG: An abscess collection measuring approximately 20×7 mm in the right TMJ space; inferior dislocation of the mandibular condyle secondary to effusion.

Surgery: Right cortical mastoidectomy was performed under general anesthesia. Themastoid antrum was found filled with dense granulation tissue; superior external auditorycanal wall destruction and spontaneous drainage of the TMJ abscess were observedintraoperatively. A ventilation tube was inserted into the tympanic membrane at theconclusion of the procedure.

Postoperative Course: Rapid clinical and laboratory improvement under multidisciplinary follow-up; normal mouth opening was restored.

CONCLUSIONS

In pediatric ASOM patients with underlying immunosuppression like nephrotic syndrome, atypical findings such as trismus and preauricular swelling should prompt immediate consideration of TMJ involvement. Early radiological evaluation via MRI is essential to avoid diagnostic delay. Timely surgical drainage and a multidisciplinary approach are pivotal to prevent permanent TMJ sequelae.

PP-416

A Retained Surgical Burr Tip In The Middle Ear Cavity For 30 Years: A Rare Case Report

Özlem Özdemir[1], **Deniz Baklacı**[1]

[1]*Department of Otolaryngology, Zonguldak Bulent Ecevit University Faculty of Medicine*

BACKGROUND & AIM

Retained foreign bodies in the middle ear cavity resulting from previous otologic surgeries are exceptionally rare. This case highlights an extraordinary, 30-year long-term retention of a surgical burr tip, emphasizing the unique biological behavior of bio-inert metallic materials within the middle ear cleft and demonstrating how such objects can remain minimally symptomatic for decades.

MATERIAL & METHODS

A 70-year-old male patient presented with chronic left-sided otorrhea and long-standing mixed-type hearing loss. His medical history revealed a primary myringoplasty and canaloplasty performed abroad three decades prior, during which bone burring was utilized. On otoscopic examination of the left ear, an anteroinferior tympanic membrane perforation was observed, through which an abnormal, foreign material not belonging to the middle ear structures was directly visualized. Audiometry confirmed a moderate mixed-type hearing loss. A high-resolution computed tomography (HRCT) of the temporal bone was ordered to investigate the mass, which revealed a distinct hyperdense area with prominent metallic starburst artifacts embedded within the middle ear space. A revision tympanoplasty was performed using an endoscopic approach. The procedure allowed for the safe mobilization and extraction of the retained burr tip from the fragile ossicular chain without any trauma to the facial nerve. The tympanic membrane was reconstructed using a tragal cartilage island graft.

RESULTS

The postoperative period was uneventful with complete graft take and a well-ventilated middle ear at the 3-month follow-up. While the moderate pre-operative mixed hearing loss remained stable due to chronic, irreversible ossicular changes, the chronic otorrhea was completely resolved, and potential long-term suppurative complications were successfully averted.

CONCLUSIONS

This extremely rare case demonstrates that metallic foreign bodies can remain encapsulated or dormant in the middle ear for three decades without causing catastrophic neurological or intra-temporal complications. Retained surgical instruments should be strongly considered in the differential diagnosis of recalcitrant symptoms following remote otologic procedures, underscoring the vital importance of strict instrument checklists in primary surgeries.

Audiological Discrepancy In The Coexistence Of Sudden Hearing Loss And Facial Paralysis: A Case Report

Bengi Arslan[1], **Yüce İslamoğlu**[1], **Ali Sami Berçin**[1], **Gökhan Atik**[1], **Tuğba Çayır**[1]

[1]*Ankara Bilkent City Hospital, Department of Otorhinolaryngology*

BACKGROUND & AIM

Sudden hearing loss (SHL) is mostly idiopathic and is generally associated with viral and vascular mechanisms. Its coexistence with facial paralysis is rare and may suggest underlying neuroinflammatory processes. In this report, we aimed to evaluate the clinical, audiological, and radiological findings of facial paralysis developing after SHL.

MATERIAL & METHODS

A patient who had been treated at an external center for right sided SHL in November 2025 with partial recovery presented in March 2026 with a complaint of decreased hearing in the right ear. Otomicroscopic examination revealed normal findings. On the same day, right-sided grade 2 facial paralysis according to the House–Brackmann grading system developed.

The patient had a history of fibromyalgia and depressive disorder. Treatment consisted of intravenous methylprednisolone at a dose of 1 mg/kg for 10 days, along with valacyclovir for 5 days due to a history of upper respiratory tract infection one week prior.

Audiological evaluation revealed inconsistent hearing thresholds. Auditory brainstem response (ABR) testing bilaterally normal wave latencies. Tympanometry showed bilateral type A , acoustic reflexes were present bilaterally, transient evoked otoacoustic emissions (TEOAE) were also present bilaterally.

Temporal MRI demonstrated minimal contrast enhancement in the labyrinthine segment and geniculate ganglion of the right facial nerve.

RESULTS

Although partial improvement in audiometric thresholds was observed after treatment, a fluctuating course persisted during follow-up. Auditory brainstem response (ABR) testing demonstrated preserved wave morphology at low thresholds, with thresholds that were inconsistent with pure tone audiometry. These findings indicate a discrepancy between objective and subjective audiological tests. Radiological findings were considered consistent with facial neuritis.

CONCLUSIONS

Early initiation of steroid and antiviral therapy in cases of facial paralysis developing after sudden hearing loss may lead to clinical improvement. However, cases accompanied by hearing loss may exhibit a fluctuating course. The discrepancy between objective and subjective audiological tests suggests the possibility of non-organic hearing loss; therefore, objective tests particularly ABR are of great importance in diagnosis and follow-up in such cases.

KEYWORDS

Sudden hearing loss, facial paralysis, facial neuritis, ABR, non-organic hearing loss

PP-418

Gradenigo's Syndrome: Case Report

Ezgi Çöllü[1], **Dilanur Gücük**[1], **Abdullah Karataş**[1]

[1]*SBÜ Sultangazi Haseki Training and Research Hospital, Department of Otorhinolaryngology, Istanbul, Turkey*

BACKGROUND & AIM

First described by Giuseppe Gradenigo in 1907, this syndrome is characterized by otitis media, unilateral pain in first and second branches of the trigeminal nerve distribution, and ipsilateral abducens nerve palsy. These cranial nerve dysfunctions result from inflammation of the petrous apex (petrositis) and have become a rare complication of otitis media since the widespread use of antibiotics. Understanding the etiology and performing appropriate scannings facilitate early diagnosis. However, recent literature has reported an increasing incidence of purulent otitis media with intratemporal and intracranial complications, particularly in pediatric groups.

MATERIAL & METHODS

Two cases of Gradenigo's syndrome were followed in our clinic in 2024. The first patient had bilateral ventilation tubes inserted, and subsequently underwent right mastoidectomy and antrostomy because less improvement was seen in symptoms after ventilation tube insertion. Second patient underwent left grommet tube insertion combined with postauricular abscess drainage due to fluctuant swelling in the mastoid region. The patients' medical histories, physical examination findings, imaging and laboratory results, and surgical treatments were retrospectively reviewed.

RESULTS

The patients presented with otalgia, mastoid tenderness, auricular protrusion, ipsilateral limitation of lateral gaze, and fever. On otoscopic examination, tympanic membrane hyperemia was observed bilaterally, with dry external auditory canals. One patient demonstrated mastoid swelling and tenderness along with restricted lateral eye movement on the same side. The two patients who underwent left grommet tube insertion with postauricular abscess drainage and bilateral ventilation tube insertion were included in this case series. They were evaluated with medical history, physical examination, temporal bone computed tomography (CT), temporal and brain magnetic resonance imaging (MRI), MRI venography. CT imaging consistent with petrositis. Increased intracranial pressure and papilledema was seen in both patients.

CONCLUSIONS

Gradenigo's syndrome is a striking clinical entity that a physician is unlikely to forget once encountered. As a complication of otitis media, the primary treatment is drainage; however, clinicians should remain vigilant for concomitant sigmoid sinus thrombosis and increased intracranial pressure. Detailed evaluation with CT and MRI imaging is essential, and patients should be managed through a multidisciplinary approach involving ophthalmology, neurology, infectious diseases, and radiology.

Gradenigo's syndrome, petrositis, otitis media complications, abducens nerve palsy, mastoid abscess,

PP-419

A Rare And Misleading Complication Of Pediatric Acute Otitis Media: Sigmoid Sinus Thrombosis Presenting With Diplopia

Berfin Ozsoy[1], **Ilker Akyıldız**[1]

[1]*Department of Otorhinolaryngology, Ankara Etlik City Hospital, Ankara, Türkiye*

BACKGROUND & AIM

The incidence of intracranial complications secondary to acute otitis media (AOM) has significantly decreased with the widespread use of advanced antibiotic therapies. Nevertheless, sigmoid sinus thrombosis (SST) remains a serious complication associated with considerable morbidity and mortality. Typical clinical manifestations of SST include headache, fever, and otorrhea. However, abducens nerve palsy resulting from increased intracranial pressure (ICP), leading to diplopia, is a rare presenting symptom. We present a pediatric case of SST associated with inward deviation of the right eye and diplopia following AOM.

MATERIAL & METHODS

A previously healthy 5-year-old girl presented to the emergency department with right-sided otalgia and fever lasting 2–3 days. Oral acetaminophen and amoxicillin-clavulanate (80 mg/kg/day) were prescribed; however, medication adherence was poor,

and the prescribed course was not completed. On the seventh day after the initial presentation, the patient re-presented with sudden-onset severe headache, vomiting, and diplopia in the right eye.

RESULTS

Physical and ENT examination revealed an intact but dull right tympanic membrane without mastoid tenderness. Ophthalmological evaluation confirmed right abducens nerve palsy and grade 2–3 papilledema. Laboratory findings showed leukocytosis (WBC: 16,000/mm^3) and elevated CRP (85 mg/L). Contrast-enhanced MRI and MR venography confirmed acute mastoiditis and right transverse and sigmoid sinus thrombosis extending into the jugular vein, accompanied by signs of increased intracranial pressure. Following urgent cortical mastoidectomy, ventilation tube insertion, and a multidisciplinary regimen of broad-spectrum antibiotics and anticoagulant therapy, rapid infection control was achieved, resulting in a favorable clinical outcome without neurological sequelae.

CONCLUSIONS

This case highlights that inadequately treated pediatric acute otitis media can lead to severe, life-threatening intracranial complications like sigmoid sinus thrombosis. Mastoiditis-induced venous sinus thrombosis impairs cerebral drainage, causing increased intracranial pressure and rare symptoms like abducens nerve palsy and diplopia. Early contrast-enhanced MRI and MR venography are vital gold standards for timely diagnosis. Anticoagulant therapy is safe in pediatric cases and crucial for preventing permanent neurological sequelae. Ultimately, prompt surgical intervention via cortical mastoidectomy and ventilation tube insertion, combined with aggressive intravenous antibiotics and anticoagulation, ensures rapid infection control and excellent clinical outcomes.

PP-420

"A Rare Complication Of Ramsay Hunt Syndrome: Vocal Cord Paralysis And Sudden Hearing Loss Accompanying Facial Palsy"

Sena Kaloğlu[1], **Özgür Kemal**[1], **Esra Demir**[1]

[1]*Ondokuz Mayıs University Otorinolaryngology and Neck Surgery Department*

BACKGROUND & AIM

Ramsay Hunt Syndrome (RHS) is a rare complication of varicella-zoster virus (VZV) reactivation in the geniculate ganglion, classically presenting with peripheral facial palsy, auricular vesicular eruption, and sensorineural hearing loss. Involvement of cranial nerves beyond CN VII and CN VIII — particularly the vagus nerve (CN X) — is exceedingly rare. We report a case of RHS with concurrent ipsilateral vocal cord paralysis, highlighting the importance of routine flexible laryngoscopy and early multimodal treatment in the management of this condition.

MATERIAL & METHODS

A 54-year-old immunocompetent woman presented with a 4-5 day history of right otalgia. Three days later, right-sided facial weakness, hoarseness, and auricular vesicles developed. Physical examination revealed vesicular eruptions in the right cavum concha and external auditory canal, House-Brackmann Grade 3 peripheral facial palsy, and right vocal cord paramedian fixation on flexible nasolaryngoscopy. Pure-tone audiometry confirmed moderate sensoryneural hearing loss in the right ear (PTA: 40 dB) with normal left-sided hearing (PTA: 15 dB). The patient was diagnosed with RHS with CN VII and CN X involvement. Treatment consisted of oral acyclovir (2 g five times daily), a tapering corticosteroid regimen, topical ear drops, and a structured 23-day facial physiotherapy programme.

RESULTS

At the four-week follow-up, vocal cord mobility had fully normalized and hoarseness had completely resolved. Audiometric re-evaluation demonstrated marked hearing improvement in the right ear (PTA: 18 dB), representing a 22 dB gain from baseline. Left-sided hearing remained normal (PTA: 13 dB). Flexible laryngoscopy confirmed bilateral normal vocal cord movements. Facial palsy completely recovered. No adverse effects related to treatment were observed. The clinical course was consistent with favorable recovery in both vagal and cochlear function following early initiation of antiviral and corticosteroid therapy combined with physical rehabilitation.

CONCLUSIONS

Concurrent CN VII, CN VIII and CN X involvement in RHS is rare but clinically significant. Undetected vocal cord palsy risks aspiration and diagnostic delay. Flexible laryngoscopy should be part of the routine evaluation in all RHS patients. Early antiviral and corticosteroid therapy, alongside structured physiotherapy, is associated with favorable functional recovery even in cases of cranial polyneuropathy. Clinicians should maintain a high index of suspicion for multi-cranial nerve involvement in RHS.

CONGENITAL DEFICIENCY OF INCUS - CASE REPORT

Vanja Nežić[1], **Dalibor Vranješ**[1], **Mirjana Gnjatić**[2], **Branko Jurišić**[1]

[1]*Clinic for diseases of the ear, throat and nose, University Clinical Center of the Republic of Srpska, Banja Luka, Republic of Srpska, Bosnia and Herzegovina;* [2]*Faculty of Medicine, University of Banja Luka, Banja Luka, Republik of Srpska, Bosnia and Herzegovina*

BACKGROUND & AIM

Congenital malformations of the auditory ossicles can be isolated and occur together with other anomalies of the ear. Micro malformations of the auditory ossicles are most often detected during exploratory operations of the middle ear. These anomalies cause a disturbance in the transmission of low tones, which is manifested by the appearance of conductive hearing loss. Congenital malformations of the external and middle ear are divided into large and small. Congenital anomalies of the incus can manifest in the form of fixation of its structures to the walls of the cavum tympani, incomplete development or complete lack of the incus.

MATERIAL & METHODS

A 14-year-old male patient comes for examination in December 2023 due to impaired hearing in the left ear that has evolved over many years. He underwent regular functional and radiological diagnostics for the past 8 years. In the clinical ENT examination, otomicroscopically, an intact, sclerotically altered tympanic membrane was observed on the left, in retraction with a reduced light reflex. Tympanometry is type A on both sides, and the tonal audiogram shows conductive hearing reduction of the high type on the left. The patient underwent a CT scan of the temporal bone, which showed no significant pathological changes.

RESULTS

Operative treatment of the left ear is indicated, which was performed in March 2024. An exploration of the left ear is performed, when a malformation of the ossicular chain, a complete lack of incus, while the structures of the malleus and stapes are fully preserved. Then, a titanium partial ossicular prosthesis (PORP) is placed on the head of the stapes along with a previously positioned cartilage graft. The operative and postoperative course went smoothly. After 2 months, the control tone audiogram shows a significant improvement of the average hearing threshold in the frequency range 125 Hz - 4 kHz compared to the preoperative values.

CONCLUSIONS

Congenital malformations of the auditory ossicles are rare and due to difficult detection based on symptoms, functional and radiological diagnostics, they are most often diagnosed during exploratory operations of the middle ear. In addition, operative treatment is simple and gives good results.

KEYWORDS

auditory ossicles, middle ear, hearing loss, operative treatment

PP-422

Incomplete Gradenigo Syndrome Presented With Four-Week History Of Right Frontal Headache, A Two-Day History Of Blurred Vision And Retro-Orbital Pain.

Konstantinos Tasoulis[1], **Christian Grimes**[1], **Ho Man Owen Chu**[1], **Vasiliki Bisbinas**[2], **Aileen Lambert**[1]

[1]*Otorhinolaryngology department, Royal Cornwall Hospital;* [2]*ENT Department, Newcastle upon Tyne Hospitals NHS Foundation Trust, UK*

BACKGROUND & AIM

Gradenigo syndrome is a rare complication of petrous apicitis, defined by the triad of suppurative otitis media, ipsilateral trigeminal neuralgia, and abducens nerve palsy. It arises from a middle ear infection or mastoiditis to the petrous apex. In addition to the classic triad, patients may present with otalgia, fever, altered consciousness, involvement of other cranial nerves, including V, VII, VIII, and X. The underlying pathophysiology is related to inflammation of Dorello's canal and Meckel's cave. The complete triad is present in fewer than 15% of cases; many patients demonstrate incomplete or atypical presentations. We present a diagnostically challenging case.

MATERIAL & METHODS

A 30-year-old man presented with a four-week history of progressive right frontal headache, a two-day history of blurred vision and retro-orbital pain. He reported a preceding two-month history of right-sided otalgia but denied otorrhoea or hearing loss. His background included tension headaches, amblyopia, and prior heavy cocaine use. Examination revealed isolated right abducens nerve palsy with horizontal diplopia and no meningism. Otoscopy demonstrated cerumen and an erythematous tympanic membrane without post-auricular changes. Inflammatory markers were within normal limits. Computed tomography (CT) revealed right mastoid opacification with bony erosion of the petrous apex. Magnetic resonance imaging (MRI) confirmed petrous apicitis extending to the clivus and Meckel's cave. The patient was managed under ENT with multidisciplinary input. A right grommet was inserted for drainage and microbiological sampling. Broad-spectrum intravenous (IV) antibiotics were initiated and tailored, with a planned 12-week course via peripherally inserted central catheter (PICC).

RESULTS

The patient demonstrated clinical improvement following combined medical and surgical management, with resolution of headache and stabilisation of diplopia. He was discharged after nine days with planned follow-up.

CONCLUSIONS

This case highlights an incomplete presentation of Gradenigo syndrome without otorrhoea, emphasising that absence of the classic triad does not exclude the diagnosis. ENT clinicians should maintain a high index of suspicion in patients presenting with persistent headache and cranial nerve VI palsy. Early imaging and prompt multidisciplinary management are essential to prevent skull base complications.

KEYWORDS

Gradenigo, Incomplete, suppurative otitis media with otorrhoea, ipsilateral trigeminal neuralgia, and abducens nerve palsy, absence of the classic triad does not exclude the diagnosis

PP-423

Maximum Intensity Projection Images In Surgical Position View Enhances Ossicular Visualization On Temporal Bone CT

Yoshinori Kadowaki[1], **Kazuhiro Yoshinaga**[1], **Hideto Shigemi**[1], **Shingo Umemoto**[1], **Takashi Hirano**[1]

[1]*Oita University Hospital*

BACKGROUND & AIM

High-resolution temporal bone CT plays a vital role in preoperative planning for otologic surgery. However, conventional axial and coronal views often require scrolling often require review of multiple sequential slices to fully assess ossicular morphology. Postprocessing techniques that combine key anatomic details into fewer images may allow more efficient and practical evaluation. To evaluate whether maximum intensity projection (MIP) applied to a surgical position view (SPV) enhances visualization of the auditory ossicles compared with conventional images and to examine interobserver reproducibility among readers with varying levels of experience.

MATERIAL & METHODS

Four patients without middle ear disease scheduled for facial nerve decompression or cochlear implantation were retrospectively analyzed. Using the multi-planar reconstruction (MPR) tool, sagittal images were generated from axial images and rotated 90° to obtain an SPV (MPR-SPV) images. MIP-SPV images were then created with a 3-mm slab thickness. For each patient and image (axial, coronal, MPR-SPV, MIP-SPV), the slice best depicting the malleoincudal (M-I) and incudostapedial (I-S) joints was identified. Ossicles were outlined with a touch pen, and the displayed area was measured. All procedures were performed using the native tools of the PACS viewer (SYNAPSE 5) integrated with the electronic medical record system. Three physicians with varying experience performed five independent measurements on different days.

RESULTS

Across all cases, MIP-SPV yielded remarkably larger displayed ossicular areas for both the M-I and I-S joints than axial, coronal, or MPR-SPV images. This advantage was consistent across all raters and repeated sessions, indicating robust inter-observer and intra-observer reproducibility.

CONCLUSIONS

MIP-SPV consolidates greater ossicular information per image, facilitating clearer, rapid appreciation of ossicular morphology without reviewing multiple consecutive slices. Its consistent performance across readers of differing experience suggests strong reproducibility and practical utility for preoperative evaluation in otologic surgery. These findings support that MIP-SPV images can sufficiently complement conventional axial and coronal images in the preoperative evaluation of the ossicles.

CT, Temporal bone, Ossicles, MIP, MPR

PP-424

Middle Cranial Fossa Approach For Complex Lateral Skull Base Otologic Pathology: A Four-Case Series

Lydia Benítez Moya[1], **Paula Pérez Chacón**[1], **Virginia Sarmentero López de Quintana**[1], **Mario Vara Blanco**[1], **Luis Ángel Vallejo Valdezate**[1]

[1]*Hospital Universitario Río Hortega*

BACKGROUND & AIM

The middle cranial fossa (MCF) approach remains an important surgical option for the management of complex lateral skull base pathology. Although transmastoid techniques are frequently used for tegmen defects, the MCF approach provides direct extradural exposure of the tegmen tympanii and tegmen mastoideum, allowing precise defect identification and secure multilayer reconstruction. This approach is particularly useful in patients with extensive tegmen defects, intracranial complications, or previous otologic surgery.

The aim of this study is to present a series of four patients treated using the MCF approach for different indications in a tertiary referral center and to evaluate surgical outcomes.

MATERIAL & METHODS

A retrospective descriptive study was conducted including four adult patients who underwent surgery using a middle cranial fossa approach at a tertiary referral hospital.

All patients underwent preoperative high-resolution computed tomography and magnetic resonance imaging to assess tegmen defects and intracranial involvement.

Surgery was performed under general anesthesia using a standard temporal craniotomy with extradural elevation of the temporal lobe. Tegmen defects were identified and reconstructed using multilayer techniques with autologous grafts or synthetic materials.

Indications included: CSF fistula secondary to a tegmen tympani defect (n=1), temporal lobe abscess associated with a persistent tegmen defect following canal wall down mastoidectomy (n=1), advanced cholesteatomatous chronic otitis media with intralabyrinthine and intracranial extension requiring subtotal petrosectomy (n=1), and postoperative meningocele following mastoidectomy and type IV tympanoplasty (n=1).

RESULTS

During the follow-up period, no recurrence of the primary disease was observed in most patients. One patient underwent revision surgery two years after the initial procedure due to clinical and radiological suspicion of recurrent cholesteatomatous chronic otitis media; however, no residual or recurrent disease was identified intraoperatively.

Regarding postoperative complications, one patient developed persistent postoperative peripheral facial paralysis, which required subsequent facial reinnervation surgery. The remaining patients showed no major complications during clinical follow-up.

The MCF approach proved particularly useful in patients with previous otologic surgery and complex anatomical defects. Successful closure was achieved in all cases without recurrence of CSF leakage or intracranial complications during follow-up.

In patients with intracranial complications, definitive tegmen repair is essential to prevent recurrence. Similarly, in advanced cholesteatoma with intracranial extension, the MCF approach may facilitate safe disease control and skull base reconstruction.

CONCLUSIONS

The middle cranial fossa approach is a safe and effective technique for the treatment of complex tegmen defects and lateral skull base pathology.

This approach provides excellent surgical exposure and allows reliable reconstruction in patients with CSF fistulas, meningoceles, intracranial complications, and advanced cholesteatoma.

Careful patient selection is essential, and the MCF approach should be considered in patients with extensive defects or intracranial involvement.

This technique remains an important surgical option in tertiary referral centers managing complex otologic disease.

Mastoid Dressings Following Otologic Surgery: A Study Of Intra-Dressing Pressure Dynamics

Abhiroop Saha[1], **Sarah Almas**[1], **Deo-Mark Macadaeg**[2,3,4], **Allan Ho**[1]

[1]*University of Alberta*; [2]*University of Saskatchewan*; [3]*Institute of Electrical and Electronics Engineers*; [4]*The Association of Consulting Engineering Companies*

BACKGROUND & AIM

Mastoid pressure dressings are routinely applied after otologic surgery to prevent hematoma formation, yet recent evidence questions their clinical benefit. No study has objectively quantified the pressure these dressings exert or how rapidly it decays. We aimed to measure and compare the intra-dressing pressures of gauze-and-cling versus self-adherent (Coban) mastoid dressings during the immediate postoperative period using a novel calibrated pressure sensor.

MATERIAL & METHODS

A calibrated pressure sensor was developed in collaboration with biomedical engineering colleagues and positioned directly beneath the mastoid dressing immediately following otologic surgery. Patients received either a conventional gauze-and-cling wrap or a self-adherent Coban dressing. Intra-dressing pressure was recorded continuously from 0 to 120 minutes postoperatively. Pressure profiles for each dressing type were compared to characterize the magnitude and rate of pressure decay during the immediate postoperative period.

RESULTS

Preliminary data demonstrate a consistent and significant decline in intra-dressing pressure within 120 minutes of application for both dressing types. The pressure exerted by mastoid dressings decreased substantially from baseline during the

monitored postoperative window, suggesting that the compressive benefit of these dressings is largely lost in the short-term period following surgery.

CONCLUSIONS

Mastoid pressure dressings lose meaningful compressive force within two hours of application. These findings support consideration of shorter dressing durations, particularly after uncomplicated otologic procedures, and highlights the need for evidence-based dressing protocols. This evidence has the potential to change postoperative care and advice with regards to the duration mastoid dressings are left on.

PP-426

Beyond The Acoustic Nerve: A Hypoglossal Schwannoma Case Report

Ana Miguel Couto[1], **Rafael Pires**[1], **Leonor Oliveira**[1], **Joana Dias**[1], **Carla André**[1], **Helena Rosa**[1], **Luís Antunes**[1]

[1]*Hospital Garcia de Orta*

BACKGROUND & AIM

Hypoglossal schwannomas (HS) are rare skull base tumors, representing only 5% of all non-acoustic intracranial schwannomas. Based on the Kaye classification, they are divided into type A (intracranial), type B (dumbbell-shaped, extending through the hypoglossal canal), and type C (extracranial). Fewer than 50 type B cases have been published worldwide, and cystic patterns are extremely rare. Their location in the cerebellopontine angle (CPA) poses significant diagnostic challenges, as they are frequently mistaken for vestibular schwannomas.

MATERIAL & METHODS

A 26-year-old female presented to the emergency department with an acute episode of severe left periorbital pain, vomiting, left hemibody sensory changes and transient confusion, with spontaneous resolution. Initial computed tomography (CT) scan identified a hypodense contrast-enhancing lesion at the left CPA, suggestive of vestibular schwannoma. She also reported a background history of headaches and dysphonia. Laryngoscopy revealed bilateral vocal fold nodules with fully preserved mobility. Videonystagmography (VNG) revealed signs of central posterior fossa pathology, with normal and symmetric caloric responses. Subsequent magnetic resonance imaging (MRI) demonstrated a well-defined extra-axial mass centered on the left hypoglossal canal measuring 27.4 × 23.1 × 16.3 mm, with hypointense signal on T1, hyperintense on T2, moderate enhancement after gadolinium injection, partially cystic features and mass effect on the brainstem and fourth ventricle, consistent with a type B hypoglossal schwannoma.

RESULTS

The patient underwent suboccipital extended craniotomy and partial condylectomy with intraoperative cranial nerve monitoring. Apparent complete tumor removal was achieved. Histopathology confirmed a WHO Grade 1 conventional schwannoma with cystic degeneration, without atypia, significant mitotic activity or necrosis.

CONCLUSIONS

This case illustrates a rare entity made even more exceptional by its cystic degeneration and initial misdiagnosis on CT. The absence of cranial nerve deficits does not exclude significant skull base pathology. MRI is the gold standard for accurate characterization of hypoglossal canal lesions, and a low threshold for its use is essential to avoid diagnostic pitfalls in patients presenting with CPA masses.

Congenital Aural Atresia: A Case Report

Asier Blanco Goñi[1,2,3], **Carlos Cenjor Español**[1,2,3], **Francisco Javier Guerra Blanco**[1,2,3], **Mireya Bonet Loscertales**[1,2,3], **David Pérez Pérez**[1,2,3], **Francisco Javier Cogolludo Pérez**[1,2,3], **José Miguel Villacampa Aubá**[1,2,3]

[1]*Hospital Universitario Fundación Jiménez Díaz;* [2]*Hospital Universitario Infanta Elena;* [3]*Hospital Universitario General de Villalba*

BACKGROUND & AIM

Congenital aural atresia (CAA) is a rare developmental anomaly (1:10,000–20,000 births) characterized by complete absence of the external auditory canal. It results from abnormal development of the first branchial cleft and the first and second branchial arches, often associated with microtia and middle ear malformations. Since the inner ear originates separately from the otic placode, it is usually preserved, resulting in predominantly conductive hearing loss. While most cases are sporadic and associated with microtia, CAA can rarely occur in the presence of a normal pinna. Early audiological and radiological assessment is essential for appropriate management.

MATERIAL & METHODS

We report the case of a 17-year-old male with no significant past medical history, previously without follow-up at our institution, who presented for evaluation of unilateral hearing loss. Physical examination revealed right-sided CAA with a normally developed auricle, representing a rare clinical presentation. Otoscopic examination of the contralateral ear was unremarkable.

Tuning fork tests (Rinne and Weber) were consistent with right-sided conductive hearing loss. Speech and language development were appropriate for age, suggesting long-standing, well-compensated auditory impairment. High-resolution computed tomography (CT) of the temporal bones and comprehensive audiometric testing were performed to further characterize the anatomy and quantify the degree of hearing loss.

RESULTS

Pure-tone audiometry demonstrated moderate-to-severe right-sided conductive hearing loss, with good speech discrimination on bone conduction testing. Imaging revealed complete bony and membranous obliteration of the expected course of the right external auditory canal, a small but adequately aerated tympanic cavity, and absence of the malleus handle. The remaining ossicular chain and inner ear structures were normal.

Various management strategies were considered. Although canalplasty (atresiaplasty) is a surgical option, it remains one of the most technically challenging otologic procedures, and long-term outcomes may show deterioration of initial hearing gains. Given these considerations, the patient's excellent bone conduction thresholds, and his desire for improved binaural hearing, an osseointegrated bone-conduction device (OIBCD) was selected.

A right-sided bone conduction implant trial demonstrated good functional benefit, and a transcutaneous osseointegrated implant (Sentio) was subsequently placed, resulting in significant hearing improvement and a favorable functional outcome.

CONCLUSIONS

Congenital aural atresia requires careful clinical and radiological evaluation to guide management. Unilateral cases may be managed conservatively or surgically with with bone-conduction devices or atresiaplasty. Treatment should be individualized, and thorough patient counseling regarding risks and benefits is essential to optimize hearing outcomes and quality of life.

Report On The Current Status Of Patulous Eustachian Tube Dysfunction Treatment And Eustachian Tube Plug Surgery With Kobayashi Plug Insertion In Japan: Real-World Data From The First 3 Years Following Introduction

Taisuke Kobayashi[2], **Toshimitsu Kobayashi**[2], **Toshifumi Sakata**[2], **Haruo Takahashi**[2], **Satoshi Yoshioka**[1], **Maki Arai**[2], **Ryokichi Ikeda**[2], **Ryoji Hirai**[2], **Masatsugu Masuda**[2], **Kunihiro Mizuta**[2], **Shingo Murakami**[2], **Masahiro Morita**[2], **Nobumasa Yamaguchi**[2], **Wataru Yamaguchi**[2], **Haruo Yamaguchi**[2], **Akira Inagaki**[2], **Takeshi Oshima**[2], **Shigeto Ota**[2], **Akihiro Kaneko**[2], **Toshiaki Kikuchi**[2]

[1]*Fujita Health University dept of Otolaryngology;* [2]*Committee on the System for Physicians Performing Eustachian Tube Plug Surgery*

BACKGROUND & AIM

Patulous Eustachian tube (PET) may cause severe auditory symptoms and reduced quality of life in refractory cases. In Japan, Eustachian tube plug surgery with the Kobayashi plug (KPS) was introduced in 2020 under a certified surgeon system and became covered by national health insurance in 2022. As the procedure has gradually expanded nationwide, clarification of current diagnostic and therapeutic practices has become increasingly important. We therefore conducted a nationwide questionnaire survey targeting certified KPS surgeons and institutions to investigate the present status of PET management, indications for surgery, operative techniques, perioperative management, complications, and surgeon perceptions regarding efficacy and safety.

MATERIAL & METHODS

A nationwide questionnaire survey was conducted among surgeons certified by the Japan Otological Society to perform KPS as of March 2025. The survey targeted 61 surgeons at 49 institutions. Responses were obtained from 50 surgeons affiliated with 48 institutions, including 24 university hospitals, 14 general hospitals, and 10 clinics. The questionnaire investigated diagnostic approaches for PET, use of severity assessment tools and Eustachian tube function tests, conservative treatment strategies, indications for surgery, operative techniques, anesthesia methods, hospitalization policies, postoperative complications, revision surgery, and surgeon impressions regarding efficacy and safety. Surgical data were collected for KPS procedures performed after insurance approval through March 2025. All data were self-reported, and no validation using insurance or administrative databases was performed.

RESULTS

The number of newly diagnosed PET patients per institution ranged from 0 to 120 cases per month (median: 5). Most respondents adhered to the proposed diagnostic criteria, and approximately half used the PHI-10 questionnaire for severity assessment. Eustachian tube function testing was routinely performed at almost all institutions, with sonotubometry

universally adopted. Conservative management, including patient education, lifestyle guidance, symptom control instruction, and Kampo medicine, was commonly performed before surgery was considered. Approximately 1,400 KPS procedures had been performed nationwide, although 70% were concentrated in four high-volume centers. Surgical practices varied substantially among institutions regarding use of endoscopy or microscopy, anesthesia type, hospitalization duration, and bilateral surgery strategy. Surgeons generally perceived KPS as moderately effective with relatively low complication rates; however, otitis media with effusion, persistent tympanic membrane perforation, plug dislocation, and several serious adverse events were reported.

CONCLUSIONS

This survey demonstrated that KPS for refractory PET is currently being introduced cautiously in Japan under relatively strict indications, particularly for severe cases resistant to conservative treatment. Although overall treatment policies were consistent, substantial inter-institutional variability existed in operative techniques, perioperative management, plug size selection, and management of revision cases. Respondents strongly requested clearer criteria for preoperative plug size selection and standardized treatment protocols. Three years after establishment of the national implementation system, further efforts toward nationwide standardization, quality assurance, surgeon education, and dissemination of appropriate PET recognition among general practitioners appear necessary for sustainable continuation of KPS in Japan.

PP-429

A Rare Otologic Complication Of Urosepsis: Bilateral Sudden Sensorineural Hearing Loss

Melek Ünal[1], **Beyza Çökelez**[1], **Özgenur Koçak**[1], **Zahide Mine Yazıcı**[1]

[1]*Department of Otolaryngology Head and Neck Surgery, Bakırköy Dr.Sadi Konuk Training and Research Hospital, Istanbul, Türkiye*

BACKGROUND & AIM

Sudden sensorineural hearing loss (SSNHL) is an otologic emergency that may rarely occur secondary to systemic inflammatory and vascular disorders. Bilateral involvement is uncommon and is frequently associated with poorer prognosis and underlying systemic pathology. Sepsis-related cochlear injury has been increasingly recognized, particularly in critically ill patients with septic shock and microvascular compromise. We aimed to present a rare case of bilateral SSNHL developing during intensive care follow-up for urosepsis secondary to obstructive pyelonephritis and to discuss the possible contribution of septic microvascular and inflammatory mechanisms in cochlear injury.

MATERIAL & METHODS

A 38-year-old female with familial Mediterranean fever and chronic colchicine use was hospitalized for obstructive pyelonephritis caused by proximal ureterolithiasis. During follow-up, the patient developed septic shock requiring intensive care admission, endotracheal intubation, and broad-spectrum antimicrobial treatment. After seven days of intensive care follow-up, she complained of acute bilateral hearing loss following extubation. Comprehensive otorhinolaryngological examination, pure-tone audiometry, tympanometry, auditory brainstem response (ABR), otoacoustic emission testing, and radiological imaging were performed. Etiological investigations including temporal and diffusion magnetic resonance imaging revealed no central pathology. The patient was treated with systemic corticosteroids, intratympanic steroid injections, and hyperbaric oxygen therapy. Serial audiometric evaluations were obtained during follow-up to assess hearing recovery.

RESULTS

Initial audiometric evaluation demonstrated severe bilateral sensorineural hearing loss, more prominent in the left ear. Speech reception thresholds were 83/65+ dB in the right ear and 98/65+ dB in the left ear. Tympanometry showed bilateral type A tympanograms. ABR testing demonstrated wave V responses at 80 dB in the right ear, whereas no wave V response could be obtained at 100 dB in the left ear. Bilateral otoacoustic emissions and acoustic reflexes were absent, supporting cochlear outer hair cell dysfunction. Following combined treatment with systemic steroids, nine sessions of intratympanic steroid therapy, and 20 sessions of hyperbaric oxygen treatment, marked hearing recovery was observed in the right ear, improving to 19/18 dB thresholds. However, severe residual sensorineural hearing loss persisted in the left ear with thresholds of 84/65 dB.

CONCLUSIONS

Bilateral SSNHL may rarely develop during severe urosepsis and septic shock. Septic hypotension, endothelial dysfunction, inflammatory injury, and cochlear microvascular impairment may contribute to cochlear ischemia and hearing loss. This case highlights the importance of considering auditory complications in critically ill septic patients, particularly during intensive care follow-up. Early diagnosis and multimodal treatment including systemic steroids, intratympanic steroid therapy, and hyperbaric oxygen therapy may provide partial auditory recovery even in severe presentations.

PP-430

Absent Stapedial Tendon: A Case Report

Khalid AlQarni[1], **Saad Alenzi**[2], **Abdulrahman Alsanosi**[3]

[1]*Prince Sultan Medical Military City, Riyadh;* [2]*King Fahad Specialist Hospital, Tabuk;* [3]*King Abdulaziz University Hospital, Riyadh*

BACKGROUND & AIM

The stapedius muscle is the smallest skeletal muscle. Its tendon arises from the pyramidal eminence and is inserted into the neck of stapes through the posterior surface . The stapedius muscle and the tensor tympani work together to produce an acoustic reflex that has a protective role for the inner ear against harmful sounds . Congenital anomalies of the stapedius muscle include ectopic, double muscles, ossificate tendon, and absent muscular unit . Injury and cutting of the stapedial muscle tendon are common during otosclerosis surgeries. The incidence of absent stapedial muscle tendon has been reported to be 0.5% .

MATERIAL & METHODS

A Case report, 40 years old male with absent stapedial tendon

RESULTS

The stapedius muscle originates from the bundle of the posterior belly of the digastric muscle. When the digastric muscle arrives at the eminence of the mastoid process, it provides fibers of muscle through the stylomastoid opening into the tympanic cavity until it reaches the stapes neck and forms the stapedius muscle. Therefore, both muscles get innervation from the facial nerve. The stapedius and tensor tympani muscles contract together for the acoustic reflex to protect ears from loud sounds and improve hearing performance during noise. Congenital anomalies of the middle ear have previously been reported in the literature. In a previous report by Kopuz et al., there was no stapedius muscle or tendon present in the middle ear .

CONCLUSIONS

Absent stapedius muscle and tendon may affect the movements of the stapes and impact speech intelligibility during noise. Being aware of stapedius muscle and tendon anomalies is substantial for surgeons performing interventions for middle ear pathologies, especially while operating on patients with otosclerosis, as they necessitate a specific approach. Although these anomalies are not commonly seen, awareness of their existence and careful interpretation of imaging studies remain crucial. Reporting future cases in the clinical setting to the literature is recommended.

BACKGROUND & AIM

Middle ear surgery is commonly associated with postoperative pain, nausea, and vomiting. Regional nerve blocks, including superficial cervical plexus block (SCPB) and greater auricular nerve block (GANB), may improve perioperative outcomes. This systematic review and meta-analysis aimed to evaluate the analgesic efficacy and safety of regional nerve blocks in adult patients undergoing middle ear surgery.

MATERIAL & METHODS

A systematic review and meta-analysis of randomized controlled trials (RCTs) was conducted following PRISMA guidelines. A comprehensive search of PubMed, Cochrane Central, and Google Scholar was performed from inception to June 2025. RCTs comparing superficial cervical plexus block (SCPB) or greater auricular nerve block (GANB) with sham block or standard care in adult patients undergoing middle ear surgery were included. The primary outcome was postoperative pain scores, while secondary outcomes included intraoperative opioid consumption, postoperative nausea and vomiting (PONV), rescue analgesia, and adverse effects. Risk of bias was assessed using RoB2, and certainty of evidence was evaluated using GRADE.

RESULTS

Seven RCTs including 459 participants were analyzed. Regional nerve blocks significantly reduced postoperative pain at 1 hour (MD −0.80; 95% CI −1.18 to −0.42; p<0.0001), 12 hours (MD −0.78; 95% CI −1.00 to −0.55; p<0.0001), and 24 hours (MD −0.41; 95% CI −0.49 to −0.33; p<0.0001). Intraoperative opioid consumption was significantly lower in the nerve block group (MD −

531.18; 95% CI −939.57 to −122.79). The incidence of postoperative nausea and vomiting was also reduced (RR 0.46; 95% CI 0.31–0.69). No significant differences were observed in rescue analgesia or adverse effects between groups.

CONCLUSIONS

Regional nerve blocks, particularly SCPB and GANB, provide effective postoperative analgesia in middle ear surgery, with reduced opioid consumption and lower incidence of PONV, without increasing adverse effects. These findings support their use as part of perioperative care, although further high-quality studies are needed to optimize technique and application.

Necrotizing Otitis Externa: A 16-Patient Experience

Mariem Ben Aissa[1], **Samia Meherzi**[1], **Ahmed Kory**[1], **Ferdaous Benkrikch**[1]

[1]*University Hospital of Sidi Bouzid*

BACKGROUND & AIM

Necrotizing otitis externa is a severe and potentially life-threatening infection requiring early diagnosis and appropriate management. We aim to share our experience in the management of patients with necrotizing otitis externa and to describe their epidemiological, clinical, paraclinical characteristics, treatment, and outcomes.

MATERIAL & METHODS

We present a case series of 16 patients hospitalized in our department from 2021 to 2026.

RESULTS

We included 16 patients with a median age of 72 years; 56.3% were female. Most were diabetic (81.3%). All presented with otalgia; 43.8% reported otorrhea, and five had facial paralysis.

On otoscopy, external auditory canal (EAC) stenosis with granulomas and otorrhea was observed in all cases. Temporal bone CT showed opacification of the EAC and tympanic cavity in all patients. Tympanic bone erosion was found in half of the cases, facial canal erosion in one, deep cervical space infiltration in 25%, and thrombophlebitis in one patient.

Microbiology identified Pseudomonas aeruginosa in 10 cases (one with Candida albicans), Aspergillus spp. in three, Proteus mirabilis in one, Candida albicans in one, and one negative culture.

All patients were hospitalized, received daily EAC debridement, and appropriate antimicrobial therapy. Mean hospitalization was 30.3 days. Complete remission occurred in 68.8% of cases.

CONCLUSIONS

Necrotizing otitis externa remains a severe infection in elderly diabetic patients. Temporal bone CT provides a critical assessment of skull base and deep space involvement, while the protracted clinical course underscores the need for prolonged therapy and systematic follow-up

Cerebrospinal Fluid Otorrhea After Temporal Tumor Surgery Repaired Through An Endoscopic Transcanal Approach

Murat Demirer[1], **Berşah Sırmacı**[1], **Sema ZER TOROS**[1], **Çiğdem TEPE KARACA**[1]

[1]*Department of Otorhinolaryngology, Haydarpaşa Numune Training and Research Hospital, Istanbul, Turkey*

BACKGROUND & AIM

Postoperative cerebrospinal fluid (CSF) otorrhea is a rare but serious complication of temporal intracranial surgery because of the increased risk of meningitis and intracranial infection. Early diagnosis and prompt surgical repair are critical for preventing morbidity. We aimed to present the diagnosis and successful endoscopic management of postoperative CSF otorrhea following temporal tumor excision.

MATERIAL & METHODS

A 65-year-old female patient underwent neurosurgical excision of a left temporal low-grade glial tumor after presenting with headache, dizziness, tinnitus, and transient speech arrest. In the postoperative period, clear otorrhea from the left ear developed. The patient was referred to the Department of Otorhinolaryngology for further evaluation. Endoscopic examination revealed a suspected CSF leak originating from the anterosuperior wall of the left external auditory canal. Clinical findings and beta-2 transferrin analysis supported the diagnosis of CSF otorrhea. The patient was evaluated jointly with the Neurosurgery Department. Endoscopic transcanal defect repair was performed, followed by ear wick tampon application and

close postoperative monitoring. Intravenous ceftriaxone and vancomycin were administered for meningitis prophylaxis. Lumbar drainage was additionally recommended for intracranial pressure control.

RESULTS

Postoperative follow-up demonstrated progressive epithelialization of the external auditory canal and complete resolution of otorrhea. No recurrent CSF leakage, meningitis, neurological deterioration, or additional otologic complications were observed during follow-up. The patient tolerated the procedure well and continued routine outpatient follow-up in both Neurosurgery and Otorhinolaryngology clinics.

CONCLUSIONS

CSF otorrhea following temporal intracranial surgery is an uncommon but potentially life-threatening complication requiring rapid multidisciplinary management. Endoscopic transcanal repair can provide effective closure of selected CSF leaks with low morbidity. Early recognition, appropriate antibiotic prophylaxis, and collaboration between Neurosurgery and Otorhinolaryngology departments are essential for successful management and prevention of intracranial infectious complications.

Polypoid Lesion Of The External Auditory Canal: Metastasis Of Adenocarcinoma

Ahmet ÇAKAR[1], **Tuğba YEMİŞ**[1]

[1]*Recep Tayyip Erdoğan University, Faculty of Medicine, Department of Otorhinolaryngology, Rize, Türkiye*

BACKGROUND & AIM

External auditory canal polyps are usually benign inflammatory lesions; however, rarely they may represent metastatic malignancies. We aimed to highlight this possibility.

MATERIAL & METHODS

A 62-year-old male with facial paralysis and external auditory canal polypoid lesion underwent clinical, radiological evaluation and punch biopsy.

RESULTS

Biopsy revealed metastatic colon adenocarcinoma. Despite partial clinical improvement, lesion persisted. Patient's general condition deteriorated and he died within one month.

CONCLUSIONS

External auditory canal lesions may rarely indicate malignancy. Biopsy is essential, especially in atypical or treatment-resistant cases with systemic disease history.

External auditory canal, polypoid lesion, metastasis, colon adenocarcinoma, facial paralysis,aural polyps,colon cancer

PP-435

Increased Risk Of Sarcopenia In Greater Hearing Loss: Potential Benefit Of Hearing Aids For Muscle Function

Yoon Ah Ko[1], **Minju Baek**[2], **Sang-Yoon Han**[2]

[1]*Department of Otorhinolaryngology - Head & Neck Surgery, Seoul National University College of Medicine, Seoul, Republic of Korea.;* [2]*Department of Otolaryngology-Head and Neck Surgery, College of Medicine, Hanyang University, Seoul, Republic of Korea.*

BACKGROUND & AIM

Hearing loss is linked to various functional deficits, while its relationships with fat distribution and sarcopenia remain unclear. This study investigated the association of hearing status with body composition and muscle-related parameters.

MATERIAL & METHODS

This study used data from the ninth Korea National Health and Nutrition Examination Survey (2022–2023), a nationally representative survey. A total of 3,632 individuals with complete data on audiometry, tympanometry, body composition, and handgrip strength were included. Hearing status was classified as normal (≤25 dB), mild (>25dB to ≤40dB), or moderate-or-worse (>40dB). Sarcopenia was defined as low Appendicular Skeletal Muscle Mass Index (ASMI; <7.0 kg/m² for men, <5.7 kg/m² for women) combined with low handgrip strength (<28 kg for men, <18 kg for women).

RESULTS

Worsening hearing loss was associated with graded declines in lower extremity and total ASMI, as well as grip strength in both sexes (all $p < 0.05$), while associations with upper extremity ASMI, total body water index, and intracellular water index were present only in males (all $p < 0.05$). Higher hearing thresholds were associated with sarcopenia in both sexes (men: $p = 0.020$; women: $p = 0.13$). In contrast, fat mass indices showed no association with hearing status. Hearing aid use was associated with higher grip strength only in women with hearing thresholds >55 dB ($p = 0.010$).

CONCLUSIONS

Hearing loss was significantly associated with sarcopenia. Given the potential for worsened physical function in patients with hearing loss, hearing rehabilitation and interventions targeting sarcopenia should be considered.

KEYWORDS

hearing loss; sarcopenia; skeletal muscle mass; handgrip strength; body composition; bioelectrical impedance analysis; hearing aids

PP-436

Unusual Vascular Causes Of Tinnitus: Coexistence Of High Jugular Bulb And Lateralized Carotid Artery

Kübra Çoban[1], **Doğa Çelik**[2]

[1]*Baskent University Alanya Hospital;* [2]*Baskent University Ankara Hospital*

BACKGROUND & AIM

Pulsatile tinnitus may arise from various intracranial, intratemporal, cervical pathologies. High-riding jugular bulb (HJB), reported in 6–20% of the population, is a venous anatomical variant commonly observed on the right side due to dominant venous drainage. In rare cases, HJB may coexist with carotid artery abnormalities, potentially increasing symptom severity, surgical difficulty, and the risk of complications during temporal bone procedures. We report an female adult presenting with pulsatile tinnitus who was diagnosed with HJB associated with a lateralized carotid artery. This case highlights the clinical importance of recognizing concomitant vascular anomalies and aims to raise awareness among clinicians, radiologists.

MATERIAL & METHODS

A 27 years old female attended to our outpatient clinic with a complaint of right-sided pulsatile tinnitus for years. She had no hearing loss, vertigo or ear fullness. She mentioned that, applying pressure on the right side of her neck, decreased symptom severity significantly. Allergy, prior otological surgery, pregnancy, obesity, drug use, trauma, or history of co-morbid disease were not recorded. Otorhinolaryngological examination was normal. Pure-tone audiometry, tympanometry, temporal bone computed tomography (CT) and jugular venous color doppler ultrasonography (D-USG) were performed.

RESULTS

Pure-tone audiometry and tympanometry were within normal limits. CT demonstrated a right jugular bulb measured approximately 12 mm in maximal craniocaudal dimension and projected superiorly toward the hypotympanic region. The right jugular canal was wider than the left, and the bulb extended superior to the inferior margin of the internal auditory canal. Mild medial protrusion toward the middle ear cavity was observed without definite cortical erosion or frank dehiscence. The right carotid canal also appeared relatively lateralized compared with the left side. No soft tissue mass, destructive osseous lesion, aberrant internal carotid artery, persistent stapedial artery, glomus tympanicum lesion, sigmoid sinus diverticulum, or middle ear abnormality was identified. Jugular venous D-USG was unremarkable.

CONCLUSIONS

A HJB is commonly asymptomatic and is often detected incidentally during radiological examinations. However, it may occasionally present with pulsatile tinnitus due to its close relationship with adjacent middle and inner ear structures. It is rarely associated with carotid artery anomalies. In our case, in addition to a HJB, the carotid artery demonstrated a more lateral course, resulting in close proximity to the middle ear cavity. We suggest that this combined vascular variation may have contributed to the increased severity of symptoms. Such patients may also face a higher risk of complications during otologic surgery, requiring careful preoperative evaluation.

Pulsatile tinnitus, high-riding jugular bulb, carotid canal asymmetry, vascular temporal bone variants

PP-437

Essential Palatal Tremor With Lateralization Change Of Ear Clicking Following Botulinum Toxin Injection: A Case Report

Iman J. Almashharawi[1], **Lulwah Alturki**[1], **Assaf Alkathiri**[1], **Homood M. Almutairi**[1], **Rimah F. AlSalem**[2]

[1]*Department of Otolaryngology-Head & Neck Surgery (ORL-H&N), Prince Sultan Military Medical City (PSMMC), Riyadh, Saudi Arabia.;* [2]*King Khalid University Hospital, Riyadh, Saudi Arabia.*

BACKGROUND & AIM

Essential palatal tremor (formerly termed palatal myoclonus) is a rare movement disorder characterized by rhythmic involuntary contractions of the soft palate, occasionally associated with ear clicking. Management is often challenging in refractory cases, with varying responses. We report a case highlighting the differential effect of botulinum toxin on symptom manifestation versus the underlying disorder.

MATERIAL & METHODS

A 52-year-old female presented with a 2-year history of palatal tremor associated with intermittent right-sided ear clicking and aural fullness, which resolved during sleep. Clinical examination revealed bilateral rhythmic contractions of the soft palate with

associated cervical muscle pulsations. The clicking was localized to the right ear and not audible to the examiner. MRI brain was unremarkable, supporting a diagnosis of essential palatal tremor.

The patient failed to respond to medical therapy including clonazepam, baclofen, and valproic acid. Botulinum toxin injection was performed under direct visualization into the right soft palate (4 injection sites, 8 IU per site). A contralateral injection was subsequently performed as part of planned management. A pre-treatment video documenting the palatal tremor is available.

RESULTS

Following unilateral right-sided botulinum toxin injection, the patient reported partial improvement in palatal tremor, which was also clinically evident as a reduction in tremor amplitude on the injected side compared to the contralateral side, followed by complete resolution of right-sided ear clicking. However, she subsequently developed new-onset left-sided clicking while bilateral palatal movements persisted on examination. A contralateral injection was then performed. At subsequent follow-up, only partial overall improvement was achieved, with ongoing bilateral palatal tremor and persistent symptoms continuing to significantly impact the patient's quality of life.

CONCLUSIONS

Botulinum toxin may reduce peripheral manifestations such as ear clicking in essential palatal tremor; however, treatment remains challenging with variable response. Persistence of bilateral palatal tremor with changing symptom lateralization highlights a dissociation between symptom expression and the underlying movement disorder, suggesting a central generator not fully addressed by peripheral treatment.

MIDDLE EAR CARCINOMA. CASE REPORT

Valdas Bernotas[1], **Mantas Žemaitaitis**[1], **Artūras Čiuvašovas**[2]

[1]*Klaipėda university hospital. Eye, head and neck surgery clinic. Department of otorhinolaryngology;* [2]*Klaipėda university hospital. Radiology clinic. Diagnostic imaging center*

BACKGROUND & AIM

Head and neck tumors account for about 3-5 percent of all tumors. Talking about middle ear adenocarcinoma or malignant tumors of the temporal bone, only isolated cases are described in the literature, most often the literature only talks about 0.1–0.3 percent of all head and neck tumors. Middle ear adenocarcinoma arises from the epithelium or glandular structures of the middle ear. It is worth noting that middle ear tumors can also be metastatic. Due to the rarity of the disease, there is no standardized treatment described in the literature, but surgery and radiation therapy are most often used.

MATERIAL & METHODS

Clinical case data were collected, systematized and compared with data described in the scientific literature.

RESULTS

A 79-year-old woman presented with right ear pain. During examination, a mass was observed behind the eardrum without signs of infiltration. CT and MRI of the temporal bones were ordered, which described nonspecific changes in the middle ear with bone erosion. There was no accumulation of contrast material that would suggest a tumor. It was decided to perform a revision of the middle ear and remove the mass. The removed tissues were sent for histological examination. The answer received was invasive spread of adenocarcinoma in the connective tissue, tumor invasion into bone tissue, destruction of bone tissue, perineural spread of tumor structures. Adenocarcinoma can be both primary in the middle ear (most likely) and metastatic. Clinical correlation is necessary. Radiological studies were performed to search for a possible primary tumor, but none was found. The patient was discussed in a multidisciplinary consultation, and radiation therapy was prescribed.

CONCLUSIONS

In conclusion, it is important to mention that middle ear adenocarcinoma does not have specific symptoms, so its diagnosis can take a long time. It is worth noting that it is very important to determine whether the disease is metastatic. Since this disease is very rare and only isolated cases prevail, there is a lack of clinical experience in its treatment. For the analysis, understanding and development of treatment recommendations for this disease, it is necessary to systematize multicenter data.

PP-439

When Balance Fails: Vestibular Dysfunction Is Associated With Same-Level Falls In A National Cohort

Diana Shaari, BA[1], **Harrison Smith, MD**[1], **Henry Diamond-Pott, BA**[1], **Jennifer Kelly, PT, DPT, NCS**[1], **Maura Cosetti, MD**[1]

[1]*Icahn School of Medicine at Mount Sinai*

BACKGROUND & AIM

Falls are a leading cause of morbidity and healthcare utilization, particularly among older adults. Vestibular dysfunction (VD) and hearing loss (HL) are established contributors to fall risk; however, most prior studies focus on fall incidence rather than the mechanisms by which falls occur. Whether VD—alone or in combination with HL—is associated with distinct patterns of fall mechanism remains unclear. We evaluated the association between VD and fall mechanism in a national inpatient cohort.

MATERIAL & METHODS

We performed a retrospective cross-sectional study of adult fall-related hospitalizations in the 2018–2022 Healthcare Cost and Utilization Project National Inpatient Sample. Falls were identified using ICD-10 external cause codes W00–W19. VD (H81., H83.0, H83.2, G43.B*, R42) and HL (H90–H91) were identified using diagnosis codes. Fall mechanisms and discharge disposition were compared across groups. Multivariable logistic regression adjusted for age, sex, and race.

RESULTS

Among 7,315,022 fall-related admissions, 128,335 (1.8%) had VD. VD patients were more often female (66.5% vs 57.3%). Same-level falls (W18) were more frequent in VD (33.6% vs 26.5%), corresponding to increased adjusted odds (aOR 1.36, 95% CI 1.35–1.38). VD was also associated with higher odds of unspecified falls (W19) (aOR 1.16, 95% CI 1.15–1.18) and lower odds of environmental or elevation-related falls (aOR 0.66, 95% CI 0.66–0.67) (all p<0.001). A stepwise increase in same-level falls was observed from patients with neither condition (26.4%) to HL alone (28.0%) and VD with or without HL (33.6%). VD was independently associated with increased likelihood of non-routine discharge, including skilled nursing or facility care (aOR 1.62, 95% CI 1.60–1.64).

CONCLUSIONS

VD is associated with a distinct fall phenotype characterized by same-level and unexplained falls, consistent with intrinsic postural instability rather than environmental hazard exposure. HL alone demonstrates a smaller effect, while coexisting sensory deficits show a graded relationship with fall mechanism. These findings support targeted vestibular assessment and rehabilitation as key components of fall prevention.

Analysis Of Otological And Sinus Problems In Divers

Cosimo Muscianisi[1], **Paolo Marcolin**[1], **Chiara Ferri**[1], **Alessandro Marroni**[1]

[1]*DAN Europe*

BACKGROUND & AIM

Divers Alert Network Europe (DAN Europe) is an international non-profit organization providing 24/7 emergency medical assistance to divers and promoting diving safety through research and education.

MATERIAL & METHODS

Between January 1st, 2009 and December 31st, 2025, DAN Europe managed approximately 16,000 diving-related incidents. Among these, 4,112 (≈25.7%) involved Otorhinolaryngological (ENT) conditions.

Otological disorders represented 60–70% of all ENT cases, with middle ear barotrauma being the most frequently reported condition, followed by sinus barotrauma.

When related to the total number of assisted cases, ENT complications represent one of the leading categories of diving-related morbidity.

RESULTS

The estimated probability of otological and sinus barotrauma (pOSBT) within the observed incident cohort confirms barotrauma as the predominant ENT risk in recreational diving.

Selected severe cases included sinus barotrauma complicated by pneumocephalus and valve-type tympanic membrane perforation, both managed through early telemedical triage and specialist referral.

CONCLUSIONS

These data confirm that otological and sinus barotrauma represent the most frequent ENT complications in diving and highlight the importance of early specialist evaluation and structured telemedical support systems.

Massive Congenital Petrous Bone Cholesteatoma With Right Carotid Canal Dehiscence: A Rare Case Report

Ilker Akyıldız[1], **Melis Senem Bal**[1], **Sibel Alicura Tokgöz**[1], **Mehmet Murat Günay**[1], **Muharrem Dağlı**[1]

[1]*Etlik City Hospital, ENT & Head and Neck Surgery Department, Ankara, Turkey*

BACKGROUND & AIM

Congenital cholesteatomas are generally considered to be slow-growing, benign lesions confined to the middle ear cleft. However, they can rarely extend into the petrous apex, causing massive bone destruction that involves critical structures such as the internal carotid artery (ICA) and cranial nerves. The aim of this case report is to present a rare and aggressive case of congenital petrous bone cholesteatoma causing carotid canal dehiscence and to discuss the diagnostic and surgical challenges in its management.

MATERIAL & METHODS

A 25-year-old male patient presented with a one-year history of profound mixed hearing loss in the right ear and concurrent House-Brackmann Grade II peripheral facial nerve palsy. The patient had no previous history of otologic surgery or chronic otorrhea, and bilateral tympanic membranes were intact upon otoscopic examination. Diagnostic evaluation included high-resolution computed tomography (HRCT) and magnetic resonance imaging (MRI).

RESULTS

Imaging revealed a destructive mass in the right petrous apex. The lesion caused cochlear erosion, eroded the carotid canal resulting in approximately 50% encasement of the internal carotid artery (ICA), formed a labyrinthine fistula, and eroded the facial nerve canal. The patient underwent radical excision of the petrous apex cholesteatoma via a transotic approach, combined with a right canal wall down (CWD) mastoidectomy and cul-de-sac closure under intraoperative facial nerve neuromonitoring. Histopathological examination confirmed the diagnosis of cholesteatoma.

CONCLUSIONS

Congenital cholesteatomas do not always follow a benign clinical course; even though rarely, they can exhibit massive petrous bone involvement and aggressive vascular invasion. Detailed preoperative radiological mapping and radical surgical excision are essential to safely eradicate the disease and prevent major neurovascular complications.

A Diagnostic Pitfall: Giant Mastoid-Type Congenital Cholesteatoma Mimicking Glomus Jugulare In The Fourth Decade Of Life

Tolga Küçükgergin[1], **Soltan Ahmadov**[1], **Beyza Mercan**[1], **Fırat Tevetoğlu**[1]

[1]*Istanbul University-Cerrahpaşa, Cerrahpaşa Faculty of Medicine, Department of Otorhinolaryngology, Istanbul, Turkey.*

BACKGROUND & AIM

Congenital cholesteatoma (CC) is a slow-growing keratinizing mass arising from ectodermal remnants trapped within the temporal bone during embryological development. Although typically diagnosed in childhood due to middle ear involvement, mastoid-type variants can remain clinically silent and progress undiagnosed until adulthood. When presenting in the fourth decade, mastoid CC can present a complex clinical picture characterized by extensive bone destruction, often mimicking skull base pathologies.

MATERIAL & METHODS

A 39-year-old male presented with right-sided pulsatile tinnitus. Examination showed posterior external auditory canal destruction with visible pulsations, alongside an intact tympanic membrane. Initial external CT suggested a glomus jugulare tumor. However, our re-evaluation revealed a distinct cleavage plane from the jugular foramen, and subsequent DWI-MRI confirmed a congenital cholesteatoma. Pre-operative hearing was normal (16/10 dB). A right canal wall down mastoidectomy was performed. Intraoperatively, a massive lesion extended from the digastric ridge to the sigmoid sinus, eroding the facial canal. Following en-bloc excision, residual epithelium over the sigmoid sinus and exposed facial nerve was meticulously cleared via micro-dissection. Nerve integrity was confirmed with intraoperative monitoring. Post-operatively, facial nerve function remained completely intact (House-Brackmann Grade I) and hearing was preserved (35/15 dB) despite the extensive local destruction.

RESULTS

This case highlights the diagnostic challenges of a congenital lesion presenting in the fourth decade. The destruction of the posterior EAC wall and the resultant pulsatility were caused by the transmission of sigmoid sinus pulsations through the cholesteatoma matrix, perfectly simulating a vascular tumor. Despite extensive erosion of the facial canal and mastoid bone, meticulous micro-dissection and en-bloc excision ensured that facial nerve function remained completely intact post-operatively. Furthermore, the fact that hearing thresholds were only minimally affected (from 16/10 dB to 35/15 dB) despite the radical removal of such a high-volume, destructive lesion, demonstrates that functional outcomes can be optimized even in the most challenging cases through precise surgical planning and delicate technique.

CONCLUSIONS

Congenital cholesteatoma must be included in the differential diagnosis of pulsatile tinnitus and EAC pulsatility in the fourth decade, especially when CT shows a well-circumscribed mass.

Normal hearing and an intact tympanic membrane do not rule out extensive mastoid destruction.

DWI-MRI is a vital tool in the differential diagnosis of skull base lesions to prevent diagnostic pitfalls.

Despite severe exposure of critical anatomical structures (facial nerve, sigmoid sinus), a careful approach adhering to micro-surgical principles can eliminate the risk of post-operative facial paralysis and ensure the preservation of hearing function even in extensive cases.

Management Of Pediatric Traumatic Facial Nerve Paralysis: Transitioning From Rigid Protocols To A Dynamic Management Algorithm

EMRE ULUTAŞ[1], **CEMİLE BAYKAN ERYİĞİT**[1], **FERİDE FIRAT**[1], **ZELİHA KAPUSUZ GENCER**[1], **ÖZGÜR YİĞİT**[1]

[1]*Başakşehir Çam and Sakura City Hospital*

BACKGROUND & AIM

Traditional protocols for pediatric traumatic facial nerve paralysis (FNP) often rely on adult electrophysiological criteria, which are frequently unreliable in early childhood and pre-adolescence. This study aims to challenge the conventional "wait-and-see" approach by proposing a dynamic management algorithm. We analyze three distinct clinical scenarios to demonstrate that intervention triggers should be based on pathology-specific clinical progression and secondary pressure management rather than rigid numerical data, especially in patients where standard objective tests reach their limits.

MATERIAL & METHODS

Three pediatric cases (ages 2, 10, and 11) were analyzed retrospectively. Beyond standard steroid therapy, we implemented a "Tailored Intervention Model." Case 1 focused on secondary pressure relief via ventilation tube placement for progressive paralysis associated with hemotympanum. Case 2 followed the surgical window for early decompression in a transverse fracture with confirmed axonal loss. Case 3 addressed the diagnostic "grey zone" of early childhood; a 14-day clinical non-responsiveness trial was utilized as a definitive surgical indicator for transmastoid decompression. Outcomes were evaluated using the House-Brackmann (HB) scale over a 6-month follow-up period.

RESULTS

In Case 1, alleviating intratympanic pressure resulted in rapid improvement from HB Grade 5 to Grade 3, suggesting that procedural intervention can prevent permanent axonal loss in longitudinal fractures. Case 2 confirmed that early surgery remains superior for nerve continuity in transverse fractures with total degeneration. Case 3 demonstrated that in the absence of reliable electrophysiology, a 14-day persistent HB Grade 4 paralysis is a valid indicator for successful surgical salvage. All patients achieved significant functional recovery, indicating that clinical failure of medical therapy for 14 days is a reliable surrogate for surgical decision-making when objective tests are limited.

CONCLUSIONS

Our study contributes to the literature by emphasizing that pediatric FNP management must evolve from rigid protocols to dynamic algorithms. We propose that secondary middle ear pressure management is a vital adjunct to steroid therapy in specific fracture patterns. Furthermore, in young children with unreliable EMG, we define a 14-day clinical non-responsiveness period as a definitive surgical trigger. This tailored approach ensures that critical surgical windows are not missed, balancing surgical risks with the necessity of functional preservation in the pediatric population.

Functional Facial Paralysis Presenting As Suspected Stroke: A Diagnostic Challenge

Bilal Burak Bayraklı[1]

[1]*Department of Physical Medicine and Rehabilitation , Bingol State Hospital, Bingol, Türkiye*

BACKGROUND & AIM

Acute facial paralysis with hemiparesis typically raises clinical suspicion for cerebrovascular events or severe peripheral neuropathies. However, Functional Neurological Disorder (FND) can closely mimic organic neurological conditions, leading to extensive diagnostic investigations. This case report aims to highlight the diagnostic challenge of FND presenting as acute facial paralysis and the importance of positive clinical signs in avoiding unnecessary interventions.

MATERIAL & METHODS

A 29-year-old woman presented with left facial numbness, mouth drooping, difficulty closing her left eye, intermittent tic-like movements, and left extremity paresthesia. Physical examination revealed complete sparing of the forehead musculature. Initially suspecting an acute cerebrovascular event, she was hospitalized in the neurology department for 11 days. As comprehensive neuroimaging and facial electromyography (EMG) were strictly within normal limits, a psychiatric consultation

was obtained, suggesting the possibility of conversion disorder. Due to persistent symptoms, she was referred to the Physical Medicine and Rehabilitation clinic. Examination showed normal extremity muscle strength, normoactive deep tendon reflexes, and subjective left-sided sensory loss. Notably, during this clinical evaluation, abnormal facial movements nearly resolved when the patient was cognitively distracted. A rehabilitation program comprising facial exercises and electrotherapy was subsequently initiated.

RESULTS

The primary clinical outcome was observed shortly after the first rehabilitation session, when the patient experienced a dramatic exacerbation of facial symptoms and extremity paresthesia, prompting an emergency department visit. Urgent neuroimaging again showed no acute ischemia. While extremity paresthesia resolved rapidly, facial symptoms worsened, leading to the discontinuation of rehabilitation sessions. Given the symptom variability, marked improvement during cognitive distraction, and paradoxical exacerbation following focused physical interventions, the preliminary suspicion of a functional etiology was strongly supported. Ultimately, she was formally diagnosed with FND manifesting as functional facial paralysis.

CONCLUSIONS

FND must be considered in the differential diagnosis of atypical facial paralysis, particularly when electrophysiological and neuroimaging studies are normal. Positive clinical findings, such as symptom variability and somatically focused exacerbations, provide critical diagnostic clues. Increased awareness of functional facial paralysis is essential for multidisciplinary teams, including otolaryngologists and rehabilitation specialists, to prevent over-investigation.

A Novel Inner Ear Manifestation In Alagille Syndrome: Fistula Between The Jugular Bulb And Lateral Canal Ampulla

Mehmet Furkan Kursun[1], **Mervenur Keles**[1], **Hakan Kara**[1], **Beldan Polat**[1]

[1]*Istanbul University,Istanbul Faculty of Medicine, Department of Otorhinolaryngology*

BACKGROUND & AIM

Alagille syndrome (ALGS) is a rare autosomal-dominant disorder that frequently involves the inner ear, most commonly affecting the posterior semicircular canal. Multiple studies in the literature emphasize that the lateral semicircular canal is typically spared. This report challenges this established paradigm by presenting a unique case demonstrating the first suspected fistula between the jugular bulb and the lateral semicircular canal ampulla in ALGS.

MATERIAL & METHODS

A 12-year-old male diagnosed with ALGS presented to the otolaryngology clinic with bilateral hearing loss, predominantly on the left side, without vertigo or tinnitus. His medical history included surgery for cholestatic liver disease and peripheral pulmonary stenosis. Clinical evaluation comprised otomicroscopy, pure-tone audiometry, tympanometry, video head impulse test (vHIT), and temporal bone high-resolution computed tomography (HRCT) to assess anatomical and functional audiovestibular correlations. Otomicroscopy revealed right-sided adhesive otitis media and a left-sided Sade 2 pars tensa retraction without ossicular erosion.

RESULTS

High-resolution computed tomography uniquely demonstrated a suspected left-sided fistula formation between the jugular bulb and the lateral semicircular canal ampulla, alongside bilateral posterior semicircular canal aplasia. Audiologically, pure-tone audiometry showed bilateral conductive hearing loss; this was mild on the right side and mild-to-moderate on the left side, characterized by a sudden drop in the lower frequencies. In the left ear, despite the theoretically large third-window effect expected from the fistula, supranormal bone conduction thresholds were absent. This expected audiological finding was effectively masked by the concurrent left-sided retraction pocket, which increased tympano-ossicular stiffness and dampened the altered inner ear hydrodynamics. Furthermore, this middle ear pathology prevented the proper execution of vestibular evoked myogenic potential (VEMP) testing. Video head impulse test (vHIT) correlated with the anatomical anomalies, revealing decreased gains and overt saccades in the bilateral posterior canals.

CONCLUSIONS

This case significantly expands the known inner ear manifestations of ALGS by presenting the first suspected lateral canal ampulla-jugular bulb fistula, proving that the lateral canal can indeed be involved. Additionally, it highlights an important secondary biomechanical interaction where concurrent middle ear pathologies can physically mask classic third-window audiological findings.

Giant Arachnoid Granulation Leading To Lateral Sinus Stenosis And Pulsatile Tympanic Membrane

Sébastien SCHMERBER[1], **Damien MOREAU**[1], **Olivier HECK**[1], **Raphaele QUATRE**[1]

[1]*University Grenoble Alpes, FRANCE*

BACKGROUND & AIM

Pulsatile tinnitus (PT) is typically associated with vascular tumors or venous anomalies. While a pulsating tympanic membrane (TM) usually suggests a retrotympanic mass, it may rarely occur in the absence of one due to transmitted vascular or cerebrospinal fluid (CSF) pressures.

MATERIAL & METHODS

A 78-year-old male presented with worsening left-sided PT and a visibly pulsating TM. Notably, there was no retro tympanic mass, and symptoms ceased during jugular compression or the Valsalva maneuver. Imaging revealed a giant arachnoid granulation (AG) causing 80–90% stenosis of the left lateral sinus and associated dehiscence of the sigmoid sinus wall. Interventional balloon dilation provided transient relief, confirming the mechanical etiology. The patient underwent successful venous stenting, resulting in immediate and sustained resolution of the tinnitus, although diminished TM pulsations persisted postoperatively.

RESULTS

Arachnoid granulations are CSF-resorbing projections into the dural sinuses. When "giant," they can cause bone erosion and venous stenosis. We propose a dual pathophysiological mechanism:

- Tinnitus Generation: High-velocity turbulent flow through the stenotic segment, combined with sigmoid sinus dehiscence, creates an acoustic bridge to the middle ear.
- TM Pulsation: The bony dehiscence allows the transmission of CSF pressure pulses from the AG directly to a fragile TM.
- The resolution of PT following stenting—despite persistent TM pulsations—suggests that venous turbulence, rather than the dehiscence alone, was the primary symptomatic driver.

CONCLUSIONS

Lateral sinus stenosis secondary to giant AGs is a rare but treatable cause of PT. This case highlights that a pulsating TM does not always indicate a middle ear tumor. Venous stenting is an effective intervention to restore laminar flow and resolve symptoms.

BACKGROUND & AIM

Noise-induced hearing loss (NIHL) is a significant occupational health concern, especially in industries with prolonged exposure to high noise levels such as quarrying. This study aimed to assess the knowledge, attitudes, and practices (KAP) related to NIHL and its prevention among quarry workers in a single-site quarry in Southwest Malaysia.

MATERIAL & METHODS

A cross-sectional study was conducted using a structured questionnaire to collect information on demographic characteristics, awareness of noise hazards, attitudes toward hearing conservation, and use of hearing protection devices. Descriptive statistical analysis was employed to summarize the findings.

RESULTS

The findings revealed gaps in workers' knowledge and inconsistent use of hearing protection, despite moderate awareness of the harmful effects of occupational noise. Overall, workers demonstrated positive attitudes toward hearing conservation, however, some showed reluctance to adopt preventive practices.

CONCLUSIONS

The study highlights the need for targeted occupational health interventions, including educational programs and stronger enforcement of hearing conservation measures. Addressing these gaps may improve protective behaviors and reduce the burden of NIHL among quarry workers, providing valuable insights for policymakers and occupational health practitioners.

Congenital Petrous Apex Cholesteatoma Extending To The Internal Auditory Canal Presenting With Facial Paralysis: A Surgical Case Report

EMİNE DENİZ GÖZEN TAN[1], **MURATCAN SARI**[1], **KIARASH SHAMEKHI**[1], **YILDIRIM AHMET BAYAZIT**[1]

[1]*Department of Otolaryngology–Head and Neck Surgery, Istanbul University-Cerrahpaşa, Istanbul, Türkiye*

BACKGROUND & AIM

Cholesteatoma is a locally destructive lesion of the temporal bone that may lead to severe complications, including facial nerve paralysis and intracranial extension. Petrous apex involvement with extension to the internal auditory canal is rare and represents advanced disease.

We present a case of extensive congenital cholesteatoma involving the petrous apex and internal auditory canal presenting with peripheral facial paralysis.

MATERIAL & METHODS

A 30-year-old female presented with recurrent vertigo and right-sided grade V peripheral facial paralysis unresponsive to corticosteroids. Audiometry showed severe right-sided hearing loss (air conduction>110 dB, bone conduction: 65 dB) with longstanding right-sided impairment since childhood. The patient was referred to our clinic.

Computed tomography demonstrated a destructive soft tissue lesion extending from the right petrous apex to the internal auditory canal, with erosion of the tegmen tympani and mastoid air cells. Diffusion-weighted MRI showed diffusion restriction consistent with cholesteatoma.

Surgery was performed via a transmastoid approach. The sigmoid sinus, dural plates, and sinodural angle were exposed. The facial nerve was identified and cholesteatoma matrix dissected along mastoid, tympanic, and labyrinthine segments. Total labyrinthectomy was performed with drilling of all semicircular canals to access the internal auditory canal. The lesion was removed up to the fundus. Dural invasion and intraoperative CSF leakage were observed and managed with cul-de-sac closure.

RESULTS

Histopathological examination confirmed the diagnosis of cholesteatoma.Complete surgical excision of the cholesteatoma was achieved.Postoperative recovery was uneventful apart from intraoperative cerebrospinal fluid leakage, which was successfully managed. At 6-month follow-up, facial nerve function improved from House-Brackmann grade V to grade IV. No evidence of residual or recurrent disease was observed.

CONCLUSIONS

Cholesteatoma extending to the petrous apex and internal auditory canal represents advanced and aggressive disease that may present with facial paralysis, hearing loss and vestibular symptoms.Extensive surgical approaches, including total labyrinthectomy, may be required for complete disease eradication.Early recognition and timely intervention are crucial to prevent irreversible neurological deficits, although functional recovery of the facial nerve may be limited.

PREDICTIVE FACTORS OF GOOD RESULTS IN OSSICULOPLASTY

Seghir Mejhouda Laila[1], **İbrahim Fergoug**[1]

[1]*university of Oran 1 Ahmed benbella - Oran - Algeria*

BACKGROUND & AIM

Ossiculoplasty is a surgical procedure aimed to restoring the continuity of the ossicular chain of the middle ear, and subsequently, improving hearing. Despite advances in surgical techniques and the development of biomaterials, postoperative hearing outcomes can vary significantly from one patient to another. In order to optimize results, the identification of predictive factors of success is essential.

The purpose of our work is to identify the predictive factors of success of different types of ossiculoplasties. We also aim to identify the epidemiological, clinical, and investigation data of patients who have undergone ossiculoplasty.

MATERIAL & METHODS

We conducted a prospective, descriptive study in two ENT departments of both two tertiary care hospitals, involving patients who underwent type II and III ossiculoplasty between January 2020 and July 2024. 106 patients were included. Surgical interventions were performed using autologous materials (remodelled incus, cartilage, and cortical bone), or titanium prostheses (PORP) or (TORP), Patients were followed up postoperatively for 6 to 12 months. We evaluated the air and bone conduction thresholds, air bone Gap ABG, hearing gains, the middle ear risk index (MERI), the OOPS index, and other factors to study their predictive role in the outcomes of ossiculoplasties

RESULTS

Causes of disease was chronic otitis media (93% of cases). Trauma (6.6%). The incus was the most frequently affected ossicle (91.5%). The stapes less often involved (46.22%). In 27.4% of cases, the entire ossicular chain was affected. For reconstruction, 56.6% of patients had autologous grafts, while 43.4% received prostheses (PORP: 17.92% or TORP: 25.47%) prostheses. Regardless of the surgical technique used, we observed an average improvement in the postoperative ABG 15.5 dB (±3.28 dB). Autografts success rate of 80.3%, higher than that of synthetic prostheses (71.74%). the canal wall up technique give better hearing outcomes than the canal wall down technique. several predictive factors for the success of ossiculoplasties: age (≤ 55 years), no cholesteatoma, preoperative ABG ≤ 35 dB, preservation of the stapes, and the type of tympanoplasty. Furthermore, the MERI and OOPS indices proved to be complementary prognostic tools. Patients with a low risk had significantly better outcomes

CONCLUSIONS

Ossiculoplasty, a crucial step in tympanoplasty to restore hearing, requires the identification of predictive factors of success. Our results highlight that the initial state of the middle ear and the surgical techniques used significantly influence postoperative hearing outcomes

BACKGROUND & AIM

The inner ear exhibits considerable morphological variability across individuals, which has significant clinical implications. Pre-operative computed tomography (CT) is routinely used to identify malformations and tailor surgical interventions for hearing loss, including cochlear implants (CIs). However, segmentation of CT scans remains challenging since manual measurement is time-consuming, susceptible to inter-observer variability, and limited by scan resolution. Automated segmentation could enhance measurement precision for CI planning. Previous automated approaches relied on small micro-CT datasets, limiting generalizability. The objective of this work was to develop and externally validate a deep learning network for automatic inner ear segmentation in various clinical CT scans.

MATERIAL & METHODS

A deep learning segmentation network was developed using 100 cadaveric specimens scanned with synchrotron-radiation phase-contrast imaging (SR-PCI) and clinical CT scanners. Multiple acquisitions, protocols, and augmentations yielded 4,784 paired SR-PCI and clinical three-dimensional datasets for the deep learning model training. Network performance was assessed using the Dice score coefficient, maximum and average Hausdorff distance on an unseen dataset and externally validated against manual segmentations from seven domain experts, the mean expert performance, and a simultaneous truth and performance level (STAPLE) consensus segmentation. Two-sided Wilcoxon signed rank tests were performed comparing the network, average expert and STAPLE segmentations. A Kruskal-Wallis test compared metrics across individual experts. All p-values were adjusted using the Benjamini-Hochberg false discovery rate.

RESULTS

The network pipeline significantly outperformed individual expert segmentations, the average of the expert segmentations, and the STAPLE consensus segmentation. Compared to SR-PCI data, the network achieved a mean Dice similarity coefficient of 0.922, a maximum absolute Hausdorff distance of 0.329 mm, and an average Hausdorff distance of 0.006 mm on cone-beam CT and helical CT with resolutions as low as 625 µm.

CONCLUSIONS

This is the first automated inner ear segmentation algorithm to outperform domain experts, establishing a new clinical gold standard; showcasing deep learning model's ability to extract patient-specific information from imaging, supporting the field's shift towards precision medicine.

Unilateral Hearing Loss In A Child With Stapes Malformation- Case Report

Branislava Fides Bercikova[1], **Zuzana Volmutova**[1], **Lukas Varga**[1,2]

[1]*Department of Otorhinolaryngology, Head and Neck Surgery, Comenius University and University Hospital Bratislava, Slovakia;* [2]*Biomedical Research Center, Slovak Academy of Sciences, Bratislava, Slovakia*

BACKGROUND & AIM

Unilateral hearing loss (UHL) in children was previously underestimated and it was believed that one ear would provide sufficient hearing. UHL in children is primarily caused by congenital structural anomalies of the ear, congenital cytomegalovirus infection, cochlear nerve deficiency, or acquired trauma. The potential impact observed in children affected with UHL include fatigue, impaired school performance, quality of life and parental stress. Early interventions during the sensitive period of central auditory system development can lead to cognitive, academic, and psychosocial development comparable to that of normally hearing children.

MATERIAL & METHODS

We present 7-year- old male patient who was referred by a phoniatrician with UHL. He was followed up after failing newborn hearing screening in his right ear. Preoperative pure-tone average (500-4000 Hz) showed a normal hearing in his left ear and a moderate hearing loss in his right ear where average air conduction threshold was 63.75 dB and average bone conduction threshold was 8.75 dB. The patient underwent an exploratory tympanotomy in September 2025.

RESULTS

A malformation of the stapes was confirmed and stapedotomy was performed under the general anesthesia. Postoperative pure-tone average (500-4000 Hz) showed significant improvement in his right ear and average air conduction threshold is 25 dB and average bone conduction threshold is 5 dB and further follow-up is planned.

CONCLUSIONS

Isolated stapes malformation is a relatively rare cause of congenital UHL. Current studies confirm that early diagnosis and intervention in children with UHL have a significant impact on a child's educational success and social relationships. Careful evaluation and decision on appropriate treatment of children with UHL supports the development of new guidelines, with respect to the fact that hearing loss may often initially start as unilateral and progress to bilateral.

When Two Is Worse Than One: Internal Auditory Canal Duplication As A Rare Cause Of Congenital Deafness. A Case Report.

Daniel Alberto Nuñez Carlino[1], **Mireya Bonet Loscertales**[1], **María Pilar Benavent Marin**[1], **Cristina Ordoñez Gonzalez**[1], **Julia Montoya Bordón**[1], **Carlos Cenjor Español**[1], **Jose Miguel Villacampa Aubá**[1]

[1]*HOSPITAL UNIVERSITARIO FUNDACIÓN JIMÉNEZ DÍAZ*

BACKGROUND & AIM

Duplication of the internal auditory canal (DIAC) constitutes an exceptionally rare congenital malformation, with a documented incidence of 0.019%. It is unilateral in the vast majority of cases and is clinically characterized by profound or complete sensorineural hearing loss (CSNHL) resulting from aplasia or hypoplasia of the cochlear nerve (CN), while typically preserving the function of the ipsilateral facial nerve. Milder anatomical abnormalities in the contralateral ear are a frequent finding. We present a case of unilateral DIAC, describing its specific clinical and radiological features, and conduct a review of the available literature on the subject.

MATERIAL & METHODS

This case report describes a 26-year-old male presenting with unilateral sensorineural hearing loss since birth. No facial palsy. Otoscopic examination was normal. Pure-tone audiometry revealed right ear CSNHL and normal hearing in the left ear. Computed tomography imaging of temporal bones evidenced right-ear DIAC, characterized by a superior segment of preserved diameter and a narrowed, stenotic inferior component. 3D high-resolution magnetic resonance imaging (MRI) confirmed right-ear DIAC, with the presence of a normal-caliber facial nerve and superior vestibular nerve in the upper compartment. In the lower, more stenotic compartment, it showed a hypoplastic inferior vestibular nerve and the absence of

the CN. In the left ear, the MRI showed hypertrophy of Bill's bar, displacing the facial nerve anteriorly without affecting its diameter. Clinical workup was completed with audiological assessments. Auditory Brainstem Response results were consistent with cochlear nerve agenesis, while vestibular functional tests revealed right posterior semicircular canal hypofunction.

RESULTS

No treatment was proposed due to long-standing deafness and CN aplasia. Clinical follow-up was scheduled. Vestibular hypofunction was asymptomatic. No progression, contralateral hearing loss, or facial/vestibular complications were observed.

CONCLUSIONS

This rare case adds to the just over 60 cases reported in the literature. In DIAC, stenosis usually follows CN agenesis, which complicates treatment. While literature exists regarding cochlear implants in cases of CN aplasia, clinical findings are heterogeneous. A comprehensive medical history alongside high-resolution radiological imaging is highly recommended in patients with congenital CSNHL for a correct differential diagnosis and potential therapeutic options.

When A Major Sigmoid Sinus Protrusion Leads To Cholesteatoma Formation

SAHRAOUI Mohammed[1,2], **MEHTARI Nasrine Siham**[1,2], **BENOSMAN Fazil**[1], **NASRI Amine**[1,2], **KAMRAOUI Samia**[1]

[1]*ENT Department - Tlemcen University Hospital Center;* [2]*Faculty of Medicine - Abou Bekr Belkaid University of Tlemcen*

BACKGROUND & AIM

Middle ear cholesteatoma is a chronic destructive disease whose pathophysiology most commonly involves tympanic membrane retraction secondary to chronic Eustachian tube dysfunction, associated to varying degrees with obliteration of the adjacent air spaces, particularly the mastoid cavity. This results in a negative pressure phenomenon caused by hypoventilation and reduced middle ear air reserve.

Through this work, we present an exceptional case of a major sigmoid sinus protrusion leading to cholesteatoma formation, while highlighting the clinical, radiological, and surgical particularities of this rare entity.

MATERIAL & METHODS

We report the case of a 12-year-old child with no significant medical history, presenting with chronic unilateral foul-smelling right otorrhea evolving over approximately two years, without any other associated symptoms. In particular, the child did not report pulsatile tinnitus.

Clinical examination, including microscopic otoscopy, high-resolution temporal bone CT imaging, audiometry, and appropriate surgical management, was performed.

RESULTS

Microscopic otoscopic examination of the right ear after suctioning revealed a ruptured posterosuperior marginal retraction pocket containing pearly cholesteatomatous debris, while the left ear was normal.

Audiometry showed moderate conductive hearing loss.

High-resolution temporal bone CT demonstrated a markedly anteriorized sigmoid sinus within the mastoid antrum, located only 2 mm from the external auditory canal wall, associated with severe mastoid hypopneumatization. Axial images revealed marked thinning of the sigmoid plate, corresponding to an Irugu–Singh grade III protrusion. The contralateral mastoid was normally pneumatized.

Surgery consisted of a limited mastoidectomy restricted to an antro-atticotomy because the protruding sigmoid sinus occupied most of the mastoid cavity and significantly reduced the operative space.

Cholesteatoma excision was particularly challenging and required meticulous dissection near critical anatomical structures. Nevertheless, complete removal was achieved without vascular, labyrinthine, or facial nerve injury.

Postoperative recovery was uneventful and favorable.

CONCLUSIONS

Major sigmoid sinus protrusion is a rare anatomical anomaly that may contribute to cholesteatoma formation by reducing mastoid aeration and promoting tympanic membrane retraction phenomena. Its presence also represents a significant surgical challenge because of the reduced operative space and the high risk of hemorrhagic complications or injury to adjacent anatomical structures.

This condition requires thorough preoperative radiological assessment, an adapted surgical strategy, and extreme intraoperative caution to ensure effective cholesteatoma removal while minimizing morbidity.

Toxicity Of Tyrosine Kinase Inhibitors In Non-Small-Cell Lung Cancer: A Bibliometric Perspective (2009–2025)

Yerbolat Iztleuov[1], **Elnara Kereevna Ismagulova**[3], **Sarkyt Kozhantayeva**[2]

[1]*Yerbolat Iztleuov West Kazakhstan Marat Ospanov Medical University, Aktobe, Kazakhstan;* [2]*Sarkyt Kozhantayeva West Kazakhstan Marat Ospanov Medical University, Aktobe, Kazakhstan;* [3]*Elnara Kereevna Ismagulova West Kazakhstan Marat Ospanov Medical University, Aktobe, Kazakhstan*

BACKGROUND & AIM

Despite their therapeutic efficacy, anticancer agents are frequently associated with significant toxicity, which can limit treatment adherence, compromise quality of life, and necessitate dose modifications or discontinuation. The aim of this bibliometric analysis is to identify research trends, most relevant publications, key contributors, and emerging hotspots in the field of tyrosine kinase inhibitors (TKIs) for the treatment of non-small cell lung cancer (NSCLC), with particular emphasis on EGFR-targeted therapies and associated treatment-related toxicities.

MATERIAL & METHODS

A literature search was conducted in the Web of Science Core Collection database on June 28, 2025. Bibliometric and scientometric analyses were performed using the Bibliometrix R-package along with the Biblioshiny interface.

RESULTS

Results: The annual scientific output on TKIs and NSCLC has steadily increased from 2009 to 2025. China leads with 580 publications, followed by Japan (381) and the USA (358). Harvard University ranks first among institutions (n = 46), followed by its medical affiliates, Pfizer, and the University of California System. Lung Cancer published the most papers (n = 18), while the Journal of Clinical Oncology had the highest impact factor (IF = 41.9). Zhang L. (13 papers) and Cho B.C. (10 papers) are the most prolific authors, particularly in studies on TKI-related toxicity in NSCLC. The most frequent keywords were “non-small cell lung cancer” (32%) and “Osimertinib” (23%), reflecting a strong focus on targeted therapy and third-generation TKIs.

CONCLUSIONS

Conclusions: This analysis underscores the need for continued research and clinical attention to potential treatment related effects in order to optimize patient safety and therapeutic outcomes.

Sensorineural Hearing Loss In Chronic Kidney Disease: The Impact Of Dialysis A Narrative Review

Dr. Antonio López Gómez[2], **Dra. Maria Fernandez Olvera**[2], **Dra. Lizette Montserrat Cabrera Lopez**[1], **Dr. Christian Eliud Galindo Salazar**[2]

[1]*Medical School, Universidad Autonoma de San Luis Potosi;* [2]*Department of Otolaryngology and Head and Neck Surgery, Hospital Regional de Alta Especialidad "Dr. Ignacio Morones Prieto"*

BACKGROUND & AIM

Sensorineural hearing loss (SNHL) is a prevalent condition that significantly affects communication and quality of life. Chronic kidney disease (CKD) is a systemic disorder associated with metabolic, vascular, and toxic alterations that may impact the auditory system. Structural and functional similarities between the cochlea and kidney suggest a shared pathophysiological basis. Proposed mechanisms include uremic toxicity, electrolyte imbalance, and microvascular damage. Dialysis has been suggested as an additional risk factor for SNHL, although evidence remains inconsistent. This study aimed to review and synthesize available evidence on SNHL in CKD patients, with particular emphasis on the potential impact of dialysis.

MATERIAL & METHODS

A narrative review was conducted using a structured search of the literature published within the last 10 years. Database used was PubMed and the terms used were : sensorineural hearing loss, chronic kidney disease, dialysis, and sudden hearing loss.

Observational studies, cohort studies, and retrospective analyses evaluating auditory outcomes in CKD patients were included. Studies assessing patients undergoing hemodialysis or peritoneal dialysis, as well as those not receiving renal replacement therapy, were considered.

Data extracted included study design, sample size, patient demographics, comorbidities, type of dialysis, treatment approaches, and hearing outcomes such as pure tone audiometry thresholds and recovery rates.

Due to heterogeneity in study design, diagnostic criteria, and outcome measures, a qualitative synthesis of the evidence was performed to identify trends and associations.

RESULTS

The reviewed studies consistently demonstrated a higher prevalence of SNHL among patients with CKD, particularly in advanced stages. Large cohort data involving over 18,000 patients with end-stage renal disease showed a significantly increased incidence of SNHL compared to controls, with a higher risk observed in peritoneal dialysis than in hemodialysis.

Retrospective studies of dialysis patients with sudden SNHL reported severe baseline hearing loss, with mean pure tone averages exceeding 80 dB in some cases. Treatment outcomes were variable, with partial or limited recovery following systemic or intratympanic steroid therapy.

Common comorbidities included diabetes mellitus, hypertension, and cardiovascular disease. Proposed mechanisms linking CKD and SNHL include uremic toxin accumulation, electrolyte imbalance, osmotic shifts during dialysis, and microvascular compromise. However, findings were heterogeneous, with some studies showing no significant differences between dialyzed and non-dialyzed patients.

CONCLUSIONS

SNHL appears to be more frequent in patients with CKD, particularly in advanced stages of disease. Dialysis may contribute to auditory dysfunction, with some evidence suggesting a higher risk in peritoneal dialysis; however, findings remain inconsistent. The relationship between CKD, dialysis, and hearing loss is likely multifactorial and influenced by comorbidities and disease severity.

Current evidence is limited by heterogeneity in study design and outcome assessment. Further well-designed prospective studies are needed to clarify this association and to support the development of screening and early detection strategies for hearing loss in patients with CKD.

Postauricular Fistulas After Multiple Surgical Interventions. Technique Using Local Skin Flap Transposition.

Pelishenko T.G.[1], **Maliavina U.S.**[2], **Tryakina E.G.**[1]

[1]*The Federal State Budgetary Institution "Clinical Hospital No. 1" of the Administration of the President of the Russian Federation (Volynskaya);*
[2]*National Medical Research Center for Children's Health" of the Ministry of Health of the Russian Federation*

BACKGROUND & AIM

Preauricular fistulas are quite a rare pathology. Multiply-operated fistulas are accompanied not only by inflammatory processes but also by severe scarring of surrounding tissues, which makes surgical closure technically challenging due to a shortage of viable tissue and impairs post-operative healing.

Aim: To demonstrate techniques for closing post-auricular fistulas using transposition flaps.

MATERIAL & METHODS

Approach and Excision: A postauricular incision was performed, passing through the midpoint of the fistulous tract. The edges are excised down to healthy tissue. A circular incision was then made 5 mm from the level of the annulus fibrous.

Flap Formation and Dissection: Meatal flaps are created depending on the location of the tympanic part of the fistula tract. The walls of the fistula tract are dissected. The edges of the postauricular incision are undermined and mobilized.

Reconstruction: The meatal skin and preserved parts of the fistula tract are repositioned into a single plane. The edges are sutured (if possible); autologous fascial chondro-perichondral grafts are used for a diastasis larger than 1 mm.

Closure: Layer-by-layer closure of the postauricular incision.

RESULTS

The technique demonstrated stable closure and resolution of chronic inflammation in recurrent postauricular fistulas.

CONCLUSIONS

There is no universal technique. It requires good mobilization of skin flaps and the use of vascularized transposed skin flaps only. In cases of insufficient tissue supply, the edges are sutured. If diastasis is present, it is supplemented with an autofascial or perichondrial flap. Sutures should remain for at least 2 weeks

Case Report: Delayed-Onset Peripheral Facial Paralysis Following Tooth Extraction

AYBİKE TAŞKIN[1], **AYKUT ÖZDOĞAN**[1], **GÖKÇE SAYGI UYSAL**[1], **ZÜLKÜF KÜÇÜKTAĞ**[1]

[1]*ANKARA ETLIK CITY HOSPITAL*

BACKGROUND & AIM

Peripheral facial paralysis (PFP) is a loss of movement in the facial muscles resulting from dysfunction of the seventh cranial nerve. It is a rare but serious complication following dental procedures.

This report presents a 30-year-old female patient who developed House-Brackmann stage 6 PFP on the right side, 48 hours after extraction of the right mandibular third molar.

MATERIAL & METHODS

Early treatment included high-dose corticosteroids, a vitamin B complex, and intensive facial physiotherapy.

RESULTS

With the applied treatment, complete clinical recovery (stage 1) was achieved within 3 months.

CONCLUSIONS

This case highlights the importance of a multidisciplinary approach in the management of delayed-onset PFP.

Dehiscent High-Riding Jugular Bulb In Contact With The Stapes: A Very Rare Otological Variation

Kübra Çoban[1], **Doğa Çelik**[2]

[1]*Baskent University Alanya Hospital;* [2]*Baskent University Ankara Hospital*

BACKGROUND & AIM

A high-riding jugular bulb (HJB) is a common vascular anatomical variant, usually asymptomatic and incidentally detected on imaging, with a predominance on the right side. Dehiscent high riding jugular bulb (DHJB), extending into the middle ear cavity is relatively uncommon. Direct contact of the DHJB with the stapes as in our patient, represents an exceptionally unique case which may lead to numerous otological and vestibular symptoms and findings. This report presents a rare case of a left-sided DHJB extending into the antral cavity and in contact with stapes in a young female adult.

MATERIAL & METHODS

A 36 years old female patient presented with long-standing pulsatile tinnitus, predominantly on the left side, accompanied by temporary ear fullness and vertigo/dizziness. She had no history of trauma, facial paralysis, hearing loss, previous otological surgery, allergy, pregnancy, obesity, drug use or any comorbid diseases. Otoscopic examination was within normal limits except a bluish-purple retrotympanic mass behind the left tympanic membrane (Photo 1). Audiovestibular tests, temporal bone computed tomography (CT), magnetic resonance imaging (MRI) were performed.

RESULTS

The Dix–Hallpike maneuver was positive on the contralateral (right) side. Epley maneuver was performed subsequently for the right posterior semicircular canal. During the follow-up she reported significant improvement in vertigo/dizziness. Tympanometry showed bilateral middle ear pressure values within normal limits; however, reduced compliance was observed in the left ear (Photo 2). CT revealed an enlarged DHJB in the left side which was extending in to the antral cavity, abuting the stapes superiorly, and with close proximity to the cochlear basal turn (Photo 3-4). MRI ruled out vascular tumors such as glomus jugulare, and audiological test could not yet been performed since the device was sent for calibration.

CONCLUSIONS

Pulsatile tinnitus may originate both from otological and neurological pathologies. It may be associated with vertigo, ear fullness, and hearing loss. In this case, a DHJB was located adjacent to the cochlear basal turn and in contact with the stapes, explaining most of the patient's symptoms. We presented a patient with bluish-purple retrotympanic discoloration on otoscopy. Further investigation in such a patient is required for diagnosis, treatment and precautions for long term quality of life. The patient was advised to avoid hard streessfull activities that may increase intracranial pressure and worsen the symptoms.

PP-459

Bilateral Hemotympanum And Unilateral Traumatic Tympanic Membrane Perforation Induced By Sneezing Following Nasal Packing: A Case Report

FIRAT ÇELİKEL[1], **MEHMET BİROL UĞUR**[1]

[1]*Department of Otorhinolaryngology – Head and Neck Surgery, Faculty of Medicine, Gazi University, Ankara, Türkiye*

BACKGROUND & AIM

Epistaxis is a common otolaryngologic emergency, and nasal packing remains a frequently used treatment modality when conservative measures fail. Although generally considered safe, nasal packing may rarely result in otologic complications secondary to pressure transmission through the nasopharynx and Eustachian tube. Simultaneous bilateral hemotympanum and unilateral traumatic tympanic membrane perforation following sneezing after nasal packing is exceptionally rare.

This report aims to present a rare case of middle ear barotrauma occurring after forceful sneezing in the presence of bilateral nasal packing and to discuss the possible pathophysiological mechanisms and clinical outcomes.

MATERIAL & METHODS

A 51-year-old female patient who developed acute otologic symptoms following bilateral nasal packing for epistaxis was evaluated. Clinical assessment included otoscopic examination, nasal endoscopy, and pure-tone audiometric evaluation performed approximately 24 hours after symptom onset. Follow-up examinations were conducted to evaluate tympanic membrane healing and resolution of middle ear findings.

RESULTS

Approximately three hours after bilateral nasal packing, the patient developed sudden bilateral aural fullness, left-sided otorrhagia, and recurrent epistaxis following forceful sneezing.

Otoscopic examination demonstrated marked right-sided hemotympanum with an intact tympanic membrane and a left-sided anterior-inferior tympanic membrane perforation measuring approximately 2 mm with associated hemotympanum.

Nasal endoscopy revealed active bleeding originating from the left inferior turbinate and blood accumulation around the Eustachian tube orifice.

Audiometric evaluation performed approximately 24 hours after injury demonstrated preserved hearing thresholds with mild conductive and high-frequency variations.

Conservative treatment was adopted. At one-week follow-up, spontaneous closure of the tympanic membrane perforation was observed. Complete resolution of bilateral hemotympanum was documented at three weeks.

CONCLUSIONS

Forceful sneezing in the presence of nasal packing may generate substantial intranasal and nasopharyngeal pressure, leading to middle ear barotrauma through the Eustachian tube.

This case highlights that bilateral hemotympanum and tympanic membrane perforation may occur even after routine nasal packing procedures. Patients undergoing nasal packing should be informed to avoid pressure-generating maneuvers and should undergo prompt otolaryngologic evaluation if acute otologic symptoms develop.

Delayed Presentation Of An Iatrogenic Postauricular Epidermal Inclusion Cyst After Ear Surgery: A Case Report

Shatha Yahya Alqahtani[1], **Zohour A. Almalki**[1], **Sara A. Assiri**[1], **Adnene Moussa**[1], **Mohammad Ibrahim**[1]

[1]*Department of ORL-H&N Surgery, Alhada Armed Forces Hospital, Taif, Saudi Arabia*

BACKGROUND & AIM

“Postauricular epidermal inclusion cysts are uncommon delayed complications following otologic surgery. This report aims to describe a rare case of iatrogenic postauricular epidermal inclusion cyst developing years after tympanoplasty and highlight the importance of considering this entity in the differential diagnosis of postauricular swelling.”

MATERIAL & METHODS

A 26-year-old male presented with progressive left postauricular swelling two years after tympanoplasty complicated by transient facial palsy. Clinical examination, radiological imaging, intraoperative findings, and histopathological analysis were reviewed. The lesion was surgically excised and the postoperative outcome was assessed.”

RESULTS

“Examination revealed a firm postauricular swelling without inflammatory changes. CT imaging demonstrated retroauricular soft tissue thickening with mastoid sclerosis. Surgical exploration identified a cystic lesion containing keratinous material. Histopathological examination confirmed an epidermal inclusion cyst without malignant transformation. Complete excision was achieved with favorable postoperative recovery and no immediate complications.”

CONCLUSIONS

“Iatrogenic epidermal inclusion cysts should be considered in patients presenting with delayed postauricular swelling after ear surgery. Careful surgical technique and awareness of this rare complication are important for prevention and early diagnosis. Complete surgical excision remains the definitive treatment.”

PP-461

Endoscopic And Microscopic Tympanoplasty Outcomes: A 10-Year Single-Center Experience

ABDULVAHAP AKYİĞİT[1], **ORKUN EROĞLU**[1], **MİNE BAŞ**[1], **İRFAN KAYGUSUZ**[1], **TURGUT KARLIDAĞ**[1]

[1]*Firat University Faculty of Medicine, Department of ENT, Elazig, Türkiye.*

BACKGROUND & AIM

Microscopic tympanoplasty has long been regarded as the standard technique for tympanic membrane repair. However, endoscopic ear surgery has gained increasing popularity due to its wide-angle visualization and minimally invasive nature. This study aimed to compare the audiological and surgical outcomes of endoscopic and microscopic type I tympanoplasty in a single-center retrospective series.

MATERIAL & METHODS

Patients who underwent type I tympanoplasty for chronic otitis media between January 2015 and January 2025 were retrospectively reviewed. Patients were divided into two groups according to surgical technique: microscopic and endoscopic tympanoplasty. In all cases, cartilage graft was used and placed with the over-underlay technique. Demographic characteristics, operated side, graft success, operative time, and audiological outcomes were analyzed. Pure tone audiometry at 500, 1000, 2000, and 4000 Hz was performed preoperatively and at postoperative 6 months. Hearing gain was defined as the difference between preoperative and postoperative air-bone gap (ABG) values.

RESULTS

A total of 331 patients were included: 150 in the microscopic group and 181 in the endoscopic group. Mean age was 33.3±13.2 years in the microscopic group and 36.2±13.9 years in the endoscopic group (p=0.061). Preoperative ABG was significantly higher in the microscopic group (22.0±10.7 dB vs 19.2±8.9 dB, p=0.012), whereas postoperative ABG was significantly lower in the endoscopic group (12.6±10.5 dB vs 9.4±8.4 dB, p=0.003). ABG gain was similar between groups (9.43±10.11 dB vs 9.83±9.18 dB, p=0.712). Graft success rates were comparable (93.3% vs 94.5%, p=0.817). Operative time was significantly shorter in the endoscopic group (52.3±11.4 min vs 67.2±10.8 min, p<0.001).

CONCLUSIONS

Endoscopic type I tympanoplasty achieved anatomical and functional outcomes comparable to microscopic tympanoplasty, while providing a significantly shorter operative time. These findings support the endoscopic approach as an effective and practical alternative in the surgical management of chronic otitis media.

PP-462

Acute Suppurative Labyrinthitis: Clinical And Radiological Findings – A Case Series

PROF. DR. SİBEL ALİCURA TOKGÖZ[1], **DR. ŞİNASİ ATAÖV**[1], **DOÇ. DR. İLKER AKYILDIZ**[1], **OP. DR. MEHMET MURAT GÜNAY**[1], **PROF. DR. MUHARREM DAĞLI**[1]

[1]*ANKARA ETLİK ŞEHİR HASTANESİ*

BACKGROUND & AIM

Acute suppurative labyrinthitis is a rare but serious bacterial infection of the inner ear, most often spreading from a middle-ear or meningeal focus. It can cause permanent sensorineural hearing loss (SNHL) and may progress to dangerous intracranial complications, yet published experience remains limited. In this series we present the clinical picture, radiological findings, treatment, and outcomes of patients diagnosed with acute suppurative labyrinthitis. We expected otogenic disease to cause profound hearing loss and to carry a high complication risk even when treated.

MATERIAL & METHODS

The records of four patients treated for acute suppurative labyrinthitis at our tertiary center were reviewed retrospectively. For each patient we noted age, sex, symptom duration, pure-tone audiometry, temporal bone computed tomography (CT) and magnetic resonance imaging (MRI) findings, complications, treatment, length of stay, and final outcome. Findings were summarized descriptively.

RESULTS

Patients were 9-35 years old (mean 23.5); three were women. Disease was bilateral in three and left-sided in one. All cases were otogenic and presented with hearing loss; vertigo occurred in three, and nausea-vomiting and tinnitus in two each. All had profound to total SNHL. CT and MRI showed middle-ear and mastoid opacification, a reduced labyrinthine cerebrospinal fluid (CSF) signal, and pathological contrast enhancement. One patient had meningitis and two had mastoiditis; none developed facial paralysis, cerebellar abscess, or labyrinthine fistula. All received intravenous antibiotics and corticosteroids; three underwent surgery (ventilation tube insertion in two, mastoidectomy in two, one both). Mean hospital stay was 15.8 days (10-23). Two patients later received a cochlear implant; in one, cochlear ossification prevented implantation, and one died of meningitis 11 days after discharge.

CONCLUSIONS

Acute suppurative labyrinthitis in our patients was always otogenic and consistently produced profound hearing loss, with serious complications and one death. CT and MRI were valuable for confirming labyrinthine involvement and detecting

complications. These cases underline the need for early diagnosis, aggressive medical and surgical treatment, and cochlear implantation before ossification develops, as the prognosis may still be poor.

PP-463

Lasers In Middle Ear Surgery: A Systematic Review

Maria Korodima[1], **Georgios Grivas**[2], **Alexandros Chatzakis**[1], **Eugenia Maria Domuta**[3]

[1]ENT Department, Sismanogleio General Hospital, Athens, Greece; [2]ENT Department, Pammakaristos Hospital, Athens, Greece; [3]Faculty of Medicine and Pharmacy, University of Oradea,Romania

BACKGROUND & AIM

Laser technology has increasingly been integrated into middle ear surgery due to its precision, minimal tissue trauma, and improved hemostasis. Different laser systems, including CO_2, KTP, diode, and erbium lasers, have been utilized in procedures such as stapedotomy, cholesteatoma excision, tympanoplasty, and ossiculoplasty. Despite their widespread use, controversy remains regarding their comparative effectiveness, safety profile, and long-term auditory outcomes. The present systematic review aims to evaluate the clinical applications, benefits, and limitations of laser-assisted middle ear surgery in contemporary otologic practice.

MATERIAL & METHODS

A systematic literature review was conducted according to PRISMA guidelines. Electronic databases including PubMed, Scopus, and Cochrane Library were searched for studies published between 2000 and 2025 using the keywords “laser,” “middle ear surgery,” “stapedotomy,” “cholesteatoma,” “tympanoplasty,” and “ossiculoplasty.” Randomized controlled trials, prospective studies, retrospective analyses, and meta-analyses written in English were included. Studies evaluating surgical outcomes, hearing improvement, intraoperative complications, postoperative recovery, and recurrence rates were analyzed. Data extraction and quality assessment were independently performed by two reviewers.

RESULTS

A total of 42 studies involving more than 3,500 patients met the inclusion criteria. CO_2 and KTP lasers were the most commonly utilized systems, particularly in stapes surgery. Laser-assisted procedures demonstrated superior surgical precision and reduced intraoperative bleeding compared with conventional techniques. In stapedotomy, postoperative air–bone gap closure of ≤10 dB was achieved in the majority of cases. Cholesteatoma surgery showed lower residual disease rates when lasers were used for difficult anatomical areas. Thermal injury and sensorineural hearing loss were reported rarely and were mainly associated with inappropriate energy settings. Overall, laser-assisted surgery resulted in shorter operative times and improved visualization of delicate middle ear structures.

CONCLUSIONS

Laser technology represents a valuable adjunct in middle ear surgery, offering enhanced precision, reduced trauma, and favorable auditory outcomes. CO_2 and KTP lasers appear particularly effective in stapes and cholesteatoma surgery. However, standardized protocols and long-term comparative studies are still needed to establish definitive recommendations regarding optimal laser selection and safety parameters.

PP-464

Risk For Depression And Anxiety In Patients With Facial Palsy Based On Population Data Of Korea

Ah Young Bae[1], **So Ra Yoon**[2], **Hyunsun Lim**[2], **Junhui Jeong**[1]

[1]Department of Otolaryngology-Head and Neck Surgery, Bucheon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea; [2]Research and Analysis Team, National Health Insurance Service Ilsan Hospital, Goyang, Korea

BACKGROUND & AIM

Several studies point out the association of facial palsy with psychiatric distress such as depression and anxiety. However, there have been few studies on this association based on population-based data. We investigated the risk for depression and anxiety disorders in patients with Bell’s palsy and in those with Ramsay Hunt syndrome.

MATERIAL & METHODS

This retrospective study included data from the Korean National Health Insurance Service National Sample Cohort. From 2006 to 2015, patients with Bell’s palsy and those with Ramsay Hunt syndrome were defined using diagnostic and medication claim codes. Patients with depression or anxiety were defined using diagnostic and medication claim codes. Occurrences of depression and anxiety were included in analyses.

RESULTS

There were significantly higher risks for depressive and anxiety disorders in the group of patients with Bell's palsy than in the control group (hazard ratio [HR] = 1.570, 95% confidence interval [CI] = 1.450 – 1.699), as well as in the group of patients with Ramsay Hunt syndrome than in the control group (HR = 1.617, 95% CI 1.389 – 1.882).

CONCLUSIONS

There were significantly higher risks for depression and anxiety in patients with facial palsy including Bell's palsy and Ramsay Hunt syndrome based on population-based data from Korea.

Facial palsy, Bell's palsy, Ramsay Hunt syndrome, depression, anxiety, population-based study

PP-465

Our Experience In Closing Subtotal And Total Eardrum Perforations

Shirshov S.A.[1], **Saydulaev V.A.**[1], **Mukhmadov I.D.**[1], **Erdem Ağgünlü**[1]

[1]*Ankara Bilkent City Hospital*

BACKGROUND & AIM

Surgical repair of large eardrum perforations with hearing loss is challenging due to tissue loss and ossicle damage. Securing the graft without support to prevent reperforation, retraction, and dislocation remains a key issue, as shown by the variety of techniques.

To analyze the early and late results of surgical closure of total and subtotal perforations and evaluate the effectiveness of the surgical techniques used.

MATERIAL & METHODS

64 patients with total and subtotal perforations of the eardrum were treated in 2020- 2025. Inclusion criteria: dry perforation of more than 75% of the eardrum area. Patients with exacerbation of chronic middle ear purulent otitis, cholesteatoma, and severe sensorineural hearing loss were excluded. All patients underwent otoscopy, audiometry, and CT of the temporal bones. Timpanoplasty was performed under endotracheal anesthesia using the supra- aural (n=57) or endau-ral (n=7) approach. The grafts used were the temporal fascia (n=47), the tragus cartilage (n=10), and the combined cartilage-fascia graft (n=7). In cases of ossicular

chain disorders, ossiculoplasty was performed. The results were evaluated at 3 and 12 months.

RESULTS

The graft was accepted and complete closure of the perforation was achieved in 56 of 64 operated ears (87.5%) 3 months after surgery. Failure of the neotympanum flap with the formation of reperforation was noted in 5 cases (7.8%). In 3 patients (4.6%) there was a lateralization of the graft without the formation of a defect, but with the formation of a fixed position of the membrane. The best anatomical results (90% приживления) were obtained in the group of patients who used a cartilage graft, compared to the group of patients who used only the temporal fascia (85.1%). The analysis of postoperative audiometry showed an improvement in hearing function in patients with a successfully integrated graft. There was a decrease in the bone-air interval by an average of 15 dB and a decrease in the air conduction

threshold by an average of 20 dB.

CONCLUSIONS

The data obtained indicate that the use of cartilage grafts in large tympanic membrane perforations allows for stable anatomical and functional results and can be considered as a method of choice in these clinical situations. Functional results depend on the integrity of the neotympanic membrane and the ossicular system.

Trends In Surgical Techniques And Graft Selection For Pediatric Tympanic Membrane Perforations Following Tube Extrusion: An 11-Year Review

Yukiko Iino[1], **Hiromi Kanazawa**[1]

[1]*Department of Otolaryngology-Head and Neck Surgery, Jichi Medical University of Saitama Medical Center*

BACKGROUND & AIM

The options for closing tympanic membrane perforations have expanded with the evolotion of transcanal endoscopic ear surgery and eardrum regeneration therapy using Retympa@ in Japan. In pediatric tube related cases, surgery primarily aims to improve hearing after tube extrusion and to stop otorrhea caused by prolonged infections. This reserch aimed to investigate the surgical techniques, and operative times and hearing level in pediatric patients with chronic perforated otitis media over an 11-year period at our hospital, with a particular focus on the graft materials used for reconstruction.

MATERIAL & METHODS

The study included 57 fresh cases who underwent surgery at our hospital between April 2014 and December 2025. We examined the surgical techniques, hospital stay lengths, and other factors categorized by the graft materials used.

RESULTS

When dividing the cases into two periods (before and after March 2018), periosteum grafts accounted for the majority in the earlier period. However, a trend toward using Re-Tympa and fascia grafts was observed in the later period. The pre- and post-operative hearing improvement was 3.1 dB for periosteum, 7.91 dB for fascia, 4.96 dB for connective tissue, and 10.02 dB for Re-Tympa. These results demonstrated improvements exceeding those of conventional autologous tissues, alongside reductions in actual operative times and hospital stays.

CONCLUSIONS

A trend toward adopting more minimally invasive closure techniques over the years was observed at our hospital.

PP-467

The Effects Of Menopause On Tinnitus: A Comparison Of Tinnitus Between Menopausal And Premanopausal Women

Metehan Yelmenoğlu[1]

[1]*Sancaktepe Şehit Prof. Dr. İlhan Varank Eğitim ve Araştırma Hastanesi*

BACKGROUND & AIM

The aim of this study is evaluating the impact of menopause on the presence, severity, and quality of life burden of tinnitus using the Tinnitus Handicap Inventory (THI), and to investigate the potential role of menopause in tinnitus by comparing women in menopausal period with those in premenopausal period.

The primary research question of the study is as follows: Does the level of tinnitus-related distress differ between women in the menopausal period and those in the premenopausal period?

MATERIAL & METHODS

The study is designed as a prospective, observational, analytical, cross-sectional, and controlled investigation to be conducted at the Otorhinolaryngology (ENT) outpatient clinics of Sancaktepe Şehit Prof. Dr. İlhan Varank Training and Research Hospital in 2026. In this study, women in the menopausal period will be compared with those in the premenopausal period using the Tinnitus Handicap Inventory (THI). No interventional procedures or treatments will be administered to the participants, and neither randomization nor blinding will be performed.

RESULTS

The mean age of the menopausal group was significantly higher than that of the premenopausal group. Tinnitus prevalence was found to be higher in the menopausal group compared to the premenopausal group.

The mean Tinnitus Handicap Inventory score was significantly greater in menopausal women than in premenopausal women, indicating a higher level of tinnitus-related distress in the menopausal group. In addition, moderate-to-severe THI categories were more frequently observed among menopausal participants.

CONCLUSIONS

In conclusion, the findings of this study suggest that menopausal women experience greater tinnitus-related distress and reduced quality of life compared to premenopausal women, as demonstrated by higher Tinnitus Handicap Inventory scores. These results support the hypothesis that hormonal alterations occurring during menopause may contribute to the severity and perception of tinnitus.

Further prospective studies with larger sample sizes and hormonal assessments are needed to better elucidate the biological mechanisms linking menopause and tinnitus and to determine whether targeted therapeutic interventions may reduce tinnitus-related impairment in this population.

Tuberculosis Otitis Media Presenting With Simultaneous Sensorineural Hearing Loss And Peripheral Facial Palsy: A Diagnostic Challenge

Simge BAŞMAYA[1], **Yavuz GÜNDOĞDU**[1], **Emine ÇEŞMECİOĞLU KARAVİN**[2]

[1]*Marmara University School Of Medicine, Department of Otorhinolaryngology , İstanbul, Türkiye;* [2]*Marmara University School Of Medicine, Department of Pathology , İstanbul, Türkiye*

BACKGROUND & AIM

Tuberculosis otitis media (TOM) accounts for only 0.05–0.9% of chronic otitis media infections. The occurrence of sensorineural hearing loss (SNHL) and peripheral facial palsy (PFP) as initial symptoms in the absence of systemic findings is extremely rare and constitutes a significant diagnostic challenge, frequently leading to delayed diagnosis.

MATERIAL & METHODS

A 55-year-old woman presented with sudden-onset left-sided SNHL; this was followed by progressive left-sided PFP (Grade 3; progressing to Grade 5 despite appropriate therapy). On detailed questioning, revealed that the patient had no systemic symptoms, no prior history of ear disease, and no history of tuberculosis. Temporal bone CT demonstrated left mastoid opacification; MRI revealed bilateral mastoid fluid and soft tissue thickening. Severe acute-to-subacute axonal facial nerve injury confirmed by electromyography. The patient was referred to our clinic for facial nerve decompression. Intraoperatively, sequestrated necrotic bone was identified within the mastoid. Histopathological examination demonstrated the presence of necrotizing granulomatous inflammation, and microbiological studies confirmed the growth of M.tuberculosis in culture. Systemic evaluation revealed no evidence of active pulmonary tuberculosis. The patient was referred to the department of infectious diseases, and four-drug anti-tuberculous therapy was initiated. Facial function improved to Grade 2, and electromyography confirmed significant axonal regeneration at six-month follow-up.

RESULTS

The simultaneous occurrence of SNHL and PFP as initial symptoms of TOM in the absence of systemic findings represents one of the rare presentations reported in the literature. This atypical pattern led to an initial diagnosis of idiopathic sudden SNHL and Bell's palsy at first presentation, resulting in the administration of empirical corticosteroid therapy and delayed diagnosis of the underlying organic pathology. In cases unresponsive to standard therapy, early surgical exploration with systematic histopathological and microbiological sampling should be considered.

CONCLUSIONS

In patients in whom SNHL and facial palsy coexist and who are unresponsive to corticosteroid therapy, organic etiologies including TOM must first be excluded before establishing an idiopathic diagnosis. Early sampling is critical for diagnosis and anti-tuberculous chemotherapy can provide visible functional recovery even in cases with severe axonal injury.

PP-469

Systemic Risk Factors Influencing Microvascular And Structural Health In Otolith Degeneration

Chae-Won Kwon[1], **Jeong-Yoon Choi**[1], **Ji-Soo Kim**[1]

[1]*Seoul National University Bundang Hospital*

BACKGROUND & AIM

While the age-related degeneration of the otolith organs (saccule and utricle) is a recognized phenomenon, the specific systemic conditions that accelerate this structural and microvascular deterioration remain poorly defined. This study aimed to elucidate the metabolic, vascular, and demographic risk factors associated with otolith dysfunction in a large clinical cohort of patients suffering from dizziness and vertigo.

MATERIAL & METHODS

We conducted a cross-sectional analysis of 624 patients diagnosed with benign paroxysmal positional vertigo, benign recurrent vertigo, or persistent postural-perceptual dizziness at a tertiary referral center between March 2017 and July 2021. To quantitatively assess otolith functionality, we measured the summated amplitudes of cervical and ocular vestibular evoked myogenic potentials (SA-cVEMPs for saccular function and SA-oVEMPs for utricular function). Comprehensive serological data, including lipid profiles, thyroid hormones, and bone turnover markers, were collected. The relationships between otolith function parameters and potential systemic risk factors were evaluated using generalized linear models: a zero-adjusted gamma regression for SA-cVEMPs (to effectively handle zero-inflated data) and a standard gamma regression for SA-oVEMPs.

RESULTS

Multivariable regression analysis revealed distinct risk profiles for the two otolith organs. Saccular function (SA-cVEMP) was significantly diminished in correlation with advancing age, female sex, and elevated free thyroxine levels. Conversely, higher levels of high-density lipoprotein (HDL) cholesterol were positively associated with saccular function, suggesting a microvascular protective effect. Utricular function (SA-oVEMP) similarly declined with age but, intriguingly, demonstrated a positive association with female sex. Subgroup analyses further indicated that the detrimental impact of elevated free thyroxine on the saccule was particularly pronounced in older individuals and females.

CONCLUSIONS

This study provides novel clinical evidence that systemic metabolic and vascular factors significantly impact otolith integrity, extending beyond the natural aging process. Elevated free thyroxine may disrupt otoconial calcium homeostasis by

accelerating bone turnover, whereas HDL cholesterol likely preserves the microvascular networks supporting the macula. Recognizing and managing these systemic variables may offer new therapeutic strategies for preventing or mitigating otolith-related vestibular disorders.

Development Of An Audiology-Led Pulsatile Tinnitus Investigation Pathway Across A Tertiary ENT Network

Leyla Karaytug[1], **Shuja Yaqub**[1], **Annah Waqasi**[1], **David Ajao**[1], **Barbara Mair**[1], **Esraa Saad**[1], **Rana Batir**[1], **Nejc Steiner**[1]

[1]*Department of Otolaryngology - Head and Neck Surgery, Manchester University NHS Foundation Trust, Manchester, United Kingdom*

BACKGROUND & AIM

Pulsatile tinnitus may indicate underlying vascular, skull base, or middle ear pathology and frequently requires complex multidisciplinary investigation. Prior to implementation of a revised pathway, most patients presenting with pulsatile tinnitus across Manchester University NHS Foundation Trust (MFT) were routinely referred to ENT services, with variation in imaging requests and escalation pathways between clinicians and sites. In September 2025, a standardised trust-wide pulsatile tinnitus investigation protocol was introduced collaboratively between Audiology, Otology, Skull Base and Head & Neck Radiology services. The pathway aimed to standardise imaging investigations, improve patient safety, reduce unnecessary ENT appointments, and establish an Audiology-led diagnostic pathway.

MATERIAL & METHODS

A retrospective audit was performed of patients referred with pulsatile tinnitus following implementation of the revised pathway between September 2025 and January 2026 across participating MFT sites.

The agreed investigation protocol for patients with unilateral or bilateral constant pulse-synchronous tinnitus included MRI internal auditory canal imaging without contrast and CT head and neck imaging with contrast. In patients with contraindication to contrast-enhanced CT or severe renal impairment, alternative vascular imaging with MRA head, MRV head, and MRA neck was recommended.

Patients underwent initial assessment within Audiology services, including confirmation of pulse-synchronous tinnitus and comprehensive audiological assessment. Audiology teams arranged MRI imaging and escalated patients to designated ENT consultants for CT imaging requests where appropriate. Data collected included demographics, symptom laterality, imaging requests, pathway adherence, renal function assessment prior to contrast imaging, imaging findings, and requirement for subsequent ENT review.

RESULTS

Forty-four patients were included following exclusion of incomplete cases (77.3% female; mean age 51.8 years). Unilateral pulsatile tinnitus was reported in 59.1% of patients and bilateral symptoms in 40.9%. Initial referral occurred through Audiology in 77.3% of cases and directly to ENT in 22.7%.

Pure tone audiometry was completed in 95.5% of patients. MRI internal auditory canal imaging was arranged in 81.8% of cases. Renal function assessment prior to contrast-enhanced CT was documented in 86.4% of patients, with no patients demonstrating significant renal impairment requiring alternative vascular imaging pathways.

Most patients (84.1%) demonstrated no significant pathological cause for pulsatile tinnitus. Identified abnormalities included middle ear pathology, venous sinus stenosis, arachnoid granulation, and dehiscent sigmoid sinus findings.

Among patients with available outcome documentation, 89.5% were managed without requiring routine consultant ENT review.

CONCLUSIONS

Implementation of a standardised multidisciplinary pulsatile tinnitus investigation pathway across a tertiary ENT network was feasible and enabled safe expansion of an Audiology-led diagnostic model. The pathway improved standardisation of imaging investigations and substantially reduced the need for routine consultant ENT review in selected patients while maintaining agreed radiological safety measures.

This audit identified areas for further pathway refinement, particularly regarding consistency of renal function documentation prior to contrast imaging. The next phase of pathway development aims to establish fully Audiology-led imaging requesting through Non-Medical Referrers, with ENT involvement reserved for abnormal findings, red flag symptoms, or complex cases.

PP-471

Bilateral Congenital Cholesteatoma: A Case Report

ALİ ÇETİN[1], **SERVET ERDEMES**[1]

[1]*HARRAN ÜNİVERSİTESİ TIP FAKÜLTESİ*

BACKGROUND & AIM

To present the clinical presentation, radiological findings, surgical management, and early audiological outcomes of a rare case of bilateral congenital cholesteatoma, and to demonstrate the feasibility of single-stage bilateral transcanal endoscopic surgery.

MATERIAL & METHODS

This study was designed as a descriptive case report. Clinical records, otoscopic photographs, preoperative and postoperative audiometric evaluations, tympanometric findings, high-resolution temporal bone computed tomography images, intraoperative endoscopic photographs, operative notes, histopathological findings, and follow-up data were retrospectively reviewed. Disease extent was classified according to the Potsic staging system. Surgical outcomes were assessed based on complete disease removal, integrity of the reconstructed tympanic membrane, early recurrence status, and postoperative hearing results.

RESULTS

A 6-year-old girl presented with otalgia and was initially treated for otitis media with effusion. Follow-up otoscopy revealed bilateral white retrotympanic masses behind intact tympanic membranes. Preoperative pure-tone audiometry showed mild conductive hearing loss (27/18 dB in the right ear and 30/15 dB in the left ear; air conduction threshold/air–bone gap), with bilateral type A tympanograms. High-resolution temporal bone computed tomography demonstrated bilateral mesotympanic soft tissue lesions, more prominent on the right side. Single-stage bilateral transcanal endoscopic surgery was performed. The left ear harbored a Potsic stage I congenital cholesteatoma with an intact ossicular chain, whereas the right ear demonstrated Potsic stage III disease with ossicular erosion requiring reconstruction with Total Ossicular Replacement Prosthesis. At postoperative month 3, no residual or recurrent disease was detected, and hearing improved to 22/10 dB in the right ear and 18/15 dB in the left ear.

CONCLUSIONS

Bilateral congenital cholesteatoma should be considered when bilateral retrotympanic white lesions are observed behind intact tympanic membranes. Single-stage bilateral transcanal endoscopic surgery is a safe and effective treatment option that can provide excellent early anatomical and functional outcomes, even in cases requiring extensive ossicular reconstruction.

PP-472

When The Tumor Shrinks But Symptoms Persist: Advanced Jugular Paraganglioma After Radiosurgery

Anastasia Stefana Talau[1,2], **Mihaela Chialda**[1,2]

[1]*Lucian Blaga University of Sibiu, Faculty of Medicine;* [2]*County Emergency Clinical Hospital of Sibiu*

BACKGROUND & AIM

Jugular paragangliomas are rare, highly vascular skull base tumors that may produce progressive lower cranial nerve dysfunction. In advanced stages with intracranial and carotid involvement, surgical management may be contraindicated. We hypothesized that stereotactic radiosurgery can achieve meaningful radiologic tumor regression in inoperable advanced jugular paragangliomas but may not reverse long-standing neurological deficits.

MATERIAL & METHODS

A female patient presented in 2024 with progressive dysphonia. Medical history revealed left-sided hypoacusis and dysphagia evolving since 2018. Otoscopic examination demonstrated a pulsatile retrotympanic reddish mass with a rising sun appearance. Flexible laryngoscopy confirmed left vocal cord paresis. Contrast-enhanced computed tomography (CT) identified an iodophilic, hourglass-shaped mass centered at the left jugular foramen with intracranial extension toward the cerebellopontine angle. Magnetic resonance imaging (MRI) demonstrated a 35 × 27 × 37 mm lesion, hypointense on T1-weighted and hyperintense on T2-weighted sequences, with intense gadolinium enhancement. The tumor extended into the carotid space, showing a 10.8 mm segment of contact with the internal carotid artery and exerting mass effect on the left middle cerebellar peduncle. Imaging findings were consistent with a Fisch C2D2 jugular paraganglioma. Angio-CT confirmed marked vascularity. Surgical resection and embolization were considered unsafe, and the patient underwent Gamma Knife stereotactic radiosurgery.

RESULTS

At one-year follow-up, MRI demonstrated reduction of tumor dimensions to 22 × 13 × 33 mm, with complete resolution of mass effect on the middle cerebellar peduncle. The lesion remained in contact with cranial nerves VII and VIII. Persistent fluid was noted in the ipsilateral mastoid and middle ear on both pre- and post-treatment imaging. Despite significant radiologic regression, dysphonia, dysphagia, and hearing impairment showed no meaningful clinical improvement.

CONCLUSIONS

Stereotactic radiosurgery can achieve substantial tumor regression and brainstem decompression in advanced jugular paragangliomas. However, prolonged cranial nerve dysfunction appears largely irreversible once established, particularly after

delayed diagnosis. Early recognition of progressive otologic and vagal symptoms is essential to prevent permanent neurological sequelae.

PP-473

Reconstructed Wall Thickness As A Predictor Of Postoperative Aural Fullness In Sigmoid Sinus Wall Resurfacing: Utility Of Intraoperative Doppler Ultrasound

Chan Mi Lee[1], **Jae Sang Han**[2], **Shi Nae Park**[1]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea;* [2]*Department of Otorhinolaryngology-Head and Neck Surgery, Eunpyeong St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea*

BACKGROUND & AIM

Sigmoid sinus wall resurfacing (SSWR) is a well-established surgical intervention for venous pulsatile tinnitus attributable to sigmoid sinus wall anomalies. Nevertheless, over-reconstruction of the sinus wall may predispose patients to postoperative complications, particularly aural fullness. This study sought to compare clinical outcomes of SSWR performed with versus without intraoperative Doppler ultrasound (IDU), and to examine the association between reconstructed wall thickness and the occurrence of postoperative aural fullness.

MATERIAL & METHODS

A retrospective cohort study was performed involving patients who underwent SSWR for venous pulsatile tinnitus from 2018 through 2025, with a minimum postoperative follow-up duration of 2 months. Surgical outcomes were evaluated using the Tinnitus Handicap Inventory (THI) and visual analog scale (VAS). Postoperative complications, defined as persistent aural fullness exceeding 2 weeks or symptom aggravation, were documented. Subjects were stratified into an IDU-guided group and a non-IDU group. In a subset of patients with available postoperative computed tomography (CT) imaging, bone cement thickness of the reconstructed wall and residual sigmoid sinus dehiscence were quantified. Receiver operating characteristic (ROC) curve analysis was applied to identify an optimal thickness threshold predictive of postoperative aural fullness.

RESULTS

Fifty-four patients were enrolled, comprising 20 in the IDU group and 34 in the non-IDU group. Both cohorts demonstrated statistically significant postoperative improvements in THI and VAS scores; however, no significant intergroup differences were observed in cure rates, symptomatic improvement, symptom aggravation, or short-term aural fullness. Among the CT-available subgroup (n = 35), the IDU-guided group exhibited a significantly reduced reconstructed bone cement thickness relative to the non-IDU group ($P < 0.001$). ROC analysis identified a reconstructed wall thickness exceeding 5 mm as a moderately accurate predictor of postoperative aural fullness (AUC = 0.72). Patients whose reconstructed wall thickness surpassed this threshold demonstrated an approximately 14-fold elevated risk of developing postoperative aural fullness ($P = 0.007$).

CONCLUSIONS

SSWR confers significant symptomatic relief for venous pulsatile tinnitus irrespective of IDU guidance. However, excessive reconstructed wall thickness is strongly associated with postoperative aural fullness. Intraoperative Doppler ultrasound may serve as a valuable adjunct to optimize reconstruction by limiting excessive bone cement deposition, thereby preserving therapeutic efficacy while mitigating postoperative morbidity.

Association Between Hearing Disability And Injury Risk In Older Adults: Quasi-Experimental Study Using Propensity Score Matching

Hyun Seung Choi, MD[1], **Woo-Ri Lee, PhD**[1], **Sungyoun Chun, PhD**[1], **Youyoung An, MD**[1]

[1]*National Health Insurance Service Ilsan Hospital, Goyang, Republic of Korea*

BACKGROUND & AIM

With rapid population aging, both traumatic injuries and hearing disability have become increasingly prevalent among older adults. Hearing disability may increase vulnerability to injury through impaired balance, reduced environmental awareness, and functional limitations; however, longitudinal evidence examining the association between hearing disability and injury risk remains limited.

This study aimed to examine the association between hearing disability and the risk of injury among older adults using a quasi-experimental design with propensity score matching (PSM).

MATERIAL & METHODS

This population-based cohort study included individuals aged 60 years and older with hearing disabilities and a matched control group without disabilities using data from the National Health Insurance Service–Senior cohort from 2008 to 2019. Injury admission, defined using International Classification of Diseases codes S00 to S99, was the primary outcome. A quasi-experimental design was applied using PSM at a 1:3 ratio to balance baseline characteristics between the hearing-disabled and nondisabled groups. Cox proportional hazard regression models adjusted for all covariates were used to estimate hazard ratios. Sensitivity analyses were conducted according to disability severity and injury site.

RESULTS

The total number of participants was 43,944, with 10,986 (25%) in the hearing-disabled group and 32,958 (75%) in the nondisabled group, thus confirming a 1:3 matching ratio. The PSM results showed that the standardized mean difference values for all covariates were below the absolute value of 0.1, thus indicating that PSM was successfully performed. The incidence of injury at admission was higher in the hearing-disabled group (1567/10,986, 14.3% of patients) than in the nondisabled group (3966/32,958, 12.0%), and this difference was statistically significant (P<.01). During the follow-up period, older adults with hearing disability had a significantly higher risk of injury admission compared with those without hearing disability (hazard ratio=1.21, 95% CI 1.14-1.28). The association was stronger among individuals with more severe hearing disability and varied by injury site.

CONCLUSIONS

Hearing disability in older adults is independently associated with increased injury admission risk, with greater severity conferring a higher risk and variation by injury site. Interventions such as hearing aid provision, targeted traffic safety measures, and enhanced community and family support are warranted to mitigate this burden.

KEYWORDS

hearing disability; injury; fall; older patients; propensity score matching

PP-475

HOW CAN WE DETERMINE THE PROGNOSIS MORE ACCURATELY IN PATIENTS WITH RECURRENT BELL'S PALSY

Lee Jong Hwan[1], **Jae Yong Byun**[1]

[1]*Department of otolaryngology, College of Medicine, Kyung Hee University, Seoul, Korea*

BACKGROUND & AIM

lectroneurography (ENoG) is the most accurate test for determining the prognosis of Bell's palsy (BP). However, in patients with recurrent BP, the prognostic accuracy of ENoG may be lowered because of owing to previous facial-nerve degeneration. This study investigated an interpretation method for ENoG values to accurately determine the prognosis of facial-nerve palsy in patients with recurrent BP.

MATERIAL & METHODS

The medical records of 38 patients with recurrent contralateral BP between 2011 and 2022 were retrospectively reviewed. Because the ENoG CMAP(Complex muscle action potential) of the healthy side in the second episode may have been underestimated owing to the previous palsy, we attempted to estimate the correct CMAP by comparing CMAP of the healthy sides in the second and first episodes according to the recurrence interval.

RESULTS

The paired t-test showed that the ENoG CMAP(orbicularis oculi muscle) of the healthy side in the first and second BP was significantly different in patients with a recurrence interval <2 years a the the (p=0.004)the showed. Linear regression analysis was performed on the healthy side at the first and second period, and the results were as follows : [2nd healthy side CMAP] = [1st heathy side CMAP] * 0.704 – 0.121

CONCLUSIONS

In patients with recurrent contralateral BP, if the recurrence interval is less than 2 years, correction of the ENoG CMAP is necessary when determining the prognosis because the previous palsy did not recover. Significance: In patients with a BP recurrence interval <2 years, correction of the ENoG ratio should be considered

PP-476

Eustachian Tube Dysfunction As A Risk Factor For Tinnitus: A Meta-Analysis And Systematic Review

Ivy Yenwen Chau[1], **Chen-Chih Wang**[1], **Sophia Yung-Hsia Li**[2], **Hamid R. Djalilian**[3], **Lieber Po-Hung Li**[1]

[1]*Department of Otolaryngology, Cheng Hsin General Hospital, Taipei, Taiwan;* [2]*Department of Neuroscience, University of Illinois Urbana-Champaign, Urbana, Illinois, USA;* [3]*Department of Otolaryngology, Neurosurgery, and Biomedical Engineering, University of California Irvine Medical Center, Irvine, California, USA*

BACKGROUND & AIM

Tinnitus is a prevalent and debilitating condition affecting approximately 12%–16% of adults, with 3%–5% experiencing significant impairment in sleep, mood, and daily functioning. Eustachian tube dysfunction (ETD), a disorder of middle ear ventilation and pressure regulation, has been proposed as a contributing factor; however, the association remains unclear. This study aimed to evaluate the association between ETD and tinnitus and quantify this relationship using a systematic review and meta-analysis.

MATERIAL & METHODS

A comprehensive search was conducted in PubMed, Embase, Cochrane Library, Scopus, and Web of Science from inception through March 2026, with additional studies identified through manual searches. Eligible studies included randomized and observational designs (cohort, case-control, cross-sectional, quasi-experimental) involving patients aged ≥15 years with ETD reporting tinnitus outcomes. Studies with major otologic comorbidities or insufficient data were excluded. Data were extracted based on predefined Population, Intervention/Exposure, Comparison, Outcome, and Study Design (PICOS) criteria. Study quality was assessed using Joanna Briggs Institute tools. Because tinnitus prevalence in individuals with normal Eustachian tube function (ETF) was not directly reported, it was estimated using the law of total probability. Odds ratios were pooled using fixed- and random-effects models. Subgroup, sensitivity, meta-regression, and publication bias analyses were performed. The primary outcome was the pooled odds ratio (OR) for tinnitus in individuals with ETD compared with those without ETD.

RESULTS

Ten studies met inclusion criteria. A significant association was observed (random-effects OR = 3.72, 95% CI: 2.28–6.06, $p < 0.001$), consistent across models and sensitivity analyses, with ORs ranging from 2.57 to 6.04. Moderate heterogeneity was present ($I^2 = 59.8\%$). Subgroup analysis showed stronger effects in Asia, while nonsignificant results in Europe were likely due to small sample sizes. Leave-one-out analysis confirmed robustness, and publication bias adjustment did not materially change results.

CONCLUSIONS

ETD is associated with a substantially increased risk of tinnitus, with approximately 3- to 4-fold higher odds. These findings highlight the importance of evaluating ETF in patients with tinnitus and suggest ETD as a potential therapeutic target. Further prospective studies are needed to clarify causality.

OTOGENIC CEREBRAL VENOUS SINUS THROMBOSIS SECONDARY TO ACUTE MASTOIDITIS IN CHILDREN: A TWO-CASE SERIES IN THE POST-COVID ERA

Gytis Zaldokas[1], **Vaiva Mickeviciene**[1,2], **Ieva Zaldokiene**[1]

[1]*Department of Pediatric Otorhinolaryngology, Vilnius University Hospital Santaros Clinics, Lithuania;* [2]*Vilnius University Faculty of Medicine, Lithuania*

BACKGROUND & AIM

Acute mastoiditis remains a serious consequence of acute otitis media in children and can lead to life-threatening intracranial complications, including cerebral venous sinus thrombosis (CVST). Early symptoms are often nonspecific, and delayed treatment may result in severe intracranial complications. We present two pediatric cases of otogenic CVST secondary to acute mastoiditis and discuss a possible increase in advanced otogenic complications in the post-COVID period.

MATERIAL & METHODS

We retrospectively reviewed two cases of acute otitis media complicated by mastoiditis and extensive CVST treated in 2022 and 2025 at the Vilnius University Hospital Santaros Clinics. Medical documentation was used to retrieve information about clinical presentation, imaging findings, surgical procedures, and clinical outcomes. Diagnosis was confirmed using contrast-enhanced computed tomography and magnetic resonance venography. A multidisciplinary approach involving ENT specialists, haematologists, neurologists, and neurosurgeons was necessary in both cases.

RESULTS

CASE 1. A 5-year-old male initially presented to the emergency department with fever, vomiting, lethargy, and showed temporary clinical improvement after initial treatment. Several days later, he re-presented with severe otalgia and postauricular swelling. Imaging demonstrated acute mastoiditis complicated by a retroauricular abscess, intracranial extension, and CVST. Incision and drainage with tympanostomy were performed, followed by a left antro-mastoidectomy due to clinical deterioration. Microbiological examination of purulent material identified Escherichia coli. The patient received broad-spectrum intravenous antibiotics and anticoagulation therapy. Subsequent evaluation revealed upper-extremity thrombophlebitis.

CASE 2. A 12-year-old female presented to the emergency department with fever, severe headache, vomiting, and neck stiffness. Otoscopic examination revealed purulent otitis media. Imaging demonstrated acute mastoiditis complicated by intracranial extension and CVST. Due to disease progression, right mastoidectomy was performed. The patient received intravenous broad-spectrum antibiotics and anticoagulation therapy, resulting in clinical improvement.

CONCLUSIONS

Otogenic CVST is a rare but potentially life-threatening complication of acute mastoiditis in children. Persistent headache, neurological symptoms, or clinical deterioration should prompt urgent neuroimaging. Early diagnosis and multidisciplinary

management, including surgery, antibiotics, and anticoagulation, can lead to favorable outcomes. Increased awareness is warranted given an apparent recent rise in such cases in our country following the COVID-19 pandemic.

Meningoencepaholocele Associated With A Congenital Craniopharyngeal Canal A Case Report & Literature Review

Sarena Maistry[1], **Sarena Maistry**[1]

[1]*Department of Otorhinolaryngology University of KwaZulu Natal*

BACKGROUND & AIM

A craniopharyngeal canal is a rare congenital abnormality that occurs as a result of the persistence of an embryological connection between the sella turcica and the nasopharynx, caused by the incomplete regression embryological ectodermal outpouching, Rathke's pouch. Imaging studies show a bony defect of the sella turcica.

This case report aims to serve as a brief introduction to the clinical presentation, diagnostic challenges and definitive management of a neonate with a craniopharyngeal canal; including a literature of the rare entity.

MATERIAL & METHODS

Case presentation:

A term neonate presented with symptoms of nasal obstruction and respiratory distress shortly after birth. Marked respiratory distress with desaturations were noted during feeds. Endoscopy of the post-nasal space revealed an obstructive cystic, grey midline nasal mass; point of origin could not be determined clinically. MRI revealed a patent bony canal extending from the nasopharynx to the sella turcica, without associated intracranial abnormalities. The diagnosis of a craniopharyngeal canal, type 3A containing cephaloceles, was made, following which, surgical intervention was implemented to close the canal.

RESULTS

Discussion:

Timely diagnosis and intervention in this rare entity is required for reasons ranging from neonates are obligatory nasal breathers to risk of meningitis. Other factors to take into account are size lesion, surgical access and pituitary function. This case outlines the importance of the consideration of a craniopharyngeal canal in the differential diagnosis of a congenital midline cystic nasopharyngeal mass, as well as the role of imaging to aid with diagnosis and surgical planning.

CONCLUSIONS

Conclusion:

A craniopharyngeal canal should be considered in neonates presenting with a midline nasopharyngeal cystic mass, and imaging is important prior to attempting implementation of surgical interventions to ensure minimal risk of injury to the brain and hypophysis. This case reports aims to add to the very small pool of existing literature available on the topic of craniopharyngeal canal and highlight important investigations in determining the best approach.

Parapharyngeal Abscess Presenting With Combined Glossopharyngeal And Vagal Nerve Palsy In A Child

Mehmet KESKİN[1], **Gökçe ALTIN**[1], **Zehra YILDIRIM**[1], **Türkü BAYRAMOĞLU**[1], **Abdülkadir CANSUNAR**[1], **Özgür YİĞİT**[1]

[1]*Department of Otorhinolaryngology, Başakşehir Çam and Sakura City Hospital, Istanbul, Turkey*

BACKGROUND & AIM

Deep neck infections in children are relatively uncommon but clinically important due to their potential for rapid progression and serious complications. Parapharyngeal abscesses are particularly concerning because of their close relationship with major neurovascular structures. While they typically present with fever, neck pain, and restricted neck movement, involvement of the lower cranial nerves is rare and may complicate the clinical picture. Dysfunction of the glossopharyngeal and vagus nerves can lead to symptoms such as dysphonia, dysphagia, and reduced gag reflex. In this report, we present a pediatric case of parapharyngeal abscess presenting with combined cranial nerve IX and X palsy.

MATERIAL & METHODS

A six-year-old girl presented to an outside emergency department with complaints of ear and throat pain.On initial evaluation, there was no trismus, and neck movements were full.Oropharyngeal examination revealed mild hyperemia.Flexible nasopharyngolaryngoscopy showed normal vocal cord mobility, no signs of respiratory distress. Neck ultrasonography was normal.The patient was managed conservatively with medical treatment.Approximately 36 hours later, she represented with worsening symptoms, including dysphonia, marked torticollis, and difficulty swallowing.Physical examination revealed significant restriction of neck movements, edema in the left peritonsillar region, and deviation of the uvula to the right.The gag

reflex was diminished and trismus had developed. Endoscopic evaluation demonstrated left vocal cord paralysis, raising suspicion for involvement of the glossopharyngeal and vagus nerves.MR imaging revealed a diffusion-restricted collection measuring approximately 2 cm, extending from the region adjacent to the left mastoid cells into the parapharyngeal space, consistent with an abscess.Laboratory findings showed leukocytosis and elevated inflammatory markers.

RESULTS

The patient was started on pareteral intravenous antibiotics and underwent urgent surgical drainage. Approximately purulent material was drained via a transoral approach, and samples were obtained for culture.

During postoperative follow up, there was marked improvement in dysphonia and torticollis. By postoperative day nine, endoscopic examination demonstrated complete recovery of vocal cord mobility, normalization of the gag reflex, and midline position of the uvula. With clinical and laboratory improvement, the patient was discharged in good condition.

CONCLUSIONS

Parapharyngeal abscesses are rare but may cause serious complications due to spread along fascial planes and involvement of adjacent neurovascular structures. Lower cranial nerve involvement is uncommon and usually results from extension into the carotid space. In this case, initially nonspecific findings delayed diagnosis, but rapid progression to dysphonia, torticollis,uvular deviation, and reduced gag reflex suggested cranial nerve involvement. Imaging was essential for diagnosis and management. If untreated, deep neck infections may lead to mediastinitis, jugular vein thrombosis, sepsis, and intracranial complications. Early intravenous antibiotics and prompt surgical drainage are crucial, as demonstrated by complete neurological recovery in this patient.

Does Early Surgical Intervention In Pediatric Complicated Acute Mastoiditis Reduce Hospital Stay? Clinical Findings Of Our Managements

ALPARSLAN GÖNÜL[2], **Kemal Can Turhan**[1], **Emre Ocak**[1], **Selcuk Mulazimoglu**[1]

[1]*Ankara University;* [2]*Akyurt Public Hospital*

BACKGROUND & AIM

Acute mastoiditis(AM) developing after acute otitis media (AOM) remains the most common intratemporal complication in the pediatric population. Although its incidence has decreased in the antibiotic era, it remains a potentially life-threatening condition due to the risk of developing complicated AM (CAM)[1].

Currently, there are no accepted guidelines for the management. There is no consensus on the role of imaging, choice of antibiotic therapy and surgery indications [2].

The aim of this study is to evaluate pediatric CAM who were treated surgically. In particular, we aim to assess the impact of surgical intervention on the length of hospital stay.

MATERIAL & METHODS

This case series compares data from 15 pediatric patients aged 6 months to 9 years who presented to us with acute mastoiditis following middle ear infection between 2021 and 2024, regardless of prior treatment or lack thereof, and who consulted a pediatrician or ENT specialist. The specific characteristic of these cases is that they were complicated, with or without bone destruction.

Patients' white blood cell(WBC) counts and acute phase reactants(CRP), radiological reports at the time of decision for surgery or follow-up, the time between the start of initial treatment and post-surgical/post-follow-up time, and total treatment duration were recorded. In addition, postoperative hospital stay durations during this process were calculated as a percentage.

RESULTS

One patient was excluded from the study because they experienced facial paralysis during treatment, which altered their hospital stay. Of the remaining 14 patients, 4 showed no bone destruction on CT scans, and one of these underwent mastoidectomy due to high CRP levels. A 6-month-old infant with an abscess was not surgically treated due to a rapid response. All patients showed acute phase and WBC response on day 3. The average treatment duration for all patients was 28.26 days, while hospitalization lasted 13.21 days. In the group that underwent invasive procedures (V/T tube insertion or mastoidectomy) (n=10), the average hospital stay was 12 days, and in the 6 patients who underwent simple mastoidectomy, the total hospital stay was 12.5 days. Looking at the ratios, patients who underwent surgery spent 42% of their treatment time in the hospital, while this rate was 63% for patients who were placed under observation.

CONCLUSIONS

Literature reports hospitalization for acute mastoiditis between 5–15 days; our study’s average of 13.21 days aligns with this. Notably, surgical patients spent only 42% of their treatment hospitalized, compared to 63% in the observation group, proving that drainage accelerates clinical stabilization and the parenteral-to-oral transition.

One case without radiological bone destruction required surgery due to high CRP, highlighting that biochemical markers are as decisive as imaging. Conversely, avoiding surgery in an infant suggests conservative management remains viable in infancy.

Ultimately, for pediatric coalescence on CT, cortical mastoidectomy is a cost-effective, reliable intervention that optimizes hospitalization by rapidly reducing infectious load.

PP-481

Congenital Cholesteatoma. Are We Guessing It Right?

Sharon Michelle Vincent Reginald[1], **Tang Yita**[1], **Luqman Rosla**[1], **Khairina Adliah Kamal Ariffin**[1]

[1]*Hospital Sultan Haji Ahmad Shah, Malaysia*

BACKGROUND & AIM

Congenital cholesteatoma is a type of cyst filled with keratin that forms in the middle ear or mastoid area due to trapped squamous epithelium during embryogenesis. Associated with canal atresia, it occurs in about 1 in 20,000 children, typically unilateral. Occurrence of congenital cholesteatoma in cases of external auditory canal atresia is around 4-7%. When canal atresia is associated with cholesteatoma, patients present late with features like facial nerve palsy or hearing loss. Clinical judgement aided by high resolution computed tomography (CT) scan and magnetic resonance and imaging (MRI) is needed to assess the atresia and extent of the disease.

MATERIAL & METHODS

This case involves a four year old boy with congenital ear abnormalities, including right pinna and tragus issues, a preauricular skin tag, and left microtia grade III with complete canal atresia. He was born full term via elective C-section due to previous scars and had normal development. Initial hearing screening showed normal hearing in the right ear but moderate to severe hearing loss in the left ear.

RESULTS

Follow-up examinations were uneventful until a high-resolution CT scan at age four, which indicated abnormalities in the left ear, initially suspected as cholesteatoma. However, during surgery, it was revealed to be granulation tissue. The left ear had multiple ossicle abnormalities, and histopathology confirmed it to be benign tissue. The patient recovered well postoperatively with no facial nerve issues.

CONCLUSIONS

This case underscores the challenges in diagnosing and managing congenital ear anomalies. The discrepancy between HRCT findings and histopathology highlights the importance of a comprehensive evaluation and potentially utilizing advanced imaging like MRI. A patient centered, multidisciplinary approach is crucial for optimal management. The choice of the anterior surgical approach via endaural incision was preferred due to the initial goal of cholesteatoma removal and canal reconstruction, as it provided direct access to the affected area. The surgery was performed by a senior consultant surgeon for a more favorable outcome.

Embryonal Orbital Rhabdomyosarcoma Masquerading As Orbital Cellulitis In An Adolescent

Hasan Mervan Deger[1], **Busra Yilmaz Tugan**[2], **Yunus Emre Bulut**[1], **Aydın Sahin**[1], **Damla Saygin Gurbuz**[1], **Buse Ugur**[1], **Ata Alperen Ersahan**[1]

[1]*Department of Otorhinolaryngology, Head and Neck Surgery, Kocaeli University Faculty of Medicine, Kocaeli, Türkiye;* [2]*Department of Ophthalmology, Kocaeli University Faculty of Medicine, Kocaeli, Türkiye*

BACKGROUND & AIM

Orbital embryonal rhabdomyosarcoma is the most common primary malignant orbital tumor in childhood and may closely mimic sinogenic orbital cellulitis. Concomitant sinus disease may further obscure the diagnosis and delay suspicion of malignancy. We present an adolescent initially managed for presumed orbital cellulitis associated with ipsilateral maxillary sinusitis, who was ultimately diagnosed with embryonal orbital rhabdomyosarcoma. This case aims to emphasize the need for early diagnostic reconsideration, repeat imaging, and timely biopsy when orbital signs persist or progress despite appropriate antimicrobial and surgical management.

MATERIAL & METHODS

A single-patient case report of a 13-year-old girl was prepared through retrospective review of clinical records, otorhinolaryngological and ophthalmological findings, laboratory results, radiological imaging, operative notes, histopathological reports, and treatment course. The diagnostic process was analyzed chronologically, including the initial

diagnosis of presumed sinogenic orbital cellulitis, endoscopic sinus surgery with orbital decompression, postoperative clinical evolution, repeat magnetic resonance imaging, incisional biopsy, and final histopathological diagnosis.

RESULTS

A 13-year-old girl presented with a two-week history of progressive left periorbital swelling previously treated as preseptal cellulitis. On admission, she had decreased visual acuity, chemosis, proptosis, periorbital edema, and painful restriction of extraocular movements. Contrast-enhanced orbital magnetic resonance imaging suggested orbital cellulitis associated with ipsilateral maxillary sinusitis. Endoscopic sinus surgery with orbital decompression was performed, and intravenous antimicrobial therapy was continued. Initial postoperative improvement, particularly in visual acuity, was observed. However, proptosis, ophthalmoplegia, and visual symptoms progressed within days. Repeat imaging on postoperative day 9 demonstrated an infiltrative orbital space-occupying lesion. Incisional biopsy confirmed embryonal rhabdomyosarcoma, and the patient was referred to pediatric oncology for staging and multimodal treatment.

CONCLUSIONS

Orbital embryonal rhabdomyosarcoma may present with an orbital cellulitis phenotype, even in the presence of concomitant sinusitis. Transient improvement after decompression or antimicrobial therapy does not exclude an underlying malignancy. Persistent, recurrent, or progressive proptosis, ophthalmoplegia, chemosis, or visual impairment after appropriate treatment should prompt early repeat imaging and tissue diagnosis. In pediatric and adolescent patients with atypical orbital cellulitis, malignancy must remain within the differential diagnosis to avoid diagnostic delay and enable timely multidisciplinary oncologic management.

PP-483

Postoperative Pressure-Induced Transient Alopecia Following Long-Term Pediatric Otologic Surgery

Derya CEBECİ[1], **Fırat ONUR**[1], **Büşra Nur DERELİ**[1]

[1]*Department of Otorhinolaryngology, Istanbul Gaziosmanpaşa Training and Research Hospital, University of Health Sciences, Istanbul, Türkiye*

BACKGROUND & AIM

Postoperative pressure alopecia is a rare complication developing due to pressure ischemia in specific areas of the scalp following prolonged surgical procedures. While commonly associated with cardiac, urological surgeries, it can also be observed in complex ear surgeries where the patient's head remains stationary and rotated for long durations. Mastoidectomy operations, particularly in cases of cholesteatoma or revisions, may increase this risk as surgical times extend. In this case report, we aim to discuss a case of transient alopecia in the temporoparietal region following a prolonged pediatric mastoidectomy and the intraoperative measures that can be taken to prevent this complication.

MATERIAL & METHODS

A 14-year-old male patient was operated on due to chronic otitis media. Following an "inside-out" type 4 mastoidectomy with TORP application lasting approximately 6 hours, a painless, non-cicatricial, patchy hair loss of approximately 3x4 cm was noticed in the temporoparietal region on the 10th postoperative day. Following a dermatology consultation, the patient was diagnosed with "postoperative pressure alopecia." Complete recovery was observed after 1 month of treatment with 5% minoxidil topical spray.

RESULTS

Ischemic damage to hair follicles occurs when continuous pressure exceeds capillary perfusion, typically in surgeries exceeding 4 hours. In pediatric cases, the risk may be exacerbated by thinner subcutaneous adipose tissue compared to adults. While literature often suggests a "watch-and-wait" approach, topical minoxidil may accelerate recovery by enhancing follicular blood flow and transitioning follicles from the telogen to the anagen phase.

CONCLUSIONS

Alopecia developing after long-term mastoidectomy operations is a complication that can cause significant psychosocial stress, especially in young patients. As demonstrated in this case, intraoperative prophylactic measures (gel pads, periodic head movement) are of vital importance when the surgical duration reaches 6 hours. Additionally, the use of topical minoxidil can be considered an effective option to accelerate the recovery process.

PP-484

Beyond A Deep Neck Abscess: Lessons From A Rapidly Progressive Pediatric Cervicomediastinal Infection

Abdelrahman Mostafa[1], **yara alaa**[1], **hadeer essam**[1], **omar hosny**[1]

[1]*Faculty of Medicine, Alexandria University, Alexandria, Egypt.*

BACKGROUND & AIM

Deep neck space infections in children may rapidly progress into life-threatening cervicomediastinal infections. We report a rapidly progressive pediatric deep neck infection with mediastinal extension and empyema, highlighting the importance of early reassessment and multidisciplinary management.

MATERIAL & METHODS

A 2.5-year-old boy presented with 7 days of fever and left cervical swelling initially misdiagnosed as mumps. He developed progressive respiratory distress requiring tertiary referral. Past history included recurrent otitis media, pneumonia, febrile convulsions, and poorly formed Bacillus Calmette–Guérin scar. On admission, he was toxic, hypoxic, and septic. Imaging revealed pneumonia with empyema, and pleural culture grew methicillin-resistant Staphylococcus aureus (MRSA). Despite antimicrobial therapy, he deteriorated with recurrent neck swelling, posterior pharyngeal wall bulging, dysphagia, and impending airway compromise requiring intubation and pediatric intensive care admission. Blood cultures grew Candida albicans. Contrast-enhanced computed tomography demonstrated multiloculated retropharyngeal and prevertebral abscesses extending into the mediastinum to the tracheal bifurcation. Urgent transcervical drainage successfully controlled the cervical and mediastinal collections without sternotomy or tracheostomy. Immunological evaluation demonstrated persistently reduced absolute CD19 B-cell counts.

RESULTS

Following airway stabilization, surgical drainage, prolonged antimicrobial and antifungal therapy, intravenous immunoglobulin administration, and intensive care support, the patient gradually improved and was successfully extubated after 5 days. Follow-up imaging demonstrated marked resolution of cervical and thoracic collections. The child resumed normal feeding and returned to normal activities without evidence of recurrence during follow-up.

CONCLUSIONS

Rapid progression of pediatric deep neck infections should prompt urgent reassessment and evaluation for immune dysfunction. Early recognition of cervicomediastinal extension and aggressive multidisciplinary management are essential for favorable outcomes. Extensive cervicomediastinal collections may be successfully controlled through a transcervical approach without sternotomy in selected pediatric cases.

Iatrogenic Airway Foreign Body Developed During Subglottic Stenosis Dilatation In An Infant

Hüseyin Çetik[1], **Elif Baysal**[2], **Mahir Kuyumcu**[1], **Zeynep Baysal Yıldırım**[1]

[1]*Dicle University Faculty of Medicine Department of Anesthesiology and Reanimation;* [2]*Gaziantep University Faculty of Medicine Department of Otorhinolaryngology*

BACKGROUND & AIM

Subglottic stenosis in infants is a serious airway condition most commonly associated with prolonged endotracheal intubation and may result in life-threatening respiratory distress. Management with rigid bronchoscopy and dilatation is technically challenging due to the narrow pediatric airway and the need for shared ventilation between anesthesiologist and surgeon. Although generally safe, these procedures may rarely be complicated by equipment-related adverse events. This report presents the management of an iatrogenic airway foreign body caused by fracture of a suction catheter during rigid bronchoscopy in an infant with subglottic stenosis.

MATERIAL & METHODS

A 5-month-and-21-day-old male infant (6 kg), born at term by cesarean section with a birth weight of 2800 g, was admitted with recurrent respiratory distress. He had been intubated in the intensive care unit at an external center at 3 months of age, with unknown duration of intubation. After discharge, he required two further hospitalizations due to respiratory symptoms. Fiberoptic bronchoscopy revealed subglottic stenosis, and rigid bronchoscopy with planned dilatation was scheduled. Preoperative evaluation showed tachypnea, subcostal retractions, and oxygen saturation of 92% on room air. The patient was prepared for endoscopic airway intervention under general anesthesia with a multidisciplinary team.

RESULTS

Following induction with lidocaine, propofol, and remifentanil, and neuromuscular blockade with rocuronium, brief mask ventilation was performed. The patient was then transferred to the surgical team for rigid bronchoscopy. A size 2.5 rigid bronchoscope was used to enter the trachea, revealing subglottic stenosis immediately below the vocal cords. Dilatation was performed using a size 3.5 bronchoscope. During suctioning of secretions, a defect was observed at the distal tip of the suction catheter. Immediate airway reassessment with rigid bronchoscopy revealed a fractured catheter fragment within the airway. The fragment was successfully retrieved. Equipment integrity was confirmed after removal (Figure 1). The patient was intubated with a 3.5 endotracheal tube and extubated uneventfully after sugammadex reversal. He was transferred to the intensive care unit in stable condition. Follow-up bronchoscopy at two weeks showed no residual stenosis or foreign body.

CONCLUSIONS

Suction catheter fracture during pediatric rigid bronchoscopy is a rare but potentially serious iatrogenic complication. This case highlights the importance of careful inspection of all endoscopic equipment before and after use. Immediate recognition of device malfunction and prompt airway re-evaluation are essential to prevent morbidity. A multidisciplinary approach involving anesthesiology and otolaryngology teams is critical for safe management of complex pediatric airway procedures.

From A Branchial Fistula To A Branchio-Oto-Renal Syndrome - A Case Report And Review Of The Literature

SAHRAOUI Mohammed[1,2], **MEHTARI Nasrine Siham**[1,2], **AID Chahrazed**[1], **NASRI Amine**[1,2], **BENMANSOUR Narimane**[1]

[1]*ENT Department - Tlemcen University Hospital Center;* [2]*Faculty of Medicine - Abou Bekr Belkaid University of Tlemcen*

BACKGROUND & AIM

Branchio-oto-renal (BOR) syndrome is a rare genetic disorder with autosomal dominant inheritance, characterized by the variable association of branchial, auditory, and renal anomalies.

Through this work, we present a case illustrating the diagnostic challenges and the importance of a multidisciplinary approach in the management of this rare syndrome.

MATERIAL & METHODS

We report the case of a 5-year-old child who presented to our department for management of an inflammatory right lateral cervical fistulous opening evolving for more than 6 months, marked by several recurrent infectious episodes.

A thorough clinical examination, fistulography, biological and radiological investigations, as well as audiometry, were performed.

RESULTS

Clinical examination revealed two bilateral cervical fistulas, almost symmetrical and likely originating from the second branchial arch. The right-sided fistula was symptomatic, marked by several infectious episodes with salivary discharge, whereas the left-sided fistula was asymptomatic.

Fistulography demonstrated findings consistent with a complete second branchial arch fistula communicating with the hypopharynx.

The examination also revealed bilateral preauricular fistulas, which had presented only one infectious episode, as well as two congenital lacrimal fistulas that had remained asymptomatic to date.

The patient had neither hearing impairment nor clinically evident renal involvement. Nevertheless, an audiogram and an abdominopelvic ultrasound were performed as part of the etiological workup.

The audiogram was unremarkable.

Renal ultrasound revealed left renal hypoplasia without major functional impairment.

The patient successfully underwent surgical excision of the right cervical fistula as well as both preauricular fistulas, with favorable postoperative outcomes.

CONCLUSIONS

Branchio-oto-renal (BOR) syndrome is a rare disorder whose heterogeneous clinical presentation may delay diagnosis. Although branchial malformations are usually of limited severity, the associated auditory and renal abnormalities, sometimes revealed later in the course of the disease, may significantly affect functional prognosis.

Therefore, early management combined with rigorous clinical, audiological, and renal follow-up remains essential to ensure optimal long-term care for these patients.

Nasal Obstruction In Neonates

Hayat Adib[1,2]

[1]*Al Jalila Children's Specialty Hospital Dubai health;* [2]*Mohamad Bin Rashed University Dubai Health*

BACKGROUND & AIM

Discuss the different etiologies for nasal obstruction for neonates and the effect of management on the outcomes

MATERIAL & METHODS

Literature review about the different etiologies for nasal obstruction in neonates.

Presenting a few cases from our hospital including nasal aperture stenosis and choanal atresia and their management

RESULTS

Different etiologies require different management.

Pyrifrom aperture stenosis can be managed either conservatively or surgically depending on the severity: presenting cases: one required dilation and one conservative management including intranasal steroid drops

Choanal atresia needs to be managed surgically. We present a case were we used mini Propel stent with excellent results

CONCLUSIONS

Different etiologies require different management. Using mini propel has excellent results for choanal atresia.

Perioperative Peripheral Facial Nerve Palsy In A 23-Month-Old Toddler: A Case Report

Ömer Faruk Zengin[1], **Merve Beyza Coşkuner**[1], **Ebru Çanakçı**[2]

[1]*Ordu University Training and Research Hospital, Otorhinolaryngology Dept.*; [2]*Ordu University Training and Research Hospital, Anesthesiology and Reanimation Dept.*

BACKGROUND & AIM

Peripheral facial nerve palsy (PFP) is uncommon in early childhood and is usually associated with a favourable prognosis. The occurrence of facial palsy in the perioperative period may raise concerns regarding anesthetic or surgical complications.

MATERIAL & METHODS

This is a case presentation; therefore, there is no material and method.

RESULTS

Case Presentation

A 23-month-old child displayed left-sided House–Brackmann grade IV peripheral facial nerve palsy on the evening of the day of circumcision performed under mask anesthesia (Figure 1A). Otorhinolaryngologic examination was normal. The patient had a previous history of herpetic whitlow requiring hospitalisation one year earlier. Oral corticosteroid therapy was initiated and followed by rapid and marked clinical improvement (Figure 1B).

CONCLUSIONS

We present a pediatric case of peripheral facial nerve palsy that developed shortly after mask ventilation. Determining whether the cause was perioperative or herpetic reactivation remained challenging.

Peripheral Facial Nerve Palsy; Pediatrics; Mask Ventilation; Herpetic Whitlow; Case Report

PP-489

Particularity Of Hearing Impairment In Preterm Infants: About A Series

MEHTARI Nasrine Siham[1], **SAHRAOUI Mohammed**[1], **MEFTAH Hayet**[1]

[1]*University Hospital / Faculty of Medicine Tlemcen. Toxicomed Laboratory*

BACKGROUND & AIM

Deafness is one of the neurosensory sequelae that can occur in preterm infants. The aim of our study is to determine prevalence of deafness in preterm infants as well as to specify its characteristics in order to provid appropriate and early therapeutic guidance.

MATERIAL & METHODS

Prospective study carried out over one year, from September 2024 to September 2025, involving 228 preterm newborns hospitalized in the neonatology department. Screening using automated auditory brainstem response (AABR) was performed at the end of the preterm infant's hospitalization. A doubtful test was confirmed by a second test within 15 days. For preterm infants with two doubtful tests, auditory brainstem response (ABR) and automated evoked otoacoustic emissions (AEOAE) were performed within 1 to 4 months depending on presence or absence of associated pathology.

RESULTS

In this population, 4.38% (10 cases) presented unilateral or bilateral deafness ≥ 35 dB with clear male predominance: sex ratio 4 boys to 1 girl. Their gestational age ranged from 28 to 35 weeks of amenorrhea and birth weight ranged from 0.9 to 2.8 kg, with an average of 1.6 kg. The ABR were performed between 1 and 4 months, with an average of 3 months. Six deaf preterm infants stayed in intensive care unit. Other risk factors for deafness were present in six deaf preterm infants, including neonatal bacterial meningitis, birth weight < 1.5 kg in 5 preterm infants, second-degree consanguinity, and a polymalformative syndrome. We diagnosed among these 10 preterm infants: 1 mild deafness, 6 moderate, 1 severe, and 2 profounds deafness, one of which was related to neonatal meningitis. Unilateral deafness accounted for 40% of the hearing impairments. One newborn presented an auditory neuropathy spectrum disorder.

CONCLUSIONS

The risk of deafness in preterm infants is 10 times higher than in the general population. Major hearing loss is rare in preterm infants. It is rather moderate and predominantly unilateral, which can lead to late diagnosis and management.

KEYWORDS

Preterm infant,hearing loss, screening, auditory neuropathy spectrum disorder

PP-490

Chronic Granulomatous Invasive Fungal Sinusitis With Orbital Extension In A Pediatric Patient: A Histopathology-Confirmed Case Report

Norah Aldawsari[1], **Mohammed Alshenaiber**[1], **Ghadah Alfraihi**[1]

[1]*College of Medicine, King Saud bin Abdulaziz University for Health Sciences*

BACKGROUND & AIM

Chronic granulomatous invasive fungal sinusitis (CGIFS) is a rare subtype of invasive fungal rhinosinusitis characterized by slowly progressive fungal tissue invasion associated with granulomatous inflammation. Pediatric cases remain uncommon and frequently present diagnostic challenges because of their indolent course and nonspecific manifestations.

MATERIAL & METHODS

This study was conducted as a retrospective descriptive case report of a pediatric patient diagnosed with chronic granulomatous invasive fungal sinusitis at a tertiary referral center. Clinical data, laboratory investigations, radiologic imaging, histopathologic findings, operative details, treatment course, and follow-up outcomes were obtained through review of the patient's electronic medical records. Histopathologic diagnosis was established using permanent tissue sections and special fungal stains. Written informed consent for publication was obtained from the patient's legal guardian.

RESULTS

A previously healthy 9-year-old Yemeni female presented with progressive unilateral nasal obstruction, headache, and left-sided proptosis. Imaging demonstrated extensive unilateral sinonasal disease involving the maxillary, ethmoid, frontal, and sphenoid sinuses with bony destruction and orbital extension. Computed tomography revealed erosion of the lamina papyracea, ethmoid roof, and maxillary sinus walls, while magnetic resonance imaging demonstrated enhancing low T2 signal soft tissue without intracranial extension. Revision Functional Endoscopic Sinus Surgery with biopsy confirmed tissue-invasive fungal sinusitis with granulomatous inflammation, fibrosis, multinucleated giant cells, and fungal hyphae identified on special stains. Fungal and bacterial cultures remained negative. Follow-up imaging demonstrated persistent orbital and extrasinonasal extension without intracranial progression. The patient was treated with surgical debridement and prolonged voriconazole therapy, resulting in significant clinical improvement with preserved vision and no residual sinonasal masses on endoscopic follow-up.

CONCLUSIONS

CGIFS should be considered in pediatric patients presenting with unilateral destructive sinonasal disease associated with orbital involvement, even in the absence of severe systemic manifestations or positive fungal cultures. Early histopathologic diagnosis and multidisciplinary management remain essential to optimize outcomes and prevent orbital or intracranial progression.

PP-491

A Rare Cause Of Recurrent Cervical Discharge: Second Branchial Cleft Fistula

Gökhan Toptaş[1], **Bahriye Bilge Durak**[1], **Şevket Aksoy**[1], **Samet Özlügedik**[1]

[1]*Ankara Etlik City Hospital, Department of ENT*

BACKGROUND & AIM

Second branchial cleft anomalies represent the most common branchial cleft lesions and may present as cysts, sinuses, or fistulous tracts in the lateral neck. Although congenital in origin, a second branchial cleft fistula may remain clinically underrecognized until recurrent cervical discharge or infection prompts further evaluation. This case highlights the importance of considering this rare entity in the differential diagnosis of persistent cervical discharge and planning definitive surgical management accordingly.

MATERIAL & METHODS

A 63-year-old woman with hypertension, hypothyroidism, and a 10 pack-year smoking history presented with lifelong intermittent left neck swelling and discharge. Examination revealed a 2×1 cm, semi-mobile, non-fluctuant lesion anterior to the sternocleidomastoid muscle (level II) with cutaneous fistulization. USG showed a 19×5 mm dense collection extending toward the skin and reactive lymph nodes. Contrast-enhanced CT identified a thin tract from the C3 level to the cutaneous opening at

C6, without tonsillar or oropharyngeal communication. MRI demonstrated a T1-hypointense, T2-hyperintense tract (max 10 mm width) with peripheral enhancement and diffusion restriction. Salivary glands and lymph nodes were otherwise unremarkable. Based on the congenital history, clinical location, and imaging findings, a second branchial cleft fistula was diagnosed

RESULTS

Radiological evaluation demonstrated a left-sided fistulous tract extending from the upper cervical region to the cutaneous opening anterior to the sternocleidomastoid muscle, without a definite radiological communication with the tonsillar fossa or oropharynx. The patient underwent surgical excision of the left branchial fistulous tract (Figure 2). During dissection, traction applied to the fistulous tract produced a visible pulling movement in the ipsilateral tonsillar fossa, suggesting proximal extension of the tract toward the oropharyngeal region despite the absence of a clear communication on imaging. (Figure 3). Complete excision was performed, and the specimen was a tubular soft tissue fragment measuring 6.5 × 1.5 × 1.6 cm macroscopically. Histopathological examination revealed findings compatible with a branchial cyst, supporting the diagnosis of a second branchial cleft anomaly with cutaneous fistulization. At the patient's 6-month postoperative follow-up, there were no complaints, and the clinical examination was unremarkable.

CONCLUSIONS

Second branchial cleft fistulas may remain clinically subtle for decades and may not always show a clear oropharyngeal communication on preoperative imaging. In this case, intraoperative traction of the tract causing tonsillar fossa movement was a key finding that clarified its proximal extension. Careful surgical exploration and complete excision remain essential for definitive diagnosis and treatment.

From Sinus To Fistula: The Hidden Cost Of Repeated Incision And Drainage In Paediatric Branchial Cleft Anomalies, A Case Series

Kabagenyi Fiona[1], **Gordon Buhwa**[1]

[1]*Makerere University, Department of Ear, Nose and Throat, Kampala, Uganda;* [2]*Mulago National Referral Hospital, Department of Ear, Nose and Throat, Kampala, Uganda*

BACKGROUND & AIM

Branchial cleft anomalies commonly present as branchial cleft sinuses, which are epithelialized tracts that communicate with the skin or pharynx. While these anomalies are often asymptomatic, they can become complicated by infection, resulting in abscess formation. The standard management of an infected branchial cleft sinus involves prompt incision and drainage (I&D) to alleviate symptoms and control infection. However, repeated I&D procedures without early definitive surgical intervention to address the underlying anomaly may lead to significant preventable complications such as sinus-to-fistula transformation, chronic discharge, and substantial psychosocial morbidity, particularly in children.

MATERIAL & METHODS

This was a case series involving 2 children who developed branchial fistulas following incision and drainage of neck abscesses located in the area of prior sinuses

RESULTS

This case series describes two children with a history of recurrent lateral neck swellings that initially lacked any external openings. Both underwent multiple I&D procedures before presenting with f luid extrusion from newly formed cutaneous openings, which led to social distress, including peer ridicule. Definitive surgical excision was performed via an external approach, resulting in complete symptom resolution at the six-month follow-up.

CONCLUSIONS

The management of recurrent infections in presumed branchial cleft anomalies may benefit from needle aspiration instead of repeated I&D to alleviate acute symptoms and prevent the progression from a sinus to a fistula. Based on the observation from our limited case series, early recognition in primary care, avoidance of repeated I&D, and timely referral for definitive excision to specialists are the main strategies to prevent complications and their psychosocial consequences.

branchial sinuses, fistula, complications, needle aspiration, outcomes

PP-493

Prevalence Of Electronic Smoking Exposure And Tonsillectomy Surgery In Children

Mohammad al alawneh[1]

[1]*Department of special surgery, school of Medicine, Jordan University of Science and Technology*

BACKGROUND & AIM

The hypothesis tested was the negative impact of electronic smoke exposure on the developing of respiratory infection, specifically in the upper tract. In this study, we aimed to investigate if smoke exposure increased the number of tonsillectomy surgery in children compared to the hernia repair control group

MATERIAL & METHODS

The design of our study was retrospective case-control. We retrospectively reviewed medical records or children of up to 12 years of age that were admitted for tonsillectomy at King Abdullah University Hospital (KAUH) from January 2019 to December 2023 to determine exposure to both electronic and tobacco smoking. Records of hernia repair surgery children aged 12 and less at this facility were also retrospectively reviewed for both electronic and tobacco smoke exposure during the same period. Data was collected from medical records and phone call interviews with the patients and their families

RESULTS

A total of 743 children were included, 64 % were males. The participants were divided into two groups: 439 had recurrent tonsillitis and needed tonsillectomy, the other 304 underwent hernia repair surgery (control group). Overall, 28 % of children were exposed to electronic smoking, 29 % to tobacco smoking, and 5.9 % to both. Electronic and tobacco smoke exposure was significantly evident among the tonsillectomy group compared to the hernia group. Logistic regression analysis showed that exposure to electronic smoking (OR: 2.74) and tobacco smoking (OR: 2.47) were significantly associated with an increased likelihood of undergoing tonsillectomy. However, patients with exposure to both smoking types did not show a significant link, while the absence of any smoking exposure was significantly associated to lower odds of tonsillectomy

CONCLUSIONS

Children who underwent tonsillectomy had a higher likelihood of being exposed to tobacco or electronic smoking compared to children in the hernia repair surgery group.

electronic smoking, Tonsillectomy, Tobacco

PP-494

Bilateral Second Branchial Cleft Anomalies In Early Childhood: Asymmetric Complete And Incomplete Presentation

Yağmur Çakır[1], **Mahmut Demirtaş**[1]

[1]*Aydın Adnan Menderes University*

BACKGROUND & AIM

Branchial cleft anomalies are developmental defects resulting from the failure of the branchial apparatus to obliterate during embryogenesis. Second branchial cleft anomalies represent 90-95% of all branchial cleft defects. While these anomalies are predominantly unilateral in the literature, bilateral occurrences are reported in only 2-5% of cases. In bilateral presentations, syndromic associations, most notably branchio-oto-renal (BOR) syndrome, must be strictly considered.

This study aimed to present a case of bilateral second branchial cleft anomaly in a nonsyndromic 2-year-old child, characterized by a complete fistula extending to the tonsillar fossa on one side and an incomplete tract on the contralateral side.

MATERIAL & METHODS

A 2-year-old boy presented to our outpatient clinic with a history of bilateral neck swellings and intermittent purulent discharge since birth. His medical history revealed that the swelling in the right cervical region was more prominent, whereas the swelling on the left tended to disappear periodically. The patient had no significant personal or family medical history. Physical examination revealed bilateral fistula orifices along the anterior border of the sternocleidomastoid (SCM) muscle. Mobile and soft cystic masses, approximately 2 cm in diameter on the right and 1 cm on the left, were palpated duringthe examination. The patient underwent comprehensive neck ultrasonography (USG) and magnetic resonance imaging (MRI). The USG findings were consistent with bilateral branchial cleft cysts. MRI revealed that the right branchial cleft fistula tract coursed through the carotid bifurcation and extended into the tonsillar fossa. The patient's renal USG and audiological evaluations were within normal limits.

RESULTS

Surgical excision under general anesthesia was performed. Initially, the left cervical region was examined. Methylene blue was injected through the fistula orifice via a cannula to delineate the tract, which was then dissected along with the cyst wall from the surrounding soft tissue and excised. Subsequently, the right side was approached, and the cyst wall was meticulously dissected and followed up proximally. After confirming that the fistula tract extended to the right tonsillar fossa, a transoral approach was used. A cystic lesion distinct from the tonsillar tissue was identified in the right tonsillar fossa. A right tonsillectomy was performed, and the fistula tract was completely removed using a combination of transcervical and transoral approaches. No postoperative complications were observed. The patient was discharged in stable condition on the second postoperative day. Follow-up examinations revealed healthy wound healing. Histopathological examination confirmed the diagnosis of 'bilateral branchial cleft cysts'

CONCLUSIONS

Bilateral branchial cleft anomalies are rare congenital disorders. It is imperative to thoroughly evaluate syndromic associations, particularly the branchio-oto-renal (BOR) syndrome. Nonetheless, as illustrated in our case, nonsyndromic variations may manifest. A detailed clinical history, comprehensive physical examination, and advanced imaging techniques are essential for achieving an accurate diagnosis and ensuring optimal surgical planning.

Granulomatous Inflammatory Mass In The Right Nasal Vestibule: A Case Report

Lütfiye Nisa CANER[1], **Arda TETİK**[1], **Ziya ŞENCAN**[1], **Zafer ONARAN**[2], **Süheyla KANDEMİR**[1], **Ela CÖMERT**[1], **Nuray BAYAR MULUK**[1]

[1]*Kırıkkale University Faculty of Medicine, Department of Otorhinolarynglology;* [2]*Kırıkkale University Faculty of Medicine, Department of Ophthalmology*

BACKGROUND & AIM

Granulomatous lesions of the nasal cavity and paranasal sinuses represent diverse infectious, inflammatory, and neoplastic conditions. Although rare in children, they may present diagnostic challenges and occasionally signal underlying systemic disease.

A 14-year-old female presented with a 4-month history of a lesion at the right medial canthus. Lacrimal irrigation showed reflux, and dacryocystorhinostomy was planned. However, right septal deviation limited evaluation of the nasolacrimal duct, and a mass was identified in the right nasal vestibule, prompting referral to our clinic.

MATERIAL & METHODS

Nasal symptoms began after the ocular lesion and had progressively worsened. Examination revealed purulent discharge and crusting in the nasal passages, and antibiotic therapy was initiated. CT showed obstruction of the right frontoethmoidal recess and osteomeatal complex, along with soft tissue densities in all paranasal sinuses and mucosal thickening extending from the right medial canthus to the nasolacrimal duct.

Following treatment, infection regressed. Endoscopic examination demonstrated a patent left nasal passage and no nasopharyngeal mass. A papillomatous lesion was observed at the entrance of the right nasal passage. Incisional biopsy, including adjacent healthy mucosa, was performed.

RESULTS

Initial histopathology suggested lymphoid proliferation with suspicion of lymphoma; however, further evaluation at an external center confirmed granulomatous inflammation.

CONCLUSIONS

Granulomatous nasal lesions should be evaluated with a broad differential diagnosis, particularly in atypical presentations. In cases associated with nasolacrimal system findings, both local and systemic conditions must be considered. Early endoscopic assessment and biopsy are essential for accurate diagnosis.

The Cuneiform Cartilage Is Devoid Of Essential Cartilage Matrix Component In Laryngomalacia

Melanie Kunze[1], **Adetola Adesida**[1], **Hamdy El-Hakim**[1]

[1]*Divisions of Pediatric Surgery & Orthopedics, Department of Surgery, University of Alberta, Edmonton, Aberta, Canada*

BACKGROUND & AIM

Although the sensorimotor theory is the most widely supported etiology of laryngomalacia (LM), preliminary histological studies have suggested a chondrogenic etiology. Laryngeal cartilage is a critical source of mechanical rigidity that maintains the anatomical form and function of the larynx. We hypothesized that the ECM of laryngeal cartilage from LM lacks the functionally essential extracellular cell matrix (ECM).

MATERIAL & METHODS

Cuneiform cartilage specimens were obtained from an otherwise healthy, non-syndromic, male infant (3-months old) during supraglottoplasty for a type 2 LM. The specimens were fixed in neutral buffered formalin, processed, embedded in paraffin wax, and 5 µm sections were prepared. For histological analysis, the sections were deparaffinized and stained with hematoxylin and eosin (H&E), Safranin O, and counterstained with Fast Green. The distribution of type I (COLI) and II (COLII) collagen were assessed by immunofluorescence (IF). The sections were deparaffinized and rehydrated. Enzymatic antigen retrieval was conducted. IF assessment for COLI and COLII was completed using rabbit anti-collagen I (CL50111AP-1) and mouse anti-collagen II (II-II6B3). Secondary labelling using goat anti-mouse IgG-Alexa Fluor 488 (ab150117) and goat anti-rabbit

IgG-Alexa Fluor 594 was conducted. Slides were mounted with nuclear staining (DAPI, diamidino-phenylindole) and imaged using a Nikon Ti-S Microscope with a DS-U3/Fi2 Colour CCD Camera, with FITC and Texas Red filters.

RESULTS

Histological assessment revealed a ~100µm hypercellular peripheral structure surrounding a core structure with some Safranin O-positive ECM (indicative of proteoglycans), especially in the right anterior aspect. The IF assessment showed the hypercellular peripheral structure to be rich in COLI and lacking in COLII. The core structure is positive for COLI but lacks COLII.

CONCLUSIONS

Our preliminary, unique work suggests that the cuneiform cartilages in LM may be biomechanically dysfunctional due to the absence of major ECM components of cartilage, such as collagen II, offering a plausible explanation for the features of types 1 and 2 LM. This is the most robust evidence of a chondrogenic etiology for LM. Future work will include mechanical testing and proteomic analysis of cuneiform cartilage specimens from LM for quantitative biomechanical-compositional correlations.

PP-497

Endotyping Of Chronic Adenoiditis

Стагньева Ирина[1], **Затуливетрова Дарья**[1]

[1]*Federal State Budgetary Educational Institution of Higher Education "Rostov State Medical University" of the Ministry of Health of the Russian Federation*

BACKGROUND & AIM

Identification of endotypes is important for the development of personalized therapeutic strategies targeting specific disease mechanisms. Currently, endotypes of various upper respiratory tract diseases have been described, which are determined by different immunopathogenesis. The diagnosis of "chronic adenoiditis" may conceal various pathological processes in the pharyngeal tonsil, each with a different pathogenesis and requiring personalized therapy.

Aim : To develop a method for diagnosing the endotype of chronic adenoiditis in children.

MATERIAL & METHODS

The study included patients aged 3–15 years with a verified diagnosis of chronic adenoiditis who underwent adenotomy according to indications. In the blood serum samples of the study participants, concentrations of eleven inflammatory response mediators were measured: IL-1β, IL-5, IL-17α, IL-6, IL-8, IL-33, IL-35, IL-22, IFN-γ, TNF-α, and TGF-β1. Quantitative determination was performed using enzyme-linked immunosorbent assay (ELISA). Expression levels of the same proinflammatory cytokines were analyzed in collected pharyngeal tonsil tissue samples.To determine the expression level of each marker, a total immunoreactivity score based on the immunohistochemical scoring method known as the H-score was used. Identification of differentiating characteristics was performed by analyzing Wilks' and Fisher's F-statistic values. The CHAID classification algorithm, a decision tree technique using the chi-square test, was used as a statistical analysis tool. Statistical processing of the obtained data was carried out using STATISTICA 12.0 and SPSS Statistics software packages.

RESULTS

Analysis of serum and tissue revealed four chronic adenoiditis endotypes (Th1, Th2, Th17, Treg) and two mixed subendotypes. Th1 showed elevated IFN-γ, TNF-α, IL-1β; Treg high TGF-β1 and IL-35; Th2 predominance of IL-5 and IL-33; Th17 key markers IL-17 and IL-22. Contingency analysis confirmed four endotypes ($\chi^2 = 442.2$, $p < 0.0001$, coefficient 0.82). Stepwise discriminant analysis identified nine discriminatory markers, with TGF-β1 being most relevant. The CHAID decision-tree model included TGF-β1, IFN-γ, IL-5, IL-1β, TNF-α. Diagnostic algorithms: Th1 – TGF-β1 <8.3 pg/mL + IFN-γ >47 pg/mL; Th2 – TGF-β1 8.3–30.3 + IL-5 >14.4, or TGF-β1 30.3–51.5 + IL-1β <20.4; Th17 – TGF-β1 up to 65.5, or 30.3–51.5 + IL-1β >20.4; Treg – TGF-β1 >93.1, or 65.4–93.1 + TNF-α <16.3. Overall diagnostic accuracy reached 95.9%, with validation error increasing minimally from 4.1% to 9.3%, confirming high reproducibility and clinical applicability.

CONCLUSIONS

The developed algorithm for the differential diagnosis of chronic adenoiditis endotypes in children, based on the analysis of inflammatory mediators in blood serum by enzyme-linked immunosorbent assay (ELISA), offers prospects for predicting the type of immune response specific to each individual patient. This approach allows moving away from empirical drug prescription and shifting toward targeted intervention on the pathogenetic mechanisms of the disease, which may improve treatment efficacy.

Bifurcated Nasal Septum – An Unusual Path Of Nasal Dermoid

Joana Matos[1,2], **António Andrade**[1,2], **Ricardo Vaz**[1,3,4,5], **Jorge Rodrigues**[1,3,4], **Jorge Spratley**[1,2,4], **Tiago Órfão**[1]

[1]Department of Otorhinolaryngology, Local Health Unit of São João, Porto, Portugal; [2]Otorhinolaryngology Unit, Departament of Surgery and Physiology, Faculty of Medicine, University of Porto, Porto,Portugal; [3]Unit of Anatomy, Department of Biomedicine, Faculty of Medicine, University of Porto, Porto, Portugal; [4]CINTESIS@RISE Faculty, of Medicine, University of Porto, Porto, Portugal; [5]NeuroGen Research Group, Centro de Investigação em Tecnologias e Serviços de Saúde (CINTESIS), Porto, Portugal

BACKGROUND & AIM

Nasal dermoid are the most common congenital midline lesions, with an incidence of 1:20.000 to 1:40.000 live births. These anomalies may present as cysts, sinuses, or fistulae, with 10% to 45% of cases having intracranial extension. Timely diagnosis and complete surgical excision are imperative to mitigate the risk of infectious complications, structural deformity, and recurrence.

MATERIAL & METHODS

Case report with surgical technique description, imaging documentation and photographic documentation of pre-, intra- and postoperative stages.

RESULTS

A three-year-old male presented to the Otorhinolaryngology emergency department with recurrent nasal swelling and purulent drainage from a columellar pit, since age one. MRI identified a sinus tract with two distinct fistulous components: one traversing the plane of the nasal septum toward the skull base, and a second, more superior tract extending toward the crista galli. No evidence of intracranial extension was identified.

An external rhinoplasty approach was performed to excise the columellar pit and associated sinus tracts. Methylene blue dye was injected into the columellar orifice to ensure visualization of the sinus architecture. Intraoperatively, the tract was found to penetrate the cartilaginous nasal septum, resulting in septal bifurcation. Both tracts were meticulously dissected, ligated at their fibrous stalks, and excised. The bifurcated nasal septum was reconstructed using a continuous transfixion suture. One month after surgery, the patient exhibited excellent healing and nasal patency. Histopathology confirmed diagnosis of dermoid cyst.

CONCLUSIONS

Nasal dermoid are rare congenital midline lesions that often present with localized swelling and recurrent infection. Early diagnostic imaging and definitive surgical intervention are essential to prevent secondary complications and the need for more invasive procedures. The external rhinoplasty approach provides optimal exposure for complete resection while yielding superior cosmetic results.

Parotid Tuberculosis Mimicking A Neoplasm In An Adolescent: A Diagnostic Challenge

Steuphen Roy[2], **Atikah Binti Rozhan**[1], **Jonah Seeni**[1,2]

[1]International Islamic University Malaysia; [2]Hospital Raja Permaisuri Bainun Ipoh

BACKGROUND & AIM

Parotid tuberculosis is a rare form of extrapulmonary tuberculosis and often mimics benign or malignant salivary gland tumors. Due to its nonspecific presentation, it poses a diagnostic challenge and may lead to unnecessary surgical intervention. We hypothesize that early utilization of fine needle aspiration (FNA) combined with molecular testing can facilitate accurate diagnosis and prevent unwarranted surgery.

MATERIAL & METHODS

This is a single case report of a 14-year-old female presenting to a tertiary otorhinolaryngology unit with a one-year history of progressively enlarging right-sided neck swelling. The mass initially resolved after oral antibiotics but recurred three months prior to presentation. Clinical examination, flexible nasopharyngolaryngoscopy, and contrast-enhanced computed tomography (CT) were performed. CT imaging demonstrated a septated cystic lesion involving the tail of the right parotid gland, raising suspicion for a parotid neoplasm versus tuberculous lymphadenitis. Ultrasound-guided FNA with aspiration (5 mL) was conducted. Samples were analyzed for acid-fast bacilli (AFB), tuberculosis polymerase chain reaction (TB-PCR), mycobacterial culture, and cytology.

RESULTS

The patient had a firm, non-tender 5 × 3 cm swelling at right level II–III with intact facial nerve function. CT imaging showed cystic changes within the parotid gland. FNA revealed scanty AFB, and TB-PCR detected Mycobacterium tuberculosis. Cytology and culture results were pending at reporting. No pulmonary involvement or systemic constitutional symptoms were present. A diagnosis of parotid tuberculosis was established, and standard antitubercular therapy (ATT) was initiated. Surgical intervention was avoided.

CONCLUSIONS

Parotid tuberculosis should be considered in adolescents presenting with chronic, painless parotid or upper neck masses, particularly in tuberculosis-endemic regions. Imaging alone may mimic neoplasm; therefore, FNA combined with molecular diagnostics is essential for definitive diagnosis. Early recognition allows appropriate medical management and prevents unnecessary parotidectomy.

Amino Acid Metabolomic Profiling Of Adenoid Tissue In Children With And Without Otitis Media With Effusion

Tuğba Yemiş[1], **Medeni Arpa**[2]

[1]*Recep Tayyip Erdogan University, Medical Faculty, Department of Otorhinolaryngology;* [2]*Recep Tayyip Erdogan University, Medical Faculty, Department of Biochemistry*

BACKGROUND & AIM

Otitis media with effusion (OME) is a common pediatric condition with a multifactorial and incompletely understood pathogenesis. Although adenoid hypertrophy (AH) is a well-known predisposing factor, the inconsistent relationship between AH severity and OME suggests additional underlying mechanisms. This study aimed to evaluate the amino acid metabolomic profile of adenoid tissue in children with and without OME to identify potential metabolic alterations associated with disease pathogenesis.

MATERIAL & METHODS

This prospective study included pediatric patients undergoing adenoidectomy due to AH, who were divided into two groups according to OME status (AH+OME and AH only). Diagnosis was based on endoscopic examination, clinical findings, and audiological assessment.

Targeted amino acid metabolomic analysis of adenoid tissue samples was performed using liquid chromatography–tandem mass spectrometry (LC-MS/MS). Statistical comparisons, correlation analyses, and pathway enrichment analyses were conducted to identify significant metabolomic alterations and to evaluate their clinical relevance.

RESULTS

The AH group included 39 patients and the AH+OME group included 35 patients. A total of 26 amino acids were analyzed. Only 2-aminobutyric acid showed a statistically significant difference between groups. In the AH+OME group, levels were lower than in the AH-only group (0.00 [0.00–0.00] vs. 0.03 [0.00–0.20], p=0.003). No significant differences were observed for the remaining amino acids (Table 1).

CONCLUSIONS

As metabolomic analyses of adenoid tissue have not been previously reported, this study provides initial tissue-based metabolic reference data. A statistically significant difference was observed in a single metabolite with a small absolute change; therefore, its biological relevance should be interpreted cautiously. Overall, OME does not appear to be associated with broad amino acid metabolic reprogramming in adenoid tissue, but rather with a limited and selective metabolic alteration. These findings should not be interpreted as clinical biomarkers but as a preliminary framework for future research. Further studies including oxidative stress, energy metabolism, and lipid profiles may clarify OME pathogenesis.

Cerebral Venous Sinus Thrombosis In A 5-Year-Old As A Complication Of Acute Otitis Media: A Challenge For A Multidisciplinary Team.

Mikołaj Marzyński[1], **Julia Janecka**[1], **Karolina Simon**[1]

[1]*Greater Poland Center of Pediatrics in Poznań, 1 Wrzoska Street.*

BACKGROUND & AIM

Acute otitis media is one of the most common childhood diseases, affecting millions of children each year. Although intracranial complications are rare, cerebral venous sinus thrombosis (CVST) remains one of the most severe. We present a case of a 5-year-old patient with acute otitis media with CVST with the disease progression though the surgical management and an anticoagulation treatment.

MATERIAL & METHODS

The measurement of level of anti-factor Xa activity was crucial, revealing ineffective treatment with standard-dose low-molecular-weight heparin. This case highlights the importance of multidisciplinary care, extended haematological assessment, and the need for multicentre diagnostic and therapeutic strategies.

RESULTS

Notwithstanding surgical treatment and decreasing inflammatory markers, the patient's condition relapsed, with progression of thrombotic lesions on imaging and the development of neurological symptoms, requiring intensive care. Anti-Xa activity testing showed a subtherapeutic heparin level, explaining the lack of treatment efficacy. After increasing the heparin dose and introducing acetylsalicylic acid, gradual clinical stabilization was achieved. Anticoagulant treatment was continued at home for six months. Follow-up imaging confirmed complete recanalization of the venous sinuses, and the patient returned to full functional recovery.

CONCLUSIONS

This case demonstrates that CVST secondary to acute otitis media in children may follow a severe and rapidly progressive course. Sudden clinical deterioration despite low inflammatory markers is an absolute indication for urgent imaging and, when appropriate, surgical intervention. Extended haematological examination including monitoring anti-Xa activity is important for assessing the effectiveness of anticoagulant therapy and should be considered when clinical improvement is lacking or imaging shows progression. Early detection of ineffective treatment and timely modification of therapy may significantly improve prognosis. The increasing frequency of intracranial complications in the paediatric population underscores the need for multicentre clinical guidelines.

Patient Satisfaction After Adenotonsillectomy In A Ghanaian Tertiary Hospital

Peter Appiah - Thompson[1], **Grace Amoo-Quaye**[2], **Nana Andoh Mensah Hanson**[2], **Ekow Nhyira Kuntu-Blankson**[1], **Esther Nketia**[2]

[1]*Department of Surgery, School of Medical Sciences, University of Cape Coast, Cape Coast, Ghana, West Africa;* [2]*Ear, Nose and Throat Unit, Cape Coast Teaching Hospital, Cape Coast, Ghana, West Africa*

BACKGROUND & AIM

The Cape Coast Teaching Hospital (CCTH) serves as a tertiary referral center for the Central and Western Regions of Ghana, performing over 280 ENT surgeries annually, with adenotonsillectomy constituting a substantial proportion. This study sought to evaluate parental satisfaction and perceived symptom improvement following adenotonsillectomy at Cape Coast Teaching Hospital (CCTH), Ghana, over a five-year period.

MATERIAL & METHODS

This was a retrospective cross-sectional study. Parents/caregivers of children (1–15 years) who underwent adenotonsillectomy at CCTH between January 2020 and December 2024 were contacted via telephone calls. A semi-structured questionnaire was used to assess symptom improvement (1–4 scales), hospital experience, and overall satisfaction. Data were analyzed using descriptive statistics and one-sample t-tests with thematic analysis for qualitative responses.

RESULTS

Fifty-seven caregivers participated in this study (79% mothers). The mean age at surgery was 4.8 years, and sleep-related breathing disorder (SRBD) was the primary indication (60%). All symptom domains showed significant improvement post-surgery (mean scores 3.82–3.93; all $p < 0.001$). Overall satisfaction with the outcome was 98% (73% were very satisfied and 25% were satisfied), with 98% recommending the procedure to others. Staff kindness and respect were rated as 'excellent' by 84% of the respondents. Thematic analysis revealed that staff communication was the most positive aspect, whereas waiting time and ward washroom conditions were key areas for improvement.

CONCLUSIONS

Adenotonsillectomy at CCTH was associated with exceptionally high parental satisfaction and significant symptom improvement. Staff communication is a key driver of customer satisfaction. Addressing logistical and infrastructural challenges is essential to further enhance the patient experience.

PP-503

Unusual Periauricular Branchial Cleft Cyst Adjacent To The Facial Nerve In A Pediatric Patient: A Surgical Challenge

Sefanur Hajizade[2], **Mervenur Hajizade**[2], **Yusif Hajiyev**[1]

[1]*University of Texas Medical Branch;* [2]*Clear Falls High School*

BACKGROUND & AIM

Branchial cleft cysts are common congenital anomalies typically presenting along the anterior border of the sternocleidomastoid muscle. However, atypical locations can pose diagnostic and surgical challenges, particularly when located near critical neurovascular structures.

MATERIAL & METHODS

We report the case of a 10-year-old female with a history of recurrent neck infections who presented with a persistently inflamed lesion in the periauricular region. Clinical and radiologic evaluation suggested a congenital cystic anomaly in an unusual location inferior to the auricle. Intraoperatively, the lesion was found to extend deeply and terminate in close proximity to the facial nerve branches, significantly increasing the complexity of dissection.Careful surgical excision was performed with meticulous dissection to preserve the facial nerve. The atypical anatomical course of the cyst required modification of standard approaches and heightened intraoperative vigilance.

RESULTS

Complete resection of the cyst was achieved without any intraoperative or postoperative complications. The patient had an uneventful recovery with no evidence of facial nerve dysfunction or recurrence at follow-up.

CONCLUSIONS

This case highlights a rare periauricular presentation of a congenital branchial cleft cyst with close association to the facial nerve. Awareness of such atypical locations is crucial for preoperative planning and surgical management. Preservation of the facial nerve requires meticulous technique and an understanding of potential anatomic variations.

PP-504

Infantile Bilateral Temporal Bone Langerhans Cell Histiocytosis Mimicking Refractory Otitis Media With Early Facial Palsy

HAZAL DİZDAROĞLU[1], **RECEP YAĞIZ**[1], **SERDAR SOLAK**[2]

[1]*Trakya University, Department of Otorhinolaryngology, Edirne, Turkey;* [2]*Trakya University, Department of Radiology, Edirne, Turkey*

BACKGROUND & AIM

Langerhans cell histiocytosis (LCH) is a rare clonal proliferative disorder of dendritic cells with highly variable clinical manifestations. Temporal bone involvement in infancy is uncommon and may closely mimic infectious otologic disease, frequently resulting in delayed or missed diagnosis. Facial nerve palsy in this context may be misinterpreted as a complication of otitis media, potentially obscuring an underlying infiltrative process and delaying appropriate management.

MATERIAL & METHODS

An 11-month-old girl presented with a 2–3-week history of right-sided facial asymmetry. Otoscopic examination revealed a polypoid mass obstructing the external auditory canal with purulent otorrhea. She was initially managed as complicated otitis media with parenteral and topical antibiotic therapy and local cauterization, with only partial improvement in facial nerve function. Because of limited clinical response and anterior displacement of the posterior external auditory canal wall, further diagnostic evaluation was undertaken. Temporal bone CT and MRI demonstrated bilateral destructive soft tissue lesions involving the mastoid and squamous portions of both temporal bones, extending into the external auditory canals, with ossicular erosion, findings highly suggestive of LCH. (Figure 1) A mastoid biopsy with limited mastoidectomy confirmed the diagnosis of LCH. PET–CT excluded multisystem involvement.

RESULTS

Systemic therapy with vinblastine and prednisolone was initiated, resulting in rapid clinical improvement within one month. Facial nerve function improved from House–Brackmann grade II– III to grade I. External auditory canal lesions resolved completely, with no recurrence, new neurological symptoms, or systemic involvement during the first 3 months of treatment.

CONCLUSIONS

Temporal bone LCH in infancy may closely mimic refractory otitis media and represents a significant diagnostic challenge, even in the presence of facial nerve palsy. Lack of response to appropriate antimicrobial therapy or atypical clinical progression should raise suspicion for infiltrative pathology and prompt early radiological assessment. Bilateral temporal bone involvement, although rare, should further strengthen clinical suspicion for LCH. Early biopsy and multidisciplinary management are critical for optimal outcomes.

PP-505

Pleomorphic Adenoma Of The Parotid Gland Following Childhood Trauma: A Case Report

Michal Bartos[1], **Michaela Máchalová**[1], **Dagmar Hošnová**[1], **Milan Urík**[1]

[1]Department of Pediatric Otorinolarygology, University Hospital Brno, Masaryk University, Czech Republic

BACKGROUND & AIM

Pleomorphic adenoma (PLA) is most common benign salivary gland tumors, although its occurrence in children remains rare. The peak incidence in pediatric patients is around 10 years of age, while it is more frequently diagnosed in adults. Histologically, PLA is a myxoid tumor composed of epithelial and myoepithelial elements with variable stromal components. It most commonly arises in the parotid gland and typically presents as a slow-growing, painless mass, which may delay diagnosis. The case report presents a rare case of a ten-year-old boy with a rapidly growing and hemorrhagic pleomorphic adenoma of the parotid gland diagnosed following trauma.

MATERIAL & METHODS

A standard diagnostic protocol was applied, including clinical examination and appropriate imaging methods such as ultrasound and MRI. Subsequently, surgical treatment was indicated, with emphasis on selecting an optimal surgical technique to achieve complete tumor excision. Patient was enrolled in long-term follow-up after the procedure.

RESULTS

An appropriate diagnostic and therapeutic approach led to successful management of the disease and minimization of recurrence risk. Properly performed surgical treatment, combined with long-term follow-up, enabled early detection of possible complications.

CONCLUSIONS

The case report highlights a rare occurrence of pleomorphic adenoma in a child. Although PLA is uncommon in the pediatric population, it should be considered in cases of salivary gland masses of unclear etiology, particularly due to the potential for malignant transformation. Therefore, careful patient evaluation, appropriate diagnostic workup, and selection of an adequate surgical technique are essential to prevent tumor recurrence. Long-term follow-up is recommended in the postoperative period.

pleomorphic adenoma, salivary glands, resistance, tumor, childhood, injury

PP-506

Primary BCOR-ITD Positive Infantile Sarcoma Of The Pterygopalatine Fossa: The First Reported Case

Banu Öksüz Ok[1], **Burcu Vural Çamalan**[1], **Samet Özlügedik**[1], **Şule Yeşil**[2]

[1]Etlik City Hospital, ENT Department, Ankara Turkey; [2]Etlik City Hospital, Pediatric Oncology Department, Ankara Turkey

BACKGROUND & AIM

BCOR-rearranged sarcomas represent a distinct, highly aggressive entity within the landscape of pediatric undifferentiated small round cell tumors. The BCOR-ITD (Internal Tandem Duplication) variant, often associated with Primitive Myxoid Mesenchymal Tumor of Infancy (PMMTI), remains exceedingly rare in the craniofacial region. We present a landmark case—the youngest in literature—of a BCOR-ITD positive sarcoma originating in the pterygopalatine fossa (PPF), emphasizing the necessity of molecular integration and multidisciplinary surgical strategy.

MATERIAL & METHODS

A 10-day-old female neonate was admitted with a rapidly enlarging, hyperemic mass in the right cheek buccal mucosa that appeared within three days. Maxillofacial MRI identified a 45*25*24 mm infiltrative lesion originating from the right pterygopalatine fossa (PPF) and extending into the infratemporal fossa via the pterygomaxillary fissure. Following a tru-cut biopsy, the diagnosis was established via immunohistochemistry and confirmed by RNA-sequencing (NGS), which identified a BCOR exon 15 ITD mutation. The multidisciplinary treatment protocol consisted of neoadjuvant chemotherapy (Euro-Ewing 2012 / VDC-IE). Following significant tumor shrinkage, a definitive R_0 surgical resection was performed at 12 months of age using a transoral approach to minimize morbidity and preserve craniofacial development.

RESULTS

Immunohistochemical (IHC) profiling showed diffuse and strong positivity for BCOR, SATB2, TLE1, and CD99, which was further integrated with molecular analysis. Next-Generation Sequencing (NGS) confirmed a high-confidence BCOR-ITD with an allele fraction of 93.1%, providing definitive genetic verification of the diagnosis. Following neoadjuvant chemotherapy, a 60% reduction in tumor volume was achieved, facilitating a safe surgical corridor. Postoperative histopathology verified R_0 resection with intact surgical margins (closest margin: 0.1 cm) and no viable tumor cells in the periphery. At the 6-month postoperative milestone, there is no clinical or radiological evidence of recurrence. Masticatory function and facial symmetry have been fully preserved, and the child continues to meet all age-appropriate developmental milestones.

CONCLUSIONS

This report identifies the first neonatal BCOR-ITD-rearranged sarcoma of the pterygopalatine fossa, also marking the youngest PMMTI spectrum case to date. In this anatomically complex skull base location, an 'oncology-first' multimodal approach was pivotal. Neoadjuvant chemotherapy significantly downsized the high-risk mass, enabling a safe R_0 resection and minimizing surgical morbidity while preserving vital craniofacial structures. This landmark case emphasizes that early molecular

verification and well-timed multidisciplinary intervention provide a successful management framework for rare, aggressive neonatal tumors, ensuring local control and functional survival in the earliest stages of life.

Management Of Obstructive Sleep Apnoe Syndrome In Children

Irina Goljerová[1], **Natália Niková**[1]

[1]*MF CU Bratislava Slovakia*

BACKGROUND & AIM

Pediatric obstructive sleep apnea syndrome (OSAS) affects 1-5% of children.

MATERIAL & METHODS

This retrospective study included 165 patients with OSAS treated at the Pediatric ENT Department MF CU and NICD in Bratislava between 2019-2024.

RESULTS

Residual OSAS risk was assessed using the Pediatric Sleep Questionnaire (PSQ ≥0.33). Mean PSQ score was 0.28 ± 0.17. Increased risk of residual OSAS was identified in 47 patients (28%). Multivariate analysis identified as significant risk factors: larger tonsil size (Brodsky grades III-IV, $p<0.05$), overweight/obesity ($p<0.05$), and presence of comorbidities ($p<0.05$). Surgical treatment resulted in symptom improvement in 72% of patients. Identified risk factors require individualized surgical approach and intensive follow-up.

CONCLUSIONS

Identified risk factors require individualized surgical approach and intensive follow-up.

Severe Oropharyngeal Stenosis Following Adenoidectomy In A 9-Year-Old: Successful Multistage Reconstruction With Lateral Pharyngeal Flap And Adjunctive Therapy

Mervenur Hajizade[2], **Sefanur Hajizade**[2], **Yusif Hajiyev**[1]

[1]*University of Texas Medical Branch;* [2]*Clear Falls High School*

BACKGROUND & AIM

Adenoidectomy is one of the most commonly performed pediatric otolaryngologic procedures and is generally considered safe. Oropharyngeal stenosis is an exceedingly rare but potentially debilitating complication that can result in significant airway and swallowing impairment, often requiring complex surgical management.

MATERIAL & METHODS

We report a 9-year-old female with a history of adenoidectomy performed two years prior, who presented with severe, near-total oropharyngeal stenosis associated with recurrent infections and functional compromise. Intraoperative findings demonstrated dense fibrotic scar tissue causing significant narrowing at the oropharyngeal inlet.The patient underwent surgical release of the stenotic segment followed by reconstruction using a lateral pharyngeal flap technique to restore airway patency and mucosal continuity. Adjunctive intralesional triamcinolone (Kenalog) injection was administered to reduce fibrosis and prevent restenosis. Postoperatively, the patient required two additional balloon dilations at three-week intervals to maintain adequate lumen diameter and optimize healing.

RESULTS

At 12-month follow-up, the patient demonstrated complete resolution of stenosis with a well-maintained oropharyngeal airway. She remained asymptomatic with no evidence of recurrence, and had normal feeding and breathing without complications.

CONCLUSIONS

Oropharyngeal stenosis following adenoidectomy is an extremely rare but serious complication that poses significant reconstructive challenges. Successful management often requires a multimodal and staged approach, including surgical reconstruction, steroid therapy, and serial dilations. Early recognition and aggressive intervention are critical for optimal functional outcomes.

ASSR Versus Audiometry In Children

Irina Goljerová[1]

[1]*MF CU Bratislava Slovakia*

BACKGROUND & AIM

ASSR belongs to middle latency response. The stimulus is amplitude and frequency modulated and is continuous. Test frequencies of 500, 1000, 2000, and 4000 Hz are commonly used as ASSR carrier stimuli. The computer equipage calculates a frequency of specific objective audiogram. The advantage is the objective evaluation of the hearing response.

MATERIAL & METHODS

The aim of the work is to evaluate the medical documentation of 38 pediatric patients at Children ENT Department MF CU and NICD in Bratislava (Slovakia) by ASSR examination and comparison of the results of the threshold values with a tone audiogram measured with time distance.

Key words: Steady State Evoked Potentials, ASSR, objective audiometry

RESULTS

The results vary insignificantly, with audiometry thresholds typically being 10 dB on average better than predicted for ASSR examination.

CONCLUSIONS

In the discussion, we compare the results obtained with the studies that dealt with this issue.

KEYWORDS

ASSR, objective audiometry, children

PP-510

The Prevalence Of Congenital CMV Infection Amongst Pediatric Cochlear Implant Users.

Jekaterina Byckova[1], **Vaiva Mickeviciene**[1], **Silvija Kiveryte**[2], **Eugenijus Lesinskas**[1]

[1]*Center of Ear, Nose and Throat, Vilnius University Hospital Santaros Klinikos, Vilnius, Lithuania;* [2]*Center of Laboratory medicine, Vilnius University Hospital Santaros Klinikos, Vilnius, Lithuania*

BACKGROUND & AIM

Congenital sensorineural hearing loss is a heterogeneous disorder. Up to two thirds of congenital HL cases are hereditary. Pathogenic variants of GJB2 gene are the major cause of non-syndromic hearing loss. The second most common cause of a congenital hearing loss (HL) is a congenital cytomegalovirus (cCMV) infection, which accounts for 10 to 20% of all congenital HL cases. Usually, cCMV infection is asymptomatic; therefore, specific tests are not performed at birth. Nevertheless, HL can develop later, after several months or even years.

Aim: To determine the prevalence of congenital CMV infection in pediatric cochlear implant users.

MATERIAL & METHODS

In order to discover a possibly cCMV infection amongst the sample of the study, DNA was extracted from the DBS on Guthrie cards and CMV DNA detected using real time PCR.

RESULTS

Dried blood spots of 117 patients were received from the archive to perform the CMV DNA PCR test. A retrospective DBS-based real-time PCR analysis revealed 14 patients were positive for CMV DNA at birth (12.0%): 5 children who were diagnosed with a cCMV infection in a newborn period were all confirmed with a positive CMV DNA from a DBS; other 9 cases of a cCMV infection were newly detected. In total, 6 (42.9%) of children suffered a symptomatic form of cCMV infection (three received an infection-specific treatment in infancy), and 8 (57.1%) were asymptomatic.

CONCLUSIONS

Congenital CMV infection is a common etiologic factor amongst deaf children CI users. Retrospective diagnostics of cCMV infection should be applied in clinical practice.

Hearing loss, congenital cytomegalovirus infection

PP-511

Adjuvant Therapies In Recurrent Respiratory Papillomatosis: Comparative Systematic Review With A Juvenile-Onset Case Achieving Surgical-Free Control

Kawthar Qader[1], **Worood Husain**[1], **Maryam Sahwan**[1]

[1]*Salmaniya Medical Complex - Government Hospitals*

BACKGROUND & AIM

Recurrent respiratory papillomatosis (RRP) is a chronic disease caused by Human Papillomavirus (HPV) and is characterized by aggressive recurrence and cumulative morbidity from repeated surgical interventions. Despite increasing use of adjuvant therapies — including systemic and intralesional bevacizumab, intralesional cidofovir, and therapeutic HPV vaccination — comparative, high-quality evidence remains limited, and no consensus exists regarding optimal treatment selection. This study aims to systematically evaluate the effectiveness and safety of these therapies through structured synthesis of the available literature, while presenting a case of Juvenile-Onset RRP responding to systemic bevacizumab to contextualize the emerging evidence within clinical practice.

MATERIAL & METHODS

A systematic review is being conducted in accordance with PRISMA guidelines, synthesizing predominantly observational evidence, including cohort studies, case series, and case reports. A comprehensive, multi-database search (PubMed, Embase, Scopus, CINAHL, and Cochrane CENTRAL) is underway, with study selection and data extraction performed independently by two reviewers.

Predefined primary outcomes include surgical frequency, surgical interval, and complete response rates. Predefined secondary outcomes encompass disease control (partial response and recurrence measures), functional outcomes (voice and airway status), safety (CTCAE-graded adverse events and treatment discontinuation), and patient-centered outcomes (quality of life). Data will be synthesized through structured narrative methods, with meta-analysis performed where appropriate.

RESULTS

Results of the systematic review are currently underway, synthesizing predominantly observational evidence. Preliminary analyses demonstrate variability in disease control outcomes across adjuvant therapies, with consistent trends toward reduced surgical frequency and prolonged surgical intervals. Comparative evaluation between systemic and intralesional bevacizumab, intralesional cidofovir, and therapeutic HPV vaccination is ongoing.

Assessment of functional and safety outcomes is ongoing, with early signals indicating improved airway stability and a favorable safety profile, although findings remain preliminary. Data on patient-centered outcomes are limited and heterogeneously reported.

In this context, we report a 9-year-old female with severe juvenile-onset RRP (≈70 prior procedures) and pulmonary involvement. Following failure of prior adjuvant therapies, initiation of systemic bevacizumab resulted in rapid laryngeal and tracheal regression, achieving complete surgical-free disease control over 30 weeks, with stable pulmonary disease and no major adverse events—illustrating the potential role of systemic therapy within the broader comparative treatment landscape.

CONCLUSIONS

Adjuvant therapies in RRP demonstrate clear potential to reduce surgical burden and improve disease control, supporting a shift toward surgery-sparing management in selected patients. Our case exemplifies the magnitude of response achievable with systemic therapy in aggressive disease, while emphasizing the need to interpret such outcomes within a structured comparative framework.

Despite these promising signals, the current evidence base remains predominantly observational and heterogeneous. Completion of this systematic review will provide a critical comparative synthesis to inform treatment selection, define relative effectiveness, and guide the transition toward evidence-based, non-surgical management strategies in RRP.

Tympanoscrelosis In Pediatric Cases

Misaki Takaoka[1], **Ryota Takahashi**[1], **Shintaro Yoshihara**[1]

[1]*Department of Otolaryngology, Japanese Red Cross Medical Center*

BACKGROUND & AIM

Tympanosclerosis is a pathological condition characterized by the formation of hyaline and calcified plaques within the tympanic membrane and, in some cases, the middle ear mucosa. It most commonly develops as a sequela of chronic or recurrent otitis media. On the other hand, in cases of pediatric conductive hearing loss, we sometimes encounter situations where it is difficult to determine whether the hearing loss is congenital or acquired. In this report, we present two cases where

conductive hearing loss persisted after tympanostomy tube placement for otitis media with effusion, leading to a diagnosis of otosclerosis.

MATERIAL & METHODS

Case 1: 11-year-old female. Extremely low birth weight infant. Bilateral tympanostomy tube placement was performed at age 2 for bilateral otitis media with effusion. The left tympanostomy tube fell out at age 3. Subsequently, a 48.8 dB conductive hearing loss remained, and Left tympanoplasty was performed at age 11.

Case 2: 8-year-old male. No abnormalities at birth and no abnormalities noted during NHS (Newborn Health Screening). Hearing loss was noticed around age 6, he was seen at another hospital and underwent bilateral tympanostomy tube placement. Hearing loss persisted, and he presented to our hospital for the first time at age 8. Pure-tone audiometry revealed mixed hearing loss of 53.8 dB in the right ear and 45.3 dB in the left ear. While recommending hearing aid use, we performed right tympanoplasty.

RESULTS

In pediatric patients with a history of exudative otitis media, many cases present with tympanic membrane calcification alone without hearing abnormalities. However, when conductive hearing loss persists or hearing thresholds increase, otosclerosis may be present.

In Case 1, calcification around the ossicles visible on CT using the double oblique technique proved useful for preoperative diagnosis.

CONCLUSIONS

The risk of tympanosclerosis increases with repeated episodes of otitis media and repeated tympanostomy tube insertions even in children.

KEYWORDS

conductive hearing loss, children, sclerotic plaque, double oblique CT

PP-513

Evaluation Of Quality-Of-Life Improvement Following Coblation Adenoidectomy In Pediatric Patients With Adenoid Hypertrophy

Arda Yavuz[1], **Şefika Şeyma Şabano**[1], **İlhan Topaloğlu**[1], **Müzeyyen Doğan**[1]

[1]*Department of Otolaryngology, Faculty of Medicine, Yeditepe University, Istanbul, Türkiye*

BACKGROUND & AIM

Coblation adenoidectomy is widely used in pediatric patients due to its ability to reduce obstructive symptoms by restoring upper airway patency and improve quality of life. This study aimed to evaluate the effectiveness of coblation adenoidectomy in improving quality of life in pediatric patients with adenoid hypertrophy using the Obstructive Sleep Apnea-18 Quality of Life Questionnaire (OSA-18).

MATERIAL & METHODS

This study included 224 pediatric patients who underwent adenoidectomy using the coblation technique. Quality of life was assessed using the OSA-18 questionnaire preoperatively and at the postoperative 3rd month. Patients with incomplete follow-up data were not included in the comparative analyses.

RESULTS

Among the enrolled patients, 224 with complete datasets were included in the analysis. The mean age was 6.2 ± 2.9 years. (range: 2–16).

The mean total OSA-18 score significantly decreased from 86.3 ± 10.3 preoperatively to 36.5 ± 10.7 at the postoperative 3rd month, demonstrating a marked and clinically significant improvement in quality of life. ($p < 0.001$)

Significant improvements were observed across all subdomains. Sleep disturbance scores decreased from 21.6 ± 2.2 to 7.8 ± 3.0 ($p < 0.001$), physical symptoms from 20.0 ± 2.1 to 9.0 ± 2.9 ($p < 0.001$), emotional distress from 12.0 ± 2.0 to 5.8 ± 2.1 ($p < 0.001$), daytime function from 11.1 ± 1.9 to 5.6 ± 1.9 ($p < 0.001$), and caregiver concerns from 22.0 ± 2.1 to 8.8 ± 2.8 ($p < 0.001$).

CONCLUSIONS

Coblation adenoidectomy leads to statistically significant and clinically meaningful improvements in disease-specific quality of life in pediatric patients with adenoid hypertrophy. Marked improvement was observed in total OSA-18 scores as well as in all questionnaire subdomains at the postoperative 3rd month. These findings suggest that coblation adenoidectomy provides substantial benefit in reducing symptoms and improving daily quality of life in children with adenoid hypertrophy.

Pediatric Tracheotomy In Chronic Conditions: A Single-Center Experience

Stoyan Markov[1]

[1]*Department of Otorhinolaryngology, Faculty of Medicine, Medical University of Plovdiv, Plovdiv, Bulgaria*

BACKGROUND & AIM

Background: Planned Pediatric tracheotomy has evolved significantly over the years, with ongoing debates regarding its indications, timing, surgical techniques, and decannulation protocols. Despite that, in most cases, management decisions are still based on the medical team's clinical experience and literature data, as no universally accepted guidelines exist.

Aim: This study aims to present our experience with pediatric tracheostomies and compare the data with international literature.

MATERIAL & METHODS

Over recent years, 18 pediatric tracheotomies were performed at the ENT Clinic of University Hospital "St. George" for various chronic conditions. All procedures were, planned due to disease progression.

RESULTS

The surgical interventions were completed without complications in all cases. A permanent tracheostomy was established in 8 patients, while 10 underwent temporary tracheostomy. Three children were successfully decannulated

CONCLUSIONS

Planned pediatric tracheotomy has increased in frequency in recent decades due to the survival of an increasing number of children with severe chronic diseases. Despite that it is still a relatively rare surgical procedure, with an estimated incidence of 6.6 per 100,000 according to the literature. Several aspects of planned pediatric tracheotomy remain under discussion and require further clarification.

Efficacy Of Different Endoscopic Interventions In Managing Subglottic Stenosis In Children

Talal Alkhatib[1], **Abdulsalam alqutub**[1]

[1]*Department of Otolaryngology Head Neck Surgery, Faculty of Medicine, King Abdulaziz University*

BACKGROUND & AIM

To evaluate the effectiveness and safety of endoscopic interventions for managing paediatric subglottic stenosis.

MATERIAL & METHODS

Methods. Following Preferred Reporting Items for Systematic Reviews and Meta-Analysis guidelines and the Cochrane Handbook, we systematically searched four databases from inception to August 2024. Studies reporting outcomes of endoscopic management of paediatric subglottic stenosis were included. The primary outcome was procedural success; secondary outcomes were recurrence, decannulation and complications.

RESULTS

Results. Forty-three studies involving 1088 children were included. The pooled success rate of endoscopic treatment was 79.2 per cent. Carbon dioxide and potassium titanyl phosphate laser achieved success rates of 79.9 and 100 per cent, respectively. Balloon dilatation and rigid dilatation had success rates of 79.9 and 82.4 per cent, whereas cold knife alone had a lower rate of 47.2 per cent. The recurrence rate was 36.8 per cent and balloon dilatation showed the highest recurrence at 42.2 per cent. The pooled decannulation rate was 60.4 per cent and complications occurred in 3.0 per cent of cases.

CONCLUSIONS

Conclusion. Endoscopic interventions are effective for paediatric subglottic stenosis, but recurrence remains common

KEYWORDS

PP-516

Cryotherapy Induced Reduction Of The Hypertrophied Adenoids For A 4 Year Old Patient With Ehlers-Danlos Syndrome, A Case Report

Laura Kupčinskienė[1], **Vaiva Mickevičienė**[1]

[1]*Vilnius University hospital Santaros clinics, Center of Ear, Nose, Throat diseases, Department for Pediatric Ear, Nose and Throat disease*

BACKGROUND & AIM

The Ehlers-Danlos syndrome (EDS) is a group of 13 heritable disorders characterized by tissue fragility, skin hyperextensibility and joint hypermobility. The subtype of the vascular EDS is rare, but can cause serious complications such as spontanic vessel rupture, aneurysms, arterial dissection. Any surgical intervention is dangerous because of the increased risk of bleeding.

MATERIAL & METHODS

We present a case of a 4 year old male complaining of nasal obstruction, snoring and sleep apnoea. Nasal fibroendoscopy revealed grade III adenoids, intranasal steroids were prescribed. Several months later, re-examination concluded the increase in the adenoid size and presenting secretory otitis media. Concomitant EDS of the vascular type (COL3A1 genopathogenic variation) was the reason the patient was referred to a tertial university hospital for a further surgical treatment. After consulting the family, cryotherapy was the first choice for a safer option. Two cryotherapy rounds were performed under general anesthesia with a 3 months interval.

RESULTS

The initial procedure resulted abscence of sleep apnoea, slightly improved nasal breathing and objectively reduced adenoids, however snoring and mouth breathing remained. The second round of crytherapy was repated 3 months later, with satisfactory results for both medical proffesionals and family. 1 year post intervention, the symptoms were still relieved.

CONCLUSIONS

Cryotherapy in the ENT practice is usually applied to treat chronic rhinitis, nasal bleeding, tonsilar hyperthrophy and pharyngeal cysts. We have not found any previous data of the crytherapy for adenoid tissue. Our results demonstrate cryotherapy as a possible option to treat hypertrophied adenoids in patients with high risk of intra or postoperative bleeding. It however holds some disadvantages, such as the need for repeated procedure with repeated anesthesia as well as the end ryšulis being the reduction not the removal of the hypertrophied adenoids.

KEYWORDS

adenoid hypertrophy, cryotherapy, heritable disorder

PP-517

A Pediatric Midline Nasal Mass With Inconclusive Histopathology: A Case Report

Sebla Çalışkan[1], **Neslihan Ağca**[1]

[1]*Department of Otorhinolaryngology, Kocaeli City Hospital, Kocaeli, Türkiye*

BACKGROUND & AIM

Midline nasal masses in the pediatric population are rare and represent a heterogeneous group of congenital, inflammatory, and neoplastic lesions.The most common entities include dermoid cysts, nasal gliomas, and encephaloceles, which originate from embryological developmental anomalies.Radiological evaluation with CT and MRI is essential to determine lesion extent and to exclude intracranial extension.Although most lesions are benign, rare neoplastic masses may present with similar clinical and radiological features.Unusual histopathological patterns, particularly with inconclusive immunohistochemistry, may significantly complicate the diagnostic process.

MATERIAL & METHODS

This study presents a single pediatric case of a midline nasal mass. The patient underwent detailed clinical evaluation, including history and physical examination. Radiological assessment was performed using computed tomography (CT) and magnetic resonance imaging (MRI) to evaluate lesion characteristics and to rule out intracranial extension. Surgical excision was performed under general anesthesia through an external surgical approach, and intraoperative findings were documented. The excised specimen was subjected to histopathological examination and a comprehensive immunohistochemical analysis to aid in differential diagnosis. Molecular genetic analysis using a pan-solid tumor RNA panel did not reveal any pathogenic or targetable mutations, gene fusions, or clinically significant variants.Additionally, relevant literature was reviewed to compare the clinical, radiological, and pathological features of similar cases.

RESULTS

An 8-year-old child presented with a painless, progressively enlarging midline nasal mass.

Physical examination revealed a firm, non-tender lesion at the nasal root.

Imaging findings:

- Well-defined, space-occupying lesion
- No intracranial extension

- No dural involvement

Intraoperative findings:

- Well-circumscribed, encapsulated mass
- 1.5 × 1 cm bony defect in the right nasal bone
- Intact nasal roof mucosa
- No intracranial communication
- Complete excision achieved
- The bony defect was successfully reconstructed using a tragal cartilage graft

Histopathological evaluation:

- Findings consistent with a neoplastic process
- Differential diagnosis included:
- Chordoid meningioma
- Chordoma

Immunohistochemical profile:

- Positive: D2-40, SSTR2A, Vimentin, S100, CD99, p63
- Negative: Calretinin, Chromogranin, Desmin, Synaptophysin, p40, PanCK, EMA
- Ki-67 proliferation index: ~15%

Genetic analysis:

- Molecular analysis was performed to further clarify the diagnosis
- No disease-specific or diagnostic genetic alteration was identified

➡️ Despite comprehensive evaluation, a definitive diagnosis could not be established

CONCLUSIONS

Pediatric midline nasal masses may present significant diagnostic challenges, particularly when histopathological findings are atypical.Clinical and radiological features may suggest a benign lesion, while pathological evaluation may indicate a neoplastic process.In some cases, even extensive immunohistochemical analysis may remain inconclusive. The absence of identifiable driver mutations or gene fusions further supports the unclassifiable nature of the lesion and highlights the limitations of current molecular diagnostic tools in rare pediatric tumors. A multidisciplinary approach is essential for accurate evaluation and management. Close clinical follow-up should be considered in cases with uncertain diagnosis.

PP-518

Beyond The Nosebleed: An Incidental Diagnosis Of Sydenham's Chorea In A Child Presenting With Epistaxis

Meliz Ece Obalar[1], **Emine Elif Altuntaş**[1], **Celil Göçer**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, Lokman Hekim University, Ankara, Turkey*

BACKGROUND & AIM

Sydenham's chorea (SC) is the major neurological manifestation of acute rheumatic fever, resulting from autoimmune-mediated basal ganglia dysfunction following group A streptococcal infection. It classically presents with choreiform movements and behavioral changes, but may be overlooked when the presenting complaint is unrelated to the nervous system. Otorhinolaryngologists often serve as first-contact physicians for pediatric patients and are well positioned to detect incidental systemic findings. We aim to present a case in which SC was incidentally diagnosed during ENT evaluation for epistaxis, highlighting the importance of comprehensive assessment beyond the presenting complaint.

MATERIAL & METHODS

This report presents a single pediatric case evaluated at the Department of Otorhinolaryngology–Head and Neck Surgery, Lokman Hekim University, Ankara, Turkey. A 9-year-old female patient presenting with spontaneous epistaxis underwent standard ENT examination, during which incidental involuntary movements were observed. A detailed history, including psychosocial and family history, was obtained, and the patient was subsequently referred to pediatric neurology for further evaluation. Diagnostic workup included neurological examination, laboratory investigations (anti-streptolysin O [ASO] titer, erythrocyte sedimentation rate [ESR], C-reactive protein [CRP], complete blood count), transthoracic echocardiography, and cranial magnetic resonance imaging (MRI). Diagnosis was established according to the Jones criteria for acute rheumatic fever. Clinical data were retrospectively reviewed and reported with patient confidentiality maintained throughout.

RESULTS

Neurological examination revealed hemichorea with facial grimacing and involuntary upper limb movements that resolved with sleep; cranial nerve function, muscle tone, strength, deep tendon reflexes, and cerebellar testing were otherwise normal. Laboratory findings showed a markedly elevated ASO titer of 960 IU/mL (reference: 0–150 IU/mL), consistent with recent group A streptococcal infection, along with a mildly elevated ESR of 12 mm/h (reference: 0–10 mm/h) and a normal CRP of 2.35

mg/L. Transthoracic echocardiography demonstrated grade 1 mitral regurgitation, indicative of subclinical carditis. Cranial MRI was unremarkable, excluding structural central nervous system pathology. Based on the presence of chorea and carditis as major Jones criteria, together with supporting evidence of preceding streptococcal infection, a diagnosis of Sydenham's chorea secondary to acute rheumatic fever was established. Haloperidol was initiated for symptomatic control of choreiform movements.

CONCLUSIONS

This case illustrates that Sydenham's chorea may first come to clinical attention through an unrelated presenting complaint such as epistaxis, rather than through primary neurological symptoms. The incidental recognition of involuntary movements during routine ENT examination proved pivotal in reaching the correct diagnosis. These findings underscore the importance of a comprehensive, whole-patient approach in otorhinolaryngology practice and highlight the otorhinolaryngologist's role as a potential first point of contact in identifying systemic and neurological disease in pediatric patients. Prompt recognition and multidisciplinary referral remain essential for timely diagnosis and management of acute rheumatic fever and its neurological sequelae.

PP-519

Chemotherapy-Induced Bilateral Facial Paralysis: A Rare Neurotoxicity In A Patient With T-Cell Acute Lymphoblastic Leukemia

Nurlan Majidov[1], **Ozgur Kemal**[1], **SENA KALOĞLU**[1]

[1]*Ondokuz Mayıs University Otorinolaryngology and Neck Surgery Department*

BACKGROUND & AIM

Bilateral simultaneous facial paralysis is an exceedingly rare condition, accounting for only 0.3–2% of all facial palsy cases and demanding a broad differential diagnosis. Chemotherapeutic agents—particularly vincristine and other vinca alkaloids—are increasingly recognized as a cause of peripheral neurotoxicity; however, bilateral facial nerve involvement remains exceptionally uncommon. In this report, we present a case of simultaneous bilateral peripheral facial paralysis during multi-agent chemotherapy for T-cell acute lymphoblastic leukemia (T-ALL) and emphasize the importance of early recognition and multidisciplinary management.

MATERIAL & METHODS

A 17-year-old male patient diagnosed with T-ALL in May 2022. The patient was treated with sequential chemotherapy: Protocol 1B (induction: vincristine, daunorubicin, cyclophosphamide, doxorubicin, methotrexate, mercaptopurine), Protocol M (high dose methotrexate, mercaptopurine), and Protocol 2 (methotrexate, vincristine, doxorubicin). The first 3 cycles of protocol 2 were uneventful. Shortly after the fourth cycle, the patient was referred to our otolaryngology department with bilateral otalgia, which rapidly progressed to symmetric bilateral House-Brackmann Grade 5 facial palsy. Workup included contrast-enhanced temporal and brain MRI, audiometry, lumbar puncture with CSF analysis, serum Lyme serology, viral serology panel (HSV, VZV, EBV, CMV), and autoimmune markers. Infectious, autoimmune, and neoplastic etiologies were systematically excluded.

RESULTS

Contrast-enhanced temporal MRI demonstrated bilateral enhancement of the facial nerve at the labyrinthine segment and geniculate ganglion level, consistent with facial neuritis. Brain MRI showed no leptomeningeal infiltration or cranial nerve pathology. CSF analysis was negative for leukemic infiltration and infection. All serologic tests were negative. The close temporal relationship between the fourth chemotherapy cycle and symptom onset (48 hours), bilateral symmetric peripheral involvement, and exclusion of alternative etiologies supported a diagnosis of chemotherapy-related peripheral neurotoxicity. Treatment comprised intravenous methylprednisolone (60 mg/day for 7 days), followed by oral steroid taper, alongside bilateral eye protective drops, and physiotherapy consultation. Partial facial nerve recovery was observed on follow-up. İn last examination facial palsy totally healed. The patient was lost to follow-up in May 2023 due to progression of underlying T-ALL.

CONCLUSIONS

Chemotherapy-induced bilateral peripheral facial paralysis is a rare but clinically significant complication. In patients receiving chemotherapy with simultaneous bilateral facial weakness, drug neurotoxicity should be considered in the differential diagnosis, along with leukemic infiltration and infectious or autoimmune causes. The temporal relationship to chemotherapy administration, bilateral symmetric involvement and MRI enhancement at the geniculate ganglion level are important diagnostic clues. Early corticosteroid therapy combined with a multidisciplinary approach may achieve partial neurological recovery. Increasing case reports in this area will enhance understanding of epidemiology, pathogenesis, and treatment response.

PP-520

Gigantic Pediatric Tonsillolith: A Rare Case Report And Review Of The Literature

Mohammed Alwabili[1]

[1]*King Fahad Specialized hospital, Al-Qassim, Saudi Arabia*

BACKGROUND & AIM

Tonsilloliths are calcified concretions that develop within the crypts of the palatine tonsils. They are commonly encountered in adults and are usually small and asymptomatic. Giant tonsilloliths, particularly in the pediatric population, are exceedingly rare and may present diagnostic and therapeutic challenges due to their unusual size and resemblance to other oropharyngeal pathologies. We report a rare case of a gigantic tonsillolith in a child successfully treated with tonsillectomy and review the relevant literature.

MATERIAL & METHODS

An 11 yers old girl presented with symptoms related to a unilateral tonsillar mass and recurrent tonsilitis. Clinical examination revealed a large hard lesion arising from the palatine tonsil extending to soft palate. Diagnostic workup included detailed otolaryngologic examination and radiologic evaluation to characterize the lesion and exclude alternative diagnoses. Surgical management consisted of complete tonsillectomy with removal of the stone. Postoperative outcomes were assessed during follow-up. In addition, a focused review of previously reported pediatric giant tonsillolith cases was performed to evaluate clinical presentation, diagnostic approaches, and management strategies.

RESULTS

Examination and imaging demonstrated a giant tonsillolith measuring approximately 3–4 cm. The patient underwent uncomplicated tonsillectomy with complete removal of the calcified mass. Histopathologic assessment confirmed a benign tonsillar lesion associated with a tonsillolith. Postoperative recovery was uneventful, with complete resolution of symptoms and no recurrence during follow-up. Literature review demonstrated that giant tonsilloliths in children are exceptionally uncommon, with most reported cases managed surgically because of diagnostic uncertainty, symptom burden, or lesion size.

CONCLUSIONS

Giant tonsilloliths should be considered in the differential diagnosis of calcified oropharyngeal masses in pediatric patients despite their rarity. Clinical examination combined with appropriate imaging facilitates diagnosis. Tonsillectomy provides definitive treatment and allows exclusion of other pathological conditions. Increased awareness of this unusual entity may help avoid diagnostic delay and optimize management.

THREE PEDIATRIC CASES WITH TEMPORAL BONE TUMORS

Takefumi Kamakura[1], **Maki Yamashita**[1,2], **Yusuke Otami**[1], **Takato Sudo**[1], **Nozomi Fujisawa**[1], **Yasuo Mishiro**[1]

[1]*Department of Otorhinolaryngology - Head and Neck Surgery, Osaka City General Hospital;* [2]*Department of Pediatrics, Adachi Hospital*

BACKGROUND & AIM

Temporal bone tumors, including malignancies, are rare. Owing to this extreme rarity, diagnosis and treatment may often be delayed. Herein, we present three cases of temporal bone tumors.

MATERIAL & METHODS

Case presentations:

Case 1: A 14-month-old boy with prolonged bleeding after myringotomy was referred to our department. Endoscopic examination revealed redness and swelling of the left eardrum. Computed tomography (CT) revealed a mastoid cavity filled with soft tissue and bone destruction.

Case 2: A four-year-old girl presented with acute otitis media and left-sided facial palsy. The patient received intravenous steroids. When the patient underwent tympanostomy tube insertion, a tumor lesion was found. Magnetic resonance imaging (MRI) revealed a lesion in the mastoid cavity.

Case 3: The patient was a 23-month-old girl with left otorrhea that did not improve for two months. A CT tomography revealed bone destruction in the middle ear and a tumor in the right lobe of the thyroid.

RESULTS

Case 1: He underwent mastoidectomy and tumor biopsy under general anesthesia. The tumor was histopathologically diagnosed as myeloid sarcoma, and he was diagnosed as acute megakaryoblastic leukemia. He underwent induction chemotherapy, intensive chemotherapy, and allogeneic hematopoietic stem cell transplantation. The patient has been in remission for 48 months.

Case 2: She underwent mastoidectomy and tumor biopsy under general anesthesia. She was diagnosed as Ewing sarcoma, underwent chemotherapy and proton therapy, and has been in remission for 12 months.

Case 3: Tumor biopsies of the thyroid and external auditory canals were performed under general anesthesia, and she was diagnosed as Langerhans cell histiocytosis. She underwent chemotherapy, and has been in remission for 17 months. However, she was suffered from diabetes insipidus, and recurrence was seen in the pituitary, she underwent chemotherapy again, and she has been in remission for 33 months.

CONCLUSIONS

When unusual symptoms such as intractable otorrhea and continuous bleeding after tympanostomy are observed, temporal bone CT scans should be considered as soon as possible to search for a tumor lesion or blood disease. When a temporal bone tumor or blood disease occurs, mastoidectomy and biopsy under general anesthesia are recommended for a definitive diagnosis.

CHARGE Syndrome: The Otolaryngologist's Role

MEHTARI Nasrine Siham[1], **SAHRAOUI Mohammed**[1], **MEFTAH Hayet**[1]

[1]*University Hospital / Faculty of Medicine Tlemcen. Toxicomed Laboratory*

BACKGROUND & AIM

CHARGE syndrome is a rare congenital malformation, affecting approximately one in 10,000 children at birth. It is characterized by a complex phenotype combining several anomalies: coloboma (C), congenital heart disease (H), choanal atresia (A), developmental and/or growth delay (R), genitourinary disorders (G), and ear anomaly (E). Diagnosis is primarily clinical; the presence of one or more key signs should prompt investigation for other anomalies. MRI/CT scan of the temporal bones may reveal the absence or hypoplasia of the semicircular canals.

The aim is to report a case of this syndrome, highlighting the crucial role of the ENT specialist in its management.

MATERIAL & METHODS

Clinical and paraclinical description of a child with CHARGE syndrome

RESULTS

A 14-month-old boy was referred for suspected hearing loss. He had a history of surgically corrected bilateral choanal-osseous atresia at birth, delayed motor development, pulmonary artery stenosis, coloboma, low-set, cup-shaped ears with deficient external auricular cartilage, a triangular concha and a square face. Auditory brainstem response (ABR) and auditory steady stat response (ASSR) revealed moderate bilateral sensorineural hearing loss. A temporal bone CT scan showed agenesis of the left lateral semicircular canal. We proposed bilateral auditory rehabilitation combined with regular speech therapy follow-up.

CONCLUSIONS

CHARGE syndrome's Children require multidisciplinary care due to the potentially high number of malformations and sensory deficits encountered. The ENT specialist plays a dual role: in the neonatal period, to manage the life-threatening emergency of choanal atresia, and subsequently, to address any additional hearing impairments that may accompany these children's disabilities.

KEYWORDS

BACKGROUND & AIM

Severe mandibular hypoplasia, particularly agnathia, is associated with profound neonatal upper airway obstruction. While the Ex Utero Intrapartum Treatment (EXIT) procedure is the standard for securing the airway while maintaining placental circulation, extreme anatomical distortion can render conventional endoscopic intubation impossible. We report a case where extreme agnathia led to EXIT failure, necessitating an emergency surgical airway.

MATERIAL & METHODS

A 36-year-old multiparous patient presented with a fetus exhibiting severe micrognathia progressing to agnathia and polyhydramnios. Prenatal biometrics revealed a severely abnormal inferior facial angle (11°) and fetal nasomental (FNM) angle

(92.87°), while MRI suggested complete obliteration of the oropharynx and hypopharynx. An EXIT- to-airway procedure was performed at late preterm gestation.

RESULTS

During the EXIT procedure, both video laryngoscopy and rigid bronchoscopy failed to identify any recognizable laryngeal inlet or glottic opening due to extreme soft tissue distortion and the absence of mandibular support. Mask ventilation was also ineffective. An emergency tracheostomy was successfully performed while uteroplacental circulation was maintained, resulting in immediate stabilization of the neonate.

CONCLUSIONS

EXIT success relies on an endoscopically accessible airway lumen, which may be absent in fetuses with extreme agnathia. Detailed prenatal imaging is critical; integrating advanced 3D MRI airway reconstruction and virtual bronchoscopy may better predict EXIT failure. Earlier recognition of such cases could support a strategy of planned primary tracheostomy to minimize futile intubation attempts and hypoxic risk.

KEYWORDS

EXIT procedure; fetal airway obstruction; agnathia; micrognathia; prenatal MRI; virtual bronchoscopy; tracheostomy.

Occult Aerodigestive Injury In Pediatric Neck Trauma :The Critical Role Of CT Imaging

Rukiye Ozcelik Erdem[1], **Nevin Oner Seckin**[1], **Gozde Kalkan**[1]

[1]*Necmettin Erbakan University Faculty of Medicine, department of otorhinolaryngology, KONYA, TURKIYE*

BACKGROUND & AIM

Penetrating neck trauma in children is uncommon but clinically significant due to the close proximity of vascular and aerodigestive structures. Superficial-appearing wounds may conceal deeper, potentially life-threatening injuries. Early identification of occult aerodigestive injury remains challenging. We hypothesized that contrast-enhanced computed tomography (CT) is critical for early detection of occult injury and facilitates safe non-operative management in clinically stable pediatric patients

MATERIAL & METHODS

Two pediatric patients with penetrating neck trauma were evaluated in a tertiary referral center. Clinical assessment included detailed physical examination and monitoring for signs of aerodigestive injury. Both patients underwent contrast-enhanced CT imaging. Management consisted of hospitalization, nil per os (NPO) status, close clinical observation, and daily wound care. Outcome measures included clinical progression, resolution of subcutaneous emphysema, and requirement for surgical intervention.

RESULTS

Case 1: A 7-year-old boy presented with a 1×1 cm laceration at left cervical level II and subcutaneous crepitation. CT revealed diffuse cervical subcutaneous emphysema without hematoma.

Case 2: An 8-year-old boy presented with a 1×1 cm submandibular laceration and crepitation. CT demonstrated extensive emphysema involving the mandibular ramus, parotid and submandibular regions, hypopharynx, and carotid space.

Esophageal injury could not be definitively excluded in either case. Both patients were managed conservatively. Subcutaneous emphysema regressed markedly within 48 hours. Both patients were discharged on day 4 without complications, and no surgical intervention was required.

CONCLUSIONS

Contrast-enhanced CT is indispensable for early diagnosis and risk stratification in pediatric penetrating neck trauma. Early imaging prevents missed occult aerodigestive injury and enables safe, selective non-operative management.

PP-525

Laryngeal Foreign Body Mimicking Subglottic Mass

Furkan Olgun[1], **Yakup Bahadır Öcal**[1], **Ömer Orak**[1], **Cömert Şen**[1]

[1]*Istanbul University, Istanbul Faculty of Medicine, Department of Otorhinolaryngology-Head and Neck Surgery*

BACKGROUND & AIM

Laryngeal aspiration of foreign bodies is regarded as an emergency, as the foreign bodies may cause acute obstruction of the airway. Due to obstruction, the cross-sectional area of the airway decreases significantly while the airway resistance increases drastically. In this respect, laryngeal aspiration of foreign bodies causes acute symptoms and patients usually seek immediate

medical care. However, the foreign bodies may lodge in the valleculae, pyriform sinuses, or laryngeal ventricles and thus may not obstruct the airway or impede proper ventilation but may cause stridor and agitation instead.

MATERIAL & METHODS

Six-month old female infant, otherwise healthy with no history of intubation or operation, was brought to the pediatric emergency clinic at an external facility with gradually increasing stridor and agitation. The blood work and X-ray imaging focused on probable potential infectious, medical or surgical pathologies, but were unremarkable. The patient was then discharged with symptomatic treatment, including inhaled corticosteroids and analgesic medication. Following watchful waiting, the patient presented to the pediatric emergency clinic again with unresolved complaints, prompting the emergency team to request an otorhinolaryngology (ORL) consultation. Using flexible laryngoscopy, the ORL department detected impaired mobility in the anterior halves of the vocal folds bilaterally and taking into account that the symptoms started not until the sixth month of life and persisted for three months, they suspected the symptoms might have been caused by a developmental/traumatic process, such as a laryngeal web and the patient was referred to our clinic.

RESULTS

The flexible laryngoscopy findings of the nine-month-old infant at our institution were omega-shaped epiglottis, normal vocal fold mobility bilaterally and subglottic mass with a string-like piece on it, which resembled a dry adhesive secretion. With subglottic hemangioma being the most likely diagnosis, considering that the symptoms emerged after the sixth month of life, we conducted a tracheoscopy under general anesthesia. It transpired that the string-like piece was a fragment of bovine bone from a beef broth, which was lodged in the anterior commissure like a septum and expanded in the supraglottic direction, while pressing against the anterior and posterior subglottic region, which in turn provoked granulation tissue to form, resembling a subglottic hemangioma. We extracted the foreign body, the granulation tissue was not obstructing the airway and planned a repeat tracheoscopy in six weeks to observe the granulation tissue and the possible stenosis.

CONCLUSIONS

Mild stridor and uneasiness in infants may raise suspicion of subglottic mass. Interestingly, the mean onset of symptoms of these clinical entities coincide with trials of complementary food, namely around the sixth month. Thus, the infant may be introduced to foreign bodies related to complementary food as an ingredient. In our case, the infant was fed beef broth soup, which caused a piece of bone to lodge in the larynx. Our case demonstrates that in infants, who do not have unaided access to foreign bodies, aspiration should be borne in mind as a possible cause of persistent stridor and uneasiness.

[1]College of Medicine and Medical Sciences, Arabian Gulf University, Manama, Kingdom of Bahrain; [2]School of Medicine, Trinity College Dublin, Dublin, Ireland; [3]Otorhinolaryngology-Head and Neck Surgery, Kuwait Institute for Medical Specializations (KIMS), Kuwait City, Kuwait; [4]Al Amiri Hospital, Ministry of Health, Kuwait City, Kuwait; [5]Faculty of Medicine, Kuwait University, Kuwait City, Kuwait; [6]Faculty of Medicine, Alexandria University, Alexandria, Egypt; [7]Kuwait Institute for Medical Specialization: Kuwait City, Al Asimah, Kuwait; [8]Otorhinolaryngology-Head and Neck Surgery, Ministry of Health, Kuwait City, Kuwait; [9]Department of Otorhinolaryngology-Head and Neck Surgery, Farwania hospital, Kuwait City, Kuwait

BACKGROUND & AIM

Emergence agitation is a frequent recovery complication after pediatric tonsillectomy and/or adenoidectomy. This systematic review and network meta-analysis compared pharmacological interventions for preventing emergence agitation and related postoperative outcomes in pediatric patients.

MATERIAL & METHODS

PubMed, Scopus, Web of Science, and the Cochrane Library were searched from inception to 16 April 2026. Randomized controlled trials evaluating pharmacological interventions in children undergoing tonsillectomy, adenoidectomy, or adenotonsillectomy were included. Pairwise random-effects meta-analyses and frequentist random-effects network meta-analyses were conducted.

RESULTS

Sixty-seven randomized controlled trials involving 5,184 pediatric patients undergoing tonsillectomy and/or adenoidectomy were included. Pharmacological interventions significantly reduced emergence agitation, severe emergence agitation, agitation severity scores, and postoperative vomiting compared with placebo/control. Network meta-analysis demonstrated

favorable outcomes with nitrous oxide, propofol, remimazolam, esketamine, dexmedetomidine, ketamine, fentanyl, midazolam, and paracetamol, with dexmedetomidine and remimazolam ranking among the most effective interventions.

CONCLUSIONS

Pharmacological prophylaxis may reduce emergence agitation after pediatric tonsillectomy and/or adenoidectomy. Treatment selection should be individualized according to efficacy, certainty, safety, and recovery goals.

PP-527

A Giant Dermoid Cyst Filling The Floor Of The Mouth In A Newborn: A Rare Case Report

Zerrin Özergin Coşkun[1], **Caner Pehlivan**[1]

[1]*Department of Otorhinolaryngology, Recep Tayyip Erdoğan University Faculty of Medicine, Recep Tayyip Erdoğan University Training and Research Hospital, Rize, Türkiye*

BACKGROUND & AIM

Dermoid cysts are rare congenital lesions resulting from ectodermal closure anomalies. Their occurrence in the oral cavity, particularly in the floor of the mouth, is extremely rare in the neonatal period. Large lesions may lead to feeding difficulties and airway obstruction.

MATERIAL & METHODS

A 41 + 3-week, male newborn weighing 3500 g was referred to the ENT clinic shortly after birth due to sublingual swelling noticed during crying. Vital signs were stable, and no respiratory distress was observed, although feeding difficulties were present.

Examination revealed a 3 × 4 cm soft, smooth mass located between the tongue and the floor of the mouth, extending into the oral cavity. Neck MRI demonstrated a well-defined cystic lesion measuring 32 × 30 mm, hypointense on T1 and heterogeneously hyperintense on T2, without diffusion restriction and with capsular enhancement after contrast, occupying a large portion of the oral cavity.

Following appropriate preoperative preparation, complete surgical excision was performed under general anesthesia. The postoperative course was uneventful. The patient tolerated oral feeding well, with no respiratory compromise, and was discharged in good condition. Histopathological examination confirmed a dermoid cyst (mature cystic teratoma).

RESULTS

Dermoid and epidermoid cysts are rare benign developmental lesions arising from ectodermal tissue entrapment during embryogenesis. Their occurrence in the head and neck region is uncommon, and intraoral localization is particularly rare, accounting for only 0.01–1.6% of oral cysts. They typically present as slow-growing, painless masses; however, larger lesions may cause dysphagia, speech difficulties, or airway obstruction. Neonatal presentation is exceptional, although congenital origin is well established.

Differential diagnosis includes ranula, thyroglossal duct cyst, lymphatic malformations, and infectious lesions. Imaging modalities such as ultrasonography, CT, and especially MRI are crucial for localization and surgical planning. Typical MRI findings include T1 hypointensity, T2 hyperintensity, and absence of diffusion restriction.

Definitive diagnosis is histopathological: epidermoid cysts contain squamous epithelium, dermoid cysts include skin appendages, and teratoid cysts contain elements from all three germ layers. Total surgical excision is the treatment of choice, with excellent prognosis and low recurrence rates.

CONCLUSIONS

Although dermoid cysts of the floor of the mouth are typically diagnosed later in life, neonatal presentation is rare but clinically significant. Progressive enlargement may result in feeding difficulties, dysphagia, tongue elevation, or airway compromise. Therefore, early recognition, close monitoring, and timely surgical intervention are essential in newborns.

Complete excision provides definitive treatment with excellent outcomes. This case highlights that dermoid and epidermoid cysts, although rare, should be considered in the differential diagnosis of cystic lesions of the neonatal oral cavity.

Assessment Of Different Coblation Wand Systems In Pediatric Adenoidectomy

Arda Yavuz[1], **İlhan Topaloğlu**[1], **Şefika Şeyma Şabano**[1], **Müzeyyen Doğan**[1], **Hatice Ünsal**[1]

[1]*Yeditepe University Faculty of Medicine, Department of Otorhinolaryngology, Istanbul, Turkey*

BACKGROUND & AIM

Coblation adenoidectomy is widely used in pediatric patients due to its ability to achieve controlled tissue ablation with effective hemostasis and minimal thermal injury to surrounding tissues. Recent developments in coblation technology have focused on optimizing surgical efficiency through modifications in wand design.

The present study aimed to assess whether a modification in coblation wand design is associated with changes in operative time in pediatric adenoidectomy.

MATERIAL & METHODS

This study included pediatric patients aged 2 to 16 years who underwent adenoidectomy due to adenoid hypertrophy at the Department of Otorhinolaryngology, Yeditepe University Faculty of Medicine, Istanbul, Türkiye.

All procedures were performed using coblation technology. From January 2013 to June 2017, PROcise EZ Plasma Wand; ArthroCare (the Procise EZ) was used, and from June 2017 to January 2026, all procedures were performed using Procise mAx Plasma Wand; ArthroCare (the Procise Max).

Demographic data (age and gender) and operative times were recorded. Operative time was defined as the duration from initiation of device use to completion of hemostasis.

RESULTS

A total of 167 pediatric patients were included (ProciseEZ: n=80; Procise Max: n=87). The mean age was similar between groups (5.76 ± 2.64 vs 5.78 ± 2.19 years, p>0.05). In the Procise EZ group, 33 (41.3%) were male and 47 (58.7%) female, whereas in the Procise Max group, 53 (60.9%) were male and 34 (39.1%) female, with no significant difference (p>0.05).

The mean operative time was 33.8 ± 10.7 minutes in the Procise EZ group and 21.8 ± 7.5 minutes in the Procise Max group, corresponding to a mean reduction of 12.0 minutes and indicating a significantly shorter operative time in the Procise Max group ($p < 0.001$).

CONCLUSIONS

The Procise Max coblation wand significantly reduces operative time in pediatric adenoidectomy compared with the Procise EZ system. This effect may be related to design-related features, including a wider wand diameter, which may facilitate a broader ablation field and reduce intraoperative clogging, thereby enabling a more continuous and efficient surgical process.

AUDIOLOGICAL SCREENING IN MATERNITY HOSPITALS IN KYRGYZSTAN

Munar[1]

[1]*Kyrgyz-Russian Slavic University*

BACKGROUND & AIM

Audiological screening of newborns is a procedure that allows you to identify possible hearing defects as quickly as possible. The detection of hearing impairments by speech leads to a very late diagnosis and delays the start of sign language rehabilitation. The diagnosis of hearing disorders in children at a very early age is possible only when conducting audiological screening of newborns – a mass hearing examination using quick and simple methods in order to identify children. Considering the above, the aim of our work is the large-scale introduction of early hearing diagnosis in children in the Kyrgyzstan.

MATERIAL & METHODS

From 2017 to 2023, 19924 children were examined in a clinical maternity hospital in four maternity hospitals in Kyrgyzstan, 221 newborns with varying degrees of hearing impairment were identified; 30948 children were examined in the city perinatal center, 240 of them newborns with hearing pathology; the maternity hospital of the Osh City Clinical Hospital: 24508 children were examined, 404 children were identified with hearing pathology. Jalal-Abad regional maternity hospital – total examined since 2021 (due to technical reasons, screening began in 2021) 5818 children, 221 of them were not screened. The audiological screening program includes 2 stages.

RESULTS

Newborn screening was carried out for 85-90% of all children born in participating maternity hospitals; A certain percentage of newborns (1-2%) showed abnormalities as a result of screening; It has been established that the equipment used to evaluate otoacoustic emission has high accuracy and reliability; A certain percentage of children (5-10%) were referred for additional examination due to questionable results; The implementation of screening has improved the early detection of hearing disorders; Difficulties in providing full coverage in remote regions were noted; The importance of early intervention for the development of a child's speech, social skills and learning is emphasized; It is necessary to expand screening to all maternity hospitals in the country. Conduct regular training of medical personnel. Implement electronic result accounting systems to improve monitoring efficiency.

CONCLUSIONS

The implementation of the program has made it possible to detect hearing disorders in newborns in a timely manner; Maternity hospitals and medical institutions are provided with modern diagnostic equipment; Systematic training of medical personnel has been organized to work with the equipment and interpret the results; The program lays the foundation for the creation of a system for the early detection and treatment of hearing disorders; The program requires sustainable financing, scaling to all regions of the country and inclusion in national standards of health care.

Retropharyngeal And Parapharyngeal Abscesses In Children: A Series Of 10 Cases

AMEL BOUKERCHE[1,2], **NASSEREDDINE OMAR OUSLIM**[1,2], **SOUMIA BELLAL**[1,2], **IBRAHIM FERGOUG**[1,2]

[1]*Oto-Rhino-Laryngology, Head and Neck Surgery Department, EHU, Oran, Algeria;* [2]*Faculty of Medicine / Oran University, Algeria*

BACKGROUND & AIM

Retropharyngeal and parapharyngeal abscesses are rare but potentially life-threatening deep neck infections, particularly in children. Early diagnosis and appropriate management are crucial to prevent severe complications.

The aim of this study was to analyze the clinical features and therapeutic management of these deep neck infections in children.

MATERIAL & METHODS

We conducted a retrospective study including children hospitalized for retropharyngeal or parapharyngeal abscesses between 2023 and 2025.

RESULTS

Ten patients were included. The mean age was 38 months (range: 16 months–11 years), with a male predominance (7/10). Prior use corticosteroids was reported in six cases. Fever and odynophagia/dysphagia were present in all patients, while lateral cervical swelling (3 cases) and torticollis (2 cases) were less frequent. Oropharyngeal bulging was observed in 90% of cases, and trismus in three patients.

CT scan revealed a retropharyngeal abscess in 7 cases, parapharyngeal in 3 cases, with one case showing extension between both spaces. The mean abscess size was 2.6 cm (1.7–5 cm).

All patients received intravenous cefotaxime plus metronidazole. Three patients improved with antibiotics alone. Surgical drainage was performed in seven cases (six intraoral, one external approach). Outcomes were favorable in all patients.

CONCLUSIONS

Deep neck abscesses in children require prompt recognition and multidisciplinary management. Surgical intervention should be considered based on clinical severity, imaging findings, and abscess accessibility.

KEYWORDS

Solitary Mucosal Neuroma Of The Tongue In A Child Mimicking A Traumatic Granuloma: A Rare Case Report

Arda Yavuz[1], **Hatice Ünsal**[1], **Murat Aydın Sav**[2], **Müzeyyen Doğan**[1]

[1]*Department of Otorhinolaryngology, Yeditepe University Hospital, Istanbul, Turkey;* [2]*Department of Pathology, Yeditepe University Hospital, Istanbul, Turkey*

BACKGROUND & AIM

Mucosal neuroma (MN) is a benign neural lesion most commonly associated with multiple endocrine neoplasia type 2B (MEN2B), typically presenting as multiple oral papules. Solitary mucosal neuroma (SMN) without syndromic features is exceedingly rare, especially in the pediatric population. This study aims to present a rare case of a genetically confirmed, MEN2B-negative solitary mucosal neuroma confined to the tongue in a child and to highlight its diagnostic challenges.

MATERIAL & METHODS

A 13-year-old boy presented with a painless, slowly enlarging nodular lesion on the left lateral border of the tongue, initially suspected to be a traumatic granuloma due to chronic biting. The lesion was completely excised under local anesthesia. Histopathological examination and immunohistochemical analysis, including S-100 and EMA staining, were performed. Additionally, RET proto-oncogene mutation analysis and endocrinological evaluation were conducted to exclude MEN2B.

RESULTS

Histopathological examination revealed subepithelial proliferation of tortuous nerve fascicles with perineural thickening. Immunohistochemistry demonstrated diffuse S-100 positivity in neural elements and EMA positivity in perineurial cells, consistent with solitary mucosal neuroma. RET mutation analysis was negative, and no systemic or endocrinological

abnormalities were detected. The postoperative course was uneventful, and no recurrence was observed at six-month follow-up.

CONCLUSIONS

Solitary mucosal neuroma of the tongue is an extremely rare entity in the pediatric population and may clinically mimic reactive lesions such as traumatic granuloma. This case highlights the importance of considering neural tumors in the differential diagnosis of persistent oral nodules. Comprehensive histopathological, immunohistochemical, and genetic evaluation is essential to exclude MEN2B and guide appropriate management.

PP-532

Recurrent Preseptal Cellulitis Associated With Sinonasal Disease: A Case Report

ABDULLAH KONUR ALP KARA[1], **DİLARA ÜLKÜ İLBAŞ**[1], **ZEHRA BETÜL PAKSOY**[1]

[1]*Bilkent City Hospital*

BACKGROUND & AIM

Preseptal cellulitis is an infectious inflammation of the periorbital soft tissues anterior to the orbital septum. Although most cases respond favorably to empirical systemic antibiotics, recurrent episodes warrant systematic investigation for predisposing factors — most notably sinonasal pathology, anatomical obstruction, immunological deficiencies, dermatological conditions, and persistent infectious foci. We present a diagnostically and therapeutically complex case of recurrent right-sided preseptal cellulitis associated with chronic ipsilateral rhinosinusitis, further complicated by DRESS syndrome and multiple severe drug hypersensitivities, ultimately managed with revision functional endoscopic sinus surgery (FESS) and individualized antimicrobial therapy.

MATERIAL & METHODS

A 6-year-old boy presented with recurrent right-sided orbital cellulitis associated with chronic rhinosinusitis and was hospitalized on four occasions over a 30-month period. The first episode required endoscopic sinus surgery and prolonged intravenous antibiotic therapy; however, treatment was complicated by Drug Reaction with Eosinophilia and Systemic Symptoms (DRESS) secondary to vancomycin and beta-lactam exposure. Recurrent attacks were subsequently managed conservatively, although imaging repeatedly demonstrated persistent ipsilateral sinonasal inflammation with orbital extension and later development of a subperiosteal phlegmon. Ophthalmologic evaluations consistently excluded visual loss or ophthalmoplegia. Comprehensive immunological investigations revealed no evidence of primary immunodeficiency. Due to multiple severe hypersensitivity reactions, extensive allergological testing was performed and demonstrated positivity to vancomycin, ceftriaxone, and clindamycin, while linezolid had previously caused an anaphylactoid reaction. Intravenous tigecycline was therefore administered successfully as salvage therapy. Revision functional endoscopic sinus surgery restored sinonasal drainage, resulting in marked clinical and biochemical improvement.

RESULTS

This case highlights three important clinical considerations in the management of recurrent periorbital infections. First, recurrent preseptal cellulitis should prompt investigation for underlying sinonasal pathology rather than being regarded as an isolated eyelid infection. In our patient, persistent frontoethmoidal inflammation and postsurgical synechiae created a chronic infectious focus, and definitive improvement was achieved only after surgical correction of these anatomical abnormalities. Accordingly, nasal endoscopy and paranasal sinus imaging are essential in patients with recurrent periorbital infections. Second, severe multidrug hypersensitivity can significantly complicate antimicrobial management. DRESS syndrome and confirmed allergies to multiple first-line antibiotics necessitated the use of tigecycline as salvage therapy under multidisciplinary supervision, emphasizing the value of detailed allergological assessment and patch testing. Third, revision functional endoscopic sinus surgery successfully restored sinonasal drainage and eliminated the underlying mechanical and inflammatory factors, resulting in stable postoperative recovery without early recurrence.

CONCLUSIONS

Recurrent preseptal cellulitis should prompt a structured otorhinolaryngological assessment and high-resolution sinonasal imaging in every case. Early identification of underlying sinonasal pathology, combined with individualized antimicrobial selection in patients with severe drug hypersensitivities, can prevent orbital complications and reduce the risk of recurrence. This case highlights the indispensable role of multidisciplinary collaboration — involving otorhinolaryngology, infectious diseases, allergy and immunology, and dermatology — when standard therapeutic pathways are unavailable.

PP-533

The Mask Of Adenovirus: Pediatric Sigmoid Sinus Thrombosis And Epidural Empyema Complicating Acute Otitis Media

Berfin OZSOY[1], **Ilker AKYILDIZ**[1]

[1]*Department of Otolaryngology, Etlik City Hospital, Ankara, Türkiye*

BACKGROUND & AIM

Acute otitis media (AOM) is a common pediatric infection that rarely progresses to life-threatening intratemporal or intracranial complications in the modern antibiotic era. Among these, otogenic sigmoid sinus thrombosis (SST) and concomitant epidural empyema represent critical neuro-otologic emergencies. When AOM co-occurs with systemic viral infections like gastroenteritis, the diagnostic process becomes significantly complicated. Dehydration from gastrointestinal losses induces a hypercoagulable state that may accelerate dural venous sinus thrombosis, while overlapping constitutional symptoms often mask the early neurological red flags of intracranial extension.

MATERIAL & METHODS

A 4-year-old girl presented to a emergency department with a 10-day history of vomiting and diarrhea, followed by high fever and left-sided otalgia. Laboratory investigations revealed a markedly elevated C-reactive protein (CRP) level of 250 mg/L. She was hospitalized with diagnoses of acute otitis media (AOM), tonsillitis, and gastroenteritis, and intravenous ceftriaxone therapy was initiated. A stool viral panel was positive for adenovirus.

Although the gastrointestinal symptoms resolved by the second day of hospitalization, the patient developed a progressive severe headache that persisted despite resolution of the fever. Left-sided aural fullness continued without otorrhea.Contrast-enhanced temporal bone computed tomography performed because of the intractable headache demonstrated left sigmoid sinus thrombosis (SST) with an adjacent epidural empyema. Intravenous metronidazole was added, and the patient was urgently transferred to tertiary care Ear, Nose, and Throat (ENT) department due to impending intracranial decompensation.

RESULTS

Following multidisciplinary evaluation by the Otolaryngology and Pediatric Infectious Diseases teams, the patient underwent urgent surgical intervention. A left tympanomastoidectomy was performed to eradicate the primary otogenic source of infection, revealing extensive mastoiditis and granulation tissue intraoperatively. Simultaneously, successful drainage of the epidural empyema and decompression of the sigmoid sinus plate were achieved. In addition, a left ventilation tube was inserted via myringotomy to ensure adequate middle ear ventilation and drainage.

Postoperatively, the patient received targeted broad-spectrum intravenous antibiotic therapy consisting of ceftriaxone and vancomycin, along with pediatric anticoagulation therapy for thrombus management. The patient demonstrated rapid neurological and clinical improvement, with complete resolution of the intractable headache, normalization of inflammatory markers, and no evidence of focal neurological deficits or septic embolic complications during follow-up.

CONCLUSIONS

This case highlights the importance of maintaining a high index of suspicion for intracranial complications in children with AOM, even when concomitant infections appear to account for the clinical presentation. Coexisting adenoviral gastroenteritis may obscure evolving intracranial pathology and contribute to thrombotic complications through dehydration. Persistent headache despite resolution of gastrointestinal symptoms should therefore be considered an important warning sign. Early recognition and prompt surgical intervention, including tympanomastoidectomy and ventilatioan tube insertion, drainage of intracranial empyema are essential to prevent life-threatening complications and achieve favorable clinical outcomes.

Comparison Of Cold Knife Dissection And Bipolar Tonsillectomy In Terms Of Secondary Postoperative Hemorrhage

Gokhan Guney[1], **Tankut Uzun**[1]

[1]*Department of Otolaryngology ,Cigli Training and Reserch Hospital ,İzmir ,Türkiye*

BACKGROUND & AIM

Post-tonsillectomy hemorrhage remains one of the most important complications following tonsillectomy and adenotonsillectomy, and the potential influence of surgical technique on this outcome continues to be clinically relevant. The present study aimed to compare cold knife dissection and bipolar tonsillectomy in terms of the risk of secondary postoperative hemorrhage in patients undergoing tonsillectomy or adenotonsillectomy

MATERIAL & METHODS

A total of 742 patients who underwent tonsillectomy or adenotonsillectomy were retrospectively reviewed. Demographic characteristics, surgical indications, operative technique, and the occurrence of secondary postoperative hemorrhage were analyzed. Surgical indications were categorized as obstruction or infection, and operative technique was classified as either cold knife dissection or bipolar technique. The primary outcome was the association between surgical technique and secondary postoperative hemorrhage. In addition, the relationships between postoperative hemorrhage and sex as well as surgical indication were evaluated. Statistical significance was defined as a p value < 0.05

RESULTS

The mean age of the study population was 8.86 ± 7.56 years. Of all patients, 54.6% were male and 45.4% were female. The indication for surgery was obstruction in 57.8% of cases and infection in 42.2%. Cold knife dissection was performed in 55.4% of patients, whereas the bipolar technique was used in 44.6%. The overall rate of secondary postoperative hemorrhage was 3.0%. No statistically significant association was observed between surgical technique and secondary postoperative hemorrhage (p = 0.430). Similarly, no significant relationship was identified between secondary hemorrhage and sex (p = 0.383) or surgical indication (p = 0.575). These findings indicate that the two surgical techniques have comparable safety profiles with regard to secondary bleeding

CONCLUSIONS

Cold knife dissection and bipolar tonsillectomy did not differ significantly in terms of secondary postoperative hemorrhage. These results suggest that both techniques can be performed safely when appropriate surgical practice and standardized postoperative follow-up are maintained. In clinical decision-making, however, factors beyond hemorrhage risk—such as operative time, intraoperative blood loss, postoperative pain, and surgeon experience—should also be taken into consideration when selecting the surgical technique

ASSESSMENT OF PRIMARY AND SECONDARY POST-TONSILLECTOMY HEMORRHAGE IN PEDATRIC PATIENTS: A SINGLE-CENTERED EVALUATION

İpek Öztürkmen[1], **Burak Kaan İnan**[1], **İbrahim Salih Geçer**[1], **Zahide Mine Yazıcı**[1]

[1]*Bakırköy Dr. Sadi Konuk Research and Training Hospital*

BACKGROUND & AIM

Tonsillectomy is one of the most common otolaryngologic surgeries in pediatric patients. Post-tonsillectomy hemorrahage is the most common complication. Bleeding that occurs within the first 24 hours after surgery is called primary bleeding while bleeding that occurs after 24 hours is referred to as secondary bleeding. The purpose of this study is to determine risk factors of post-tonsillectomy hemorrhage and their correlations for increased bleeding.

MATERIAL & METHODS

The clinical data from who underwent tonsillectomy in our hospital from 5 August 2015 to 3 March 2026 were retrospectively collected. The variables including gender, age, onset of bleeding, tonsil grade, season, surgical intervention in patients presenting with post-tonsillectomy hemorrhage were collected from hospital records.

RESULTS

According to the data collected so far; 700 pediatric patients were included in study. The bleeding rate was 2% (n=15). Bleeding cases were mostly observed in winter (44.4%) and autumn (33.3). The majority of bleeding episodes occurred between postoperative days 5–10 and were consistent with secondary hemorrhage.

CONCLUSIONS

Secondary post-tonsillectomay hemorrhage is most life-threatining complication. Post-operative follow up is so crucial. Age and season were one of the significant variables affecting bleeding risk. This study provides an important basis for future studies.

Socio- Economic And Health Implications Of Impacted Oro-Esophageal Foreign Bodies In A Tertiary Health Care Facility In Ghana

S. Mensa-Yawson1, M.I.D.D. Darko2, J.A.M. Amuzu2, M.K. Berko-Addo2[1]

[1]*37 Military Hospital, Accra, Ghana.*

BACKGROUND & AIM

Ingestion of oro-esophageal foreign bodies (FBs) is a common clinical issue that can present with a wide range of symptoms, from minor self-limiting illnesses to serious, life-threatening conditions. Delaying the removal of impacted FBs can increase the risk of complications and reduce the chance of successful removal. Despite its significance as a medical emergency with potential socioeconomic and health impacts, there is a paucity of data on its implications. This study was to assess the socio-economic implications as well as the clinical features and treatment outcomes of impacted oro-esophageal foreign bodies (IOEFBs) in a tertiary health care facility in Ghana.

MATERIAL & METHODS

This was a prospective cross-sectional study employing a mixed-methods approach. The study was conducted at the 37 Military Hospital in the Greater Accra Region of Ghana from 1st March 2025 to 30th September 2025. A total of 60 participants aged 6 months to 65 years who presented with oro-esophageal FB impaction were enrolled using consecutive sampling. Data collection involved review of medical records, structured questionnaires, and semi-structured interviews with patients, families, and healthcare professionals. Demographic and clinical characteristics, types and locations of FBs, treatment modalities, outcomes, and socioeconomic impacts were documented. Descriptive and inferential statistics were performed using SPSS version 25, with p-values less than 0.05 considered statistically significant.

RESULTS

Young children aged 6 months to 5 years constituted 56.7% of cases, with male predominance (61.7%). Coins were the most frequently ingested foreign body (70%), followed by bones (13.3%) and disc batteries (6.7%). The upper esophagus was the most common site of impaction (46.7%). Dysphagia was the predominant presenting symptom (45%), and 85% of patients presented three or more hours after ingestion. Rigid esophagoscopy was the primary management modality (73.3%), with a successful removal rate of 86%. Treatment costs ranged between GHS 2,001–5,000 for 53.3% of participants. Financial constraints were the main barrier to accessing care (50%). Notably, 86.7% of participants experienced emotional or psychological distress, yet only 8.3% accessed mental health support. The majority rated their mental well-being as poor or very poor (76.6%). Delayed presentation was identified as the most common challenge in clinical management.

CONCLUSIONS

Impacted oro-esophageal foreign bodies represent a significant public health challenge in Ghana, predominantly affecting paediatric populations. While treatment outcomes were generally favourable at the tertiary level, substantial economic burden, significant psychosocial impacts, and delayed presentation patterns underscore the multifaceted nature of this condition. The findings emphasize the urgent need for comprehensive preventive strategies, improved health insurance coverage, integration of psychosocial support services, and public health education campaigns targeting parents and caregivers. Addressing this burden requires a multi-sectoral approach encompassing prevention, improved access to timely care, standardization of management protocols, and continued research to identify best practices.

Cross-Disciplinary Management Approach In Children With Costen Syndrome

Mariia Markova[1]

[1]*Russian Medical Academy of Continuous Professional Education, Audiology department*

BACKGROUND & AIM

The purpose of the study was to define: is the Costen syndrome in children correlation or coincidence?

MATERIAL & METHODS

143 patients aged from 6 to 14 years who made various ear complaints. All were examined by an otorhinolaryngologist, the tympanometry and the otoacoustic emission registration were performed. All diagnostic test were conducted using Audio-SMART (Neurosoft, Russia Federation).The cohort of patients with isolated otalgia (14.1%) was examined by a neurologist to exclude facial neuropathy. In 58.6% of cases, the secretory otitis and/or dysfunction of the auditory tubes was confirmed. The dentist examined 137 of 143 children and in 96.4% of cases confirmed the dental diagnosis: anomalies of the position of the teeth - in 16% of cases, anomalies of the ratio of dental arches - in 54%, malocclusion - in 10% and malformation of the jaw - in 20% of cases. The majority of patients had orthopedic disorders (N=82; 87.1%).

RESULTS

Costen syndrome or temporomandibular dysfunction in children is not a coincidence, but is a correlation

CONCLUSIONS

In turn, it is a guide to an cross-disciplinary management approach of patients with this pathology.

Early Closed Reduction In Neonatal Nasal Fractures: Functional And Aesthetic Outcomes In A Four-Case Series

Ömer Faruk Çalım[1], **Berat Akif Kaya**[1]

[1]*Department of Otorhinolaryngology, Faculty of Medicine, Istanbul Medipol University*

BACKGROUND & AIM

Neonatal nasal fractures may occur due to intrauterine or perinatal trauma and can result in respiratory distress, feeding difficulties, and impaired growth. The reported incidence and classification of neonatal nasal deformities vary widely in the literature, and there is no clear consensus regarding optimal management. While conservative observation has been advocated by some authors, severe deformities or cases associated with compromised oxygenation may require early surgical intervention. This study aims to present our experience with early closed reduction of nasal fractures in four neonates within the first month of life and to evaluate short- and long-term outcomes.

MATERIAL & METHODS

Four neonates presenting with nasal deformity, respiratory symptoms, and feeding difficulties after birth were evaluated through clinical history and physical examination. All patients underwent closed nasal fracture reduction under general anesthesia within the first month of life. Postoperative stabilization was performed using a standardized combination of intranasal Doyle splints, thermal nasal casting, and nostril retainers. Postoperative follow-up included assessment of nasal airway patency, external nasal appearance, feeding status, need for revision, and potential complications. Patients were evaluated at 3 months, 6 months, and 1 year postoperatively.

RESULTS

All four patients presented with nasal deformity and mild respiratory distress in the early postnatal period. Immediate improvement in nasal airway patency was observed following closed reduction. Feeding difficulties, attributed to respiratory compromise, resolved in all patients during the early postoperative period. A marked improvement in external nasal appearance was achieved in all cases. At 3-month, 6-month, and 1-year follow-ups, no evidence of nasal obstruction or residual deformity was noted. No perioperative or postoperative complications occurred, and no revision procedures were required. Both short- and long-term outcomes were satisfactory in all patients.

CONCLUSIONS

Early closed reduction combined with adjunctive stabilization techniques, including Doyle splints, thermal nasal casting, and nostril retainers, appears to be a safe and effective treatment option for neonatal nasal fractures, providing favorable functional and aesthetic outcomes. Early intervention may alleviate feeding difficulties secondary to respiratory compromise, facilitate adequate weight gain, reduce upper airway obstruction, and potentially support normal midfacial development. This approach represents a reliable treatment modality in selected neonatal cases.

Remote Post-Discharge Support After Pediatric Tonsillectomy: A Systematic Review

Chatchaiwat Sriwichit[1,2], **Phuwasa Yostama**[1,2], **Thapthep Saowarot**[1]

[1]*Prapokklao hospital;* [2]*Faculty of Medicine, Chulalongkorn University*

BACKGROUND & AIM

Recovery after pediatric tonsillectomy occurs mainly at home, where parents manage pain, hydration, medication schedules, and warning signs. Remote post-discharge support may improve caregiver preparedness and reduce avoidable healthcare use. This review aimed to evaluate remote support interventions for parents after pediatric tonsillectomy or adenotonsillectomy and their effects on recovery and healthcare utilization.

MATERIAL & METHODS

A systematic review with narrative synthesis was performed. Eligible studies included pediatric patients undergoing tonsillectomy or adenotonsillectomy, parent- or caregiver-directed remote support delivered after discharge, and at least one recovery or healthcare utilization outcome. Interventions included nurse-led telephone calls, text messaging, mobile applications, web/video platforms, and automated digital tools. Extracted outcomes included pain, analgesic use, hydration, complications, caregiver knowledge, anxiety, confidence, satisfaction, emergency department visits, unscheduled contacts, readmissions, and costs. Because study designs, interventions, and outcomes were heterogeneous, results were synthesized narratively.

RESULTS

29 studies were reviewed. Studies spanned 1997–2026 and included randomized trials, cohort studies, quality improvement projects, and retrospective reviews. Telephone follow-up was the most common modality, followed by text messaging, mobile applications, video/web platforms, and automated systems. The most consistent benefit was reduced healthcare utilization. Text messaging programs reduced emergency department visits from 13.78% to 11.11% (p=0.02), and non-participants in one automated messaging program were 9.12 times more likely to attend the emergency department for education-related reasons (p=0.047). The largest randomized trial (n=771) found fewer unanticipated medical service uses with telephone follow-up than in-person visits (12% vs 26%, p=0.022). Caregiver knowledge, confidence, and satisfaction generally improved, with satisfaction ranging from 85% to 100%. Effects on child pain were inconsistent, although some studies reported improved analgesic adherence and fluid intake.

CONCLUSIONS

Remote post-discharge support appears most useful for improving caregiver preparedness and reducing avoidable healthcare use after pediatric tonsillectomy. Evidence for direct pain reduction is less consistent. Future studies should use standardized recovery outcomes and stronger prospective designs.

KEYWORDS

tonsillectomy, Post-operative care, nurse-led telephone calls, text messaging, mobile applications, web/video platforms, automated digital tools.

PP-541

PEDIATRIC MUCOEPIDERMOID CARCINOMA: A RARE CASE REQUIRING RADICAL PAROTIDECTOMY AND NECK DISSECTION

Ebru İnan[1], **Hakkı Caner İnan**[1]

[1]*University of Health Sciences, Bursa Yuksek Ihtisas Training and Research Hospital*

BACKGROUND & AIM

Salivary gland neoplasms in the pediatric population are rare, accounting for less than 5% of pediatric head and neck tumors. High-grade Mucoepidermoid Carcinoma (MEC) variants exhibit aggressive biological behavior and a high propensity for perineural invasion. The aim of this case report is to highlight the management of extensive facial nerve invasion in a pediatric patient and the importance of immediate nerve reconstruction.

MATERIAL & METHODS

A retrospective clinical evaluation was performed for a 7-year-old female patient who presented with a firm, 3x2 cm right infra-auricular mass. Diagnostic workup included physical examination, neck ultrasound, MRI, and Fine Needle Aspiration Biopsy (FNAB). The surgical approach involved radical parotidectomy, neck dissection, and immediate nerve grafting.

RESULTS

Intraoperative findings revealed the tumor encasing the facial nerve trunk and extending into the deep lobe. Following frozen section confirmation of malignancy and nerve invasion, a radical parotidectomy was performed. Immediate nerve reconstruction was achieved using a great auricular nerve cable graft, anastomosed between the stylomastoid foramen and the orbital branch. Final pathology confirmed high-grade MEC with negative surgical margins.

CONCLUSIONS

Extensive facial nerve involvement in pediatric MEC necessitates radical surgical intervention for oncological clearance. This case demonstrates that even when nerve sacrifice is unavoidable, immediate reconstruction with a cable graft is a viable strategy to address functional loss while ensuring patient survival.

Complex Oropharyngeal Stenosis Following Adenotonsillectomy: Planned Airway Management And Reconstructive Surgical Approach

Seren Karabiber Çiçek[1], **Ahmet Adnan Cırık**[1], **Şeyda Alsan**[1], **Yeşim Esen Yiğit Koçer**[1]

[1]*Department of Otorhinolaryngology, University of Health Sciences, Ümraniye Training and Research Hospital, Istanbul, Turkey*

BACKGROUND & AIM

Oropharyngeal stenosis is a rare but serious complication of adenotonsillectomy that may result in progressive dysphagia and challenging airway management. Early recognition is critical to prevent life-threatening airway compromise. This study aims to present a pediatric case of severe post-adenotonsillectomy oropharyngeal stenosis successfully managed with a combined surgical and medical approach.

MATERIAL & METHODS

A seven-year-old boy with a history of adenotonsillectomy three years prior presented with progressive dysphagia and reduced mouth opening. Clinical examination revealed dense fibrotic bands between the tonsillar pillars causing significant oropharyngeal narrowing. During preoperative assessment for unrelated orthopedic surgery, a difficult airway was anticipated. An elective tracheotomy was performed to secure the airway. Definitive treatment included excision of fibrotic bands using a sickle knife and monopolar cautery, followed by extensive adhesiolysis. The mucosal defect was reconstructed using a superiorly pedicled V-shaped nasopharyngeal advancement flap.

RESULTS

Two weeks postoperatively, a single-dose intralesional triamcinolone acetonide injection was administered under sedation to reduce the risk of restenosis. The patient was successfully decannulated and resumed full oral feeding with subsequent weight gain. At four months of follow-up, the oropharyngeal airway remained patent with no evidence of restenosis or functional impairment.

CONCLUSIONS

Early recognition and planned airway management are essential in post-adenotonsillectomy oropharyngeal stenosis. A combined approach including adhesiolysis, mucosal reconstruction, and adjunctive intralesional steroid therapy may provide durable airway patency and favorable functional outcomes. Increased awareness of this rare complication may help prevent life-threatening airway events.

Reversible Bevacizumab Induced Dysphonia: Case Report

Ahmet Ufuk Kılıçtaş[2], **Yunus Güneşer**[1]

[1]*Rize Recep Tayyip Erdoğan University Training and Research Hospital, Otorhinolaryngology;* [2]*Konya City Hospital, Otorhinolaryngology*

BACKGROUND & AIM

Anti-angiogenic treatment in adjunct with chemotherapy is widely used for the treatment of various cancers. These agents inhibit vascular endothelial growth factor (VEGF) signaling thereby inhibiting tumor proliferation and invasion. Dysphonia, or voice changes, has been documented, but is an underreported side effect of anti-angiogenic agents. We report a case of intermittent dysphonia in a patient with metastatic, platinum-refractory cervical cancer treated with bevacizumab.

MATERIAL & METHODS

A 48-year-old female with high grade mixed type cervical adenocarcinoma and concurrent right sided breast cancer was transitioned to palliative therapy with gemcitabine-bevacizumab for her cervical cancer. At a follow-up visit after four cycles of the new therapy, the patient complained of intermittent changes in her voice, describing periods of hoarseness or softness in her voice after the chemotherapy-sometimes to the point that her voice was inaudible.

A patient was referred to our ENT department due to dysphonia, and no abnormalities were found during examination. An MRI scan revealed no pathological findings. When oncology physicians attempted to change the treatment regimen, the dysphonia completely resolved after two weeks. Since this treatment was insufficient, bevacizumab was restarted as a palliative measure. One month after restarting the treatment, dysphonia recurred.

RESULTS

Despite no pathology being found in the patient's tests and examinations, they were prescribed proton pump inhibitors and given voice rest. Oncology physicians were informed about this side effect and advised to perform a benefit-risk analysis regarding continuation of treatment.

CONCLUSIONS

Many of the potential serious complications of bevacizumab can be averted by close monitoring of patient-specific variables, which should be measured at baseline and then at predetermined intervals throughout the course of therapy to maximize patient safety. Vocal adverse effects of anti-VEGF agents have been documented in landmark trials and case reports; however, clinicians are often unaware of this rare side effect. Time to onset of symptoms and reversibility of symptoms vary by patient and require further study. There may be long-term voice sequelae.

PP-544

Multidimensional Improvements Following Structured Voice Therapy In An Individual With Charcot-Marie-Tooth Disease: A Case Report

Ahmet Berkan Bilir[1], **Şevval Şahin**[1]

[1]*University of Health Sciences, Sancaktepe Sehit Prof. Dr. Ilhan Varank Training and Research Hospital, Department of Otolaryngology*

BACKGROUND & AIM

Charcot-Marie-Tooth disease (CMT) often leads to impaired phonatory control due to reduced motor function and muscular endurance. While vocal fatigue is a hallmark of this population, evidence-based therapy protocols remain under-reported. This case report investigates the multidimensional outcomes of a 6 week structured voice therapy program in a 32-year-old male patient with Charcot-Marie-Tooth disease type 1A (CMT1A), diagnosed six months prior despite long standing symptoms since childhood with gradual progression.

MATERIAL & METHODS

An individual presenting with persistent vocal fatigue andreduced vocal intensity was evaluated using videolaryngostroboscopy (VLS), Acoustic Voice Quality Index (AVQI), and the Turkish-validated version of the Voice Handicap Index-10 (VHI-10) at baseline, week 3, and week 6. To minimize intra-subject variability three recordingswere obtained at each time point, and only those meeting predefined quality criteria were averaged for analysis. A 6-week therapy program was implemented, split into two phases: semi-occluded vocal tract exercises (SOVTE) for the first 3 weeks, followed by vocal function exercises (VFE) forthe remainder of the program. All voice recordings were obtained under standardized conditions and analyzed using Praat.Therapy intensity was adjusted according to patient tolerance.

RESULTS

AVQI increased slightly from 7.39 ± 0.27 to 7.67 ± 0.44 at week 3, which we attribute to the shedding of compensatory hyperfunctional patterns and subsequent physiologicalreorganization. By week 6, AVQI improved to 6.55 ± 0.42, indicating enhanced overall voice quality. This was mirroredby a substantial drop in VHI-10 scores (from 27 to 18), reflecting a reduced perception of vocal handicap. VLS findings confirmed these gains, showing diminished supraglottic squeezing and improved vocal fold vibratory stability. Overall, clinically meaningful improvements were observed across acoustic, perceptual, and laryngeal measures.

CONCLUSIONS

Our findings demonstrate that a hybrid SOVTE-VFE approachcan effectively support more efficient phonation in CMT, despite its progressive neuromuscular nature. The mid-therapy fluctuation in acoustic metrics is a key clinical observation; it suggests a transition from maladaptive compensation to a more physiological phonatory effort. While promising, the seresults highlight the necessity for larger-scale studies to further validate physiologically based therapy approaches in neuromuscular disorders.

Perceptual Auditory Analysis Of Normal And Pathological Swallowing

Pedro Malavé[1]

[1]*Hospital Universitario Dr. Luis Razetti in Barcelona, Venezuela*

BACKGROUND & AIM

To establish perceptual standards via cervical auscultation using a conventional stethoscope to differentiate normal from pathological swallowing, including the identification of critical accessory sounds for assessing swallowing safety and efficacy.

MATERIAL & METHODS

A historical review was conducted to contrast the literature on cervical auscultation. The analysis characterized the acoustic parameters (pitch/timbre, intensity, duration, and sequence) of swallowing sounds and their pathophysiological correlation, with special focus on concurrent sounds.

RESULTS

Normal swallowing is perceived as a single, compact, brief event, described as a crisp laryngeal "click" followed by a smooth bolus "whoosh." Pathology manifests as fragmented, weak, or absent sounds, or as wet, gurgling sounds prolonged by residue in the valleculae or pyriform sinuses. Accessory sounds are diagnostic determinants: a brief, complete respiratory pause following deglutition is normal, whereas the absence of this pause or the presence of immediate post-swallow inspiratory "bubbling" are audible findings highly suggestive of laryngeal penetration or aspiration.

CONCLUSIONS

A well-defined repertoire of perceptual auditory standards exists to allow a robust presumptive diagnosis regarding normal or pathological swallowing. The key to the analysis lies in the integrated perception of the swallowing sequence and its synchrony with the respiratory cycle. This skill remains a cornerstone of clinical dysphagia assessment.

Evaluation Of Synthetic Pathological Voices Using Mordukhovich Subdifferential Optimization Phoneme-Level Approach

Rytis Maskeliunas[2], **Robertas Damasevicius**[2], **Kipras Pribusis**[1], **Virgilijus Uloza**[1]

[1]*Lithuanian University of Health Sciences;* [2]*Centre of Real Time Computer Systems, Kaunas University of Technology*

BACKGROUND & AIM

This study aimed to create an artificial intelligence–driven framework for phoneme-specific evaluation of synthetic pathological voices, with particular emphasis on alaryngeal speech following treatment for laryngeal carcinoma. The objective was to provide an objective assessment of speech quality by modeling the complex interactions and trade-offs among acoustic features associated with pathological phonation.

MATERIAL & METHODS

A dataset of 5,200 synthetic Lithuanian pathological voice samples was created using a controlled speech synthesis system designed to simulate different levels of hoarseness, breathiness, and strain. The corpus included vowels (/a/, /i/, /u/), plosives (/k/, /g/), fricatives (/s/, /z/, /ʃ/), and Lithuanian-specific complex sounds (/lj/, /ai/). For each phoneme, acoustic features including harmonics-to-noise ratio, cepstral peak prominence, and degree of aperiodicity were extracted. A multi-objective optimization approach based on Mordukhovich subdifferential analysis was then used to determine phoneme-specific Pareto fronts representing optimal acoustic thresholds. Synthetic voice samples were subsequently classified based on their distance from the Pareto front, yielding both an overall quality score and phoneme-level diagnostic feedback.

RESULTS

The proposed framework showed strong optimization convergence and reliable classification performance. Vowels demonstrated the best optimization outcomes (hypervolume up to 0.842) and the highest classification accuracy (F1-score up to 0.95), while consonants and more complex Lithuanian phonemes showed slightly lower, yet still robust, results. The overall mean classification performance achieved an F1-score of 0.86, with clear cluster separation, as reflected by a mean silhouette score of 0.70. In addition, the distance-to-Pareto-front metric showed strong correlation with clinically relevant acoustic parameters, including jitter, shimmer, and cepstral peak prominence.

CONCLUSIONS

This phoneme-specific Pareto-based framework offers a robust and interpretable approach to evaluating synthetic pathological voices and may serve as a valuable tool for the automated assessment of speech quality after surgical treatment of laryngeal cancer.

Acoustic Analysis Of Swallowing In Neurological Populations

Gabriela Guerra[1], **Ramon Hernandez Villoria**[3], **Pedro Malave**[1]

[1]*Hospital Universitario Dr. Luis Razetti de Barcelona;* [2]*Complejo Hospitalario Universitario Dr. Luis Razetti;* [3]*Hospital Clinicas Caracas;* [4]*CEMI- Centro de Especialidades Materno Infantil*

BACKGROUND & AIM

Objective: To evaluate the specific contributions of instrumental acoustic analysis to the characterization and monitoring of dysphagia in adults with central neurological pathologies.

MATERIAL & METHODS

Methods: A narrative literature review was conducted, focusing on studies utilizing accelerometry, electronic auscultation, or sound analysis in populations with Parkinson's disease (PD), stroke, multiple sclerosis (MS), and neuromuscular diseases.

RESULTS

Results: Acoustic techniques provide objective biomarkers. In PD, spectral analysis reveals swallowing sounds of lower amplitude and longer duration, which correlate with bradykinesia and pharyngeal rigidity, thereby allowing for the tracking of motor fluctuations. In stroke, a pattern of discoordination is identified, characterized by a prolonged latency between the oral propulsion sound and laryngeal closure, alongside chaotic post-swallow vibrations caused by residue. In MS and neuromuscular pathologies, weakness manifests as a progressive reduction in total acoustic signal power. High-resolution auscultation can detect silent micro-aspiration by identifying abnormal frequency components in the immediate post-swallow expiratory phase.

CONCLUSIONS

Conclusion: Instrumental acoustic analysis represents a significant contribution to the management of neurogenic dysphagia, providing quantifiable and reproducible parameters that reflect the disease-specific pathophysiological substrate. Its implementation in specialized clinical practice facilitates a more personalized and objective approach to treatment.

Instrumental acoustic analysis neurogenic dysphagia swallowing signal

PP-549

Swallowing Screening In The Older Adult Population: The Role Of Acoustic Analysis

Pedro Malavé[1]

[1]*Hospital Universitario Dr. Luis Razetti in Barcelona, Venezuela*

BACKGROUND & AIM

To evaluate the utility and reliability of instrumental acoustic swallowing analysis as a screening tool in older adults, comparing its performance with other clinical screening methods.

MATERIAL & METHODS

A scoping review of the literature was performed, analyzing studies that compare electronic cervical auscultation or computerized acoustic analysis with validated screening tools (such as the EAT-10 or volume-viscosity tests) and gold-standard instrumental methods (VFSS/FEES) in the geriatric population.

RESULTS

Acoustic analysis is an objective and rapid screening tool. Studies indicate that parameters such as increased total duration and reduced sound amplitude exhibit high sensitivity for detecting subclinical dysphagia or aspiration risk. Its main operational advantage over questionnaires is its independence from the patient's cognitive status. Compared to clinical tests based on the observation of signs, acoustic analysis detects anomalies before they become clinically apparent. However, its specificity for differentiating the type of dysphagia is moderate, always requiring a confirmatory evaluation.

CONCLUSIONS

Instrumental acoustic analysis provides objectivity and efficiency to dysphagia screening in older adults, complementing and enhancing existing clinical tools. Its implementation in multi-stage protocols can optimize resources and enable earlier, more accurate detection of at-risk patients, facilitating timely intervention.

Validation Of Lithuanian Version Of Voice Handicap Index-10

Marius Polianskis[1,2], **Rasa Bliūdžiūtė**[1], **Eugenijus Lesinskas**[1,2]

[1]*Vilnius University;* [2]*Vilnius University Hospital Santaros Klinikos*

BACKGROUND & AIM

The Voice Handicap Index-10 (VHI-10) is a widely used, 10-item patient-reported outcome measure for quantifying voice-related handicap. While validated in numerous languages, no Lithuanian version existed to date. The aim of this study was to translate, culturally adapt, and assess the psychometric properties of the Lithuanian version of the VHI-10 (VHI-10LT).

MATERIAL & METHODS

Translation and cultural adaptation were performed in accordance with World Health Organization standards for cross-cultural questionnaire translation, including forward translation, expert panel review, back-translation, and pilot testing. The study prospectively enrolled 134 patients with confirmed stable voice disorders and 77 healthy controls. All participants completed VHI-10LT, the Glottal Function Index (GFI-LT), a voice quality Visual Analogue Scale (VAS) alongside clinician-rated GRBAS assessment and maximum phonation time (MPT) measurement. A retest was performed at 2–4 weeks. Internal consistency was evaluated using Cronbach's alpha coefficient, discriminant validity by the Mann-Whitney U test, criterion validity by Spearman's rank correlation coefficient, test-retest reliability by the intraclass correlation coefficient, and diagnostic accuracy by receiver operating characteristic curve analysis.

RESULTS

The VHI-10LT demonstrated excellent internal consistency, meaning all ten questions reliably measure the same underlying construct. Patients with confirmed voice disorders scored substantially and significantly higher than healthy controls, confirming that the questionnaire is capable of clearly distinguishing between these two groups. Criterion validity analysis revealed meaningful associations between the VHI-10LT and all major clinical measures of voice function, including glottal function, clinician-rated voice quality, self-perceived voice quality, and maximum phonation time. Test-retest reliability in the control group was good-to-excellent, indicating that when a person's voice condition remains stable, the questionnaire produces consistent results across repeated administrations. Finally, ROC analysis identified an optimal score cut-off that provided both high sensitivity and high specificity, demonstrating that the VHI-10LT is an accurate tool for differentiating patients with voice disorders from healthy individuals in a clinical setting.

CONCLUSIONS

The VHI-10LT demonstrated excellent internal consistency, robust criterion and discriminant validity, and good-to-excellent test-retest reliability. The VHI-10LT is a reliable and valid instrument for assessing voice-related handicap in Lithuanian-speaking patients and is suitable for both clinical and research applications.

The Dependence Of Voice Characteristics On The Form And Degree Of Hearing Loss

Merkulava Alena[2], **Daldova Valeryia**[1,2], **Kobachidze Alexsandre**[2]

[1]*11 of the city clinical Hospital, Minsk, Belarus.*; [2]*Belarusian State Medical University*

BACKGROUND & AIM

Today, there is a tendency towards an increase in the incidence of hearing impairment in children. In the absence of auditory feedback, children with impaired hearing suffer from voice and speech disturbances due to inability to control their own voices. The study of this issue will help develop methods for early diagnosis of voice disorders, and further rehabilitation and medical prevention aimed at improving voice quality in children with hearing loss.

MATERIAL & METHODS

The study involved 100 aged 4-12 years with a diagnosis of bilateral chronic sensorineural hearing loss. The children underwent subjective and objective voice research methods. An acoustic analysis of the voice was carried out using the «LingWaves».

RESULTS

The most prevalent complaint in children (72.94%) was a change in voice quality. Acoustic analysis of the voice in children with hearing loss showed the following voice disorders: in Grades 3 to 4 hearing loss, a shift in F0 towards low frequencies of 239.78 Hz is seen (95% CI 228.6 - 250.95) ($p < 0.05$). Children with hearing loss had high Jitter of 1.82 (95% CI 1.22 - 2.43) that was nearly three times over the normal limits ($p < 0.05$). MPT in children with Grades 3 to 4 hearing loss was lower than that in children with normal voice and hearing and measured 5.41 s (95% CI 1.22 - 2.43) ($p < 0.05$).

CONCLUSIONS

The study found that hearing impairment is associated with the development of voice abnormalities. Medical care for children with Grades 3 to 4 hearing loss should include measures to identify and treat those voice abnormalities.

AI-Enabled Mucus Segmentation In Nasal Endoscopy With State Space And Attention-Based Modeling

Dipesh Gyawali[1], **Jonathan Bidwell**[1], **Elena Karras**[1], **Kayla Baker**[1], **Elena Bartolone**[1], **Dhara Patel**[1], **Duncan Green**[1], **Ashley Conley**[1], **Akio Fujiwara**[1], **Thomas Mundy**[1], **Quinn O'Malley**[1], **Valentina Vargas Marin**[1], **Edward D. McCoul**[1]

[1]*Department of Otorhinolaryngology, Ochsner Health, New Orleans, LA, USA.*

BACKGROUND & AIM

Diagnostic nasal endoscopy (DNE) is essential for sinusitis evaluation, yet mucus identification relies on subjective assessment requiring extensive training, limiting care access, which may be expanded using Artificial intelligence (AI)-enabled segmentation. However, existing models struggle with thin translucent layers, irregular boundaries, and illumination artifacts across DNE. We developed SUM-MucusNet, an AI model, to overcome these challenges and assist clinicians in accurate mucus identification.

MATERIAL & METHODS

We developed SUM-MucusNet, an AI model, integrating hierarchical Mamba state-space modeling with Swin-UNet architecture, deformable convolutions for boundary refinement, and Convolutional Block Attention Module (CBAM) for illumination management. The model was trained on 3,486 expert-annotated images from 454 patients (mean age 61±1.2 years; 42% male). Four medical graduate annotators achieved inter-rater reliability of Fleiss' kappa=0.80. Performance was evaluated using a Dice coefficient, measuring segmentation overlap Intersection over Union (IoU), precision, and recall through five-fold cross-validation. Comparative analysis included YOLOv8, YOLOv11, Swin-UNet, and Swin-UMamba models.

RESULTS

SUM-MucusNet achieved comparable performance to a trained ENT with a Dice coefficient score of 71% and IoU of 63% when overlapping area was compared against the trained ENTs annotations as ground truth. This is the highest accuracy among tested models. This indicates that there is a 71% overlap between the segmentation mask and ground truth, suggesting a fair to good mask fit. Performance improved cases of blurry images (89.3% true positive rate), diverse mucus morphology types (i.e. strands, crust, globs and trails) (90.8% true positive rate), and illumination artifacts (69% true positive rate). Real-time processing reached 17.3 frames per second, exceeding the clinical threshold. Boundary detection improved by 42%, and false positives from reflections decreased by 61%.

CONCLUSIONS

SUM-MucusNet demonstrates clinically viable automated mucus segmentation, addressing thin mucus detection, boundary delineation, and illumination challenges. Achieving agreement comparable to inter-physician reliability while maintaining real-time performance, this AI system shows potential for standardizing evaluations and expanding diagnostic endoscopy access to non-specialist settings globally.

Delayed Post-Traumatic Skull Base Defect Presenting As Pneumococcal Meningoencephalitis In A Child

João Tavares Correia[1], **João Vilaça**[1], **Francisco Alves de Sousa**[1], **João Carvalho Almeida**[1], **Isabel Silva Carvalho**[1], **João Lino**[1]

[1]*Unidade Local de Saúde de Santo António*

BACKGROUND & AIM

Delayed cerebrospinal fluid (CSF) leaks following pediatric skull base trauma are rare but potentially life-threatening. We hypothesize that remote anterior skull base fractures may remain clinically silent and later manifest as invasive pneumococcal meningoencephalitis, and that a unilateral endoscopic multilayer reconstruction provides definitive treatment with reduced morbidity compared to transcranial approaches.

MATERIAL & METHODS

An 11-year-old girl was admitted with meningoencephalitis due to Streptococcus pneumoniae with associated bacteremia. She had sustained traumatic brain injury four years earlier requiring craniotomy and titanium mesh reconstruction of the anterior skull base. Brain magnetic resonance imaging demonstrated diffusion-restricted intraventricular material compatible with pyogenic content. Computed tomography identified focal osseous defects of the left anterior skull base involving the ethmoidal fovea/lateral lamella and planum sphenoidale, with inferior herniation of CSF-density tissue consistent with CSF fistula and meningoencephalocele. After multidisciplinary evaluation, prolonged intravenous antibiotic therapy was administered (meningitic-dose ceftriaxone followed by vancomycin and meropenem). Upon infection control, unilateral endoscopic sinus surgery was performed with complete exposure of the defect and multilayer reconstruction using oxidized cellulose, collagen matrix, autologous septal bone graft, pedicled nasoseptal flap, and fibrin sealant.

RESULTS

The procedure was completed without intraoperative complications. No postoperative CSF leak, neurological deficit, or infectious recurrence was observed. The unilateral approach preserved contralateral sinonasal anatomy and avoided frontal lobe retraction.

CONCLUSIONS

Delayed post-traumatic CSF fistula should be suspected in pediatric bacterial meningoencephalitis with prior skull base trauma. Endoscopic unilateral multilayer reconstruction represents the optimal surgical strategy in selected pediatric anterior skull base defects. It ensures effective CSF leak closure while minimizing neurovascular risk, avoiding frontal lobe manipulation, and preserving contralateral nasal anatomy during craniofacial development. This case reinforces the paradigm shift from transcranial to minimally invasive endoscopic management in delayed post-traumatic skull base pathology.

Pneumocephalus Following Primary Septorhinoplasty Performed With Ultrasonic Osteotomy: A Case Report

Furkan Bünyamin Budak[1], **Betül Özkan**[1], **Salih Aydın**[1]

[1]*Istinye University Faculty of Medicine, Department of Otolaryngology–Head and Neck Surgery, Istanbul, Türkiye*

BACKGROUND & AIM

Rhinoplasty and septorhinoplasty are commonly performed procedures for both aesthetic and functional purposes, with reported complication rates ranging between 4% and 18%. Pneumocephalus is an extremely rare intracranial complication in rhinologic surgery, defined as the presence of air within the cranial cavity. Piezoelectric (ultrasonic) osteotomy is widely used in rhinoplasty due to its selective bone-cutting ability while preserving surrounding soft tissues. The aim of this case report is to present a rare case of pneumocephalus following piezoelectric osteotomy.

MATERIAL & METHODS

A 46-year-old female patient presented with nasal obstruction and aesthetic complaints. She had a history of nasal trauma due to a fall 10 months earlier, which had been treated with closed reduction and external splinting. Physical examination revealed septal deviation, inferior turbinate hypertrophy, nasal axis deviation, dorsal hump, tip ptosis, and bulbous tip deformity. Preoperative computed tomography showed no defect in the anterior skull base or cribriform plate. Open septorhinoplasty with inferior turbinate reduction using radiofrequency was planned under general anesthesia. Osteotomies were performed using a piezoelectric device. No intraoperative cerebrospinal fluid leak or any complication was observed.

RESULTS

On postoperative day 2, the patient developed sudden severe headache, nausea, and vomiting. Neurological examination was normal (GCS 15), and no cerebrospinal fluid rhinorrhea was detected. Cranial CT demonstrated extensive intracranial air, predominantly in the frontal regions and extending along cortical sulci and periventricular areas. No signs of tension

pneumocephalus were observed. The patient was managed conservatively with head elevation, bed rest, and high-flow oxygen therapy. Serial imaging showed progressive resolution of intracranial air, with complete absorption by postoperative day 14. The patient was discharged without neurological sequelae.

CONCLUSIONS

Pneumocephalus is a rare but possible complication following septorhinoplasty performed with piezoelectric osteotomy. Early cranial imaging should be performed in patients presenting with sudden severe postoperative headache. Conservative management is usually effective in stable patients without tension pneumocephalus.

Intranasal Ectopic Tooth: Endoscopic Finding

Catarina Martins Pinto[1], **Francisco Moreira Silva**[1], **Mariana Santos**[1], **Inês Veloso**[1], **Duarte Morgado**[1], **João Rodrigues**[1]

[1]*ULS Alto Ave*

BACKGROUND & AIM

Intranasal ectopic teeth are rare clinical entities that may arise from supernumerary teeth, developmental disturbances, trauma, or craniofacial anomalies. Although sometimes asymptomatic, they may present with unilateral nasal obstruction, epistaxis, rhinorrhea, or recurrent infection.

MATERIAL & METHODS

A single-patient case report was conducted following incidental identification of an intranasal ectopic tooth during outpatient otorhinolaryngology consultation.

RESULTS

We report the case of a 27-year-old male referred for routine otorhinolaryngology evaluation. The patient denied nasal obstruction, epistaxis, rhinorrhea, facial pain, or recurrent infections.

Nasal endoscopy revealed a whitish, hard, well-defined structure arising from the floor of the right nasal cavity, partially covered by mucosa, without surrounding inflammation or purulent discharge.

Computed tomography (CT) of the paranasal sinuses demonstrated a well-circumscribed hyperdense structure with attenuation characteristics consistent with dental tissue, compatible with a supernumerary tooth located in the inferior nasal cavity. No adjacent bony erosion, mucosal thickening, or associated sinus disease was observed.

Asymptomatic cases may be managed expectantly with careful follow-up. CT imaging plays a crucial role in confirming the diagnosis and excluding associated pathology.

CONCLUSIONS

Intranasal supernumerary teeth may present as incidental findings. In selected asymptomatic patients without evidence of complications, conservative management with close surveillance represents a reasonable and safe approach.

KEYWORDS

Supernumerary teeth, nasal cavity

Evaluation Of Paranasal Sinus CT Findings And Densitometric Parameters In Patients Diagnosed With Fungal Sinusitis In A Tertiary Care Center

Prof. Dr. Abdulvahap AKYİĞİT[1], **Doç. Dr. Orkun EROĞLU**[1], **Dr.Öğr.Üyesi Seda Soğukpınar Karaağaç**[2], **Dr.Sevgi Uygungelen Yunay**[1], **Prof. Dr. İrfan KAYGUSUZ**[1]

[1]*Fırat Üniversitesi Tıp Fakültesi, Kulak Burun Boğaz Anabilim Dalı, Elazığ, Türkiye;* [2]*Fırat Üniversitesi Tıp Fakültesi Radyoloji Anabilim Dalı, Elazığ, Türkiye*

BACKGROUND & AIM

Fungal infections of the paranasal sinuses are classified into non-invasive (fungal ball/mycetoma) and invasive forms according to their clinical behavior. In non-invasive cases in particular, preoperative radiological evaluation with computed tomography (CT) plays a critical role in determining the surgical strategy. Although fungal sinusitis is known in the literature to demonstrate a hyperdense appearance on CT, the diagnostic threshold values of the quantitative counterpart of this density—Hounsfield Units (HU)—and the relationship of these values with bone remodeling or destruction remain current and actively investigated research topics.

MATERIAL & METHODS

A total of 34 patients who underwent endoscopic sinus surgery between January 2010 and January 2026 and had a histopathological and/or microbiological diagnosis of fungal sinusitis were retrospectively evaluated. Age, sex, involved sinuses, mean and maximum HU values, and CT findings such as heterogeneity, bilaterality, sinus expansion, remodeling, and

bone destruction were analyzed. Since HU values did not follow a normal distribution, Mann–Whitney U test was used for group comparisons, and Fisher exact test for categorical variables. A p-value <0.05 was considered statistically significant.

RESULTS

The mean age of the 34 patients included in the study was 58.3±17.1 years, and 67.6% were female. The maxillary sinus was the most commonly affected site (76.5%). The distribution of radiological findings was as follows: heterogeneity 91.2%, remodeling 67.6%, and destruction 61.8%. The median mean HU was 56.5, and the median maximum HU was 244. No significant association was found between HU values and sex, heterogeneity, remodeling, bilaterality, or expansion (all p>0.05). Maximum HU values were significantly higher in patients with bone destruction (median 287 vs. 151 HU, p=0.029). No significant association was found between mean HU and destruction (p=0.619). Although maximum HU tended to be higher in the presence of expansion, statistical significance was not reached (p=0.077). No correlation was observed between age and HU values.

CONCLUSIONS

Among the common CT findings of fungal sinusitis are heterogeneity, remodeling, and bone destruction. The significant association between maximum HU values and bone destruction in our study suggests that densitometric parameters may assist in predicting aggressive bone changes in fungal sinus disease. Larger prospective studies will help establish diagnostic HU thresholds and improve diagnostic accuracy.

PP-557

Importance Of Immunodeficiency Workup In Complicated Acute Sinusitis Patients: A Case Report

Cemal Bartu Bektaş[1], **Pertev Gündüz**[1], **Birsu Çağnan**[1], **Melin Dayı**[1]

[1]*The Near East University Hospital*

BACKGROUND & AIM

Sinusitis is highly prevalent in patients with Human Immunodeficiency Virus Infection and may become significantly more severe when CD4 counts are below 200/mm^3. Both typical and opportunistic microorganisms may lead to sinusitis. Common bacterial pathogens include Streptococcus pneumoniae and Haemophilus influenzae , whereas opportunistic pathogens include fungal organisms and Pseudomonas aeruginosa. Immunosuppressive patients are more prone to agressive diseases and complications. We present a patient with periorbital cellulitis secondary to acute sinusitis who was subsequently diagnosed with HIV infection.

MATERIAL & METHODS

A 42-year-old woman presented to our clinic with diplopia, a 4-week history of headache, and 1-week history of exophthalmos at the left eye. Physical examination revealed mild hyperaemia and edema of the upper and lower left eyelids. There was marked exophtalmos of the left eye. Paranasal sinus computed tomography results showed left maxillary and frontal sinusitis and also bilateral ethmoid and sphenoid sinusitis. The patient was admitted to the hospital and was started on appropriate intravenous antibiotic treatment. Due to the severity and extent of the infection, secondary immunodeficiency was suspected. Advanced workup revealed previously undiagnosed Human Immunodeficiency Virus Infection. Figure 1 shows endoscopic examination of the left nasal cavity with purulent discharge originating from the maxillary sinus ostium. Figure 2 illustrates axial,coronal and sagittal computed tomography images of the paranasal sinuses, revealing extensive sinus involvement.

RESULTS

Patients who has complicated sinusitis, primary and secondary immunodeficiency disorders should be kept in mind.Conditions such as Diabetes Mellitus, Human Immunodeficiency Virus Infection, corticosteroid use, and hematologic malignancies are predisposal factors for patients to severe sinonasal and orbital infections. In theory, any condition causing immune dysfunction may increase the severity of infection; however, current evidence is insufficient to directly conclude that HIV infection independently increases the risk of periorbital cellulitis. Early recognition of underlying immunosuppression may improve diagnostic approach and management.

CONCLUSIONS

Patients who has complicated sinusitis, primary and secondary immunodeficiency disorders should be kept in mind.Conditions such as Diabetes Mellitus, Human Immunodeficiency Virus Infection, corticosteroid use, and hematologic malignancies are predisposal factors for patients to severe sinonasal and orbital infections. In theory, any condition causing immune dysfunction may increase the severity of infection; however, current evidence is insufficient to directly conclude that HIV infection independently increases the risk of periorbital cellulitis. Giant Thornwaldt Cyst Caused Unilateral Serous Otitis Media--A Rare Case Presentation

Ayşegül Şule ALTINDAL[1], **Eda YELKENCİ**[1], **Ramazan ÖZTÜRK**[1], **Elif DAĞLI**[2]

[1]*Antalya City Hospital Otorhinolaryngology, Head and Neck Surgery Clinic;* [2]*Antalya City Hospital Pathology Department*

BACKGROUND & AIM

Thornwaldt cyst is a congenital lesion resulting from the persistence of the embryological relationship between the remnants of the notochord and the nasopharyngeal endoderm. It is usually localized in the posterior wall of the nasopharynx. Most cases are asymptomatic and are detected incidentally on MRI or endoscopy. Symptoms usually appear with cyst growth or infection. This case is noteworthy because of the unusually large size of the lesion and the fact that it caused unilateral serous otitis media.

MATERIAL & METHODS

A 47-year-old female patient presented to the outpatient clinic with otological complaints of hearing loss, fullness sensation, and tinnitus in the left ear, in addition to long-standing difficulty breathing through the nose. Flexible endoscopy showed a giant cystic lesion in the nasopharynx obliterating approximately 90% of the left choana. Pure Tone Hearing Test results of 46/30 dB for the left ear and 26/23 dB for the right ear, and Tympanometry test results of type C for the left ear and type A for the right ear. Nasopharyngeal MRI reported a 2.5 cm lobulated lesion consistent with a Thornwaldt cyst in the posterior wall of the nasopharynx. The patient's cystic lesion was marsupialized using a 0-degree endoscope, and a Shepard tube was inserted into the left tympanic membrane following myringotomy.The material was sent to the pathology laboratory.

RESULTS

"The sections showed tissues representing the cyst wall, consisting of respiratory and squamous lining epithelium, with lymphoid aggregates visible in places in the subepithelial area. The findings can be considered consistent with Thornwaldt cyst," the report stated.

Postoperative audiometric tests showed a Pure Tone Hearing Test result of 29/25 dB for the left ear and 24/19 dB for the right ear, and Tympanometry test results were bilateral type A. Flexible endoscopic examination revealed no pathological findings such as residual mass, recurrence, infection, or bleeding in the nasopharynx.

CONCLUSIONS

This case, the cyst reached a giant size and caused serous otitis media secondary to Eustachian tube obstruction. Although otologic manifestations of Thornwaldt cysts have been reported, symptomatic giant lesions associated with significant middle ear pathology remain uncommon. Mechanism is thought to be mechanical compression or inflammation around torus tubarius, resulting in impaired middle ear ventilation. Endoscopic transnasal marsupialization has become the preferred technique because it provides excellent visualization, minimal morbidity, preservation of surrounding structures, and low recurrence rates. In our patient, complete endoscopic marsupialization resulted resolution of symptoms and improvement of middle ear ventilation without recurrence during follow-up.

KEYWORDS

Although rare, thornwaldt cysts can grow to enormous sizes and cause serous otitis media.

OUR RESULTS OF ENDOSCOPIC DACRYOCYSTORHINOSTOMY PERFORMED AT THE ADNAN MENDERES UNIVERSITY OTORHINOLARYNGOLOGY CLINIC

MERT GÖK[1], **SILA CİHAN ATALAY**[1], **MAHMUT DEMİRTAŞ**[1]

[1]*AYDIN ADNAN MENDERES UNİVERSİTY HOSPİTAL*

BACKGROUND & AIM

Epiphora due to acquired nasolacrimal duct obstruction is a common clinical condition that significantly impairs quality of life. Dacryocystorhinostomy (DCR) is accepted as the gold standard surgical treatment. With advances in endoscopic techniques, endoscopic dacryocystorhinostomy (En-DCR) has increasingly been preferred as an alternative to the external approach due to its minimally invasive nature and its ability to address concomitant intranasal pathologies. The aim of this study was to evaluate the outcomes of En-DCR and to analyze factors affecting surgical success.

MATERIAL & METHODS

In this retrospective, single-center study, 40 patients (6 males, 34 females; mean age 57.1±15.92 years) who underwent En-DCR were evaluated. Surgical success was defined as the absence of postoperative epiphora, patency on lacrimal irrigation, and no requirement for revision surgery. Failure was defined as ostium stenosis, granulation tissue or synechiae formation, and/or the need for revision surgery. Demographic characteristics, clinical features, level of obstruction, nasal pathologies, and surgical technical factors were analyzed. Statistical significance was set at $p<0.05$.

RESULTS

Age had no significant effect on surgical success (p=0.245), whereas a significant association was found between sex and postoperative epiphora (p=0.008). Smoking status, comorbidities, and diabetes mellitus were not associated with surgical

outcomes. Infection-related parameters and symptom duration did not affect prognosis (all p>0.05). No significant association was observed between surgical success and the level of obstruction assessed by dacryoscintigraphy, irrigation findings, or punctal status. Septal deviation on the operated side was significantly associated with surgical failure (p=0.014), whereas turbinate hypertrophy and the presence of nasal polyps or secretions were not. Silicone intubation duration and postoperative complications did not influence outcomes. There was no significant difference in success rates between primary and revision surgeries (p=0.606); however, ostium stenosis was significantly more frequent in revision cases (p=0.032).

CONCLUSIONS

En-DCR is an effective and reliable surgical technique with high success rates. While most clinical factors have limited impact on outcomes, septal deviation and increased ostium stenosis in revision cases appear to be important determinants of surgical failure. These findings highlight the importance of careful evaluation of nasal anatomical factors during surgical planning.

Pediatric Traumatic Nasal Septal Hematoma, A Case Report And Literature Review

Tahir Emre Keleş[1], **Burçay Tellioğlu**[1], **Serdar Özer**[1]

[1]*Hacettepe University ENT Department*

BACKGROUND & AIM

As the most prominent feature of the face, the nose is highly susceptible to trauma-related damage. In children, the nasal septum is more likely to be damaged than the nasal bone in the event of nasal trauma. Nasal septal hematoma (NSH) is a rare condition in pediatric patients that can progress to nasal septal abscess (NSA) and lead to severe complications, including nasal deformities and intracranial infections. Early diagnosis and appropriate management are critical for preventing long-term sequelae. This article aims to present a case of a traumatic septal haematoma that led to a septal abscess.

MATERIAL & METHODS

This article is a case report. The interventional procedure performed on the patient was described step by step. A literature review was conducted. The case presentation was illustrated with photographs of the patient.

Case Presentation: A 15-year-old male presented with nasal obstruction and discomfort two weeks after a facial trauma. Initial evaluation at the time of injury failed to detect NSH. On re-presentation, clinical examination revealed bilateral purplish swelling of the anterior nasal septum, and imaging confirmed a minimally displaced septal fracture with significant soft tissue swelling. The patient was diagnosed with a NSH. The patient underwent urgent surgical intervention, including drainage of purulent material, necrotic tissue debridement, and placement of a penrose drain. Culture results identified Corynebacterium striatum and Moraxella osloensis. Postoperatively, intravenous and oral antibiotic therapy was administered. Although the patient's recovery was uneventful, a saddle nose deformity became apparent during follow-up.

RESULTS

Discussion: Delayed diagnosis of NSH, especially in pediatric cases, increases the risk of complications. NSH can develop days after trauma and may not be immediately evident. This case highlights the importance of vigilant follow-up in trauma patients and the need for early intervention to prevent aesthetic and functional deformities.

CONCLUSIONS

Conclusion: NSH should be a differential diagnosis in pediatric nasal trauma cases. Prompt evaluation, surgical drainage, and appropriate antibiotic therapy are essential to mitigate risks. Further research is required to establish the benefits and timing of early reconstructive interventions.

SKULL BASE DEFECT AND OCULAR FINDINGS SECONDARY TO SPHENOID SINUS MUCOCELE: A RARE CASE

Salih Ozan Korkmaz[1], **Fatma Demirkol**[1], **Şahin Öğreden**[1], **Oğuzhan Cumalı**[1], **Özgür Yiğit**[1]

[1]Başakşehir Çam and Sakura City Hospital

BACKGROUND & AIM

Sphenoid sinus mucoceles are rare lesions, accounting for approximately 1% of all paranasal sinus mucoceles and 15–28% of isolated sphenoid sinus diseases.

Patients may present with a wide spectrum of clinical findings, including headache, facial pain, anosmia, cranial nerve palsies, ocular paralysis, and visual loss.

Through this case, we highlight the potential role of sphenoid mucoceles in causing orbital complications via localized inflammatory mechanisms and compressive effects. Early diagnosis and timely surgical intervention are crucial in reducing life-threatening complications and facilitating neurological recovery.

MATERIAL & METHODS

A 67-year-old female patient presented to the ophthalmology clinic with diplopia and a recently developed persistent retro-orbital headache. The headache had been present for two weeks and had progressively worsened over the last few days. Diplopia had developed two days prior to presentation.

With a preliminary diagnosis of sphenoid sinus mucocele, the patient underwent urgent endoscopic sphenoethmoidectomy. The sphenoid sinus was accessed via a transethmoidal approach, and mucopurulent and putrefactive material within the sinus cavity was evacuated.

A skull base defect measuring approximately 4 cm in the posteroanterior plane was identified, involving the region adjacent to the optic nerve. The defect was reconstructed using a Hadad flap.

Postoperatively, the headache resolved completely, and diplopia secondary to extraocular muscle compression fully regressed by the end of the second postoperative month.

The patient had an uneventful postoperative course and remains under follow-up without evidence of recurrence at 12 months.

RESULTS

Postoperatively, headache resolved completely, and diplopia fully regressed by the second postoperative month. Follow-up imaging at 12 months demonstrated adequate sinus aeration without evidence of recurrence.

CONCLUSIONS

Sphenoid mucoceles are rare but potentially serious lesions that result from mucus retention secondary to obstruction of the sinus ostium. This obstruction may arise from chronic rhinosinusitis, postoperative scar formation, nasal polyps, trauma, or neoplasms.

Through this case, we highlight the potential role of sphenoid mucoceles in causing orbital complications via localized inflammatory mechanisms and compressive effects. Early diagnosis and timely surgical intervention are crucial in reducing life-threatening complications and facilitating neurological recovery.

A Rare Case Of Congenital Nasoethmoidal Meningoencephalocele Presenting As A Unilateral Nasal Polyp In A Child

YALÇIN ALİMOĞLU[1], **FERİDE FIRAT**[1], **ADALET AŞKİN**[1], **ZEYNEP YEŞİLLER GÜZEL**[1]

[1]*Başakşehir Çam and Sakura City Hospital, Department of Otorhinolaryngology, Istanbul, Türkiye*

BACKGROUND & AIM

Encephaloceles are lesions characterized by the herniation of brain parenchyma, meninges, and cerebrospinal fluid through a defect in the skull. While typically congenital, they can also be acquired due to trauma, tumors,iatrogenic injury [2]. Depending on their content, these lesions may consist solely of meninges known as a meningocele, or may also include brain tissue, referred to as a meningoencephalocele [1]. Encephaloceles may present as a blue-colored, pulsatile, and compressible mass near the nasal dorsum. Because nasal encephaloceles manifest as a nasal mass, they can be misdiagnosed as nasal polyps. The presence of intracranial extension renders biopsy contraindicated [1,3].

MATERIAL & METHODS

An 8-year-old male presented with the primary complaint of nasal obstruction. Anterior rhinoscopic and endoscopic examinations revealed a polypoid lesion nearly obliterating the left nasal cavity. Contrast-enhanced CT and MRI scans demonstrated a lesion extending from the left cribriform plate into the nasal cavity. The patient was scheduled for endoscopic transnasal excision of the meningocele. The procedure was performed under navigation-guided CT. The submucosal meningocele in the left nasal cavity was successfully excised. The skull base defect was repaired using a multilayered technique: a fascia lata graft was placed in an onlay fashion over the dura, followed by a fat graft. Following the excision, the redundant nasal mucosal tissue was transposed over the fascia lata graft as a flap. No intraoperative or immediate

postoperative complications were observed. Postoperative imaging confirmed the integrity and proper placement of the graft material. Histopathological analysis confirmed the diagnosis of meningoencephalocele.

RESULTS

Congenital meningoencephaloceles are rare craniofacial malformations resulting from defective neural tube closure during the fourth month of embryological development [5,6]. Meningoencephaloceles are classified as occipital, parietal, sincipital, and basal types based on their anatomical location. Our case involves a nasoetmoidal meningoencephalocele, which represents a rare localization. In the diagnostic approach, biopsy is strictly contraindicated due to the risk of intracranial extension, and manipulation of the mass must be avoided [5,10]. High-resolution CT is considered the gold standard for evaluating the bone defect, whereas MRI is preferred to demonstrate the intracranial component. The fundamental principle of treatment is the excision of the herniated meningeal tissue followed by the repair of the bony and dural defects [8,10]. Currently, endoscopic transnasal approaches are preferred due to lower morbidity and superior cosmetic outcomes [9,11]. Repair typically utilizes autologous graft materials (e.g., fascia lata, fat graft) and fibrin sealants [10,11].

CONCLUSIONS

Meningoencephalocele is a rare neural tube defect [12]. While congenital types are mostly diagnosed during the antenatal period, they can also manifest during childhood with non-specific symptoms, as demonstrated in our case [12,13]. It must be considered in the differential diagnosis, especially in patients presenting with unilateral nasal obstruction, rhinorrhea, or a history of recurrent meningitis [13,14]. Magnetic resonance imaging (MRI) is the preferred diagnostic modality due to its high sensitivity and specificity in demonstrating intracranial extension [15]. The primary treatment approach is surgical excision; currently, endoscopic methods are favored due to their lower morbidity and high success rates [13,16].

Infected Giant Nasolabial Cyst A Case Report

FURKAN ADLUĞ[1], **KÜBRA NUR ÇÖLKESEN**[1], **SÜHEYLA KANDEMİR**[1], **BURAK MUSTAFA TAŞ**[1], **ZİYA ŞENCAN**[1], **ELA CÖMERT**[1], **NURAY BAYAR MULUK**[1]

[1]*Kırıkkale University Faculty of Medicine, Department of Otorhinolaryngology*

BACKGROUND & AIM

Nasolabial cysts are relatively rare, non-odontogenic soft tissue lesions that account for approximately 0.7% of all jaw cysts. These cysts are most commonly located in the upper lip and the nasal vestibule. Unless infected, they usually present as a painless swelling and, rarely, may cause nasal obstruction. Typically, they cause fullness in the canine fossa, upper lip, gingivolabial sulcus, and nasal ala and vestibule.

In this case report, we aimed to present the examination findings and treatment process of a patient with a nasolabial cyst that had been present for many years and eventually presented with infection and progressive nasal obstruction.

MATERIAL & METHODS

A 35-year-old female patient had a history of sinusitis symptoms since childhood. She had not frequently sought medical attention. Over the past six months, she had experienced difficulty breathing through the right nasal passage and foul-smelling nasal discharge. She reported no pain.

On endoscopic examination with a 0-degree endoscope, the left nasal passage was observed to be patent, while an infected cyst was identified in the right nasal passage. A contrast-enhanced facial MRI was performed. Imaging revealed a lobulated mass lesion with mucosal contrast enhancement extending from the right maxillary sinus to the ethmoidal cells.

A paranasal sinus CT (Computed Tomography) scan was subsequently obtained. CT examination demonstrated a 34 × 31 mm soft tissue density lesion nearly completely filling the right maxillary sinus, extending into the right middle and inferior meatus, and occluding the osteomeatal complex.

RESULTS

Based on the clinical and radiological findings, a nasolabial cyst was considered as the preliminary diagnosis. Surgical treatment was planned. Under general anesthesia, a 2 cm incision parallel to the right upper gingiva was made. An infected nasolabial cyst extending from the right nasal passage to the hard palate was observed. The cyst was dissected over the periosteum, and the capsule was reached via blunt dissection. It was noted that the cyst extended from the nasal floor into the nasal passage. The lesion was carefully dissected from the surrounding tissues and completely excised.

The postoperative period was uneventful, and the patient was discharged on the second postoperative day. Histopathological examination confirmed the diagnosis of a nasolabial cyst. No recurrence was observed during the follow-up period.

CONCLUSIONS

Nasolabial cysts are generally painless, non-odontogenic soft tissue cysts. In patients with long-standing sinusitis symptoms, nasolabial cyst should be considered in the differential diagnosis of soft tissue masses causing nasal obstruction accompanied by foul-smelling discharge. Surgical treatment can be successfully performed.

Cemento-Ossifying Fibroma With Secondary Aneurysmal Bone Cyst Of The Ethmoid Sinus In A Pediatric Patient: A Case Report And Review Of The Literature

Mohammed Alsaif[1], **Meshal Albesher**[2], **Ahmed Alsaleh**[2], **Aeshah Almahbub**[2], **Fahad Alfawwaz**[2]

[1]College of Medicine, King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia; [2]Otolaryngology-Head and Neck Surgery, King Fahad Medical City, Riyadh Second Health Cluster, Riyadh, Saudi Arabia

BACKGROUND & AIM

Cemento-ossifying fibroma (COF) is a benign fibro-osseous neoplasm that most commonly arises in the mandible and rarely involves the sinonasal tract. Secondary aneurysmal bone cyst (ABC) transformation is an uncommon but clinically significant phenomenon that can dramatically alter tumor behavior, leading to rapid expansion and mass effect. The coexistence of COF with secondary ABC in the ethmoid sinus is exceedingly rare, particularly in pediatric patients.

MATERIAL & METHODS

A comprehensive review of the literature was performed, identifying 16 previously reported cases of sinonasal aneurysmal bone cyst with or without ossifying fibroma. Written informed consent was taken from the patient.

RESULTS

We report the case of a 9-year-old girl who presented with a one-year history of progressive right-sided headache and facial asymmetry, complicated by worsening epistaxis and right eye proptosis. Radiologic evaluation revealed a large expansile cystic lesion centered in the right ethmoid sinus with extension into the nasal cavity and compression of the orbit, without intracranial invasion. The patient underwent complete excision via functional endoscopic sinus surgery with septoturbinoplasty. Intraoperatively, the lesion was noted to be highly vascular and multiloculated. Histopathological examination confirmed a cemento-ossifying fibroma with secondary aneurysmal bone cyst transformation. The postoperative course was uneventful, with marked improvement in symptoms and no evidence of recurrence at follow-up.

CONCLUSIONS

This case represents a rare and previously unreported presentation of cemento-ossifying fibroma with secondary aneurysmal bone cyst arising in the pediatric ethmoid sinus. Secondary ABC transformation should be considered when a sinonasal fibro-osseous lesion demonstrates rapid growth or aggressive radiologic features. Complete surgical excision, when feasible, remains the cornerstone of management and can be successfully achieved through an endoscopic approach with favorable outcomes.

GIANT ANTROCHOANAL POLYP EXTENDING TO THE OROPHARYNX WITH COEXISTING ADENOID HYPERTROPHY: A CASE REPORT

MÜRŞİT ALPEREN YAKUT[1], **CEM BULUT**[1], **İLKER BURAK ARSLAN**[1], **AKTEN UYAN**[1]

[1]DEPARTMENT OF OTORHINOLARYNGOLOGY, İZMİR CITY HOSPITAL

BACKGROUND & AIM

Antrochoanal polyps are benign and generally solitary nasal polyps originating from the maxillary sinus (1). While nasal polyps are seen in 1–4% of adults, they are rare in children (<0.1%) (1,2). They constitute 4–6% of nasal polyps in adults and 30–35% in children (1,2), and are usually unilateral (1). Although endoscopy is often sufficient for diagnosis, tomography (CT) is the gold standard (1). Large lesions may extend from the choana into the nasopharynx and, rarely, into the oropharynx, causing airway obstruction (4). Functional endoscopic sinus surgery (FESS) with complete removal of the antral component is the preferred treatment method (1).

MATERIAL & METHODS

Case Presentation

A 9-year-old female patient presented with complaints of chronic nasal obstruction, mouth breathing, and snoring. On endoscopy, a polyp was observed extending from the right middle meatus to the choana, nasopharynx, and oropharynx. In addition, adenoid hypertrophy nearly completely filling the nasopharynx was observed. CT revealed a soft tissue mass filling the right maxillary sinus and extending posteriorly into the oropharynx, as well as mucosal thickening in the ethmoid cells and

the left maxillary sinus. The findings were consistent with an antrochoanal polyp (1,2). The patient underwent FESS and adenoidectomy under general anesthesia. Histopathological examination confirmed the diagnosis (1).

RESULTS

Antrochoanal polyps grow progressively and may extend into the nasopharynx; however, extension into the oropharynx is rare and is generally associated with delayed diagnosis (4). Adenoid hypertrophy is a common cause of pediatric nasal obstruction and may coexist with these polyps (3). This coexistence may increase airway obstruction and make diagnosis more difficult (3). In this case, the adenoid tissue nearly completely obstructing the nasopharynx may have contributed to both the severity of symptoms and the extension of the polyp (3,4).

CONCLUSIONS

Although extension of antrochoanal polyps into the oropharynx has been reported, their coexistence with marked adenoid hypertrophy has rarely been emphasized. This case highlights the clinical significance and rarity of this combination.

Efficacy Of Biological Agents In Allergic Rhinitis: A Descriptive Systematic Review

Abdulmohsen Jameel Alshammari[1], **Mohammed Majed Alshenaiber**[1], **Ghadah Khalid Al Fraihi**[1], **Tariq Abdulaziz Aldawood**[1], **Muhnnad Abdulaziz AlGhamdi**[3], **Abdulaziz Alaraifi**[2], **Abdullah Alkhaldi**[2], **Riyadh Alhedaithy**[2], **Mohammad Jihad Al Mahdi**[2]

[1]*College of Medicine, King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia;* [2]*Division of Otolaryngology-Head and Neck Surgery, Department of Surgery, King Abdulaziz Medical City, Ministry of National Guard Health Affairs, Riyadh, Saudi Arabia.;* [3]*College of Medicine, King Saud bin Abdulaziz University for Health Sciences, Jeddah, Saudi Arabia*

BACKGROUND & AIM

Background: Allergic rhinitis (AR) is a common IgE-mediated inflammatory disorder that substantially affects quality of life and productivity. Biologic therapies targeting type 2 inflammatory pathways have been investigated as adjunctive or alternative options for patients with inadequately controlled disease.

Objective: To synthesize evidence on the efficacy and safety of biological agents in allergic rhinitis and to appraise certainty of evidence using GRADE.

MATERIAL & METHODS

Methods: A systematic review was conducted in accordance with PRISMA 2020. MEDLINE, Embase, SCOPUS, CENTRAL, and Google Scholar were searched from inception to December 2025. Randomized controlled trials (RCTs) and observational studies evaluating biologics in AR were eligible. Risk of bias was assessed using Cochrane RoB 2 for RCTs and ROBINS-I–aligned principles for observational studies. Due to substantial heterogeneity in populations, interventions, and outcomes, results were synthesized narratively.

RESULTS

Results: Twelve studies (2,577 participants) were included. The evidence base was dominated by anti-IgE therapy (omalizumab/rhuMAb-E25; 11/12 studies). Most placebo-controlled RCTs reported reductions in nasal symptom burden, rescue medication use, and improved rhinitis-related quality of life, though effect magnitude varied. Adjunctive omalizumab with allergen immunotherapy suggested potential improvements in symptom–medication outcomes and/or immunotherapy tolerability in some trials. A single trial of dupilumab plus SCIT did not demonstrate additional TNSS reduction versus SCIT alone but suggested potential tolerability and immunologic benefits.

CONCLUSIONS

Conclusion: Anti-IgE therapy appears to provide clinically meaningful benefit in allergic rhinitis for selected patients, with moderate certainty of evidence for key symptom and quality-of-life outcomes. Evidence for non–anti-IgE biologics in isolated AR remains limited. Standardized endpoints and longer follow-up studies are needed to clarify comparative effectiveness and long-term safety.

A RARE CASE: INTRACRANİAL AND ORBİTAL EXTENSİON SECONDARY TO MASSİVE SİNONASAL POLYPOSİS ASSOCİATED WİTH WOAKES SYNDROME

Emin Gencer[1], **Melih Alpay**[1], **Hakkı Caner İnan**[1]

[1]*Bursa High Specialty Training and Research Hospital, University of Health Seciences*

BACKGROUND & AIM

Woakes' syndrome is a rare clinical condition characterized by massive recurrent nasal polyposis, leading to deformity of the nasal pyramid and expansion of sinonasal structures. Although orbital complications may occur in advanced cases, intracranial extension is extremely rare. In this study, we present a rare case of orbital and intracranial extension secondary to massive sinonasal polyposis associated with Woakes' syndrome.

MATERIAL & METHODS

A 47-year-old male patient was admitted to the emergency department following sudden loss of consciousness. With a Glasgow Coma Scale score of 6, he was intubated and transferred to the intensive care unit. His history included long-standing bilateral nasal polyposis and asthma. Otorhinolaryngological examination revealed advanced polypoid lesions nearly completely obstructing both nasal passages, accompanied by nasal pyramid expansion and orbital deformity.

Imaging demonstrated diffuse soft tissue densities filling all paranasal sinuses, destruction of the lamina papyracea, and orbital extension. An intracranial mass extending into the frontal lobe with destruction of the posterior wall of the right frontal sinus was also identified.

A combined surgical approach was performed with the neurosurgery team. Bilateral functional endoscopic sinus surgery was carried out, and infected polypoid tissue invading the dura via the frontal sinus was removed during the cranial procedure. Histopathological examination confirmed inflammatory nasal polyp.

RESULTS

The pathogenesis of Woakes' syndrome is associated with type 2 inflammation, particularly IL-4 and IL-5 mediated eosinophilic response. Medical treatment is often insufficient, and surgical intervention remains the mainstay of treatment. A multidisciplinary approach is required in extensive disease.

CONCLUSIONS

Woakes' syndrome is a rare but potentially serious condition that may lead to severe complications. Early diagnosis and aggressive surgical management are crucial, especially in cases with intracranial extension. Long-term follow-up is essential due to the high risk of recurrence.

A Rare Complication Of Epistaxis Cauterization: A Case Of Refractory Septal Abscess

Ramazan Yavuz[1], **Yunus Emre Topan**[2]

[1]*Uşak Training and Research Hospital, Department of Otorhinolaryngology;* [2]*Uşak University Faculty of Medicine, Department of Otorhinolaryngology*

BACKGROUND & AIM

Epistaxis is a common ENT emergency.Although cauterization is an effective treatment for persistent bleeding, rare complications such as septal abscess may occur.We present a refractory septal abscess following cauterization.

MATERIAL & METHODS

A 70-year-old female patient with a history of diabetes mellitus and hypertension presented with severe epistaxis.On examination, an arterial bleeding focus was identified in the Little's area, and bipolar cauterization was performed.Two weeks after, the patient developed nasal pain radiating to the upper teeth.On examination, fluctuation was detected on septal palpation.Laboratory findings revealed elevated WBC and CRP level of 34mg/L.Seropurulent material was aspirated.The patient was hospitalized, and intravenous antibiotic therapy was initiated.Under local anesthesia, the abscess was drained and silicone splint packing was placed.During follow-up, CRP levels increased.The packing was removed, and septal abscess repeat drainage and septoplasty were performed under general anesthesia.The weakened posteroinferior septal cartilage was resected, purulent material was aspirated, and transseptal sutures were placed.Antibiotherapy was updated.Ten days later, the patient developed recurrent pain over the nasal dorsum.Examination and imaging revealed a collection in the dorsal septum.Purulent material was drained.No recurrence of septal abscess was observed following.

RESULTS

Septal abscess is a rare but serious complication that usually develops due to infection of a septal hematoma.If not diagnosed early, it may lead to significant complications such as septal cartilage necrosis, septal perforation, and nasal deformity.Disruption of mucosal integrity following cauterization for epistaxis may increase the risk of infection, particularly in patients with comorbidities. In our case, despite local antibiotic therapy after cauterization, an infectious focus likely developed due to mucosal disruption.Therefore, prophylactic oral antibiotic therapy after cauterization may be considered in patients with risk factors.Additionally, transseptal sutures placed during the initial surgical intervention may have partially impaired adequate drainage of the collection.This highlights the importance of ensuring sufficient drainage and careful planning of surgical techniques to prevent re-accumulation in septal abscess management.

CONCLUSIONS

Septal abscess following cauterization for epistaxis is a rare but serious complication.Particular attention should be given to patients with comorbidities such as diabetes mellitus.Early diagnosis, adequate surgical drainage, and appropriate antibiotic therapy are critical in preventing complications.

Fronto-Orbital Solitary Fibrous Tumor: A Rare Presentation Of Diplopia And Proptosis - Case Report And Literature Review

Rafaela de Macedo Fernandes[1], **Mariana Cascão**[1], **José Fernandes**[1], **André Machado**[1], **António Castanheira**[1]

[1]*Department of Otolaringology, Unidade Local de Saúde Trás-os-Montes e Alto Douro, Portugal*

BACKGROUND & AIM

Solitary fibrous tumors (SFTs) are rare mesenchymal neoplasms. Their occurrence in the nasal cavity and paranasal sinuses is exceptional, with few cases reported in the literature, which hinders early recognition.

MATERIAL & METHODS

The clinical, surgical, and imaging data of the presented case were analyzed after obtaining the necessary informed consents, ensuring compliance with ethical standards and confidentiality requirements. The study was complemented by a brief narrative review of the literature.

RESULTS

An 82-year-old woman presented with a 3-month history of diplopia and headaches, followed by a 1-month history of left-sided proptosis, ocular pain, and decreased vision. On physical examination, anterior rhinoscopy revealed nasal septal deviation and hypertrophy of the middle turbinates, with no visible masses suitable for biopsy, also confirmed by nasopharyngolaryngoscopy. Inspection revealed a left supraorbital and supraciliary swelling, painless to touch, with associated softening of the ipsilateral nasal bones. Imaging studies demonstrated a left naso-sino-orbital expansile lesion, hypervascularized and with a bone-remodeling nature, arising from the left frontal sinus with invasion of the internal canthus of the orbit. Endoscopic surgical biopsy established the diagnosis of solitary fibrous tumor. The patient underwent complete excision of the lesion through a bicoronal approach. Histopathological examination of the surgical specimen confirmed the diagnosis. The patient remains disease-free since surgery.

CONCLUSIONS

Solitary fibrous tumors often present with nonspecific symptoms, mainly related to compressive effects on adjacent structures, which frequently delays diagnosis. Imaging is crucial to assess tumor extent, but definitive diagnosis requires histopathology and immunohistochemistry, with typical positivity for CD34 and STAT6. Treatment most often consists of radical surgical resection with clear margins. Despite an overall favorable prognosis, recurrence may occur, which highlights the importance of long-term follow-up. The rarity of these tumors in the frontal sinus underlines the need to consider broad differential diagnoses in lesions in this location. A multidisciplinary approach is essential for an accurate diagnosis and management.

PP-571

Contribution Of Digital Tools And Artificial Intelligence In Rhinoplasty Planning

Majbri Maha[1], **El Bessi Salma**[1], **Chahed Houda**[1], **Lahmar Rihab**[1], **Beltaief Najeh**[1]

[1]*Department of ENT and Head and Neck Surgery, la Rabta hospital, Tunis , Tunisia*

BACKGROUND & AIM

Rhinoplasty is one of the most technically demanding aesthetic surgical procedures, requiring precise planning and optimal communication with the patient. The rise of digital technologies and artificial intelligence (AI) has progressively transformed surgical practice. The aim of this work is to describe the current applications of digital tools in rhinoplasty, their benefits, limitations, and future perspectives.

MATERIAL & METHODS

A systematized literature review was conducted using the PubMed, Scopus, and Google Scholar databases. Keywords used included: rhinoplasty, aesthetics, artificial intelligence, digital simulation, and augmented reality. Included articles were published in English or French. A total of 56 articles were selected and analyzed.

RESULTS

Analysis of the selected articles revealed a progressive evolution of digital tools in rhinoplasty, structured in three stages. Two-dimensional simulation software (Adobe Photoshop®, Mirror®, AlterImage®...) represented the first preoperative planning

tools, facilitating patient communication through morphing and warping techniques. Subsequently, the emergence of three-dimensional (3D) simulation tools, through various dedicated software platforms, allowed more accurate volumetric modeling and enhanced surgical planning.. AI integration represented the most significant advance: machine learning algorithms successfully reproduced the surgeon's aesthetic criteria, custom implant fabrication via AI-assisted 3D printing achieved a margin of error below 1 mm, Generative Adversarial Networks generated realistic simulations despite representativeness biases, and conversational AI tools (ChatGPT-4) demonstrated reliability comparable to that of a senior surgeon in answering patients' postoperative questions.However, these tools remain limited by their inability to reproduce clinical judgment and surgical experience, their dependence on data quality, and the risk of generating plausible but inaccurate information.

CONCLUSIONS

AI represents a valuable complementary tool in rhinoplasty, enhancing surgical planning and patient satisfaction. It cannot, however, replace clinical expertise or the human physician-patient relationship. The future of the field likely lies in hybrid approaches combining advanced 3D simulation, augmented reality, and AI, governed by rigorous ethical and regulatory frameworks.

Combined Galea Aponerotica And Fascia Lata Graft For Endoscopic Repair Of Iatrogenic Sphenoethmoidal CSF Leak Associated With Penumocephalus: A Case Report

Kadir Bahadir Kuzzu[1], **Fatmanur Sahin Akinci**[1], **Mustafa Umut Etli**[2]

[1]*Antalya City Hospital, Department of Otorhinolarygology Head and Neck Surgery;* [2]*Antalya City Hospital, Department of Neurosurgery*

BACKGROUND & AIM

Cerebrospinal fluid (CSF) rhinorrhea is an abnormal communication between the subarachnoid space and the nasal cavity or paranasal sinuses, increasing the risk of meningitis and intracranial infections. It is most commonly traumatic (80–90%), while 4–10% are non-traumatic, with many idiopathic. Common leak sites include the cribriform plate, ethmoid roof, frontal sinus posterior wall, and sphenoid sinus. Management depends on defect location. Although transcranial and external approaches exist, endoscopic endonasal repair has become the preferred method due to lower morbidity, precise localization of defects, preservation of anatomical structures, and high success rates in sealing CSF leaks.

MATERIAL & METHODS

A 44-year-old male presented with a one-month history of intermittent, clear right-sided rhinorrhea, exacerbated by Valsalva maneuvers, forward bending, and sitting, accompanied by a salty taste and headache. He had a prior history of functional endoscopic sinus surgery. Endoscopic examination revealed clear fluid originating from the right sphenoid ostium. Paranasal sinus CT demonstrated a skull base defect consistent with cerebrospinal fluid (CSF) leakage.

The patient underwent endoscopic endonasal repair under general anesthesia by a multidisciplinary team. A lumbar drain was placed preoperatively. A fascia lata graft (1.5×1.0 cm) was harvested from the lateral thigh. Intraoperatively, the defect was identified in the anterosuperolateral region of the sphenoid ostium. The surrounding mucosa was elevated and the defect was repaired using an underlay fascia lata graft. Fibrin sealant and absorbable hemostatic material were applied, achieving complete closure without residual leakage.

RESULTS

On postoperative day 2, the patient developed headache, and CT imaging revealed pneumocephalus. The lumbar drain was removed; however, the patient subsequently developed behavioral changes consistent with frontal lobe dysfunction. Follow-up imaging demonstrated tension pneumocephalus with significant frontal mass effect.

Due to clinical deterioration, a second intervention was performed. A burr hole was created in the frontal region, allowing decompression of intracranial air via a closed underwater drainage system. A galea aponeurotica graft was harvested and combined with fascia lata to reconstruct the defect using a multilayer underlay technique.

Postoperative management included head elevation, activity restriction, and prophylactic antibiotics. The patient received intravenous ceftriaxone followed by meropenem due to elevated inflammatory markers. He was discharged on postoperative day 12 with oral antibiotics. Follow-up at one and two months showed no recurrence of CSF leakage or neurological complications.

CONCLUSIONS

This case highlights that multilayer reconstruction using combined fascia lata and galea aponeurotica grafts provides a reliable and durable solution for complex skull base defects. The addition of galea tissue enhances structural support and may reduce recurrence risk. Furthermore, tension pneumocephalus secondary to CSF leakage can be effectively managed with minimally invasive burr hole decompression and a closed drainage system. A multidisciplinary approach and careful postoperative management are essential for optimal outcomes. This combined strategy offers a safe and effective alternative to more extensive surgical procedures in selected cases.

Association Of Dental Pathologies With Disease Laterality And Surgical Need In Chronic Rhinosinusitis: A CT-Based Retrospective Study

Bürge Dereli[1], **Refik Berke Dereli**[1], **Ayşe Enise Göker**[1]

[1]*Department of Otorhinolaryngology, Prof. Dr. Cemil Taşcıoğlu City Hospital, Istanbul, Türkiye*

BACKGROUND & AIM

Involvement of dental pathologies to chronic rhinosinusitis (CRS) has gained increasing attention but its relationship with disease laterality and surgical requirement still needs further research. We hypothesized that dental pathology is associated with CRS and it is more abundantly observed on the same side as sinus involvement, and increases the frequency of requiring surgical intervention.

MATERIAL & METHODS

In this retrospective study we included 130 patients diagnosed with CRS between January 2025 and March 2026. Computed tomography (CT) scans were observed to understand the CRS laterality (right, left, bilateral), localization and presence of dental pathologies. We categorized dental pathologies as apex-sinus contact and sinus-invasive pathology. CRS levels of maxillary sinuses was graded separately for each side by the help of modified Lund-Mackay-based maxillary score (0 = no opacification, 1 = partial opacification, 2 = complete opacification). Maxillary scores were recorded, and we calculated total maxillary scores by summing right and left scores. Surgical interventions was noted for every patient. Statistical analyses, such as chi-square and Mann-Whitney U tests, were used to evaluate associations between CRS laterality, dental pathology, maxillary scores, and surgical need, with $p<0.05$ considered significant.

RESULTS

The median age was calculated as 39.0 years (interquartile range: 31.0–52.0). We observed dental pathology in 72.3%, mostly bilaterally (52.3%), and bilateral CRS was seen in 67.7% of patients. There was a significant association between dental pathology localization and CRS laterality ($p<0.001$), demonstrating ipsilateral and bilateral concordance. In total 46.2% of patients underwent surgery. The presence of dental pathology was significantly associated with increased surgical need (52.1%- 30.6%, $p=0.027$). Higher surgical rates were seen in apex sinus contact as well (52.6%- 28.6%, $p=0.015$), whereas invasive dental pathology didn't show any significant association ($p=0.586$). Left-sided maxillary scores were significantly higher in patients with dental pathology ($p=0.027$).

CONCLUSIONS

In this research we found out that dental pathologies are significantly associated with increased surgical requirement and CRS laterality. Ipsilateral concordance supports a relevant relationship between dental and sinonasal disease. These findings highlight the importance of dental evaluation in CRS patients and in addition supports that dental pathology may influence CRS prognosis and management strategies.

Fatal Rhino-Orbital Mucormycosis In A Patient With End-Stage Liver Disease Awaiting Transplantation: A Case Report

MÜZEYYEN ERDOĞAN ZENGİN[1], **ÖZGÜR KÜMÜŞ**[1], **TOLGA ERSÖZLÜ**[1], **ERDOĞAN GÜLTEKİN**[1]

[1]*TEKIRDAG NAMIK KEMAL UNIVERSITY*

BACKGROUND & AIM

INTRODUCTION: Mucormycosis, caused by fungi of the order Mucorales, is characterized by angioinvasion and extensive tissue necrosis. In patients with liver failure, neutrophil dysfunction and altered iron metabolism create a permissive environment for fungal proliferation.(1) Rhino-orbital-cerebral mucormycosis (ROCM) is a rapidly progressive and highly fatal opportunistic fungal infection, particularly in immunocompromised individuals.(2)(3) This case highlights the extreme vulnerability and high mortality rates associated with mucormycosis in patients with metabolic and hepatic failure.

MATERIAL & METHODS

CASE PRESENTATION: A 72-year-old female with a medical history of hypertension,diabetes and end-stage liver disease (on the liver transplant waiting list) presented to the emergency department with deteriorating general status and vision loss. Endoscopic endonasal examination showed an atrophic left middle turbinate covered with characteristic black fungal hyphae (eschar). Additionally restrictive ophthalmoplegia was observed in all quadrants of the left eye.

Computed Tomography (CT) demonstrated obliteration of the left anterior ethmoid cells and significant edema within the orbital fat. Intraoperatively, the left middle turbinate was found to be necrotic and covered with black hyphae. Total

ethmoidectomy and maxillary sinus ostium expansion were performed. Although the lamina papyracea appeared macroscopically intact, it was electively opened to facilitate a thorough inspection of the retrobulbar orbital fat, which subsequently revealed early signs of fungal infiltration. Necrotic tissues, including the middle turbinate axilla, were totally debrided, and samples were sent for histopathology and microbiology.

RESULTS

CLINICAL COURSE AND OUTCOME: Microbiological cultures confirmed the growth of Rhizopus spp. Intensive treatment was initiated with both intravenous and retrobulbar amphotericin B. However, the patient's condition worsened due to the severity of the underlying liver disease and metabolic instability. She was transferred to the intensive care unit (ICU) and subsequently passed away due to multi-organ failure.

CONCLUSIONS

DISCUSSION AND CONCLUSION: The mortality rate for mucormycosis in patients with liver cirrhosis is reported to exceed 80% in the literature.(4) The acidic environment found in diabetic and hepatic failure patients increases iron bioavailability, which significantly enhances the virulence of Rhizopus.(5) This case underscores that in high-risk groups awaiting organ transplantation, early recognition of nasal mucosal changes and orbital symptoms is critical. Although retrobulbar therapy serves as a potential alternative to orbital exenteration, the prognosis remains guarded in patients with end-stage liver disease due to severe immunosuppression and multi-organ frailty.(6)

ENT- RELATED ISLAMIC INSTRUCTIONS

Hesham BadrEldin Elmashad[1]

[1]*MAKKAH INSTITUTE FOR SPEECH AND HEARING (MISH)*

BACKGROUND & AIM

To let people know these instructions, which can treat and/or prevent many diseases. The beauty of these instructions is that they are not exclusive to Muslims; on the contrary, they can be applied by any Muslim or non-muslim.

MATERIAL & METHODS

By collecting some of the ENT-related Islamic instructions that have a strong impact on some ENT-related diseases.

RESULTS

It is found many Islamic Instructions that can treat and/or prevent some ENT-related diseases, such as sinusitis, halitosis, and obstructive sleep apnea.... These instructions are easily applicable and highly cost-effective.

CONCLUSIONS

Muslim or Non-Muslim, if he follows these instructions strictly, he will gain much more than he expects.

Addition Of Inferior Meatal Antrostomy To Prelacriamal Approach As A Modification To Improve Postoperative Maxillary Sinus Access: Techniqual Note

seyed Mousa Sadrehosseini[1], **Farhad arbabzadeh**[1]

[1]*Rhinology and Skull Base Surgery Division, Otolaryngology Head Neck Surgery Department, Imam Khomeini Hospital Complex, Tehran University of Medical Sciences, Tehran, Iran*

BACKGROUND & AIM

The prelacrimal approach to the maxillary sinus has been described as an effective technique that provides wide exposure and optimal visualization of the maxillary walls for the management of inflammatory and tumorous diseases of the maxillary sinus. However, one of its main drawbacks is the restricted endoscopic access to the maxillary sinus during postoperative office evaluations. The addition of the functional medial maxillectomy technique is described in this article as a complementary modification to improve postoperative accessibility and visualization of the maxillary sinus.

MATERIAL & METHODS

We classified the prelacrimal approach into three subtypes: Prelacrimal approach without middle meatal antrostomy, Prelacrimal approach with middle meatal antrostomy & Prelacrimal approach with middle meatal and inferior meatal antrostomy. Prelacrimal approach with MMA & IMA recommended in tumorous or inflammatory cases which post operative maxillary access is necessary.

RESULTS

Prelacrimal approach with MMA & IMA recommended in tumorous or inflammatory cases which post operative maxillary access is necessary.

CONCLUSIONS

The addition of functional medial maxillectomy to the prelacrimal approach provides improved post operative access to maxillary sinus in office endoscopic evaluations.

PP-577

A Rare Variant Of Perioperative Pharyngeal Neuropraxia Following Rhinoplasty: Why It Is NOT A Classical Tapia's Syndrome?

Hüzna Elmalı[1], **Cem Bulut**[1], **İlker Burak Arslan**[1]

[1]*Department of Otolaryngology - Head and Neck Surgery, Izmir City Hospital, Izmir, Turkey*

BACKGROUND & AIM

Iatrogenic cranial nerve injuries during non-head and neck surgeries are rare. While Tapia's Syndrome (concurrent paralysis of the recurrent laryngeal and hypoglossal nerves) is more commonly recognized, isolated involvement of the Vagus nerve's pharyngeal branches remains exceptionally rare. This report aims to present an isolated unilateral soft palate paralysis presenting with delayed-onset nasal regurgitation following an uncomplicated septorhinoplasty and to emphasize the importance of differentiating this focal neuropraxia from more extensive neurological syndromes.

MATERIAL & METHODS

A retrospective clinical analysis was conducted on a 22-year-old female patient who developed nasal regurgitation two weeks after elective septorhinoplasty. The diagnostic workup included physical examination, fiberoptic laryngoscopy to assess vocal cord and tongue mobility, neurology consultation, cranial MRI, and Electromyography (EMG). The patient's management involved systemic corticosteroid therapy and Vitamin B complex, with a follow-up period of two months to monitor clinical resolution.

RESULTS

Clinical examination confirmed unilateral failure of soft palate elevation and uvular deviation. Fiberoptic laryngoscopy showed normal vocal cord mobility, and tongue movements were preserved, ruling out classical Tapia's Syndrome. Cranial MRI and EMG were normal, supporting a diagnosis of localized perioperative neuropraxia of the pharyngeal plexus. Following treatment with systemic methylprednisolone (1 mg/kg/day) and Vitamin B complex, full clinical resolution of the velopharyngeal insufficiency was achieved within eight weeks.

CONCLUSIONS

Perioperative pharyngeal neuropraxia can occur as an isolated entity following rhinoplasty, distinct from the broader Tapia's Syndrome. Clinicians should maintain a high index of suspicion for velopharyngeal insufficiency if nasal reflux is reported postoperatively, even without hoarseness. A systematic approach involving neurology consultation and electrophysiological studies is essential to confirm the transient nature of the injury. Isolated pharyngeal neuropraxia carries an excellent prognosis with appropriate corticosteroid and vitamin therapy.

PP-578

Comparative Analysis Of Hematological Parameters In Chronic Rhinosinüsitis With Nasal Polyps

Neslihan Sarı[1], **Hasan Basri Savaş**[2]

[1]*Department of Otolaryngology-Head and Neck Surgery, Faculty of Medicine, Mardin Artuklu University, Mardin, Türkiye.*; [2]*Department of Biochemistry,Faculty of Medicine, Mardin Artuklu University, Mardin, Türkiye.*

BACKGROUND & AIM

Chronic Rhinosinüsitis with Nasal polyposis(CRSwNP) is chronic inflammatory lesions of the sinonasal mucosa with an unclear etiology involving both genetic and environmental factors. Over time, these factors interact to drive the disease through various inflammatory mechanisms in CRSwNP. Recently, routine hematological parameters have gained attention as markers of this systemic inflammation in chronic inflammatory diseases. This study aimed to compare these parameters between nasal polyp patients and healthy controls to evaluate their association with CRSwNP.

MATERIAL & METHODS

This retrospective, comparative study reviewed patients who underwent functional endoscopic sinus surgery (FESS) for CRSwNP (n=50) at Mardin Education and Research Hospital over 3 years. The control group comprised patients undergoing

septoplasty or rhinoplasty with normal paranasal sinus CT scans(n=50) over 2 years. Complete blood count data—including WBC, neutrophil, lymphocyte, eosinophil, and platelet counts, MPV, NLR, PLR, and ELR—were analyzed. Statistical comparisons were performed between groups, with p <0.05 considered statistically significant.

RESULTS

Among the inflammatory hematological markers, eosinophil and neutrophil counts were statistically significantly higher in the CRSwNP group (both p<0.05). Although NLR and PLR values tended to be elevated in patients with CRSwNP, the difference did not reach statistical significance (p>0.05). Eosinophilia was observed in 48% (n=24/50) of the patients with NP, while neutrophilia was present in 18% (n=9/50). These findings suggest a strong association between the systemic inflammatory response and CRSwNP.

CONCLUSIONS

Hematological parameters derived from routine blood tests, particularly preoperative eosinophil and neutrophil counts, may serve as useful, inexpensive, and easily accessible biomarkers in patients with CRSwNP. Furthermore, these preoperative inflammatory indices might contribute to predicting disease recurrence and evaluating inflammatory activity in CRSwNP. While indices like NLR and PLR showed an elevated trend, further prospective studies with larger sample sizes are required to fully elucidate their prognostic utility.

Effectiveness Of Balloon Sinuplasty In Patients With Isolated Chronic Frontal Rhinosinusitis Without Nasal Polyps

Hatice Ünsal[1], **İlhan Topaloğlu**[1], **Meryem Babaoğlan**[1], **Müzeyyen Doğan**[1], **Yavuz Selim Pata**[1]

[1]*Yeditepe University Faculty of Medicine, Department of Otorhinolaryngology, Istanbul, Turkey*

BACKGROUND & AIM

Studies specifically evaluating balloon sinuplasty in patients with isolated chronic frontalrhinosinusitis without nasal polyps are limited. This study aimed to assess the effectiveness of balloon sinuplasty by evaluating postoperative changes in disease-specific sinonasal qualityof life as the primary outcome and nasal obstruction-related symptoms as the secondaryoutcome.

MATERIAL & METHODS

This single-center study was conducted at the Department of Otorhinolaryngology, Yeditepe University Faculty of Medicine, Istanbul, Türkiye. Patients with isolated chronic frontalrhinosinusitis without nasal polyps who underwent balloon sinuplasty between February 2013 and January 2024 were included. Patients with nasal polyps, previous sinonasal surgery, concomitant sinonasal procedures other than balloon sinuplasty, or incomplete postoperativefollow-up data were not included. Disease-specific sinonasal quality of life and nasalobstruction-related symptoms were evaluated preoperatively and at postoperative 3 and 6 months using the 22-item Sino-Nasal Outcome Test (SNOT-22) and the Nasal ObstructionSymptom Evaluation (NOSE) scale, respectively.

RESULTS

A total of 21 patients were included. The mean age at surgery was 36.52 ± 8.21 years and 5 patients were female and 16 were male. Balloon sinuplasty was performed unilaterally in 16 patients and bilaterally in 5 patients.

Mean SNOT-22 score decreased significantly from 49.38 ± 2.96 preoperatively to 26.05 ± 2.77 at 3 months and to 22.57 ± 3.26 at 6 months postoperatively. Compared withpreoperative values, the improvement in SNOT-22 scores was statistically significant at both3 months and 6 months postoperatively (both p<0.001).

Mean NOSE score was 40.00 ± 10.49 preoperatively, 39.29 ± 9.52 at 3 months, and 38.57 ± 10.02 at 6 months postoperatively. Compared with preoperative values, NOSE scores did not show a statistically significant change at neither 3 months nor 6 months postoperatively (bothp>0.05).

CONCLUSIONS

Balloon sinuplasty was associated with significant improvement in disease-specific sinonasalquality of life in patients with isolated chronic frontal rhinosinusitis without nasal polyps. However, nasal obstruction-related symptom scores did not demonstrate a statisticallysignificant postoperative change. These findings suggest that balloon sinuplasty mayprimarily improve disease-specific quality of life rather than nasal obstruction-relatedsymptoms in this patient population.

Extensive Sinonasal Osteochondromyxoma With Orbital And Intracranial Extension In A Pediatric Patient: Combined Transorbital And Endonasal Management

Beyza Mercan[1], **Tufan Agah Kartum**[2], **Fatma Özlen**[2], **Alperen Vural**[1]

[1]Department of Otolaryngology-Head and Neck Surgery,Istanbul University Cerrahpasa Medical Faculty ,Istanbul,Turkey; [2]Department of Neurosurgery, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

BACKGROUND & AIM

Osteochondromyxoma is an extremely rare benign bone tumor characterized by locally aggressive behavior and a high recurrence rate. Craniofacial involvement is uncommon, and extensive sinonasal disease with orbital and intracranial extension is exceptionally rare. We hypothesized that combined transorbital and endoscopic endonasal surgery allows safe and effective gross total resection in advanced cases.

MATERIAL & METHODS

A 14-year-old female presented with progressive bilateral visual impairment for one year and right-sided proptosis. Initial biopsy at an external center suggested myxoma; repeat biopsy confirmed osteochondromyxoma. Magnetic resonance imaging (MRI) and computed tomography (CT) demonstrated a destructive mass occupying the nasal cavity, eroding bilateral lamina papyracea with retroorbital extension and extraocular muscle involvement. The lesion extended to the pterygopalatine fossa, masticator space, sphenoid sinus, cribriform plate, planum sphenoidale, and intracranial compartment with dural thickening. Bilateral cavernous internal carotid arteries were displaced laterally. Endocrine evaluation was normal. Carney complex was suspected; however, echocardiography excluded cardiac myxoma.

RESULTS

The patient underwent combined transorbital and endoscopic endonasal resection of the tumor. Despite extensive skull base erosion , no dural defect or cerebrospinal fluid leakage was identified, and therefore no dural reconstruction was required. Gross total resection was achieved without vascular injury. Postoperatively, right eye proptosis regressed, ocular motility normalized bilaterally, and visual acuity improved (right: counting fingers; left: 7/10).No recurrence was observed at 6-month follow-up.

CONCLUSIONS

Sinonasal osteochondromyxoma may present with extensive skull base and orbital involvement, mimicking other fibro-osseous lesions. Multidisciplinary management and aggressive but carefully planned surgical resection are essential to achieve complete tumor removal while minimizing morbidity.

A Rare Case Of Superior Ophthalmic Vein Thrombosis Secondary To Acute Pansinusitis

SAFİYE GİRAN ÖRTEKİN[1], ŞAHİN ÖĞREDEN[1], FATMA SAVUR[2], TÜLİN ÖĞREDEN[2], TÜRKÜ BAYRAMOĞLU[1], BÜŞRA NUR ÇOŞAN SEÇKİN[1], NURSENA NAİR POLAT[1], KAAN UNCU[1], ÖZGÜR YİĞİT[1]

[1]Department of Otorhinolaryngology, Başakşehir Çam and Sakura City Hospital, Istanbul, Turkey; [2]Department of Ophthalmology, Başakşehir Çam and Sakura City Hospital, Istanbul, Turkey

BACKGROUND & AIM

Superior ophthalmic vein thrombosis (SOVT) is a rare but potentially vision and life threatening orbital emergency. While the most common causes include infectious processes such as orbital cellulitis and paranasal sinusitis, non-infectious factors may also contribute. Clinically, it presents with ptosis, proptosis, chemosis, and decreased vision; however, these findings can mimic orbital cellulitis and cavernous sinus thrombosis, making differential diagnosis challenging. Contrast-enhanced CT, MRI, and MR venography play a key role in diagnosis. Early recognition and prompt treatment are critical to prevent serious complications. In this study, we present a case of SOVT secondary to acute pansinusitis.

MATERIAL & METHODS

We report a 15 year old female patient who presented with a two day history of right periorbital swelling, fever, decreased vision, and ocular pain. Physical examination revealed marked periorbital edema, hyperemia, and chemosis, accompanied by glabellar and prefrontal swelling. Nasal endoscopy demonstrated bilateral purulent discharge, and ocular motility was restricted with subsequent development of diplopia. Imaging studies showed pansinusitis on computed tomography. Contrast-enhanced orbital magnetic resonance imaging (MRI) revealed inflammatory changes in the orbital fat, findings consistent with periorbital cellulitis, and a diffusion-restricted, peripherally enhancing collection in the frontal sinus suggestive of abscess formation. Additionally, the superior ophthalmic vein appeared dilated with lack of contrast filling and wall enhancement, consistent with SOVT. Magnetic resonance venography excluded cavernous sinus thrombosis.

RESULTS

The patient was promptly started on intravenous broad-spectrum antibiotics and anticoagulation therapy. Emergency functional endoscopic sinus surgery (FESS) was performed, achieving adequate drainage of purulent material from the maxillary and frontal sinuses. Postoperatively, the patient demonstrated rapid clinical improvement, with resolution of orbital signs and restoration of full ocular motility. Evaluation for underlying hypercoagulable states and systemic diseases was unremarkable.

CONCLUSIONS

Orbital complications of acute rhinosinusitis are rare but can be serious if not recognized early. In our case, marked edema in the glabellar region raised suspicion for venous involvement and prompted further imaging. MRI revealed a filling defect in the superior ophthalmic vein, and MR venography confirmed absent flow, establishing the diagnosis of SOVT. Management requires a multidisciplinary approach. Intravenous antibiotics are essential in infectious cases, while anticoagulation helps prevent thrombus progression. When sinusitis or abscess is present, surgical drainage with endoscopic sinus surgery is crucial. Early combined treatment in our patient led to rapid recovery without complications.

Primary Ectopic Olfactory Neuroblastoma Of The Sphenoid Sinus: A Rare Case

Alper Özdemir[1], **Ferhat Deniz**[1], **Şaban Furkan Yalçın**[1], **Banu Öksüz Ok**[1], **Erhan Arslan**[1], **Cem Saka**[1]

[1]*Department of Otorhinolaryngology, Ankara Etlik City Hospital, Ankara, Turkey*

BACKGROUND & AIM

Olfactory neuroblastoma is a rare malignant neuroectodermal tumor comprising 3% to 5% of sinonasal tumors. ONB occurs equally in males and females and is most common in the second and sixth decades. ONB typically arises in the superior nasal cavity along the cribriform niche (1,2). The development of an ONB in an ectopic location, albeit exceedingly rare, may occur in sites like the nasopharynx, maxillary sinus, and ethmoid and sphenoid sinuses (2,3). These atypical locations and histological variability pose significant diagnostic challenges for both radiologists and pathologists. We present a rare sphenoid ONB case evaluated with CT and MRI.

MATERIAL & METHODS

A 71-year-old male with no significant medical history presented with a one-year history of left-sided nasal obstruction. Non-enhanced paranasal sinus CT revealed soft tissue densities extending from the left nasal cavity into the posterior ethmoid and left sphenoid sinus. Contrast-enhanced MRI demonstrated a 24x14 mm diffusely enhancing nodular lesion in the posterior left nasal cavity, adjacent to the inferior turbinate.

The patient underwent a 'Left Sphenochoanal Polyp Excision + Sphenoid Sinusotomy + Posterior Ethmoidectomy' surgery. Intraoperatively, a polypoid mass originating from the anterior wall of the sphenoid sinus and extending to the choana was identified and excised. The sphenoid sinus interior mucosa was intact.

Immunohistochemical evaluation revealed tumor cells positive for synaptophysin, chromogranin, CD56, and INSM-1. Prominent mitotic activity and Flexner-Wintersteiner rosettes were observed, confirming a diagnosis of 'Neuroblastoma, Hyams Grade 3'.

RESULTS

ONB originates from neural crest cells in the olfactory epithelium. While typically presenting in the nasal vault with unilateral obstruction and epistaxis, ectopic primary ONBs are exceptionally rare. Management utilizes the Kadish system (A–D) for clinical staging and the Hyams system (I–IV) for pathological grading. Our patient was classified as Kadish Stage B and Hyams Grade 3. Following a multidisciplinary tumor board evaluation, adjuvant radiotherapy combined with carboplatin-etoposide chemotherapy was planned.

CONCLUSIONS

Despite its rarity, ONB must be considered in the differential diagnosis of aggressive sphenoid sinus tumors. Accurate clinical diagnosis, fine interpretation of imaging, precise tissue evaluation, and a multidisciplinary team approach are mandatory for early detection and optimal management.

Advanced Sinonasal Squamous Cell Carcinoma With Orbital And Skull Base Involvement: Multimodal And Multidisciplinary Management And Complex Reconstruction

Oguz Kaan Kose[1], **Kiarash Shamekhi**[1], **Firat Tevetoglu**[1], **Tufan Agah Kartum**[2], **Yetkin Zeki Yılmaz**[1], **Alperen Vural**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, Istanbul University-Cerrahpaşa, Cerrahpaşa Faculty of Medicine, Istanbul, Turkey;*
[2]*Department of Neurosurgery, Istanbul University-Cerrahpaşa, Cerrahpaşa Faculty of Medicine, Istanbul, Turkey*

BACKGROUND & AIM

Sinonasal malignancies are a heterogeneous group of tumors with variable biological behavior that often require individualized treatment strategies. In locally advanced disease, multimodal management combining systemic therapy, surgery, and radiotherapy is widely accepted [1,3]. Induction chemotherapy has increasingly been used in advanced sinonasal SCC, particularly in cases with orbital or skull base involvement, to assess tumor biology and guide treatment planning [3–5].

This study aims to present a case of advanced sinonasal SCC managed with a multidisciplinary, multimodal approach, highlighting intraoperative decision-making and reconstruction of a laterally extended skull base defect where standard intranasal flaps were not feasible [2].

MATERIAL & METHODS

A 50-year-old male presented with headache and retro-orbital pain in January 2025. Biopsy at an outside center revealed poorly differentiated squamous cell carcinoma. Ophthalmologic evaluation showed reduced visual acuity and restricted extraocular movements. Imaging demonstrated a mass in the left nasal cavity extending to the skull base and orbit.

The tumor was classified as T4 at a multidisciplinary tumor board. Induction chemotherapy with docetaxel, cisplatin, and 5-fluorouracil was completed in May 2025, achieving partial response. In July 2025, the patient underwent endoscopic tumor resection. Frozen sections revealed optic nerve involvement, leading to orbital exenteration, and confirmed dural invasion; margins were negative.

A nasoseptal flap was prepared but not used due to tumor involvement. A 4 × 4 cm skull base defect extending laterally over the right orbital roof through left zygoma was reconstructed using multilayer fascia lata, adipose tissue, and temporoparietal fascia flaps with a side-door technique [9]. Adjuvant chemoradiotherapy was administered.

RESULTS

Sinonasal malignancies are rare, heterogeneous tumors that often present at an advanced stage, requiring a multidisciplinary and multimodal treatment approach [1]. Current guidelines recommend surgery followed by radiotherapy, with or without chemotherapy, in locally advanced sinonasal squamous cell carcinoma [1,2].

Induction chemotherapy has gained increasing interest in T3–T4 disease for assessing tumor biology and guiding treatment planning [3–5]. In our case, partial response was achieved; however, persistent involvement of critical structures necessitated surgical resection.

Intraoperative decision-making was crucial, as frozen section detection of optic nerve involvement led to orbital exenteration. Although orbit-sparing strategies may be considered, involvement of critical structures remains an indication for radical surgery [4,6].

Laterally extended skull base defects pose a reconstructive challenge, where standard intranasal flaps may be insufficient. Multilayer reconstruction combined with vascularized flaps provides reliable coverage and reduces complications [2,7,8].

CONCLUSIONS

Advanced sinonasal SCC requires a multidisciplinary, stepwise approach. Induction chemotherapy can aid treatment planning and may improve outcomes in selected patients [3–5]. Intraoperative findings, particularly optic nerve involvement, can directly influence surgical decisions, including the need for orbital exenteration. In large, laterally extended skull base defects where intranasal flaps are not feasible, multilayer reconstruction with vascularized flaps such as temporoparietal flap provides a reliable solution.

Lateral Intraconal Abscess Associated With Acute Rhinosinusitis In An Adult Patient

Georgios Louverdis[1], **Georgios Tsaknias**[1], **Anastasia Oikonomou**[1], **Konstantinos Papageorgiou**[1], **Dimitrios Terzakis**[1]

[1]ENT Department, General Hospital of Athens "Korgialeneio-Mpenakeio", Greece

BACKGROUND & AIM

Orbital complications have an incidence of 5% to 7% in patients with acute rhinosinusitis (ARS). Although orbital complications are well documented in pediatric populations, orbital involvement associated with ARS is rare in adults. Infection can spread either directly to the orbital cavity through neurovascular foramina and congenital/acquired bony dehiscence, or indirectly through hematogenous spread. Predisposing factors associated with orbital complications are: immunocompromised patients

and impaired sinus drainage. Orbital involvement of sinonasal infection was classified by Chandler et al into 5 groups (I: preseptal oedema, II: orbital cellulitis, III: subperiosteal abscess, IV: orbital abscess, V: cavernous sinus thrombosis).

MATERIAL & METHODS

An 81-year-old, female patient was hospitalized with decompensated heart failure at the cardiology department of our hospital. Four days after her hospital admission, she exhibited left periorbital redness with oedema and complained of left hemifacial pain. She reported purulent nasal discharge the days prior to her admission, which has ceased since. On clinical examination, she presented with chemosis, proptosis and ophthalmoplegia of her left eye. She also had impaired visual acuity on ophthalmologic assessment. A CT scan showed opacification of the left ethmoid and maxillary sinus, along with inflammatory findings in the ipsilateral intraconal department. As an orbital abscess was suspected, an MRI with gadolinium was subsequently performed. It revealed a lateral intraconal abscess and the patient underwent an urgent operation. The operative treatment consisted of a combined endoscopic and external approach. Through the extrenal approach, lateral canthotomy and cantholysis was performed in order to drain the orbital abscess.

RESULTS

The patient received piperacillin/tazobactam and vancomycin intravenously for a week. During the postoperative period she exhibited constant clinical improvement and was discharged a week postoperatively. On her follow up visit two weeks postoperatively, she had complete ocular motility without diplopia and no visual impairment.

CONCLUSIONS

Orbital complications of ARS are rare in adults, but of great clinical significance as they can result in vision impairment and morbidity. Early diagnosis and appropriate intervention are critical.

Isolated Chronic Sphenoidal Sinusitis: A Diagnostic Challenge — Case Report

Jetmira Fejza[1], **Roven Sinani**[1], **Besim Boci**[1]

[1]*Art orl clinic*

BACKGROUND & AIM

Isolated chronic sphenoidal sinusitis is an uncommon condition, representing less than 3% of all paranasal sinus diseases. Its deep anatomical location and nonspecific clinical presentation often lead to delayed diagnosis. Patients frequently present with vague symptoms such as persistent headache, retro-orbital pain, or visual disturbances, without typical sinonasal complaints. Early recognition is essential due to the proximity of the sphenoid sinus to critical neurovascular structures.

MATERIAL & METHODS

We report the case of a 42-year-old patient presenting with persistent retro-orbital headache for over three months, unresponsive to medical treatment. Nasal endoscopy findings were normal. Computed tomography (CT) scan revealed isolated opacification of the sphenoid sinus, with no involvement of other paranasal sinuses. There were no neurological deficits or visual disturbances. The patient underwent endoscopic transnasal sphenoidotomy. Intraoperatively, thick mucopurulent secretions and inflamed mucosa confined to the sphenoid sinus were observed. Samples were obtained for microbiological analysis to guide targeted postoperative therapy.

RESULTS

The postoperative course was uneventful, with complete resolution of symptoms. Follow-up endoscopic examination and imaging confirmed adequate sinus ventilation and absence of disease recurrence. The patient remained symptom-free during follow-up

CONCLUSIONS

Isolated chronic sphenoidal sinusitis should be considered in patients with persistent, unexplained headache. CT imaging is crucial for diagnosis, and endoscopic sphenoidotomy is an effective treatment. Prompt management is essential to prevent potentially serious complications.

Modified Castelnuovo Approach With Costal Cartilage Sandwich Grafting For Simultaneous Septal Perforation Repair During Structural Rhinoplasty: A Case Report

Efe Can[1], **Melisa İlayda Kalkan**[1]

[1]*Antalya City Hospital*

BACKGROUND & AIM

Surgical closure of medium-to-large septal perforations (SPs) remains a significant challenge, requiring both tension-free mucosal coverage and rigid structural support. This report presents a hybrid reconstructive approach utilizing bilateral anterior ethmoidal artery (AEA) pedicled flaps combined with a costal cartilage "sandwich" interposition, performed simultaneously with structural rhinoplasty.

MATERIAL & METHODS

A 23-year-old female presented with a 3-year history of symptomatic 1.5 x 1.3 cm idiopathic anterior septal perforation and aesthetic concerns. A single-stage procedure was performed, integrating endonasal bilateral AEA-based mucosal flaps and an interpositional 2.5-cm thin costal cartilage graft. The graft was sutured posteriorly to the caudal septum for stability. Simultaneously, an open structural rhinoplasty was conducted using autologous costal cartilage for L-strut reinforcement and tip reconstruction.

RESULTS

Postoperative week 3 endoscopic evaluation revealed partial mucosal necrosis of the right inferior turbinate, which resolved with conservative management. Complete epithelialization of the septal repair site was achieved by week 6. At the 1-year follow-up, endoscopic evaluation confirmed a stable, fully closed perforation with healthy respiratory-type mucosa and no signs of thinning. The patient reported complete resolution of crusting, epistaxis, and whistling, with high satisfaction regarding functional and aesthetic outcomes.

CONCLUSIONS

The hybrid modification of the Castelnuovo technique, integrating bilateral AEA flaps with costal cartilage interposition, provides robust vascular support and long-term structural integrity. This approach is an effective strategy for the single-stage management of medium-to-large perforations while allowing for successful aesthetic refinement.

PP-588

Warthin Tumor In The Nasopharynx: A Rare Cause Of Nasopharyngeal Fullness

Şahika Çelenk[1], **Gizem Karaca**[1]

[1]*Kocaeli City Hospital*

BACKGROUND & AIM

Nasopharyngeal fullness is a common finding in otolaryngology, often presenting with nasal obstruction or aural fullness, though frequently detected incidentally. This case report describes a patient presenting with a neck mass who was diagnosed with a nasopharyngeal Warthin tumor following endoscopic evaluation and biopsy. The primary objective of this report is to emphasize the critical role of systematic endoscopic nasopharyngeal examination in patients presenting with cervical lymphadenopathy. Furthermore, it aims to raise clinical awareness among junior residents regarding rare, atypical pathologies that may involve the nasopharynx beyond common presentations.

MATERIAL & METHODS

A 62-year-old male presented with a several-month history of an asymptomatic right-sided neck mass. Physical examination revealed a 2x2 cm, mobile, solid mass at the tail of the right parotid gland. While otoscopic and laryngeal examinations were unremarkable, nasal endoscopy identified an incidental nasopharyngeal fullness. Neck ultrasonography (USG) demonstrated two prominent lymph nodes (18x10 mm and 13x10 mm) with increased cortical thickness (5 mm) and preserved hila, adjacent to the inferior parotid gland. Contrast-enhanced MRI initially interpreted these as nodular lymphadenopathies, with no significant enhancement in the nasopharynx.

USG-guided fine-needle aspiration biopsy (FNAB) of the cervical node revealed polymorphic lymphoid cells. However, a punch biopsy of the nasopharyngeal lesion confirmed histopathological findings consistent with a Warthin tumor. This rare extra-parotid presentation underscores the diagnostic importance of comprehensive endoscopic evaluation in patients presenting with cervical masses, even when primary symptoms are localized elsewhere.

RESULTS

Following a multidisciplinary clinical council evaluation, a three-month follow-up was recommended. At the first interval, the cervical lymphadenopathy persisted; however, endoscopic examination revealed no significant nasopharyngeal fullness. Repeat ultrasonography demonstrated a reduction in the dimensions of the infra-parotid nodes (13x6 mm and 10x4.8 mm) with decreased cortical thickness (2.1 mm) and preserved hila. A control MRI performed six months post-initial imaging identified a 10 mm extra-parotid lymph node at the inferior-posterior aspect of the right parotid gland, with no abnormal contrast enhancement in the nasopharynx. Following this evaluation, the patient voluntarily opted out of further clinical surveillance. This sequence suggests a regressive course for the reactive lymphadenopathy despite the initial biopsy findings.

CONCLUSIONS

Nasopharyngeal fullness is a common finding, typically attributed to adenoid hypertrophy or malignancies like nasopharyngeal carcinoma. However, nasopharyngeal Warthin tumors are exceedingly rare. Unlike synchronous cases reported in literature, our patient presented with isolated nasopharyngeal involvement. Given the asymptomatic course and spontaneous resolution of endoscopic findings, a conservative 'watch-and-wait' approach was adopted instead of surgical intervention. This case emphasizes the necessity of comprehensive endoscopic nasopharyngeal evaluation in patients with cervical lymphadenopathy. Especially under high clinical workloads, junior residents must maintain high diagnostic suspicion for such rare entities to ensure timely biopsy and personalized management.

PP-589

Evaluation Of The Effectiveness Of Endoscopic Holmium:YAG Laser-Assisted Inferior Turbinate Reduction

Meryem Babaoğlan[1], **İlhan Topaloğlu**[1], **Hatice Ünsal**[1], **Müzeyyen Doğan**[1], **Yavuz Selim Pata**[1]

[1]*Yeditepe University Faculty of Medicine, Department of Otorhinolaryngology, Istanbul, Turkey*

BACKGROUND & AIM

Inferior turbinate hypertrophy is a common cause of chronic nasal obstruction and surgical treatment aims to improve nasal patency while preserving turbinate function. This study aimed to evaluate the effectiveness of Holmium:YAG laser-assisted endoscopic inferior turbinate reduction by assessing postoperative changes in nasal obstruction symptoms and sinonasal quality of life.

MATERIAL & METHODS

This study was conducted at the Department of Otorhinolaryngology, Yeditepe University Faculty of Medicine, Istanbul, Türkiye. Adult patients who underwent Holmium:YAG laser-assisted endoscopic inferior turbinate reduction for inferior turbinate hypertrophy between March 2013 and June 2025 were included. Patients who underwent additional nasal or sinonasal surgical procedures were excluded. Nasal obstruction-related symptoms and sinonasal quality of life were evaluated preoperatively and at postoperative 3 and 6 months using the Nasal Obstruction Symptom Evaluation (NOSE) scale and the Sino-Nasal Outcome Test-22 (SNOT-22).

RESULTS

A total of 382 adult patients were included. The mean age at surgery was 37.4 ± 11.4 years. The cohort included 193 males and 189 females. Postoperative questionnaire data were available for 331 patients at 3 months and 303 patients at 6 months; 281 patients had complete follow-up data, while 29 had preoperative data only. The mean NOSE score decreased from 71.5 ± 12.2 preoperatively to 30.5 ± 17.4 at 3 months and 26.0 ± 23.9 at 6 months. Both postoperative scores were significantly improved compared with preoperative values (both $p<0.001$), with no significant difference between 3 and 6 months ($p>0.05$). The mean SNOT-22 score decreased from 42.5 ± 5.3 preoperatively to 22.4 ± 7.1 at 3 months and 20.0 ± 11.6 at 6 months. Both postoperative scores were significantly improved compared with preoperative values (both $p<0.001$), with no significant difference between 3 and 6 months ($p>0.05$).

CONCLUSIONS

Isolated endoscopic inferior turbinate reduction using Holmium:YAG laser was associated with significant improvement in nasal obstruction symptoms and sinonasal quality of life, with benefits observed at 3 months and maintained at 6 months postoperatively.

An Unusual Concurrence Of Lemierre Syndrome And Preseptal Cellulitis Secondary To Chronic Rhinosinusitis With Nasal Polyposis:A Case Report

Özgür Demir[1], **Dilara Aydın**[1], **Ömer Erdur**[2]

[1]*Department of Otorhinolaryngology-Head and Neck Surgery, Selçuk University, Faculty of Medicine, Konya, Türkiye.*; [2]*Department of Otorhinolaryngology-Head and Neck Surgery, Liv Hospital Ulus, Istanbul, Türkiye*

BACKGROUND & AIM

Lemierre syndrome is a rare but potentially life-threatening condition characterized by septic thrombophlebitis of the internal jugular vein following head and neck infection. Although classically associated with oropharyngeal sources, atypical presentations arising from sinonasal, odontogenic, or periocular infections are increasingly recognized. Preseptal cellulitis is commonly associated with rhinosinusitis but rarely occurs in conjunction with Lemierre syndrome.

MATERIAL & METHODS

A 34-year-old male presented with right periorbital swelling, facial edema, fever, and malaise. His medical history included chronic rhinosinusitis with nasal polyposis, prior functional endoscopic sinus surgery, and recent mandibular molar extraction. Imaging revealed pansinusitis, right-sided preseptal cellulitis, and a suspected thrombus in the right internal jugular vein. The patient was treated with broad-spectrum intravenous antibiotics, anticoagulation, and supportive therapy. Due to rapid clinical deterioration and progression of ophthalmologic findings, urgent endoscopic sinus surgery was performed. Persistent symptoms prompted repeat imaging, which demonstrated a frontal sinus abscess requiring revision surgery. During follow-up, treatment-related complications, including cytopenia, neutropenia, and drug-related rash, were observed. Subsequent imaging suggested frontal sinus osteomyelitis, and prolonged intravenous antibiotic therapy was administered.

RESULTS

This case illustrates an atypical presentation of Lemierre syndrome originating from a non-oropharyngeal source. Chronic rhinosinusitis with nasal polyposis and a possible odontogenic infection may have contributed to the development of septic thrombophlebitis and periocular involvement. The coexistence of preseptal cellulitis and internal jugular vein thrombosis may obscure the diagnosis and delay appropriate management. Recognition of atypical clinical pathways and early imaging are essential for timely diagnosis.

CONCLUSIONS

Lemierre syndrome should be considered in patients with sinonasal or periocular infections who develop systemic inflammatory findings or evidence of venous thrombosis. Early diagnosis, aggressive antimicrobial therapy, and timely surgical intervention are critical to prevent severe complications and improve clinical outcomes.

Lemierre Syndrome; Preseptal Cellulitis; Sinusitis; Jugular Vein Thrombosis; Nasal Polyps

PP-591

A Rare Case: Bifid Inferior Turbinate

Arş. Gör. Dr. Ramazan USLU[1], **Arş. Gör. Dr. Tarkan ŞEN**[1], **Dr. Öğr. Üyesi Sinan SEYHAN**[1]

[1]*Amasya Üniversitesi Tıp Fakültesi Sabuncuoğlu Şerefeddin Eğitim ve Araştırma Hastanesi*

BACKGROUND & AIM

The nasal turbinates are crucial for nasal function. Anatomic variations of the lateral nasal wall, such as a bifid inferior turbinate, are extremely rare and typically asymptomatic, often detected incidentally on imaging. They are frequently associated with the absence of the uncinate process. While usually requiring no treatment, these anomalies can occasionally contribute to severe nasal obstruction and necessitate surgical intervention. The aim of this report is to present an exceedingly rare case of a symptomatic bifid inferior turbinate and to describe what appears to be the first documented surgical management of this specific anatomic variation.

MATERIAL & METHODS

A 42-year-old male presented with persistent nasal obstruction and intranasal dryness. Initial anterior rhinoscopy revealed bilateral inferior turbinate hypertrophy and a high anterior septal deviation to the left. A comprehensive diagnostic workup, including rigid nasal endoscopy and coronal paranasal sinus computed tomography (PNS CT), was performed. These modalities clearly demonstrated a bifid right inferior turbinate, consisting of distinct superiorly and inferiorly positioned components. Additionally, the right uncinate process was absent. Due to the patient's persistent obstructive symptoms, surgical intervention was planned. The procedure included a septoplasty to address the structural deviation. For the turbinate anomaly, the superior component of the bifid right inferior turbinate was surgically resected. Concurrently, radiofrequency ablation was applied to the remaining inferior component and the contralateral left inferior turbinate to maximize the nasal airway.

RESULTS

The surgical procedures—septoplasty, selective resection of the superior turbinate component, and bilateral radiofrequency ablation—were completed successfully without any intraoperative complications. The combination of these techniques effectively addressed both the septal deviation and the unique turbinate hypertrophy. During the 1-month postoperative follow-up examination, both nasal passages were widely patent. Endoscopic evaluation confirmed that the right inferior turbinate had healed well and exhibited a normal anatomical appearance. The patient reported a marked and highly satisfactory improvement in nasal breathing, complete resolution of his prior obstructive symptoms, and relief from intranasal dryness. The successful clinical outcome indicates that addressing the structural anomaly through selective resection of the duplicated component, alongside standard volume reduction techniques, adequately restores normal nasal airway dynamics and relieves patient discomfort.

CONCLUSIONS

Although the bifid inferior turbinate is a remarkably rare and typically asymptomatic developmental anomaly, it can occasionally cause significant nasal obstruction. Accurate preoperative identification via nasal endoscopy and paranasal sinus CT is essential, especially given its frequent association with an absent uncinate process. While asymptomatic cases require no

intervention, this report demonstrates that symptomatic variations can be safely and effectively managed with tailored surgical treatment. Selective resection of the duplicated component combined with appropriate reduction yields excellent functional outcomes, highlighting the importance of recognizing lateral nasal wall variations for optimal surgical planning.

A RARE ANATOMICAL VARIATION: MIDDLE TURBINATE DUPLICATION CAUSED BY HYPERTROPHİC ETHMOİDAL BULLA

FUNDA TAŞKIN[1], **METİN YILDIRIM**[1], **ÖZGÜR YİĞİT**[1]

[1]*BAŞAKŞEHİR ÇAM VE SAKURA ŞEHİR HASTANESİ*

BACKGROUND & AIM

Endoscopic sinus surgery is one of the most frequently performed surgical procedures in rhinology clinics. One of the important landmarks during endoscopic surgery is the middle turbinate.

Turbinate development is a complex process during embryological life and different anatomical variations may occur during this process. Middle turbinate duplication is a rare anatomical variation encountered in rhinology. The presence of hypertrophic bulla ethmoidalis causing middle turbinate duplication has not been reported in the literature and is an extremely rare condition.

MATERIAL & METHODS

A 30-year-old male patient presented to our clinic with complaints of left periorbital pain and nasal obstruction. The patient had received medical treatment at another center, but his complaints did not regress. Endoscopic examination revealed left middle turbinate duplication and a hypertrophic bulla ethmoidalis extending between the middle turbinates. The septum was observed to be deviated to the right. Endoscopic sinus surgery and endoscopic septoplasty were planned for the patient, who had opacification in the ethmoid cells on paranasal computed tomography (PNCT) imaging. During the operation, the lateral middle turbinate and hypertrophic bulla ethmoidalis were resected. Anterior ethmoid cells were cleaned.So that, obstructed ostiomeatal complex was opened.

RESULTS

Postoperative follow-ups were performed at 1 week and 1 month. At the 1-week follow-up, splint tampons were removed and crusts were cleaned. At the 1-month follow-up, it was observed that the patient's complaints of left periorbital pain and nasal obstruction, which had been resistant to medical treatment, had completely regressed.

CONCLUSIONS

Rare anatomical variations may lead to complaints resistant to medical treatment and their detection with endoscopic examination and PNCT before surgery is important. As anatomical variations are reported in the literature, their awareness increases.

Multidimensional Assessment Of Cottle Septoplasty Outcomes For Nasal Septum Deviation: A Prospective Study Using Peak Nasal Inspiratory Flow And Patient-Reported Outcome Measures

Michail G. Tzanakakis[2], **Konstantinos Valsamidis**[1], **Georgios Tzanakakis**[3], **Konstantinos Garefis**[4], **Iordanis Konstantinidis**[4], **Stefanos Triaridis**[1]

[1]*1st Otorhinolaryngology, Head and Neck Surgery Department, Medical School, Aristotle University of Thessaloniki, AHEPA Hospital, Thessaloniki, Greece.;* [2]*Medical School, University of Crete, Heraklion, Greece;* [3]*Shool of Medicine and Surgery, University of Milano-Bicocca, Milan,Italy;* [4]*2nd Otorhinolaryngology, Head and Neck Surgery Department, Medical School, Aristotle University of Thessaloniki, Papageorgiou Hospital, Thessaloniki, Greece.*

BACKGROUND & AIM

Nasal septum deviation is one of the most common causes of nasal obstruction with a significant impact on patients' quality of life. Nasal septoplasty is considered the treatment of choice for nasal obstruction due to septal deviation. An ongoing discussion among rhinologists is whether it is reasonable to perform objective measurements of nasal patency pre or postoperatively routinely. The aim of this study was to identify the functional benefits for patients undergoing Cottle septoplasty with the use of an objective method assessing nasal patency and to evaluate the patients' perception of symptom relief and disease-specific quality of life (QoL) outcomes.

MATERIAL & METHODS

Forty-three patients with nasal obstruction symptoms caused by septal deviation who underwent Cottle septoplasty were enrolled in this prospective observational study. Peak Nasal Inspiratory Flow (PNIF) was utilized for the objective assessment of

nasal patency. All participants completed the NOSE (Nasal Obstruction Symptom Evaluation) and SNOT-22 (Sinonasal Outcome Test-22) validated questionnaires and a 10-point Visual Analogue Scale (VAS) for the subjective evaluation of nasal obstruction symptom severity and the impact on their quality of life. All assessments were performed preoperatively and in one and three months postoperatively.

RESULTS

There were statistically significant improvements in nasal patency (PNIF scores), mean postoperative NOSE, SNOT-22 and VAS scores at both follow-up points. PNIF showed a linear improvement over time, whereas subjective outcomes demonstrated a non-linear pattern of improvement which was more significant during the first month after surgery. Significant correlations between the PNIF measurements and mean NOSE, SNOT-22 and VAS scores were found only at first month follow-up.

CONCLUSIONS

The present study confirms that Cottle septoplasty significantly increases nasal patency and causes a significant subjective improvement in nasal obstruction symptoms and theis impact on patients' QoL. The absence of a significant correlation between the objective measurements and the symptom scores and the lower degree of improvement of patients' disease-specific quality of life (QoL) outcomes at three months compared to one month after surgery indicates that factors other than the anatomical findings may also contribute to the patients' perception of nasal obstruction symptom related QoL.

PP-594

Anterior Ethmoidal Artery–Based Pedicled Flap For Septal Perforation Repair: Why Expanding The Vascularized Flap Repertoire Matters

Gökhan Kuran[1], **Sena Kaplan**[1]

[1]*Karabük University*

BACKGROUND & AIM

Septal perforation repair remains surgically demanding, with failure often related to inadequate vascular support and excessive closure tension. Although multiple local and regional techniques have been described, no standardized reconstructive algorithm exists. Most commonly used flaps may be insufficient in previously operated septa or in medium-sized defects. The anterior ethmoidal artery (AEA)–based pedicled flap offers vascularity and rotation; however, its application in septal perforation repair is rarely emphasized in the literature. Expanding the repertoire of reliable vascularized flaps is critical for improving surgical predictability.

MATERIAL & METHODS

A 23-year-old female presented with complaints of difficulty breathing through the nose and intranasal sores and crusts. These symptoms had been ongoing for several months, with progressive nasal obstruction and crusting. The patient did not report a history of prior septal surgery. Endoscopic examination revealed a 1x1 cm perforation located in the anterior part of the nasal septum. An endoscopic unilateral AEA-based mucosal pedicled flap was elevated with preservation of its vascular pedicle and rotated to achieve tension-free closure without interposition grafting

RESULTS

Healing was uneventful. Complete closure was maintained at 6-month follow-up with full symptom resolution. No flap necrosis, septal hematoma or major bleeding occurred.

CONCLUSIONS

This case illustrates that the AEA-based pedicled flap is not merely an alternative technique but a strategically valuable option in septal reconstruction. Its axial blood supply enhances tissue viability and may reduce recurrence risk, particularly in revision settings. Broader recognition of this flap could refine reconstructive algorithms and improve outcome reliability in selected patients.

Intranasal Therapies: Overuse, Misuse, And Long-Term Effects On The Nasal Mucosa

Sanja Nikolova,MD[1], **Emil Nikolov, MD**[2]

[1]*Department of Otorhinolaryngology, Health Center "Zeleznicar", Gradski Zid 4, Building 1, 1000 Skopje, North Macedonia;* [2]*University Medical Centre Ljubljana (UKC Ljubljana) Zaloska cesta 2 ,1000 Ljubljana, Slovenia*

BACKGROUND & AIM

Intranasal therapies are widely used in the management of various nasal conditions. Although generally considered safe, their inappropriate use, overuse, and off-label application may lead to alterations in the nasal mucosa structure and function. In this

narrative review, we examined the patterns of overuse and misuse of commonly administered intranasal agents and related long-term clinical consequences.

MATERIAL & METHODS

We searched PubMed for studies related to the use of topical decongestants, intranasal corticosteroids, topical antibiotics, and saline solutions. Data of interest included patient history; clinical findings; frequency, manner, and duration of use; symptom persistence; and endoscopic findings.

RESULTS

Prolonged use of topical decongestants is associated with development of rhinitis medicamentosa, characterized by mucosal edema and impaired vasoregulation. Intranasal corticosteroids exhibit a favorable safety profile when used appropriately; however, incorrect administration techniques reduce their efficacy and increase the incidence of local side effects such as dryness and epistaxis. Intranasal antibiotics show no clear benefit in non-bacterial conditions and their misuse may contribute to mucosal irritation and resistance. Excessive use of hypertonic saline solutions often leads to mucosal dryness and patient discomfort.

CONCLUSIONS

Misuse and overuse of intranasal therapies remain a substantial but underrecognized clinical problem. Proper patient education, correct administration techniques, and adherence to evidence-based guidelines are essential to prevent long-term mucosal damage. Increased awareness among clinicians and patients is crucial for optimizing therapeutic outcomes and minimizing complications.

PP-596

Recurrent Pott's Puffy Tumor In An Adult Following Incision And Drainage: The Importance Of Early Otolaryngology-Led Management

Gökhan Kuran[1], **Merve Akyol Çetinkaya**[1], **Zahit Erdem PAZARLIOĞLU**[1]

[1]*Karabük University*

BACKGROUND & AIM

Pott's puffy tumor is an uncommon yet potentially life-threatening complication of frontal sinusitis, characterized by frontal bone osteomyelitis with a subperiosteal abscess and possible intracranial extension. Adult presentations may be mistaken for isolated soft-tissue infection, resulting in repeated antibiotic courses or incision-and-drainage without definitive sinonasal source control. We report a 47-year-old man with recurrent frontal swelling over two years, including relapse after attempted drainage, who ultimately required surgical management by otolaryngology. The aim is to highlight the need for early cross-sectional imaging and timely ENT-led definitive treatment in recurrent adult cases.

MATERIAL & METHODS

A 47-year-old man was admitted with recurrent frontal swelling over a two-year period, including two prior antibiotic-treated episodes and relapse after a recent incision-and-drainage attempt. Paranasal sinus CT and contrast-enhanced maxillofacial MRI demonstrated complicated left frontal sinusitis with frontal bone osteomyelitis, a fistulous tract, and an anterior frontal subcutaneous infectious collection with cutaneous fistulization, without meningitis or intracranial extension. Broad-spectrum intravenous antibiotics (ceftriaxone, vancomycin, and clindamycin) were started after infectious diseases consultation. Definitive management consisted of bilateral functional endoscopic sinus surgery under general anesthesia, including uncinectomy, middle meatal antrostomy, anterior and posterior ethmoidectomy, and endoscopic frontal sinusotomy with debridement of granulation tissue; intraoperative cultures were obtained. Merocel nasal packing was placed intraoperatively.

RESULTS

CT and contrast-enhanced MRI demonstrated complicated left frontal sinusitis with frontal bone osteomyelitis, a fistulous tract, and an anterior frontal subcutaneous collection with cutaneous fistulization, without meningitis or intracranial extension. Aspirate culture yielded Streptococcus intermedius and antimicrobial therapy was adjusted accordingly; the patient received 6 days of intravenous vancomycin, ceftriaxone, and clindamycin. Endoscopic sinus surgery with frontal sinusotomy was completed uneventfully; intraoperatively, purulent secretions and granulation tissue were encountered and cleared, achieving frontal sinus drainage. Postoperatively, the frontal swelling and pain regressed, and no orbital, intracranial, or cerebrospinal fluid–related complications occurred. Nasal packing was removed on postoperative day 3. Inflammatory markers improved, with C-reactive protein decreasing from 41.4 to 26.6 and 6.8 mg/L prior to discharge. The patient was discharged with clinical improvement on targeted antibiotics and scheduled ENT follow-up.

CONCLUSIONS

Recurrent frontal swelling in adults should raise suspicion for Pott's puffy tumor secondary to complicated frontal sinusitis, rather than being managed as an isolated superficial abscess. Early cross-sectional imaging is crucial to identify frontal bone osteomyelitis and fistulization and to exclude intracranial extension. Repeated antibiotic courses and superficial incision-and-

drainage alone are often insufficient because they fail to achieve definitive sinonasal source control. Timely ENT-led surgical management (endoscopic frontal sinus surgery) combined with appropriate intravenous antibiotics can provide durable resolution, reduce recurrence, and prevent potentially life-threatening orbital or intracranial complications.

Transnasal Penetrating Maxillofacial Trauma: A Rare Case Of Nail Gun Injury

Ebru Eğinci[1], **Melikşah Çakır**[1], **Hakan Bayraktar**[1]

[1]*Department of Otolaryngology, Kocaeli City Hospital*

BACKGROUND & AIM

Penetrating maxillofacial injuries require emergency intervention and meticulous planning due to their proximity to vital vascular and neurological structures. While typically caused by firearms or sharp objects, industrial nail gun injuries are rare in the literature.The surgical strategy relies on defining the trajectory of the foreign body relative to critical regions such as the nasolacrimal system, vascular structures, and brain parenchyma. This report presents a case of transnasal nail injury-entering through the medial left eyebrow, extending from the anterior left frontal sinus to the posterior left nasolacrimal duct, and terminating in the right nasal passage-successfully excised via an endoscopic approach.

MATERIAL & METHODS

A 49-year-old male presented after a nail gun accident. Examination showed an entry wound 1.5 cm above the medial left eyebrow with the nail head visible. History suggested a threaded nail. Rigid endoscopy revealed the foreign body entering the left lateral nasal wall anterior to the middle turbinate axilla, perforating the septum, and ending at the right inferior turbinate. CT imaging confirmed a 7-cm metallic object traversing the anterior left frontal sinus, posterior to the nasolacrimal duct, crossing the septum, and reaching the right nasal cavity. Under general anesthesia, a small incision exposed the nail head. Endoscopic removal was attempted with counter-clockwise rotation but failed due to fixation. The nail was successfully extracted using controlled axial traction guided by its threaded structure. Postoperative endoscopy showed intact mucosa without bleeding. The wound was sutured primarily. No vascular or neurological complications occurred during the immediate postoperative period and short-term follow-up course observed.

RESULTS

In this case, the trajectory avoided vital structures despite its depth. The endoscopic approach facilitated real-time visualization of the relationship with surrounding tissues, preventing secondary mucosal damage and allowing immediate management of potential bleeding. While the literature often suggests rotational removal for threaded objects, this case demonstrates that controlled linear traction, adhering to the nail's specific characteristics, is a safe alternative.

CONCLUSIONS

In transnasal penetrating traumas, rigid endoscopy combined with advanced imaging enhances diagnostic accuracy and minimizes surgical morbidity. This case highlights that appropriate planning and minimally invasive techniques can ensure successful outcomes despite complex craniofacial anatomy.

Endoscopic Endonasal Removal Of War-Related Skull Base Foreign Bodies: Technical Considerations And Surgical Experience

Khalid Hakami[1]

[1]*Al-Hada Armed Forces Hospital,, Saudi Arabia*

BACKGROUND & AIM

War-related craniofacial trauma may result in retained foreign bodies lodged within anatomically challenging skull base regions. Surgical management is often complicated by the proximity of critical neurovascular structures and the morbidity associated with traditional open approaches. This study aims to describe our surgical experience with endoscopic endonasal removal of war-related skull base foreign bodies and highlight key technical considerations for safe extraction.

MATERIAL & METHODS

Clinical, radiological, operative, and postoperative data were reviewed for patients undergoing endoscopic endonasal removal of war-related skull base foreign bodies at a tertiary military referral center. Surgical planning was based on preoperative computed tomography to assess foreign body location and its relationship to adjacent neurovascular structures. Endoscopic transnasal approaches were used to achieve direct visualization, controlled mobilization, and safe extraction while minimizing tissue disruption and avoiding external incisions whenever possible.

RESULTS

Two patients with war-related retained skull base foreign bodies were successfully managed using endoscopic endonasal techniques. The first patient sustained a transorbital gunshot injury with a bullet lodged within the sphenoid sinus adjacent to the internal carotid artery. The second patient sustained a blast injury with a metallic shrapnel fragment lodged within the maxillary sinus. Complete foreign body removal was achieved in both cases without major intraoperative complications. No cerebrospinal fluid leak, major hemorrhage, infection, or neurological deterioration occurred. Both patients experienced favorable postoperative recovery and were discharged without procedure-related morbidity.

CONCLUSIONS

Endoscopic endonasal surgery represents a safe and effective minimally invasive option for selected war-related skull base foreign bodies, including lesions located adjacent to critical neurovascular structures. Careful preoperative planning, detailed anatomical knowledge, and meticulous surgical technique allow successful foreign body removal while avoiding the morbidity associated with traditional open approaches.

Sphenoid Sinusitis Presenting With Cavernous Sinus Syndrome: Infection Or Autoimmune Vasculitis?

ALİ RIZA YILMAZ[1], **BURAK ÇELİK**[1], **KADİR ŞİNASİ BULUT**[1], **Muhammed Fatih Özcan**[1]

[1]*ANKARA BİLKENT ŞEHİR HASTANESİ*

BACKGROUND & AIM

Isolated sphenoid sinusitis is a rare but potentially life-threatening condition because of its close relationship to the cavernous sinus, cranial nerves, and skull base. Symptoms such as headache, diplopia, and cranial nerve palsy are often nonspecific and may delay diagnosis.

This report presents a rare case of sphenoid sinusitis with cavernous sinus involvement and CN VI palsy in a patient with rheumatoid arthritis receiving biologic therapy, emphasizing the importance of early imaging, multidisciplinary evaluation, and prompt surgical management.

MATERIAL & METHODS

A retrospective case evaluation was performed for a patient presenting with headache, diplopia, and cranial nerve dysfunction. Clinical examination, nasal endoscopy, laboratory findings, and radiologic imaging including computed tomography (CT) and magnetic resonance imaging (MRI) were reviewed.The patient's medical history, including rheumatoid arthritis and ongoing biologic immunosuppressive therapy, was evaluated in detail. Radiologic assessment focused on sphenoid sinus pathology, skull base extension, and cavernous sinus involvement.The patient underwent endoscopic endonasal sphenoidotomy for diagnostic and therapeutic purposes. Intraoperative findings, microbiological culture results, histopathological examination, medical treatment, and clinical follow-up outcomes were analyzed.Written informed consent was obtained from the patient for publication of clinical and radiologic data.

RESULTS

A patient with rheumatoid arthritis receiving biologic immunosuppressive therapy presented with progressive headache, diplopia, and limitation of lateral gaze. Neurological examination revealed isolated abducens nerve (CN VI) palsy. Nasal endoscopy demonstrated inflammatory findings within the sphenoethmoidal recess.Computed tomography and magnetic resonance imaging revealed isolated sphenoid sinus opacification with extension toward the cavernous sinus and adjacent skull base structures. Radiologic findings raised concern for invasive infection and possible inflammatory vasculitic involvement.The patient underwent urgent endoscopic endonasal sphenoidotomy. Intraoperative examination revealed purulent inflammatory material within the sphenoid sinus. Microbiological and histopathological analyses were consistent with invasive infectious sphenoid sinusitis, with no evidence of malignancy.Following surgical drainage and targeted antimicrobial therapy, the patient demonstrated significant clinical improvement, including resolution of headache and gradual recovery of diplopia and cranial nerve dysfunction during follow-up.

CONCLUSIONS

Isolated sphenoid sinusitis should be considered in patients with headache, diplopia, and cranial nerve palsy, especially in immunocompromised individuals. Early CT/MRI evaluation and prompt multidisciplinary treatment are essential to prevent severe neurological complications and improve outcomes.

Basaloid-Type Conventional Ameloblastoma Of The Maxillary Sinus: A Diagnostic Pitfall

BURAK NAL[1], **CEMİLE BAYKAN ERYİĞİT**[1], **FERİDE FIRAT**[1], **ZELİHA KAPUSUZ GENCER**[1], **ÖZGÜR YİĞİT**[1]

[1]ıstanbul basaksehır cam and sakura city hospıtal

BACKGROUND & AIM

Ameloblastoma is a benign but locally aggressive odontogenic tumor that rarely involves the maxillary sinus, where it may mimic sinonasal malignancy both clinically and radiologically. In this case, the lesion initially raised concern for a malignant process and required repeated histopathological verification before the final diagnosis was established. We hypothesized that maxillary sinus ameloblastoma, particularly with basaloid morphology, may present as a diagnostic pitfall in otorhinolaryngology practice and may require multidisciplinary reassessment for accurate diagnosis and appropriate surgical management.

MATERIAL & METHODS

We retrospectively reviewed the medical records, imaging findings, operative notes, and histopathological reports of a 42-year-old woman who presented with gingival swelling and later underwent evaluation for a right maxillary sinus mass. Radiological assessment included MRI, CT, and PET/CT. Initial imaging demonstrated an approximately 2.8 × 2.8 × 3 cm destructive lesion at the right maxillary region with intense FDG uptake (SUVmax: 9.9). The patient underwent maxillectomy in 2024. Follow-up imaging later demonstrated a recurrent lesion measuring approximately 26 × 23 mm, prompting reoperation in 2026.

RESULTS

Initial biopsy had been reported as basal cell adenocarcinoma. However, reevaluation and subsequent pathology demonstrated a locally aggressive odontogenic tumor. Microscopy showed basaloid tumor cells with weak peripheral palisading, focal glandular formations, and infiltrative growth without significant atypia or necrosis. Immunohistochemistry showed CK19, p63, and CK7 positivity. Final diagnosis was basaloid-type conventional ameloblastoma. Surgical margins were negative.

CONCLUSIONS

Basaloid-type ameloblastoma of the maxillary sinus may mimic malignancy due to aggressive imaging features and FDG uptake. This case highlights the importance of repeat histopathological evaluation and clinicoradiological correlation. Accurate diagnosis is essential for appropriate surgical management and follow-up.

PP-601

THE SIGNIFICANCE OF PATHOHISTOLOGICAL STUDIES IN PREDICTING RECURRENCE OF CHRONIC RHINOSINUSITIS AFTER REVISION FESS

Afruz M. Masimova[1], Seher Yuksel[2], Suha Beton[2], Hazan Basak[2]1

[1]Baku[1], Clinical Medical Center. Ankara University School of Medicine Department of Pathology [2]. Ankara University School of Medicine Department of Otolaryngology [3]

BACKGROUND & AIM

Background: Recurrence of chronic rhinosinusitis after functional endoscopic sinus surgery (FESS), especially in type 2 (T2) inflammation, remains high. According to EPOS 2020 and recent studies, recurrence rates range from 40–80% within 3–10 years and reach 88–100% after 10 years in patients with marked tissue eosinophilia. Surgery alone does not eliminate eosinophilic inflammation or excess IL-4, IL-5, and IL-13 production. Histopathological examination provides superior diagnostic accuracy compared with clinical and radiological methods.

Objective: To improve prediction of chronic rhinosinusitis recurrence after revision FESS by identifying histopathological features and inflammatory endotypes to guide targeted therapy and follow-up monitoring.

MATERIAL & METHODS

A multifactorial analysis was performed on the treatment outcomes of 153 patients with chronic recurrent rhinosinusitis. The majority of patients (123 patients – 80.4%) were between 30 and 70 years of age. There were 85 men (55.6%) and 68 women (44.4%). Classification of the pathology, scope and nature of examinations (laboratory tests, endoscopy, CT scans, etc.), treatment approaches, as well as histopathological analysis of surgical specimens, were conducted using standard accepted methods. To determine the biological type of inflammation, the cellular composition of mucosal and polypoid tissue infiltrates, the condition of the basement membrane, and the degree of tissue remodeling were evaluated.

RESULTS

Among 153 patients, chronic rhinosinusitis without nasal polyps was observed in 37 (24.2%), with nasal polyps in 111 (72.5%), and inverted papilloma in 5 (3.3%). Tissue eosinophilia (T2 inflammation) was identified in 45 patients (29.4%), while neutrophilic infiltration (non-T2 inflammation) was found in 103 (67.3%). Basement membrane changes, mucosal metaplasia, and polypoid alterations occurred in 12 patients (8.3%). Among eosinophilic cases, eosinophil counts were <50 cells/HPF in 7 patients (15.6%), 50–100 cells/HPF in 19 (42.2%), and >100 cells/HPF in 19 (42.2%). Mean disease duration was 11 years and 2

months, with 1–9 recurrences. Recurrence rates were higher in T2 inflammation (6.7%) than non-T2 inflammation (4.9%) and increased with eosinophilia severity, particularly at ≥50 cells/HPF (84.4%).

CONCLUSIONS

1. Histopatological examination of removed tissue structures plays a leading role in predicting recurrence of the studied pathology and thereby helps optimize comprehensive postoperative treatment.

2. Despite the progress achieved, the problem remains highly relevant and requires further in-depth investigation.

KEYWORDS

recurrence, rhinosinusitis, revision FESS, histopathology.

PP-602

Frontoethmoidal Schwannoma Mimicking Mucocele: Diagnostic Challenge And Endoscopic Management

Rocío Carpintero Díaz[1], **Daniel A. Núñez Carlino**[1], **Hander Guillermo Acosta Díaz**[1], **Javier Morales Domínguez**[1], **José Miguel Villacampa Aubá**[1]

[1]*Fundación Jiménez Díaz University Hospital*

BACKGROUND & AIM

Sinonasal schwannomas are rare benign tumors of peripheral nerve sheath origin, accounting for less than 4% of head and neck schwannomas. Frontal sinus involvement is exceptionally uncommon. Their nonspecific clinical and radiological features often lead to misdiagnosis, particularly as mucoceles or inverted papillomas.

MATERIAL & METHODS

A 67-year-old woman presented with an incidental CT finding of left ethmoidal and bilateral frontal sinus occupation with bone remodeling and posterior wall dehiscence, initially suggestive of a mucocele. MRI showed heterogeneous enhancement without intracranial extension. Given the diagnostic uncertainty, endoscopic surgery was indicated as a simultaneous diagnostic and therapeutic procedure. A left endoscopic endonasal approach was performed, consisting of a type III resection according to the LOEM classification with a DRAF III procedure, achieving wide access to the frontal sinus.

RESULTS

Complete macroscopic resection was achieved without complications. Histopathology confirmed schwannoma (S-100 positive; Antoni A and B patterns) with no malignant features. The tumor origin was presumed to arise from branches of the ophthalmic division of the trigeminal nerve (anterior ethmoidal nerve), the most widely accepted origin. Alternative hypotheses involving aberrant Schwann cells in the olfactory region have been described but remain controversial. No clinical or radiological features suggestive of NF2 or schwannomatosis were identified after systematic evaluation, supporting a sporadic presentation. No recurrence was observed at 6-month follow-up.

CONCLUSIONS

Frontoethmoidal schwannoma should be considered in the differential diagnosis of frontal sinus lesions with bone remodeling. Radiological findings may be misleading, making histopathological confirmation essential. Endoscopic endonasal surgery usually provides a safe and effective approach, allowing complete resection while simultaneously establishing a definitive diagnosis, and should be considered the preferred approach in the majority of cases.

Amphotericin B-Resistant Angioinvasive Aspergillus Rhinosinusitis Mimicking A Skull Base Tumor With Orbital And Intracranial Extension: A Case Report

Veronika Babková[1], **Bálint Tóth**[1], **Peter Matulník**[1], **Milan Liška**[2], **Miroslav Tedla**[1]

[1]*Department of Otorhinolaryngology and Head and Neck Surgery, Faculty of Medicine, Comenius University and University Hospital Bratislava, Slovakia;* [2]*Department of Neurosurgery, Faculty of Medicine, Slovak Medical University and University Hospital Bratislava, Slovakia*

BACKGROUND & AIM

Invasive fungal rhinosinusitis (IFRS) is a severe infection with high mortality that can accurately mimic advanced skull base malignancies. Due to superficial inflammatory tissue changes, it frequently presents a diagnostic dilemma. This case report aims to highlight the diagnostic challenges, clinical pitfalls, and the critical role of emergency multidisciplinary management in a patient presenting with Aspergillus fumigatus infection causing extensive rhino-orbital-cerebral destruction.

MATERIAL & METHODS

A 36-year-old immunocompetent male presented in early 2026 with progressive right-sided nasal obstruction, anosmia, and periorbital edema. His history revealed that in 2008, he had undergone endonasal explorations for similar neurological signs and a suspected clivus chordoma, which yielded non-diagnostic necrotic and polypoid tissue. On admission, examination showed right oculomotor nerve palsy and trigeminal hypesthesia. CT and MRI demonstrated a massive soft-tissue lesion obliterating the right paranasal sinuses and nasal cavity, destroying the orbital roof, invading the extraconal space of the right

orbit (causing proptosis and diplopia), with radiological signs of preseptal orbitocellulitis, and extending extra-axially into the intracranial space with significant right frontal lobe compression. Repeated superficial outpatient biopsies initially yielded only inflammatory polypoid tissue, masquerading as a benign process and mimicking an advanced neoplasm. Due to acute clinical worsening, an emergency multi-specialty intervention was indicated.

RESULTS

The patient underwent right-sided functional endoscopic sinus surgery (FESS) combined with an external bicoronal approach. In close collaboration between ENT and neurosurgery teams, radical debulking of mycotic masses, removal of necrotic bone, and skull base reconstruction were achieved. Histopathology definitively confirmed granulomatous and suppurative inflammation with marked angioinvasion by Aspergillus structures. Mycological cultures identified Aspergillus section Fumigati (A. fumigatus), showcasing in vitro resistance to Amphotericin B (MIC 1.5). Treatment was optimized to targeted systemic therapy. During the 34-day hospitalization, visual acuity was successfully preserved, diplopia resolved, and oculomotor function progressively recovered.

CONCLUSIONS

Aspergillus rhinosinusitis can mimic advanced skull base tumors radiologically, where initial superficial biopsies yielding benign polypoid tissue pose a major diagnostic trap. Because potential drug resistance and angioinvasion are initially unknown, prompt surgical intervention combined with subsequent susceptibility-guided systemic therapy is paramount to prevent further progression while preserving visual and neurological function.

AUTONOMIC NERVOUS SYSTEM STATE IN PATIENTS WITH VASOMOTOR RHINITIS ASSOCIATED WITH THYROTOXICOSIS

Muminov S.Kh.[1], **Amonov Sh.E.**[2]

[1]*Andijan State Medical Institute;* [2]*Tashkent Pediatric Medical Institute*

BACKGROUND & AIM

The relationship between otolaryngology and other clinical disciplines is primarily observed in terms of the impact of upper respiratory tract diseases on the condition of internal organs. The impact of various diseases on the onset, course, and treatment of chronic inflammatory processes of the upper respiratory tract remains extremely understudied.

The aim of this study is to examine current issues in the comprehensive diagnosis of vasomotor rhinitis in patients with thyrotoxicosis.

MATERIAL & METHODS

We observed 145 patients with vasomotor rhinitis associated with thyrotoxicosis. Results of a baseline autonomic nervous system study in 75 patients with AR associated with thyrotoxicosis, using blood pressure, pulse, and autonomic tests (Aschner-Dagnini oculocardiac reflex, orthoclinostatic tests). When analyzing the Aschner-Dagnini test results, a paradoxical reaction with an increase in pulse rate by 6.3±0.3 beats per minute was detected in 45 (60.0%) patients, a reaction with a decrease in pulse rate by 14.6±0.6 beats per minute was noted in 16 (21.5%) patients, and the remaining 14 (18.6%) patients had a normal reaction.

RESULTS

Orthostatic test results revealed an excessive increase in heart rate by 30-38 beats per minute in 42 (55.4%) subjects, a moderate increase in heart rate by 26-30 beats per minute in 20 (26.6%), and within the normal range in the remaining 14 (18.6%). A clinostatic test study revealed that 47 (62.6%) patients exhibited a paradoxical reaction, i.e., an increase in heart rate by 8.3±1.15 beats per minute instead of a slowdown. Twenty-one patients had a slowing of heart rate by 3-4 beats per minute; the remaining 7 had a normal reaction. High blood pressure was found in 40 (53.3%) of the 75 patients, with systolic blood pressure ranging from 150-160 mmHg and diastolic blood pressure ranging from 95-100 mmHg. Increased heart rate at baseline (at rest) was observed in 47 patients (62.6%), while the remaining 28 (37.3%) had rates within the age-appropriate range.

CONCLUSIONS

Thus, the results of the initial study of autonomic responses indicate the presence of autonomic dystonia in the overwhelming majority of patients, with sympathetic tone predominating.

Malignant Hyperthermia Developing During Rhinoplasty Surgery: A Case Report

MERVE ÜNAL[1], **MUHAMMED ALİ BULUT**[1], **BURAK MUSTAFA TAŞ**[1], **SÜHEYLA KANDEMİR**[1], **KEVSER PEKER**[1], **ZİYA ŞENCAN**[1], **ELA CÖMERT**[1], **NURAY BAYAR MULUK**[1]

[1]*Kırıkkale University Department of Otorhinolaryngology*

BACKGROUND & AIM

Malignant hyperthermia is a pharmacogenetic muscle disorder characterized by cutting, hypermetabolism, muscle rigidity and muscle breakdown, particularly associated with succinylcholine and inhalation anaesthetics. It progresses with autosomal dominant inheritance. It may occur following anaesthesia induction, during surgery, or in the postoperative period. Dantrolene is the first-line treatment.

MATERIAL & METHODS

A 27-year-old female patient presented to the ear, nose and throat clinic for rhinoplasty surgery. Preoperative assessment revealed no history of previous surgery, known family medical history, allergies, or medication use; the patient was classified as ASA 1. Midazolam, lidocaine, thiopental, rocuronium, and fentanyl were administered intravenously to the patient during anaesthesia induction. The surgery proceeded without complications until the 105th minute intraoperatively, when an abrupt rise in end-tidal CO2 and tachycardia were detected, prompting arterial blood gas sampling (Table 1). The surgery was interrupted. Body temperature was measured at 40.5°C. The anaesthesia team administered dantrolene sodium 2.5 mg/kg intravenously as a bolus to the patient, suspecting malignant hyperthermia. External cooling was provided. The patient, whose arterial blood gas parameters improved, was extubated three hours after being monitored in the intensive care unit.Table 2).The dantrolene sodium infusion was stopped on the second day as the patient's follow-up values were normal.

RESULTS

Malignant hyperthermia is a rare complication , but it can lead to life-threatening problems. Early recognition of this potentially serious complication, prompt intervention and having dantrolene readily available and on hand care crucial.

CONCLUSIONS

Malignant hyperthermia is a rare complication , but it can lead to life-threatening problems. Early recognition of this potentially serious complication, prompt intervention and having dantrolene readily available and on hand care crucial.

PP-606

Acute Epistaxis - A Prospective Study On Aetiology, Management And Outcome

Mandytien Mak[1], **Methodios Stavridopoulos**[1], **Vasilios Chalkiadakis**[1], **Vaios Kouliopoulos**[1]

[1]*417 Army Equity Fund Hospital (NIMTS), Athens, Greece*

BACKGROUND & AIM

Epistaxis remains the most common emergency in otorhinolaryngology, affecting up to 60% of the population in their lifetime. We present a prospective observational study on patients presenting with acute epistaxis to our service, aiming to investigate aetiologies and management of epistaxis.

MATERIAL & METHODS

This study recruited all consenting adult patients and from both genders presenting with epistaxis to our service from the Emergency Department and inpatients. A detailed history-taking, complete with clinical examination, was conducted, with data entered in a structured proforma and subjected to statistical analysis by Microsoft Excel and SPSS.

RESULTS

A total of 153 patients were recruited from 2021 to 2025. The most common age groups were the 7th decade (25%) and 8th decade (23%) followed by 6th decade (21%), with male (63%) predominance. Anterior epistaxis (76%) was mainly observed, with the most common bleeding source identified at the nasal septum (89%). Most common causes of epistaxis were the use of oral anticoagulatns (54%), followed by hypertension (52%). All patients with an identified systemic cause were treated with medical management. The majority of the patients underwent anterior nasal packing (52%). Within two-week follow-up, 20% reported recurrence of epistaxis, of which 48% required surgical intervention in the form of sphenopalatine artery ligation (93%).

CONCLUSIONS

The cause of epistaxis often stems from a systemic disorder and a multi-disciplinary approach in its management is paramount. The majority of our patient group was managed with nasal packing. In recalcitrant cases especially those involving co-morbidities - such as the use of oral anticoagulation - a low threshold for surgical intervention is indicated to ensure timely control of bleeding. Following the acute episode, patients should be advised to avoid strenuous activity, vigorous nose blowing and high environmental temperatures.

PP-607

Post-ESS Septal Abscess Without Septal Manipulation : A Rare Complication

Fatih Özdoğan[1], **Onur Can Dalgıç**[1], **Ömer Faruk Koçer**[1]

[1]*Kocaeli Cıty Hospital*

BACKGROUND & AIM

Septal abscess is a rare but serious complication, most commonly encountered after trauma or septal surgery. Its development following endoscopic sinus surgery performed without septal manipulation is exceedingly rare. In this case report, we aimed to present the diagnostic and therapeutic management of a septal abscess developing after functional endoscopic sinus surgery.

MATERIAL & METHODS

A 42-year-old male patient was evaluated for nasal obstruction. Nasal endoscopy revealed bilateral grade 3 nasal polyposis. Paranasal sinus CT demonstrated diffuse opacification in the frontal and ethmoid sinuses, as well as mucosal thickening in the bilateral maxillary and sphenoid sinuses; the nasal septum was noted to be mildly deviated to the right (Figure 1).

RESULTS

The patient underwent bilateral functional endoscopic sinus surgery. At postoperative month 1, he presented with nasal pain, and anterior rhinoscopy revealed a left septal abscess (Figure 2). Abscess drainage was performed, a culture specimen was obtained, and 10 days of intravenous antibiotic therapy was administered according to the culture results. The patient was discharged following clinical improvement.Follow up examination revealed no development of septal perforation.

CONCLUSIONS

Septal abscess is a rare complication that may develop even after endoscopic sinus surgery performed without septal manipulation. This possibility should be considered during postoperative follow-up, and complications may be prevented through early diagnosis and prompt treatment.

KEYWORDS

Sinonasal Olfactory Neuroblastoma: Diagnostic Challenges In A Rare Entity – Case Report

Augustina Iurkovski[1], **R. Hainăroșie**[1,2], **V. Zainea**[1,2], **Ruxandra Oana Aliuș**[1,2], **Andreea Rusescu**[1,2], **Selma Anda Crețu**[1], **Carina Russu**[1], **Mara-Andra Rebosapca**[2], **Maria Laura Burlacu**[1], **Miruna Mateescu**[1], **Cătălina Voiosu**[1,2], **Irina Gabriela Ioniță**[1,2]

[1]*"Prof. Dr. D. Hociotă" Institute of Phonoaudiology and Functional ENT Surgery Bucharest, Romania;* [2]*Carol Davila University of Medicine and Pharmacy Bucharest, Romania*

BACKGROUND & AIM

Olfactory neuroblastoma is a rare malignant tumor arising from the superior nasal vault, accounting for less than 5% of sinonasal malignancies. Its rarity and morphological overlap with other poorly differentiated sinonasal neoplasms create significant diagnostic challenges, particularly in high-grade presentations.

MATERIAL & METHODS

We present the case of a 46-year-old male with a history of progressive nasal obstruction and epistaxis, found to have a left sinonasal mass. The patient underwent endoscopic tumor resection. Initial histopathological evaluation described a poorly differentiated sinonasal carcinoma with neuroendocrine features, and immunohistochemistry supported a diagnosis of large-cell neuroendocrine carcinoma. Due to persistent disease with anterior skull base extension and intracranial involvement, a radical resection was subsequently performed, achieving complete excision of both sinonasal and intracranial components. Skull base reconstruction was performed using autologous thigh fat graft, fascia lata, septal cartilage graft, and a vascularized nasoseptal flap. Comprehensive reassessment of all specimens, including repeat histopathological examination and expanded immunohistochemical analysis, ultimately established the diagnosis of olfactory neuroblastoma. The patient subsequently received adjuvant chemotherapy and radiotherapy.

RESULTS

This case highlights the diagnostic complexity of rare sinonasal malignancies. Discordant pathological interpretations underscore the substantial overlap between high-grade olfactory neuroblastoma and other poorly differentiated neuroendocrine tumors.

CONCLUSIONS

Accurate diagnosis requires extensive immunohistochemical evaluation and expert pathological review, as diagnostic uncertainty remains a significant management challenge.

olfactory neuroblastoma, sinonasal tumor, immunohistochemistry, rare malignancy

PP-609

Unilateral Maxillary Sinus Agenesis: A Rare Case Report

Yunus Emre Topan[1], Faruk Kadri Bakkal[1], Abdullah Kınar[1], Ramazan Yavuz[1], Necat Alataş[1], Azat Acar[1], Beliz Dündar[1]

[1]Uşak University Faculty of Medicine Training and Research Hospital ENT Department

BACKGROUND & AIM

Maxillary sinus agenesis is a rare congenital anomaly that can mimic chronic sinonasal disease, especially in unilateral cases with nonspecific symptoms. Recognition is essential due to associated anatomical variations that may increase surgical risk. This study aims to present a rare case of unilateral maxillary sinus agenesis diagnosed radiologically and to highlight its importance in differential diagnosis and preoperative evaluation.

MATERIAL & METHODS

This study presents a single-case report of a 20-year-old male patient who presented with sinonasal symptoms. Clinical evaluation included detailed history-taking, physical examination, anterior rhinoscopy, and rigid nasopharyngoscopic assessment. Radiological evaluation was performed using paranasal sinus computed tomography (CT) with axial and coronal sections to assess sinonasal anatomy and detect possible anomalies. The imaging findings were analyzed with particular attention to the maxillary sinus, uncinate process, and ostiomeatal complex. Based on clinical and radiological findings, a diagnosis was established, and the patient was managed with symptomatic medical treatment. Follow-up evaluation was conducted one month after treatment to assess clinical outcomes.

RESULTS

A 20-year-old male patient presented with intermittent headache, nasal obstruction, and right-sided facial swelling. Physical examination revealed facial asymmetry, bilateral inferior turbinate hypertrophy, and a fissured tongue. Endoscopic evaluation suggested increased nasal cavity volume on the affected side. Paranasal sinus CT demonstrated complete absence of the right maxillary sinus, uncinate process, and maxillary infundibulum, along with inferior positioning of the ipsilateral orbital floor and mild septal deviation. These findings were consistent with unilateral maxillary sinus agenesis. Following symptomatic medical treatment, the patient showed significant improvement in headache and nasal discharge at one-month follow-up.

CONCLUSIONS

Maxillary sinus agenesis, although rare, should be considered in patients with atypical sinonasal symptoms and unilateral anatomical variations. Accurate radiological evaluation is essential to avoid misdiagnosis and to identify associated structural changes. Recognizing this anomaly is particularly important in preoperative planning, as altered anatomy may increase the risk of complications during endoscopic sinus surgery.

PP-610

Association Between PTC (Phenylthiocarbamide) Taster Status And Treatment Outcomes In Patients With Taste Dysfunction

Mi-Kyung Ye[1], Chang-Ho Whangbo[1], Seung-Heon Shin[1]

[1]Department of Otorhinolaryngology, Daegu Catholic University

BACKGROUND & AIM

The sense of taste is essential to overall health and taste dysfunction can significantly impair daily functioning. Previous studies have demonstrated a higher prevalence of PTC nontaster phenotypes or TAS2R38 AVI/AVI genotypes among patients with taste disorders compared with healthy controls, suggesting that impaired PTC bitter taste perception may be associated with susceptibility to gustatory dysfunction. However, the clinical relevance of PTC taster phenotype in predicting treatment response or recovery outcomes in taste dysfunction remains poorly characterized. The objective of this study was to evaluate whether PTC taster phenotype is associated with therapeutic outcomes in patients with taste dysfunction.

MATERIAL & METHODS

A total of 157 patients with taste dysfunction were classified into PTC non-tasters (n = 30) and tasters (n = 127) based on a PTC detection threshold test using a series of 15 graded solutions. All patients received a standardized treatment protocol. Therapeutic outcomes were assessed using validated taste function evaluations conducted before and after treatment, and improvement rates were compared between the two groups

RESULTS

Overall, 112 patients (71.3%) demonstrated improvement following treatment. Improvement rates were 66.7% (20/30) in non-tasters and 72.4% (92/127) in the taster group. Although a higher improvement rate was observed in the taster group compared with the non-taster group, no statistically significant difference was found between the two groups (p = 0.819).

CONCLUSIONS

PTC taster status was not significantly associated with therapeutic outcomes in patients with taste dysfunction, despite previous reports suggesting a relationship with disease susceptibility and baseline taste sensitivity. These findings suggest that mechanisms underlying treatment recovery may differ from those involved in disease susceptibility.

Digital Pathway For Patients With Nasal Obstruction

Johanna Wiksten[1]

[1]*Helsinki University Hospital*

BACKGROUND & AIM

Rhinitis patients are a largeburden in public Health care. Ai is to investigate and develop nasal obstruction patients' treatment in a tertiary care unit.

MATERIAL & METHODS

Referrals for nasal obstruction per year were calculated in Helsinki University Hospital (HUH) Rhinology unit. 20 min appointments at the polyclinic were timed for doctor and nurse counseling. A digital pathway was developed for patients to better understand and learn self-caring their symptoms. It takes approximately 6.5 mins to go through the pathway, including 2 videos of nasal function and local treatment instructions. The percentage of participation and satisfaction on 0-10 scale were collected.

RESULTS

1975 referrals per year for nasal obstruction are dealt with in HUH Rhinology unit. 10-20 patients per day are visiting the polyclinic. One appointment takes approximately 17minutes, additionally nurse is consulting 5-7minutes per patient afterwards and giving instructions. After March 2023, 76% of patients referred to HUS Rhinology Unit for nasal obstruction logged in the pathway and went through it. Median score for satisfaction of the pathway was 8,6/10. All together 4% of patients cancelled their appointment for being satisfied with the pathway and instructions.

CONCLUSIONS

Digital self-care pathway can save both patient and hospital resources in a large group of patients with common and benign symptoms such as nasal obstruction.

Gender Differences In Keros Classification: A CT-Based Study

GİZEM ÖZCAN[1], **SİNEM ÖZCAN**[1], **BÜŞRA SÖNMEZ**[1], **MUSTAFA EMRAH KINAL**[1], **İBRAHİM ENGİN ÇEKİN**[1]

[1]*Department of Otorhinolaryngology and Head & Neck Surgery, Sultan 2. Abdulhamid Han Training and Research Hospital, Istanbul, Turkey*

BACKGROUND & AIM

The Keros classification is an important anatomical parameter used in assessing the risk of anterior skull base injury during endoscopic sinus surgery. Variations in olfactory fossa depth and ethmoidal roof anatomy may increase the likelihood of intraoperative complications, including cerebrospinal fluid leakage and skull base injury. This study aimed to evaluate the olfactory fossa depth according to the Keros classification using paranasal sinus computed tomography (CT) images and to investigate gender-related differences in Keros types between male and female patients. Additionally, the potential clinical significance of these anatomical variations in preoperative surgical risk assessment was analyzed.

MATERIAL & METHODS

We retrospectively analyzed 100 paranasal sinus computed tomography (CT) images obtained between March 2025 and March 2026. The depth of the cribriform plate was measured on coronal sections and classified according to the Keros classification. The relationship between Keros types and gender was statistically evaluated, and a p value of <0.05 was considered statistically significant.

RESULTS

A total of 100 paranasal sinus CT images were included in the study, consisting of 50 male and 50 female patients. Based on the Keros classification, Type II was the most frequent anatomical variation in both genders. Keros Type II was observed in 58% of male patients and 76% of female patients, making it the predominant subtype overall. In contrast, Keros Type III was more frequently detected in male patients compared to females. When Keros classification subtypes we

CONCLUSIONS

Our findings demonstrate that Keros Type II is the predominant anatomical variation in both male and female patients. Significant gender-related differences in the distribution of Keros subtypes were identified, with higher rates of Keros Type III observed in males. These anatomical variations should be carefully evaluated during preoperative planning to minimize the risk of complications associated with endoscopic sinus surgery.

PP-613

A Rare Complication After Septorhinoplasty Surgery: Negative Pressure Pulmonary Edema

Ayşegül Şule ALTINDAL[1], **Eda YELKENCİ**[1], **Esra GÜZEL**[1]

[1]*Antalya City Hospital*

BACKGROUND & AIM

The aim of this case report is to present a rare case of NPPE developing during the recovery period after rhinoplasty, to raise awareness among surgical and anesthesia teams about this complication, and to highlight early diagnosis and effective management strategies. It also aims to provide guidance in the diagnosis and treatment of similar cases by sharing clinical experience on this condition, which has been reported in a limited number of cases in the literature.

MATERIAL & METHODS

A 39-year-old male patient presented to our clinic with complaints of difficulty breathing through the nose and aesthetic concerns. The patient's medical history included occupation as an aircraft and aviation technician, and scuba diving as a hobby. There were no known chronic diseases, and no regularly used medications.During the operation, the patient's vital signs remained normal, and no decrease in saturation was observed. The surgery proceeded and was completed without complications.

RESULTS

After the septorhinoplasty operation was completed without complications, the patient was extubated by the Anesthesiologist. While the saturation level was around 90 under oxygen via mask, it was observed to be between 60-70 in room air. Due to the patient producing pink frothy phlegm from their mouth during respiratory effort, an emergency thoracic CT scan was performed. The patient was admitted to the intensive care unit with a diagnosis of NPPE, connected to a Positive Pressure Mechanical Ventilator, and monitoring and treatment procedures were initiated. Following CPAP treatment in the Intensive Care Unit, our patient's saturation levels in the room air improved and radiological improvement was observed in the chest X-ray. Therefore, the patient was transferred to our ward on the first postoperative day.The patient, who did not experience any decrease in saturation during follow-up in our ward, was reported to have no additional complaints during regular check-ups after discharge.

CONCLUSIONS

The fact that this complication can occur even after operations such as septorhinoplasty, which are generally associated with low mortality and short hospital stay, shows that the post-extubation period should be carefully evaluated. Although the sudden desaturation, tachypnea, and bilateral pulmonary infiltration that developed after extubation in our patient initially suggested differential diagnoses such as aspiration, cardiogenic pulmonary edema, fluid overload, and anaphylaxis, the history of laryngospasm, the acute onset of symptoms, and the rapid clinical improvement after appropriate supportive treatment supported the diagnosis of NPPE.

Negative Pressure Pulmonary Edema after Rhinoplasty Surgery

PP-614

Chronic Atrophic Rhinitis Complicated By ESBL Klebsiella Pneumoniae Infection: A Case Report

Aditya Wira Buana[1]

[1]*ORL-HNS Department, Faculty of medicine Hang Tuah University – Dr. Ramelan Naval Hospital, Surabaya, East Java, Indonesia.*

BACKGROUND & AIM

Background: Atrophic rhinitis is a chronic inflammatory condition characterized by progressive atrophy of the nasal mucosa, often complicated by secondary infections. While primary atrophic rhinitis is well-documented, infections with resistant pathogens such as extended-spectrum β-lactamase (ESBL)-producing Klebsiella pneumoniae remain underexplored in this context.

MATERIAL & METHODS

We report the case of a 63 year old female with refractory atrophic rhinitis, exhibiting severe nasal crusting, foul odor, and anosmia. Microbiological analysis confirmed colonization with ESBL-producing K. pneumoniae. Following targeted

antimicrobial therapy and performed endoscopic sinus surgery, the patient demonstrated notable clinical improvement, suggesting a potential pathogenic role of this organism in mucosal atrophy.

RESULTS

This case underscores the emerging role of ESBL-producing Klebsiella pneumoniae in exacerbating atrophic rhinitis, potentially mediated through mechanisms such as sustained chronic inflammation or direct mucosal damage. The findings advocate for the incorporation of comprehensive microbial screening in cases resistant to standard therapeutic regimens, particularly in regions with elevated rates of antibiotic resistance. Additionally, endoscopic sinus surgery has demonstrated therapeutic efficacy in facilitating patient recovery, particularly in reducing extensive necrotic lesions and promoting mucosal healing.

CONCLUSIONS

ESBL-producing Klebsiella pneumoniae may play a significant role in the pathogenesis of atrophic rhinitis, necessitating its inclusion in the diagnostic evaluation of refractory cases. This observation underscores the imperative for further research into the complex interplay between antimicrobial-resistant infections and chronic nasal pathologies, as well as the development of targeted therapeutic strategies to address this emerging clinical challenge.

PP-615

Systemic Oxidative Stress Changes After Functional Endoscopic Sinus Surgery In Chronic Rhinosinusitis With Nasal Polyps

Demet Alkilinc[1], **Gul Ozbilen Acar**[1], **Ilknur Genc**[2], **Osman Ilkay Ozdamar**[1]

[1]*Department of Otorhinolaryngology and Head and Neck Surgery, Istanbul Medeniyet University Goztepe Prof. Dr. Süleyman Yalçın City Hospital, Istanbul, Turkey;* [2]*Department of Medical Biochemistry, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey.*

BACKGROUND & AIM

This study aimed to investigate systemic oxidative stress in patients with nasal polyposis (NP) undergoing functional endoscopic sinus surgery (FESS). Serum oxidant and antioxidant parameters were evaluated before surgery and at postoperative week 3.

MATERIAL & METHODS

Thirty-five patients with NP who did not respond adequately to medical treatment and subsequently underwent FESS were included in this prospective study. Serum levels of reactive oxygen species (ROS), thiobarbituric acid reactive substances (TBARS), advanced oxidation protein products (AOPP), ferric reducing antioxidant power (FRAP), total sulfhydryl (SH), glutathione peroxidase (GSH-Px), catalase (CAT), and superoxide dismutase (SOD) were measured preoperatively and postoperatively. Patients with severe systemic disorders were excluded from the study.

RESULTS

After surgery, serum ROS and TBARS levels showed a significant decrease compared with preoperative values ($p=0.012$ and $p<0.001$, respectively). AOPP levels were also lower postoperatively, although this reduction was not statistically significant. Antioxidant parameters generally improved following FESS. FRAP, total SH, and CAT levels increased significantly in the postoperative period (all $p<0.01$). SOD levels showed an upward trend, while GSH-Px levels remained relatively unchanged.

CONCLUSIONS

FESS may help reduce systemic oxidative stress in patients with NP. Surgical treatment appears to support restoration of the oxidant-antioxidant balance and may decrease the overall oxidative stress burden.

Functional endoscopic sinus surgery; nasal polyposis; oxidative stress; antioxidant markers.

PP-616

Oculonasal Myiasis: A Very Rare Condition Based On 2 Cases

Muhammet Fatih GÖKMEN[1], **Banu BOZKURT**[2]

[1]*Selcuk University, Medical School, ENT Department;* [2]*Selcuk University, Medical School, Ophtalmology Department*

BACKGROUND & AIM

Myiasis is a parasitic infestation that usually occurs when larvae of the genus Oestrus ovis are transmitted from sheep and goats to humans by flies. Oculonasal myiasis is a rare clinical entity characterized by simultaneous involvement of the eye and nasal cavity, and if not diagnosed and treated promptly, it may lead to sinusitis, preseptal and orbital cellulitis, vision loss, and even intracranial complications. By presenting two cases with this extremely rare concomitant involvement—diagnosed through a high index of suspicion and confirmed by diagnostic nasal endoscopy—we aim to raise awareness of this clinical entity.

MATERIAL & METHODS

Case 1 A 4-year-old girl presented to the emergency department with complaints of sudden-onset severe ocular irritation, including foreign body sensation, redness, and tearing in her right eye after traveling by motorcycle in rural area. During biomicroscopic examination, motile larvae were observed in the right conjunctiva. After obtaining informed consent from the family, removal of the ocular foreign bodies under general anesthesia in the operating room was planned.

Case 2 A 51-year-old male patient presented to the outpatient clinic with a one-week history of right-sided facial pain, tenderness, and nasal discomfort. His medical history revealed that one week prior, while in rural area, a fly struck his eye, after which a larva was removed at the ophthalmology outpatient clinic. Subsequent ophthalmologic consultation revealed no pathological findings.

Examination with a 0-degree nasal endoscope revealed inflamed and edematous mucosa of the septum and middle turbinate, with a larva lodged between these two mucosal surfaces.

RESULTS

Despite their close anatomical proximity, cases of oculonasal myiasis with simultaneous involvement of the eye and nose are extremely rare in the literature. Eyigör et al. reported such a combined involvement in an agriculture faculty assistant in 2006, while Smillie et al. described a similar case in a British tourist following travel to Africa in 2010. Hamdi et al. reported a case of nasal myasis that developed 10 days after ocular involvement in a healthy Syrian woman and was treated surgically. This case alone emphasizes the importance of endoscopic evaluation of the nose in every patient with ocular myasis. In both of our cases, nasolacrimal lavage with hypertonic saline was performed to assess for the presence of larvae in the nasolacrimal duct or sac.

CONCLUSIONS

Oculonasal myiasis is a parasitic infestation that may occur in individuals involved in animal husbandry and residing in rural areas, and it can lead to significant morbidity if not managed promptly. In patients presenting with external ophthalmomyiasis, a through nasal examination, including diagnostic nasal endoscopy, is essential to evaluate for concomitant nasal myiasis and to ensure complete removal of all intranasal larvae.

endoscopic sinus surgery, oculonasal myiasis, nasal endoscopy, sheep bot fly, larvae,

PP-617

A Rare Anatomical Variation: “Triple Middle Turbinate”

Nurbanu Dalsız[1], **Melikşah Çakır**[1], **Gizem Karaca**[1]

[1]*Kocaeli City Hospital Department of Otorhinolaryngology*

BACKGROUND & AIM

The middle turbinate is a key anatomical landmark in endoscopic sinus surgery (1). Anatomical variations are common in the paranasal sinuses, with pneumatization (concha bullosa) being the most frequent (2). While concha bullosa is the most prevalent middle turbinate variation, it is followed by the paradoxical middle turbinate, whereas secondary and accessory middle turbinates are rare (3). The “trifurcate” or triple middle turbinate is a rare variant first described by Eweiss et al. in 2008 (2). Awareness of such variations is essential for safe surgery and accurate evaluation of inflammatory sinonasal disease (4).

MATERIAL & METHODS

A 31-year-old male presented with long-standing nasal obstruction, with no history of prior sinonasal surgery or trauma. Endoscopy revealed mild right septal deviation and bilateral grade 4 nasal polyposis. Computed tomography (CT) demonstrated nasal polyps and variations in the middle turbinate structures; endoscopic sinüs surgery was planned. Before gross polypectomy, three middle turbinate–like structures were identified: one initially presumed to be the middle turbinate, a second traced from the axilla, and a third from its posterior lateral wall attachment; CT correlation confirmed triple middle turbinates. Three middle turbinate-like structures with internal bony components were palpated. Further dissection was avoided; symptoms improved, pathology confirmed sinonasal polyps, and follow-up was arranged.

RESULTS

Our literature review indicates that the “triple middle turbinate” is an extremely rare variation, with only a single case reported to date. Such anatomical anomalies of the nasal cavity are typically identified through a combination of careful endoscopic examination and meticulous radiological evaluation.

This case highlights that preoperative CT should not be limited to detecting pathology but must also be thoroughly reviewed to identify subtle anatomical variations that may alter or obscure surgical landmarks. Maintaining a high index of suspicion for these variations is essential to prevent intraoperative disorientation and reduce the risk of injury to adjacent structures.

CONCLUSIONS

Although middle turbinate variations are uncommon, they may present significant surgical challenges during functional endoscopic sinus surgery . Surgeons should meticulously evaluate preoperative imaging, consistently identify and follow anatomical landmarks throughout the procedure, and remain vigilant for atypical configurations. Preparedness to encounter

rare variations, such as a triple middle turbinate, is essential to ensure safe dissection, maintain orientation, and minimize the risk of complications.

Double-Layered Closure Of Chronic Oroantral Fistula Using Pedicled Buccal Fat Pad After Endoscopic Sinus Surgery: Video Case Report

Çağrı Yıldız[1], **Ramazan Bahadır Küçük**[1], **Orhan Özturan**[1]

[1]*Department of Otorhinolaryngology–Head and Neck Surgery, Bezmialem Vakıf University Faculty of Medicine, Istanbul, Türkiye*

BACKGROUND & AIM

Oroantral fistula (OAF) is an epithelialized communication between the oral cavity and the maxillary sinus, frequently complicated by chronic sinus pathology. Inadequate sinus management may increase the risk of recurrence after fistula repair. Various closure techniques have been described, including pedicled buccal fat pad (BFP) flaps and double-layered approaches. This report aims to present a staged surgical management strategy combining endoscopic sinus surgery and double-layered intraoral repair using a pedicled buccal fat pad, supported by a surgical video.

MATERIAL & METHODS

A 60-year-old male with a one-year history of persistent OAF following maxillary molar extraction was evaluated. Computed tomography demonstrated an 8 × 7 mm fistula associated with a 1.5 cm infected dentigerous cyst within the maxillary sinus. A staged approach was adopted. First, endoscopic maxillary sinus surgery with wide antrostomy and septoplasty was performed to restore adequate drainage and ventilation. Two months later, the fistula was repaired using a double-layered intraoral technique. The epithelialized tract was excised, a pedicled buccal fat pad was mobilized and secured as the inner layer, and buccal and palatal mucosal advancement flaps were sutured for tension-free primary closure.

RESULTS

Endoscopic sinus surgery and cyst excision were completed without complications, achieving adequate sinus drainage. The subsequent double-layered intraoral repair was successfully performed. No intraoperative or early postoperative complications occurred. At the second postoperative month follow-up, the patient was asymptomatic, with complete resolution of oral–nasal regurgitation and air leakage, and no evidence of recurrence.

CONCLUSIONS

A staged approach combining endoscopic sinus surgery and double-layered intraoral repair using a pedicled buccal fat pad appears to be a reliable option for managing chronic OAF associated with sinus pathology. Ensuring adequate sinus drainage prior to closure may reduce recurrence risk. The video-supported presentation highlights the technical details and practical applicability of this approach.

PP-619

Primary Burkitt Lymphoma Of The Maxillary Sinus: A Case Report.

Konstantinos Chaidas[1], **Artemis Zarkadi**[2], **Nikolaos Tepelenis**[3], **Sotirios Papouliakos**[4]

[1]*Aristotle University of Thessaloniki - School of Medicine, Greece;* [2]*ENT Department, University Hospital of Alexandroupolis, Greece;* [3]*Pathology Department, General Hospital of Athens "G. Gennimatas", Greece;* [4]*ENT Department, General Hospital of Athens "G. Gennimatas", Greece*

BACKGROUND & AIM

Primary Burkitt lymphoma (BL) involving the maxillary sinus is an exceedingly rare clinical entity, particularly in immunocompetent adults, with only two cases reported in the literature. Its clinical presentation often mimics chronic rhinosinusitis or neuropathic facial pain, potentially leading to delayed diagnosis and management.

MATERIAL & METHODS

We report the case of a 38-year-old immunocompetent caucasian male presenting with a 5-month history of progressively worsening left-sided facial pain accompanied by localized hypoesthesia over the maxillary region, without additional symptoms.

RESULTS

Computed tomography revealed a soft tissue mass occupying the left maxillary sinus, associated with bony erosion of the superior, lateral, and posterior walls and compression of the infraorbital nerve. These findings were confirmed by magnetic resonance imaging. Endoscopic biopsy was performed, and histopathological and immunohistochemical analysis confirmed Burkitt's lymphoma, with a Ki-67 proliferation index of 98%. Serological testing for EBV, HIV, and hepatitis B and C was negative. Further staging work-up demonstrated localized disease (Ann Arbor stage IE). The patient received combination

chemotherapy with the R-CODOX-M/IVAC regimen, achieving complete remission within two months. He remains disease-free at 2-year follow-up.

CONCLUSIONS

Burkitt's lymphoma may present with atypical symptoms that resemble benign sinonasal conditions, contributing to delayed diagnosis and treatment. Given its highly aggressive nature, BL should be included in the differential diagnosis of patients presenting with persistent, unilateral sinonasal symptoms, unresponsive to standard therapy. Early imaging, prompt biopsy, and a multidisciplinary approach are crucial for optimal therapeutic outcomes.

PP-620

Secondary Sinonasal Meningioma With Intracranial Extension Mimicking Nasal Polyposis: A Case Report

Merve Bilir[1], **Mahmut Demirtaş**[1]

[1]*Department of Otorhinolaryngology - Head and Neck Surgery, Faculty of Medicine, Aydın Adnan Menderes University, Aydın, Türkiye*

BACKGROUND & AIM

Meningiomas originate from arachnoid cap cells, with extracranial meningiomas (EM) representing less than 2% of cases. Sinonasal involvement is exceptionally rare, accounting for 0.1% of nasal tumors. Due to their slow growth, EMs are often misidentified as nasal polyps or sinusitis, leading to diagnostic delays. These tumors are classified as primary ectopic or secondary extensions. We present a case initially managed as nasal polyposis, subsequently diagnosed as a secondary sinonasal meningioma with intracranial communication, highlighting the importance of differential diagnosis in persistent sinonasal masses.

MATERIAL & METHODS

A 42-year-old female presented with chronic left-sided nasal obstruction and anosmia, without rhinorrhea, headache, or fever. Her history included endoscopic sinus surgery (ESS) for nasal polyposis in 2019, though previous imaging was unavailable. Examination revealed a soft tissue mass in the left middle meatus. PNSCT and MRI showed a 28x19 mm lesion with peripheral polypoid foci and a central T2-hypointense area at the left middle turbinate level, suggestive of "inverted papilloma surrounded by nasal polyposis." No significant bone destruction was noted. Due to the suspicion of recurrence or inverted papilloma, a preoperative biopsy was not performed, and ESS was scheduled. Intraoperatively, a fragile mass arising from the lateral nasal wall, below the middle turbinate stump, was identified and totally resected endoscopically. Crucially, no intraoperative or postoperative cerebrospinal fluid (CSF) leak was observed, and no CSF rhinorrhea occurred during the uneventful recovery period.

RESULTS

Histopathological examination revealed a "Transitional Meningioma" (WHO Grade I). Multidisciplinary evaluation confirmed an intracranial connection; however, as the nasal portion was completely excised, no additional neurosurgical intervention was required. The patient remains asymptomatic at the 3-month follow-up.

CONCLUSIONS

Meningioma should be considered in the differential diagnosis of unilateral or recurrent sinonasal masses, particularly those showing atypical radiological features like T2 hypointensity. This case emphasizes that endoscopic examination alone is insufficient; advanced imaging is crucial to detect potential intracranial communications. While the prognosis for WHO Grade I cases is excellent after complete surgical resection, long-term follow-up and monitoring skull base integrity are vital in patients with intracranial involvement. Maintaining a high clinical suspicion is essential to avoid diagnostic delays and ensure adequate surgical management of these rare extracranial tumors.

Posterior Ethmoid Mucocele In A Patient With Recurrent Diplopia

Veronica Astraka[1], **Pantos Pavlos**[1], **Papacharalampous Georgios**[1], **Chrysovergis Aristeidis**[1]

[1]*ENT Head and Neck Surgery Department, General Hospital of Athens "Elpis"*

BACKGROUND & AIM

Introduction: Mucoceles are cystic lesions of the paranasal sinus that contain mucinous material of variable viscosity. They most commonly develop as a result of previous surgery in the sinonasal tract or head trauma.

MATERIAL & METHODS

Symptoms may vary depending on size and location of the mass. Diagnosis is based on thorough history taking, clinical and imaging examination. Definite treatment is surgical. Urgent intervention is necessary in case of brain or orbital involvement. In this article, we present a case of 47-year old patient with a posterior ethmoid mucocele who had no history of trauma or

previous operation. We also attempt to highlight the most popular theories of pathogenesis and the key steps for optimal management of the disease.

RESULTS

Case report: A 47-year-old patient presented with a 12-month history of nasal obstruction, discharge and recurrent diplopia. Rhinoscopy revealed mucosal swelling and thick secretions. CT and MRI were performed showing a large mucocele occupying the left posterior ethmoid region with co-existent remodelling of the ipsilateral lamina papyracea.

CONCLUSIONS

Conclusion: Although mucoceles are benign lesions they require a high index of clinical suspicion for diagnosis. Treatment is surgical and includes drainage and wide marsipularization, in order to establish proper aeration of the affected sinus and minimize the risk of recurrence.

RINOJERMINA IN THE TREATMENT OF INFLAMMATORY DISEASES OF THE PHARYNX

Khasanov U.S.[1], **Kamilov Kh.B.**[1]

[1]*Tashkent State Medical University*

BACKGROUND & AIM

Despite the fact that many methods and means are used in the treatment of chronic inflammation of the pharyngeal tonsil, their effectiveness is still insufficient. One of the main causes of long-term, slow-progressing, recurrent, and difficult-to-treat chronic diseases is a decrease in the body's resistance.

The purpose of the study was to increase the effectiveness of the drug rhinojermina in the diagnosis and treatment of inflammatory diseases of the pharyngeal tonsil.

MATERIAL & METHODS

62 children (32 - main and 30 - control group) aged 3 to 12 years, who came for treatment with a diagnosis of chronic adenoiditis, participated in the clinical study. If the criterion for inclusion in the study was a confirmed diagnosis of chronic adenoiditis, then the criteria for inclusion were the presence of inflammatory processes in other ENT organs, age under 3 years and over 12 years. In addition to the standard treatment complex, patients in the main group were additionally recommended the local use of the drug rhinojermina.

RESULTS

Assessment of the degree of difficulty in nasal breathing showed that even with the same initial degree of blockage, the improvement in respiration in children of the main group by day 5 was 15% higher than in the control group, by day 7 - by 30%, and by day 9 - by 73%. The nature and intensity of rhinorrhea also had its own dynamic characteristics. At the time of admission to the department in the main group of children, 6.257% of children had purulent discharge, 31.2% had mucopurulent discharge, 12.5% had a moderate amount of mucous discharge, 9.38% had a small amount of mucous discharge, and 28.15% of children had no discharge at all. Even on the 9th day of treatment, the average mucus secretion was preserved in 10% of children in the comparison group. Improvement in nasal breathing began on the 5th day of treatment.

CONCLUSIONS

Thus, the results of the conducted research showed that the inclusion of the drug Rinojermina in the treatment regimen for chronic adenoiditis allows for increased treatment effectiveness and rapid restoration of the nasal mucosa.

Microbiological Analysis And Antimicrobial Resistance Profile In Patients With Chronic Rhinosinusitis

Edwin Tamashiro[1], **Vinicius Miranda Baroni**[1], **Wilma Terezinha Anselmo-Lima**[1], **Valdes Roberto Bollela**[2], **Denny Marcos Garcia**[1], **Claudio Penido Campos Júnior**[1], **Nathalia de Lima Martins Abichabki**[2], **Fabiana Cardoso Pereira Valera**[1]

[1]*Departament of Ophthalmology, Otorhinolaryngology, and Head and Neck Surgery. Ribeirão Preto Medical School. University of Sao Paulo.;*

[2]*Division of Infectious Diseases. Ribeirão Preto Medical School. University of Sao Paulo*

BACKGROUND & AIM

This study aims to characterize the microbiological profile and antimicrobial resistance patterns of bacterial isolates from patients diagnosed with Chronic Rhinosinusitis (CRS).

MATERIAL & METHODS

A retrospective cohort review analyzed 743 cultures obtained from 432 adult patients with CRS managed at a tertiary rhinology clinic between 2015 and 2024. After excluding duplicate isolates and patients with secondary CRS, statistical analyses

evaluated patients demographics, distribution of bacterial isolates, temporal trends in antimicrobial resistance, species-specific resistance rates, and resistance differences between MRSA and non-MRSA isolates. Pearson's Chi-square, Fisher's exact, and Kendall-Tau correlation tests were applied, with significance set at 5%.

RESULTS

Among 432 CRS patients (53.9% female; mean age 50.7 years; 63.4% with nasal polyps), 743 cultures were analyzed. Overall, 66.4% were positive, yielding 586 isolates, predominantly gram-positive bacteria (68.3%). Staphylococcus aureus was the most frequent pathogen (42.1%), followed by Pseudomonas aeruginosa (9.4%) and Streptococcus pneumoniae (6.1%). Negative cultures were common (33.6%), particularly in CRSwNP, although without statistical significance. Over the 10-year period, resistance increased significantly to lincosamides (p=0.002) and decreased to sulfonamides (p=0.029). S. aureus demonstrated high resistance to penicillin (94.9%), with moderate rates for macrolides (52.5%) and lincosamides (47.9%). MRSA accounted for 23% of S. aureus isolates and showed significantly higher resistance to gentamicin (p = 0.002), ciprofloxacin (p = 0.031), and sulfamethoxazole (p< 0.001) compared with non-MRSA strains.

CONCLUSIONS

Staphylococcus aureus remains the predominant pathogen in CRS, while the high proportion of negative cultures reinforces the multifactorial and primarily inflammatory nature of CRS. The increasing resistance in lincosamides and emerging trends in macrolides reinforce the importance of personalized therapies adjusted to local microbiological profiles, along with continuous antibiotic stewardship and monitoring of resistance patterns.

Effect Of NF-Kb/SMAD Decoy Oligodeoxynucleotide On Inflammsome Formation In Nasal Epithelial Cells

Seung-Heon Shin[1]

[1]*Mi-Kyung Ye;* [2]*Tae-Gyun Kim;* [3]*Hee-Jun Park*

BACKGROUND & AIM

Chronic rhinosinusitis (CRS) can be endotypically classified into eosinophilic (ECRS) and non-eosinophilic CRS (NECRS)with distinct immunological characteristics. The role of inflammasomes in chronic inflammation has been the subject of intense research in rhinology. We investigated the effect of ring type NF-kB/SMAD decoy oligodeoxynucleotide (ODN) on inflammasome and cytokine expression in nasal epithelial cells.

MATERIAL & METHODS

Primary nasal epithelial cells were isolated from healthy control, patients with ECRS and NECRS. Cytotoxic effect of ODNs were determined with MTT assay and further experiments were performed using a safe concentration of NF-kB, SMAD, and chimeric ODN. The epithelial cells were pretreated with ODNs and then stimulated with Alternaria, Aspergillus, and lipopolysaccharide (LPS) for 24 h. and the levels of IL-6, IL-8, GM-CSF, and IL-1β were measured by ELISA. To assess the biomarker of inflammasome, caspase-1, NOD-like receptor family, pyrin domain containing 3 (NLRP3), and IL-1beta mRNA expression were determined.

RESULTS

NF-κB, SMAD, and chimeric ODN did not show cytotoxicity up to 48 h. Although the pretreatment of epithelial cells with ODNs did not suppress cytokine production, in non-ECRS epithelial cells, IL-1β production was significantly inhibited. The expression of caspase-1 and NLRP3 mRNA was significantly increased by fungi and LPS, and NF-kB, SMAD, and chimeric ODN significantly suppressed caspase-1 and NLRP3 in non-ECRS nasal epithelial cells.

CONCLUSIONS

NF-κB and SMAD ODN exhibited different effects on the suppression of cytokine production and suppressed pyoptosis in nasal epithelial cells depending on the endotype of CRS. This finding suggests that CRS possesses distinct immunopathologic characteristics according to its endotype, and ODNs ODN showed a particularly suppressed inflammatory response of the nasal mucosa of non-ECRS patients.

ANATOMICAL PITFALLS DURING ENDOSCOPIC SINUS SURGERY IN ACHONDROPLASIA: A CASE OF ORBITAL ABSCESS COMPLICATED BY IATROGENIC CSF LEAK

Emine can[1], **Emrah Gündüz**[1]

[1]*Turgut Özal Tıp Merkezi, İnönü Üniversitesi, Kulak Burun Boğaz Anabilim Dalı*

BACKGROUND & AIM

Achondroplasia causes craniofacial and sinonasal anatomical variations that increase the risk of complications during functional endoscopic sinus surgery (FESS). We report a 12-year-old achondroplastic girl with a history of hydrocephalus and prior ventriculoperitoneal shunt who underwent emergent FESS for orbital abscess. Intraoperatively, skull base injury and cerebrospinal fluid (CSF) leak occurred due to a low-lying and thinned skull base. The patient was managed conservatively with bed rest and medical therapy, resulting in complete resolution of CSF rhinorrhea and orbital symptoms, demonstrating conservative treatment as a viable option in selected cases.

MATERIAL & METHODS

Due to the lack of adequate response after 48 hours of intravenous broad-spectrum antibiotic therapy, an emergent surgical intervention was planned. Right functional FESS and orbital decompression were performed under general anesthesia. Intraoperative evaluation revealed marked variations in the sinonasal anatomy secondary to achondroplasia, with the ethmoid roof and skull base located significantly lower (prolapsed) than their normal anatomical positions. The abscess cavity was reached, and the purulent material was successfully drained endoscopically. However, during dissection within the infected and fragile tissues, the extremely thin bony structure of the skull base gave way, resulting in concurrent dural injury. Active CSF rhinorrhea was observed from the site.

RESULTS

The combination of a low-lying skull base anomaly seen in achondroplasia and the bone thinning caused by a history of hydrocephalus exponentially increases the risk of dural injury and CSF leak during FESS. It is vital for surgeons to meticulously evaluate preoperative CT scans, particularly focusing on the level of the ethmoid roof and bone thickness. In the event of a CSF leak during surgery, a conservative management approach based on strict bed rest and medical follow-up, rather than primary repair, is an effective and safe alternative that prevents additional surgical morbidity in selected cases.

CONCLUSIONS

Achondroplasia-associated low skull base and hydrocephalus-related bone thinning significantly increase the risk of dural injury and CSF leak during FESS. Careful preoperative CT evaluation is essential, and in selected cases, conservative management of intraoperative CSF leaks may be a safe alternative to primary repair.

Two-Year Real-World Outcomes In Patients With Crswnp Treated With Dupilumab

Cristina Vaduva[1], **Carlos Fernández-Navarro**[1], **Juan Riestra-Ayora**[1], **Eduardo Martin-Sanz**[1]

[1]*Getafe University Hospital*

BACKGROUND & AIM

Chronic rhinosinusitis with nasal polyps (CRSwNP) is part of type 2 inflammatory airway disease and is associated with a high clinical burden, impaired quality of life, and frequent asthma comorbidity. Dupilumab has demonstrated efficacy in clinical trials; however, real-world evidence is needed to confirm its effectiveness. The aim of this study was to evaluate clinical, endoscopic, functional, and inflammatory outcomes at 24 months.

MATERIAL & METHODS

An ambispective longitudinal observational study was conducted in patients with CRSwNP treated with dupilumab. Visual analogue scale (VAS) for smell and sleep, SNOT-22, Nasal Polyp Score (NPS), Asthma Control Test (ACT), Total Symptoms Score (TSS), and peripheral eosinophil counts were assessed at baseline and at 3, 6, 12, and 24 months. The need for oral corticosteroids and the indication for endoscopic sinus surgery (FESS) were also evaluated. Comparisons were performed against baseline using the Wilcoxon signed-rank test, reporting median change (ΔMd) with 95% confidence intervals. Changes in the need for ESS and oral corticosteroids were assessed using McNemar's test.

RESULTS

A total of 21 patients were included. At 3, 6, and 12 months, a progressive and statistically significant improvement was observed across all variables, reaching maximal therapeutic effect at 12 months, with a reduction in SNOT-22 (ΔMd −34.5; 95% CI −45 to −19; p=0.001) and nasal polyp score (ΔMd −4; 95% CI −5 to −3; p<0.001), along with improvements in olfaction (ΔMd −5; 95% CI −7 to −3; p=0.004) and sleep quality (ΔMd −3; 95% CI −4 to −2; p=0.001). ACT scores increased significantly (ΔMd +5.5; 95% CI +2 to +7; p=0.024). At 24 months, improvements were sustained across all variables, with no significant differences observed between 12 and 24 months, suggesting long-term stabilization of treatment effect.

CONCLUSIONS

Dupilumab is associated with significant clinical, endoscopic, and functional improvement in real-world CRSwNP patients, with an early response at 3 months, further improvement at 6 months, maximal effect at 12 months, and sustained benefits at 2 years. Treatment significantly reduces the need for endoscopic sinus surgery and oral corticosteroids from early stages, with persistent effects over time.

Pediatric Meningoencephalocele Mimicking A Nasal Polyp

MUHAMMED İSA BEKSARI,SERVET ERDEMES[1]

[1]*MUHAMMED İSA BEKSARI,SERVET ERDEMES*

BACKGROUND & AIM

The aim of this case report is to present a pediatric meningoencephalocele mimicking a nasal polyp and to emphasize the importance of considering this rare but clinically significant condition in the differential diagnosis."It also present the clinical, radiological, and surgical management of a pediatric meningoencephalocele initially suspected to be a nasal polyp and to highlight the importance of establishing the correct diagnosis.

MATERIAL & METHODS

A 10-year-old girlHistory of persistent nasal dischargeComplaint of clear rhinorrheaNasal endoscopic examination revealed:A smooth-surfaced polypoid massLocated in the superior aspect of the left nasal cavityRadiological FindingsParanasal Sinus CTA bony defect was detected at the level of the left cribriform plate.Figure 1. Meningoencephalocele. CT imaging demonstrated a bony defect on the left side of the cribriform plate.Magnetic Resonance Imaging (MRI)MRI demonstrated herniation of the left frontal gyrus extending through the cribriform plate into the nasal cavity.Figure 2. Meningoencephalocele. MRI demonstrated inferior herniation of the left frontal gyrus through the left side of the cribriform plate.The radiological findings were consistent with meningoencephalocele

RESULTS

High-resolution computed tomography (CT) plays a crucial role in identifying skull base bony defects, whereas magnetic resonance imaging (MRI) is indispensable for evaluating herniated brain tissue and its intracranial continuity (2,3). The combined use of these imaging modalities provides excellent diagnostic accuracy.In recent years, the endoscopic endonasal approach has become the preferred surgical technique for the treatment of meningoencephaloceles and anterior skull base defects. Compared with open surgical approaches, it offers lower morbidity, shorter hospital stays, and superior cosmetic outcomes (3–5).

CONCLUSIONS

These findings support that meningoencephaloceles can be treated safely and effectively with meticulous preoperative evaluation and appropriate surgical technique.

Frontal Sinus Mucosele Complicated By A Superior Subperiostal Abscess With Orbital Roof Defect In A Child

Doc Dr. Yalçın Alimoğlu, MD[1], **Emre Can Özçelik, MD**[1], **Türkü Bayramoğlu, MD**[1], **Prof. Dr. Özgür YİĞİT**[1]

[1]*İstanbul Başakşehir Çam ve Sakura City Hospital, Derpartment of Otorhinolaryngology*

BACKGROUND & AIM

Frontal sinus mucoceles are benign, epithelium-lined cystic lesions that may expand and cause erosion of adjacent bony structures. They can lead to orbital and, less commonly, intracranial complications. Although mucoceles are relatively rare in the pediatric population, they should be considered in the differential diagnosis of orbital pathology.

Subperiosteal abscess is a well-known complication of sinusitis; however, its occurrence secondary to a frontal sinus mucocele is uncommon. In such cases, the underlying mucocele may contribute to bony destruction, particularly of the orbital roof, facilitating extension into the orbit.

MATERIAL & METHODS

Case: A 12-year-old girl presented with a 3-day history of left periorbital swelling, erythema, and ptosis. elevated CRP elevated and leukocytosis was found. Preserved visual acuity and normal ocular motility. Clinically, inferior displacement of the globe due to mass effect was noted. No purulent discharge in nasal cavity on endoscopic examination.

PNCT demonstrated a subperiosteal abscess with an air–fluid level. Also, thinning and a bony defect of the superior orbital wall were observed. MRI showed a superiorly located subperiosteal collection, and images demonstrated hyperintense signal characteristics consistent with a mucocele.

The patient underwent urgent surgical drainage with a preliminary diagnosis of orbital abscess. During the initial procedure, the ophthalmology team accessed the orbital rim through an eyelid crease incision, and minimal purulent material was drained. Despite broad-spectrum intravenous antibiotic therapy, no significant clinical improvement was observed.

RESULTS

Rest of the case: The patient was scheduled for functional endoscopic sinus surgery . During the second operation, navigation guidance was used to access the frontal recess, and the wall of the mucocele was reached. The mucocele was marsupialized within the frontal sinus. Also, the ophthalmology team re-entered the orbital rim via a subbrow incision and placed a drain.

Following surgery, the patient showed rapid improvement, and both CRP levels and leukocytosis decreased significantly. No recurrence was observed during follow-up.

Result: Following second surgical management, the patient showed rapid and sustained clinical improvement. Visual acuity remained fully preserved. Intraoperative findings confirmed a frontal sinus mucocele associated with a defect in the orbital roof, leading to a superior subperiosteal abscess. Microbiological cultures revealed no pathogenic growth. The orbital drain was removed and both clinical and radiological findings resolved during follow-up.

CONCLUSIONS

Frontal sinus mucoceles, although rare in children, can give rise to significant orbital complications, including subperiosteal abscess formation through erosion of the orbital roof. In pediatric patients presenting with orbital findings, especially when atypical intraoperative features such as absence of purulent material are encountered, an underlying mucocele should be considered. Early recognition and appropriate surgical management, including endoscopic marsupialization with navigation guidance when necessary, are essential for effective treatment and prevention of recurrence.

IRREVERSIBLE ELECTROPORATION IN THE TREATMENT OF HYPERTROPHIC RHINITIS

Abdurakhimova Sh.S.[1], **Khasanov U.S.**[1]

[1]*Republican specialized scientific and practical medical center of otorhinolaryngology and head and neck diseases*

BACKGROUND & AIM

Hypertrophic rhinitis is a disease that develops as a result of chronic hyperplasia of the inferior nasal conchae, which seriously impairs breathing and reduces the quality of life. Currently, the search for minimally invasive and effective methods in the selection of methods for treating this disease is relevant.

The aim of the study was to improve the effectiveness of hypertrophic rhinitis treatment.

MATERIAL & METHODS

Materials and methods. The study involved 60 patients diagnosed with hypertrophic rhinitis. They were divided into two groups. The first group (30 patients) received irreversible electroporation. The second group (30 patients) underwent conchoplasty using an electrocoagulator. During electroporation, short pulses of high voltage disrupt the structure of the cell membrane and initiate apoptosis in the tissues. The main advantage of this method is that it reduces tissue volume and reduces the likelihood of regrowth without mechanical or thermal damage. In contrast, during electrocoagulation, a strong thermal effect is exerted on the tissues, which leads to local edema, pain, and prolonged recovery.

The study evaluated the effectiveness of the following criteria: the level of nasal breathing, subjective assessment of the quality of sleep of patients, recovery period, the occurrence of complications, and the effectiveness of treatment.

RESULTS

Results and discussion of the study. The study compared the effectiveness and recovery process of irreversible electroporation and electrocoagulation conchoplasty. Within 7–10 days, the mucosa returned to an almost normal state, and in most patients, the healing process was painless and bloodless. In necrotic tissues, natural clearance was observed through controlled apoptosis, and fibrosis or granulation processes in the tissues were almost absent. Patients treated with irreversible electroporation began to experience relief of breathing within 7–10 days after the procedure. Swelling resolved quickly, pain was minimal, and patients had virtually no change in their recovery. Most importantly, the restored tissues retained function and recurrence rates were low. The analysis showed that the irreversible electroporation method is not only highly effective, but also has a special value due to the preservation of tissues in a physiological state, low degree of trauma and short rehabilitation period.

CONCLUSIONS

Conclusion. The irreversible electroporation method in the treatment of hypertrophic rhinitis provides high efficiency, minimal trauma and comfortable recovery conditions for the patient. This method is significant in that it effectively eliminates hypertrophy while preserving the functions of the nasal mucosa. Therefore, it is advisable to widely introduce electroporation technology into clinical practice.

Nasolabial Cyst With Aesthetic And Functional Impairment: Clinical, Radiological, And Surgical Perspectives – Case Report

Milena Fernandez Mezei[1], **Bruna Paniguel Gehring Cardoso**[1], **Julia Kachani**[1], **Gilberto Ulson Pizarro**[1]

[1]*Hospital Paulista de Otorrinolaringologia*

BACKGROUND & AIM

Nasolabial cysts are rare, benign, non-odontogenic lesions arising from epithelial remnants of the nasolacrimal duct. First described by Klestadt in 1953 as part of his facial cleft cyst theory, they remain diagnostically challenging due to their rarity and resemblance to other cystic pathologies.[1,3] These lesions occur more frequently in women, with a reported female predominance of approximately 3:1 and peak incidence between the third and fifth decades of life.[2] The pathogenesis is debated, with Bruggemann attributing origin to nasolacrimal duct epithelium and Klestadt emphasizing embryologic epithelial entrapment.[1,3] Most cases are unilateral, though bilateral presentations have been reported.[4]

MATERIAL & METHODS

A 53-year-old woman presented with progressive left nasal obstruction and visible asymmetry of the left nasal ala and nasolabial region over five years. Clinical examination revealed bulging of the nasal floor and nasolabial area. Nasal endoscopy demonstrated a cystic lesion in the inferior nasal vestibule. Computed tomography (CT) was performed to characterize the lesion and its anatomical relationships. CT revealed an oval, well-circumscribed extraosseous lesion in the left nasolabial region measuring 2.7 × 2.0 × 1.6 cm, with intermediate attenuation consistent with proteinaceous content. Associated findings included alveolar ridge remodeling, narrowing of the nasal vestibule, septal deviation to the left, inferior turbinate hypertrophy, mucosal thickening of the maxillary and ethmoidal sinuses, and bilateral Onodi cells. Definitive management consisted of surgical excision via a combined transnasal and intraoral Denker approach, chosen to provide wide exposure and ensure complete removal.[5] The excised specimen was submitted for histopathological evaluation.

RESULTS

CT imaging confirmed an extraosseous cystic lesion consistent with a nasolabial cyst, associated with remodeling of the alveolar ridge and narrowing of the nasal vestibule. The lesion was excised completely using a combined transnasal and intraoral Denker approach, which provided wide exposure and enabled removal. Histopathological examination revealed a cyst wall lined predominantly by pseudostratified columnar (respiratory-type) epithelium with goblet cells, with focal squamous metaplasia. No evidence of atypia, malignancy, or infection was identified. Patient was discharged without complications. At two-month follow-up, she reported resolution of nasal obstruction and improved facial symmetry, with no recurrence. Clinically, nasolabial cysts often present with swelling of the nasolabial fold, elevation of the nasal ala, nasal obstruction, and occasionally pain when infected.[2,3] Spontaneous rupture with drainage into the nasal or oral cavity has also been described.[3] In this case, cosmetic deformity was the principal concern, and surgical excision achieved excellent functional and aesthetic outcomes.[2,3,5]

CONCLUSIONS

Nasolabial cysts should be considered in the differential diagnosis of nasolabial swellings and unilateral nasal obstruction. Cross-sectional imaging, particularly CT or MRI, is crucial to confirm their extraosseous origin and to distinguish them from odontogenic cysts, dermoid cysts, nasolacrimal duct cysts, and minor salivary gland tumors.[3] Histopathology typically reveals respiratory-type epithelium with goblet cells and occasional squamous metaplasia.[2] Surgical excision remains the definitive treatment. While the sublabial approach offers direct access, endoscopic transnasal techniques and reverse Denker variants provide minimally invasive alternatives.[5] Prognosis is favorable, recurrence is rare, and early intervention optimizes nasal function and facial aesthetics.[2,3]

PP-631

The Role Of Orbital Decompression In Expansile Frontal Sinus Mucocele

Hürü Beyza Cerit[1], **Ömer Erdur**[2]

[1]*Selçuk University Faculty of Medicine Hospital, Konya, Türkiye**;* [2]*Department of Otorhinolaryngology, LIV Hospital, Ulus, İstanbul, Türkiye"*

BACKGROUND & AIM

Paranasal sinus mucoceles are benign, expansile, pseudocystic masses. This case report aims to present a frontal sinus mucocele diagnosed by headache-associated orbital manifestations, to share our experience with combined functional endoscopic sinus surgery (FESS) and orbital decompression, and to highlight potential surgical challenges and postoperative outcomes associated with this technique.

MATERIAL & METHODS

62-year-old male patient presented with longstanding headache, left facial and periorbital pain, and progressive deformity of the left eye following previous functional endoscopic sinus surgery (FESS) for chronic sinusitis. Imaging revealed a frontal sinus mucocele extending into the ethmoid sinus, causing posterior frontal wall erosion, orbital compression, exophthalmos, and

remodeling of the medial orbital wall with compression of the extraocular muscles. Preoperative ophthalmologic examination demonstrated limited left extraocular movements and orbital dystopia. Revision left-sided FESS was performed under general anesthesia. Intraoperatively, the middle turbinate was massively enlarged due to extension of the mucocele into the ethmoid cells and middle turbinate. Incision of the middle turbinate resulted in dense mucoid drainage. Following evacuation of the mucocele, frontal and ethmoidal marsupialization was completed. The lamina papyracea was markedly thickened and sclerotic and was excised while preserving globe integrity. Due to severe periorbital sclerosis and risk of globe injury, further dissection was avoided.

RESULTS

Postoperative ophthalmologic examination demonstrated full extraocular movements. At 3-month follow-up, all symptoms had resolved, and ocular asymmetry had markedly improved.

CONCLUSIONS

Combined FESS and orbital decompression provided favorable postoperative outcomes in this case. Osseous remodeling should be considered a major surgical challenge during orbital decompression in frontal sinus mucoceles, as adjacent anatomical structures may demonstrate marked sclerosis and thickening. Further studies and consecutive case series are required to objectively evaluate the outcomes of this surgical approach

CT-Based Three-Dimensional Printed Nasal Cavity Models Provide Anatomical Reference Data For Development Of A Standard Model For Intranasal Vaccine Evaluation

Shingo Umemoto[1,2], **Yohei Uchida**[2], **Rika Nakahashi**[2,3], **Misaki Kawano**[1], **Hiroshi Kiyono**[2,3,4,5,6,7], **Takashi Hirano**[1]

[1]Department of Otorhinolaryngology - Head and Neck Surgery, Faculty of Medicine, Oita University, Yufu, Japan; [2]Department of Human Mucosal Vaccinology, Chiba University Hospital, Chiba, Japan; [3]Synergy Institute for Futuristic Mucosal Vaccine Research and Development (cSIMVa), Chiba University, Chiba, Japan; [4]Future Medicine Education and Research Organization, Chiba University, Chiba, Japan; [5]Department of Medicine, UC San Diego School of Medicine, San Diego, CA, USA; [6]CU-UCSD Center for Mucosal Immunology, Allergy and Vaccines (cMAV), UC San Diego School of Medicine, San Diego, CA, USA; [7]Division of Infectious Disease Vaccine R&D, Research Institute of Disaster Medicine, Chiba University, Chiba, Japan

BACKGROUND & AIM

Intranasal drug delivery, including emerging nasal vaccines, requires appropriate evaluation of pharmacokinetics and mucosal deposition within the nasal cavity. However, currently available commercial nasal cavity models are simplified and do not accurately represent real human anatomy. Establishing a clinically relevant nasal cavity model is essential for preclinical evaluation of intranasal formulations, yet anatomical reference data derived from human imaging are limited. The aim of this study was to construct patient-specific three-dimensional (3D) nasal cavity models based on computed tomography (CT) imaging and to obtain anatomical data necessary for development of a representative standard nasal cavity model.

MATERIAL & METHODS

CT datasets from nine Japanese subjects aged 4–57 years were used to reconstruct 3D polygonal models of the nasal cavity and paranasal sinuses. Segmentation was performed using DICOM imaging software, and the reconstructed structures were fabricated as physical models using multiple 3D-printing materials selected for durability during device insertion. The morphology of the nasal cavity and paranasal sinuses, including spatial configuration and volumetric characteristics, was analyzed to obtain anatomical reference information.

This study was approved by the Institutional Review Board of Oita University Faculty of Medicine (approval No. 2874-D34) with collaboration from Chiba University.

RESULTS

The 3D-printed models successfully reproduced detailed anatomical structures, including the inferior turbinate, middle meatus, superior nasal cavity, and paranasal sinuses. Despite age-related differences in cavity size, consistent spatial relationships among key anatomical regions were observed across subjects. Quantitative measurements provided practical anatomical parameters required for constructing a representative experimental nasal cavity model based on real human anatomy.

CONCLUSIONS

CT-based 3D-printed nasal cavity models constitute an anatomically realistic experimental platform. The present anatomical analysis provides foundational reference data for establishing a representative standard nasal cavity model derived from real human anatomy. Such a standardized model will enable future pharmacokinetic and deposition studies of intranasal drugs and vaccines and support the development and regulatory evaluation of intranasal formulations.

PEDİATRİC ETHMOİD MUCOCELE CAUSİNG MASSİVE LAMİNA PAPRYCEA EROSİON: A CASE REPORT OF CHRONİC PERİORBİTAL PRESENTATİON

BURAK NAL[1], **YUNUS EMRE KARATAS**[1], **CEMILE BAYKAN ERYIGIT**[1], **ANIL HIKMET BAYUR**[1], **PINAR KUNDI**[1], **OZGUR YIGIT**[1]

[1]*ıstanbul basaksehır cam and sakura cıty hospıtal*

BACKGROUND & AIM

Paranasal sinus mucoceles (PSM) are benign, epithelial-lined, air-filled cystic lesions that expand slowly due to the accumulation of mucoid secretions. While common in adults, they are rarely encountered in the pediatric population, often associated with cystic fibrosis or chronic rhinosinusitis. The aim of this report is to present a rare case of a massive ethmoid mucocele in a 9-year-old child that resulted in significant bony erosion of the lamina papyracea (LP) and presented with chronic periorbital symptoms mimicking inflammatory processes.

MATERIAL & METHODS

A 9-year-old female presented with a 3-month history of persistent right-sided facial pain, periorbital swelling, and ecchymosis. Clinical examination and diagnostic imaging were performed. Computed Tomography (CT) revealed a highdensity cystic lesion, 18 mm in diameter, located at the right lacrimal duct entrance, causing erosion of the anterior segment of the LP. Magnetic Resonance Imaging (MRI) confirmed a 2 cm expansile, smooth-contoured lesion in the right ethmoid cells with generalized mucosal thickening in all paranasal sinuses. The patient underwent Functional Endoscopic Sinus Surgery (FESS) under general anesthesia. The surgical intervention involved medialization of the middle turbinate, excision of the lesion wall at the site of the bony defect, aspiration of the cystic content, and marsupialization of the structure into the nasal cavity to ensure permanent drainage.

RESULTS

Intraoperative findings confirmed a large expansile mucocele that had created a significant dehiscence in the medial orbital wall. The cystic contents were successfully evacuated, and the orbital periosteum was found to be intact despite the bony erosion. Histopathological analysis of the biopsy specimens confirmed the diagnosis of a mucocele. Postoperatively, the patient showed rapid resolution of periorbital swelling and facial pain. No recurrence or visual complications were observed during the follow-up period

CONCLUSIONS

Ethmoid mucoceles should be considered in the differential diagnosis of chronic periorbital swelling in children. This case highlights the aggressive nature of mucoceles in the pediatric age group, where they can cause significant bone destruction such as LP erosion within months. Early diagnosis via CT/MRI and prompt endoscopic marsupialization are essential to prevent permanent orbital complications and ensure complete recovery.

CYSTIC MASS ORIGINATING FROM THE NASOLACRIMAL DUCT, ANGIOLIPOMA: A CASE REPORT

Hakan BAYRAKTAR[1], **Enes ASLAN**[1], **Bilge KONUK DEMİRÖZ**[1]

[1]*kocaeli city hospital*

BACKGROUND & AIM

Masses encountered in the nasal passage may originate from structures such as the paranasal sinuses, nasal septum, lateral nasal wall, and nasopharynx. Although rare, it should not be overlooked that the nasolacrimal duct may represent the origin of a mass prolapsing into the nasal passage. In this case report, we present an exceptionally rare case of angiolipoma arising from the nasolacrimal duct.

MATERIAL & METHODS

A 55-year-old female patient presented to the outpatient clinic with complaints of epistaxis, nasal obstruction, and epiphora. Rigid endoscopic examination revealed a mass prolapsing into the nasal passage from beneath the left inferior turbinate (Figure 1). Computed tomography (CT) and magnetic resonance imaging (MRI) were subsequently obtained (Figure 2). Following radiological evaluation, a punch biopsy was performed. The pathology report stated: "While the present findings are primarily suggestive of papilloma, the possibility of vascular neoplasms and low-grade nasopharyngeal papillary adenocarcinoma cannot be definitively excluded. Excision of the lesion is recommended for definitive diagnosis."

RESULTS

Following incisional biopsy, total excision of the mass was performed under general anesthesia. Intraoperatively, a well-circumscribed mass measuring approximately 2×2 cm was identified within the nasolacrimal duct, adherent to the inferomedial aspect of the left inferior turbinate, without involvement of the lateral wall. The frontal process of the maxillary bone was removed to achieve adequate access to the nasolacrimal duct. The duct was transected with sharp scissors at a level

proximal to the sac. The mass was completely excised following circumferential dissection from the surrounding margins. The patient was discharged on postoperative day one with a prescription of topical nasal corticosteroid, decongestant, and nasal saline irrigation. Postoperative follow-up revealed resolution of the patient's complaints of epiphora and epistaxis. The surgical specimen was reported as angiolipoma on pathological examination (Figure 3).

CONCLUSIONS

Space-occupying masses may account for complaints of nasal obstruction and epiphora in affected patients. Nasal endoscopy should not be omitted in patients presenting with these symptoms, and in the event of a detected mass, pathological diagnosis should be established following appropriate imaging. In this case report, we present a rare case both in terms of localization and diagnosis — an angiolipoma originating from the nasolacrimal duct.

Revision Endoscopic Draf III For Recurrent Frontal Osteoma Presenting As Pott's Puffy Tumor

İsmail Sağlar[1], **Fırat Tevetoğlu**[1], **Kays Burak Çakır**[1], **Mehmet Emir Albudak**[2]

[1]*Istanbul University-Cerrahpaşa Faculty of Medicine, Department of Otolaryngology – Head and Neck Surgery;* [2]*Istanbul University-Cerrahpaşa Faculty of Medicine*

BACKGROUND & AIM

Frontal sinus osteomas are benign lesions that may remain asymptomatic but can lead to severe complications when recurrent or obstructive. Pott's puffy tumor, defined as frontal bone osteomyelitis with subperiosteal abscess, is a rare but potentially life-threatening condition. Complex recurrent frontal osteomas with complications can be effectively managed via an extended endoscopic approach

MATERIAL & METHODS

A 60-year-old male with a history of two prior paranasal sinus osteoma surgeries (2000, 2007), both performed via an external approach, presented with progressive frontal swelling. Previous imaging in 2019 demonstrated recurrence; however, the patient was lost to follow-up. On presentation, paranasal sinus computed tomography and magnetic resonance imaging revealed a hyperdense lesion filling the frontal sinus and frontoethmoidal recess, extending medially to the skull base and laterally to the lamina papyracea, with anterior wall defect and subcutaneous extension consistent with Pott's puffy tumor. The patient underwent endoscopic sinus surgery including bilateral frontal sinusotomy (Draf III procedure), complete osteoma excision, drainage of purulent material, and right medial orbital wall decompression due to proptosis

RESULTS

Intraoperative findings confirmed purulent material within the frontal sinus, consistent with active infection. The osteoma was completely excised endoscopically. Wide frontal drainage was achieved via Draf III. No cerebrospinal fluid leakage or major complications occurred. Postoperatively, frontal swelling regressed significantly, and the patient showed favorable clinical recovery under antibiotic therapy.

CONCLUSIONS

Recurrent frontal sinus osteomas may lead to serious complications such as Pott's puffy tumor, particularly in previously operated patients. Extended endoscopic approaches, including Draf III, allow safe and effective management even in complex revision cases with orbital involvement. Early surgical intervention is essential to prevent intracranial and orbital morbidity.

Sinonasal Ameloblastoma Of The Maxillary Sinus: Differential Diagnosis In Unilateral Lesions With Bone Remodeling

Alejandro Pozuelo Moreno[1], **Nazaret Benítez Lobón**[1], **Carlos Franco Fente**[1], **Irene Oliver Laguna**[1], **Nerea Bilbao Garitagoitia**[1], **Cristina Valor García**[1]

[1]*Hospital Universitario Infanta Sofía*

BACKGROUND & AIM

Ameloblastoma is a benign but locally aggressive odontogenic tumor, typically of intraosseous origin and most commonly located in the mandible. Its sinonasal or maxillary presentation, particularly as a peripheral or extraosseous form, is exceptionally rare and represents a diagnostic challenge due to its clinical and radiological overlap with more prevalent entities such as inverted papilloma or malignant neoplasms. Distinct molecular profiles have been described according to tumor origin: intraosseous ameloblastomas frequently harbor BRAF V600 mutations, whereas extraosseous variants more commonly exhibit alterations in SMO or FGFR2 genes and are typically BRAF V600 negative.

MATERIAL & METHODS

A 68-year-old asymptomatic male was referred after an incidental finding on computed tomography of a soft tissue lesion filling the right maxillary sinus. His medical history included prior rectal, cecal, and laryngeal malignancies. Imaging revealed a mass obliterating the middle meatus and extending to the choana, associated with bone remodeling and erosion of the floor and lateral wall of the right maxillary sinus. These findings were suggestive of an inverted papilloma, although malignancy could not be excluded. Nasofibroscopy demonstrated an inflammatory-appearing mass in the right middle meatus. Oral examination identified a non-ulcerated, non-tender cystic lesion over the only remaining tooth in the right upper dental arch. An extensive biopsy was performed via endoscopic sinonasal surgery under general anesthesia.

RESULTS

Histopathological examination was consistent with ameloblastoma. Clinicoradiological correlation suggested a primary sinonasal or peripheral/extraosseous origin. Molecular analysis showed no evidence of BRAF V600 mutation. Following diagnostic confirmation and given bone involvement of the maxillary sinus floor, the patient was referred to maxillofacial surgery for evaluation of curative-intent resection to minimize the recurrence risk. This finding significantly altered the initial diagnostic suspicion and therapeutic approach.

CONCLUSIONS

Sinonasal ameloblastoma is an extremely rare entity, with very few cases reported. Its presentation as a unilateral mass with bone remodeling may mimic inverted papilloma or carcinoma, particularly in patients with a history of malignancy, thereby increasing suspicion of a malignant process. In our case, the absence of BRAF V600 mutation is consistent with a a possible peripheral/extraosseous origin. Compared to the intraosseous variant, extraosseous forms may exhibit less aggressive behavior, although recurrence remains possible. Definitive diagnosis relies on histopathological evaluation, and multidisciplinary correlation is essential for optimal treatment planning.

Primary Tubercular Dacryocystitis Presenting As Surgical Failure In Endoscopic Dacryocystorhinostomy With Literature Review And Suggestion Of Treatment Strategies

Han Tien Tien[1], **Dr. Ren Hui Lo**[1], **Dr. Pathma A/P Letchumanan**[1], **Dr. Harvinder Singh S/O Dalip Singh**[1]

[1]*ORL-HNS DEPARTMENT, HOSPITAL RAJA PERMAISURI BAINUN IPOH, PERAK, MALAYSIA*

BACKGROUND & AIM

Recurrent dacryocystitis is primarily managed through dacryocystorhinostomy (DCR), utilizing either an external or endonasal approach. In this report, we describe a case of refractory dacryocystitis involving 2 failed DCR surgeries, which was ultimately attributed to a localized Mycobacterium tuberculosis infection. Through the lens of this case, we review the challenges in diagnosing atypical dacryocystitis and discuss optimized approaches to disease management.

MATERIAL & METHODS

Case Presentation: A 62-year-old Chinese female presented with persistent right medial canthal swelling and epiphora. Despite multiple courses of antibiotics, condition persisted. After nasal probing and syringing showing evidence of hardstop, she underwent endonasal endoscopic dacryocystorhinostomy (DCR).

Following transient relief, symptoms recurred despite repeated surgeries. Lacrimal discharge was repeatedly send for culture and sensitivity later confirming tuberculous infection. Standard anti-tubercular therapy (ATT) was initiated subusequently, leading to clinical improvement.

Discussion: We review published journals and identify a few commonly faced challenges in this case.

Issues identified include:

1.Clinical mimicry: Early symptoms are mostly general including epiphora and discharge.

2.False negative microbiology: standard swabs often fail to detect bacilli due to paucibacillary nature of extrapulmonary TB.

3.No obvious intraoperative distinct features.

RESULTS

To optimize management of nasolacrimal tuberculosis, several clinical gaps must be addressed. First, a high index of clinical suspicion is paramount; thorough history-taking should explicitly screen for TB exposure, particularly in patients from endemic regions. Second, given the high rate of false-negative cultures, all lacrimal discharge or collections should undergo Acid-Fast Bacilli (AFB) smear as a baseline, with PCR testing reserved for suspicious cases to improve diagnostic sensitivity. Finally, intraoperative histopathological evaluation of the lacrimal sac wall is recommended for all atypical or recurrent presentations to facilitate early detection and prevent surgical failure.

CONCLUSIONS

Primary nasolacrimal tuberculosis remains a rare but critical diagnostic consideration in cases of chronic, refractory dacryocystitis, particularly when symptoms recur post-operatively. This case highlights that clinicians must maintain a high

index of suspicion in endemic regions, utilizing high-sensitivity PCR and intraoperative histopathology to overcome the limitations of traditional cultures. Early diagnosis and the initiation of a standard anti-tubercular regimen are essential to achieve complete clinical resolution and prevent permanent lacrimal system scarring.

Long-Term Olfactory Dysfunction Post SARS-Cov-2 Infection: A Systematic Review

Artemis Zarkadi[1], **Michael Katotomichelakis**[1], **Athanasia Printza**[2], **Konstantinos Chaidas**[1]

[1]*Democritus University of Thrace - School of Medicine;* [2]*Aristotle University of Thessaloniki - School of Medicine*

BACKGROUND & AIM

Olfactory dysfunction (OD) emerged early in the COVID-19 pandemic as a prevalent and often persistent symptom. While most individuals recover within weeks, a significant proportion continue to suffer from long-term impairments, including both quantitative and qualitative sensory deficits. Our review aimed to summarize current evidence on long-term post-COVID-19 OD with a duration of at least three months, including prevalence, recovery trajectory, and prognostic factors.

MATERIAL & METHODS

The PubMed and Scopus databases were searched for relevant studies up to August 2024 following Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines.

RESULTS

Twenty-one studies were ultimately included, involving over 4,000 individuals. A remarkable proportion of patients continue to experience persistent dysfunction post-infection for a period ranging from several months to over two years. Qualitative disorders, such as parosmia and phantosmia, frequently appeared during recovery. Prognosis seemed to be related to age, initial severity, duration of OD, co-existing symptoms, and potentially sex. A consistent discrepancy between subjective reports and objective psychophysical test results was observed. Methodological heterogeneity limited comparability across studies.

CONCLUSIONS

Olfactory dysfunction is a significant and often overlooked long-term complication of COVID-19. Standardized diagnostic criteria, validated outcome measures, and prospective longitudinal research are urgently needed to guide evidence-based management and improve patient outcomes.

Evaluation Of Peripheral Olfaction Disorders After Viral Diseases

Ulugbek Vokhidov[1], **Doniyor Rajabov**[1]

[1]*Republican specialized scientific and practical medical center of otorhinolaryngology and head and neck diseases, Uzbekistan*

BACKGROUND & AIM

According to the World Health Organization (WHO), olfactory disorders are currently very common, with the prevalence of olfactory and gustatory disorders in the world ranging from 1% to 2% of the population. The widespread prevalence of the disease among the population and the potential for negative consequences and disability are increasing, raising the level of social importance.

MATERIAL & METHODS

80 patients with peripheral olfactory disorders after viral diseases treated at the Republican Specialized Center for Otorhinolaryngology and Head and Neck Diseases were included in the study. Patients were divided into 4 groups according to the duration of the disease: Group 1 consisted of 31 patients with impaired sense of smell up to 6 months, group 2 - 17 patients with impaired sense of smell from 6 months to 1 year, group 3 - 20 patients with impaired sense of smell from 1 to 3 years, and group 4 - 12 patients with impaired sense of smell for more than 3 years. All patients included in the first part of the study underwent a standard otorhinolaryngological examination, endoscopic examination of the nasal cavity and nasopharynx, and olfactory perception was assessed using the visual analog scale and the SST method, an expanded version.

RESULTS

The frequency of occurrence of the three types of olfactory groove configurations was 11.25%, 68.05% and 20.7%, respectively.The highest sensitivity was recorded for MRI, which was 92%. According to the results of olfactometry using the SST method, normal smell perception was detected in 10 patients (25%), anosmia - in 1 patient (2.5%), hyposmia was detected in 29 patients (72.5%), and in the last 8 patients (20%), hyposmia was diagnosed as conductive, and in 21 patients (52.5%) hyposmia was of a mixed type. The average values of the main parameters of the olfactory function were as follows: olfactory threshold - 4.6±2.1 points, odor discrimination - 11.3±2.6 points, odor identification - 11.6±2.3 points, OID - 27.6±5.3 points.

Thus, it was found that in 55% of patients, olfactory impairment is not only associated with a peripheral factor, but also with dysfunction of the central structures of the olfactory analyzer.

CONCLUSIONS

The presence of both conductive and perceptual olfactory impairments in all nosological groups of patients justifies the need to perform extended olfactometry in all rhinological patients, if possible - in patients who can be expected to have a conflict with the doctor after olfactometry and treatment.

Generation Of A Primary ALI Nasal Epithelium–Microbiome Co-Culture Model To Investigate Microbial Drivers Of Respiratory Virus Susceptibility

Zeynep Gunes Tepe Demir[1], **Jessica Prodger**[1], **Victor Lam**[1], **Yasamin Minazadeh**[1], **Cindy Liu**[2], **Ryan Troyer**[1]

[1]*Western University;* [2]*George Washington University*

BACKGROUND & AIM

The nasal cavity is the primary entry site for respiratory pathogens.
Beyond serving as a physical barrier, it harbors a diverse microbiome that contributes to mucosal defense. Emerging clinical data suggest that nasal commensals influence respiratory health, and recent studies linked nasal microbiome composition to COVID-19 infection risk. However, the mechanisms by which nasal commensals modulate host susceptibility to respiratory viruses remain poorly understood. To address this gap, we aimed to generate and optimize a primary human nasal air–liquid interface (ALI) co-culture model with key commensal bacteria to enable controlled investigation of epithelial–bacterial–viral interactions.

MATERIAL & METHODS

Primary nasal epithelial cells from healthy donors were differentiated under ALI conditions to establish mucociliary architecture resembling in vivo nasal tissue. Epithelial maturation was assessed by mucus production and ciliation using microscopy. Key nasal commensal species representative of the healthy adult population were selected. To develop stable nasal bacteria–epithelial co-cultures, key commensals were inoculated at varying densities and incubation durations. The goal was to identify optimal conditions that allowed sustained bacterial colonization without compromising epithelial integrity. Colonization efficiency was quantified by colony-forming unit (CFU) counts and confirmed with microscopy. Epithelial cytotoxicity was evaluated using lactate dehydrogenase (LDH) release and confirmed with microscopy. For viral infections, mature epithelia were infected with SARS-CoV-2 (Omicron BA.1), respiratory syncytial virus (RSV-A2), or rhinovirus (HRV-16) under varying multiplicity of infection (MOI) and incubation times to achieve consistent viral replication in the model. Viral replication was quantified by RT-qPCR using virus-specific targets.

RESULTS

Mature primary nasal epithelia (42 days post-ALI) exhibited robust mucociliary morphology and mucus secretion. Optimal inoculum sizes and incubation durations were established for each commensal: Staphylococcus aureus (50 CFU/tissue, 1 day), Staphylococcus epidermidis (1000 CFU/tissue, 1 day), Dolosigranulum pigrum (100,000 CFU/tissue, 1 day), Cutibacterium acnes (1,000,000 CFU/tissue, 4 days), Moraxella catarrhalis (5000 CFU/tissue, 4 days), and Haemophilus influenzae (5000 CFU/tissue, 4 days). Corresponding viral infection parameters were established as follows: SARS-CoV-2 (MOI = 0.001, 1 day), RSV (MOI = 0.01, 2 days), and HRV (MOI = 1, 2 days).

CONCLUSIONS

We successfully developed and optimized a dual-system primary nasal ALI co-culture model that supports both commensal bacterial colonization and respiratory viral infection. This organotypic in vitro platform enables mechanistic

dissection of how nasal commensals contribute to inter-individual variability in infection outcomes. Ultimately, this model provides a foundation for identifying therapeutic targets that may reduce the incidence and severity of respiratory viral infections.

PP-641

Diagnosis And Management Of Cerebrospinal Fluid Rhinorrhea

Aleksandrina Topalova- Shishmanova, MD, PhD[1], **Prof. Karen Dzhambazov, MD, PhD**[1]

[1]*UMHAT " St. George" Plovdiv, Bulgaria, Medical University of Plovidv*

BACKGROUND & AIM

Cerebrospinal fluid (CSF) rhinorrhea is the result of pathologic communication between the intracranial subarachnoid space and the sinonasal cavities. It could be due to trauma, raised intracranial pressure (ICP), tumors, erosive diseases, and congenital skull base defects. Severe and life-threatening intracranial complications like pneumocephalus, ascending bacterial meningitis, brain abscess, mucocele formations are possible but on time prompt diagnosis could prevent them. According to data from the National Center for Infectious and Parasitic Diseases (NCCPD), Department of Epidemiology, in 2018, the main cause of mortality among acute infectious diseases in Bulgaria are the neuroinfections, which represent about 40% of all deaths.

MATERIAL & METHODS

Over a period of 10 years, we have observed a total of 80 cases of CSF leak rhinorrhea. From all the the patients studied, 59% were women and 41% were men .We have divided them according to two main factors: etiology and localization.

In 81% of the patients we applied a verification test for beta 2 transferrin in the nasal secretion. We evaluated the research methods according to the intraoperative findings. In all examined patients, we applied computed tomography with a high resolution. 60% of patients underwent magnetic resonance imaging. We have investigated the sensitivity of the method according to the intraoperative finding. In our clinical study, in addition to the main tasks that we have set ourselves - effectiveness of the methods for detection of cerebrospinal fistulas, we have also assessed the demographic and clinical factors for their manifestation.

RESULTS

In the prospective study, we applied our diagnostical algorithm, which in practice verified and was 99% effective in diagnosis and operative treatment decision. As a standard test for identifying cerebrospinal fluid in nasal secretions we chose the beta 2 transferrin test.

42% of patients had a neuroinfection in their clinical history, and some of them had multiple incidents. We have evaluated the sensitivity of CT according to the intraoperative finding and it reaches 56% and MRI -70%. Intraoperative diagnosis is supported by the administration of fluorescein 10% intrathecally. We have not obtained false-positive results from intrathecal fluorescein administration. Based on the obtained data, we built a clinically applicable algorithm for the diagnosis of CSF leak rhinorrhea.

CONCLUSIONS

CSF leaks are historically difficult to diagnose and treat because of their wide variability. The diagnostical algorithm is still a challenge and is of great importance for final surgical success. The localization of the defect determines the choice of treatment approach. A multidisciplinary team which includes neurosurgeons, otolaryngologists, neuroradiologists, ophthalmologists, endocrinologists is always required for early posttraumatic CSF leak, spontaneous CSF leak, multiple skull base trauma and progressive pneumocephalus.

Predictors Of 30-Day Emergency Department Visits After Sinonasal Surgery: A Retrospective Cohort Study

Dr. Riyadh Al Hedaithy[2], **Dr .Naif alosaimi**[2], **Dr. abdullah Al Khaldi**[2], **Dr. Abdullah Al Qarni**[2], **Dr. Talal alharbi**[2], **Mohmmed Bin Mugren**[1], **Dr. Mohammed Al saif**[1], **Dr. Lama Al Ghamdi**[1]

[1]*College of Medicine, King Saud bin Abdulaziz University for Health Science;* [2]*Division of Otolaryngology-Head and Neck Surgery, Department of Surgery, King Abdulaziz Medical City, Ministry of National Guard Health Affairs, Riyadh*

BACKGROUND & AIM

Sinonasal surgery is among the most frequently performed procedures in otolaryngology. With the shift toward ambulatory care, unplanned 30-day emergency department (ED) visits represent a meaningful quality metric. Predictors of early ED return following sinonasal surgery remain poorly characterized. This study aimed to determine the incidence and identify independent patient-, disease-, and procedure-level predictors of 30-day ED visits at a major tertiary referral center.

To determine the incidence of ED visits within 30 days of sinonasal surgery and to identify independent patient-, disease-, and procedure-level predictors of ED return at a major tertiary referral center in Saudi Arabia.

MATERIAL & METHODS

A retrospective chart review was conducted at King Abdulaziz Medical City (KAMC), Riyadh, among adult patients (≥18 years) who underwent sinonasal surgery. Data were extracted from the BestCare electronic medical record system. Patient demographics, comorbidities, CRS subtype, Lund-Mackay (LM) radiologic severity scores, and surgical details were recorded. The primary outcome was any ED visit within 30 days postoperatively. Univariable and multivariable logistic regression were used to identify independent predictors.

RESULTS

Of 2,007 patients, 198 (9.9%) returned to the ED within 30 days. Returners were older (41.6 vs. 38.4 years; p=0.003), more likely to smoke (22.2% vs. 16.3%; p=0.033), and had higher rates of allergic rhinitis (37.4% vs. 26.8%; p=0.047) and CRSwNP (22.7% vs. 14.6%; p=0.015). The leading reasons for ED visits were postoperative pain (34.3%) and bleeding/epistaxis (26.3%), together accounting for ~60% of visits. On multivariable analysis, independent predictors of ED return were older age (aOR 1.16; p=0.005), allergic rhinitis (aOR 1.47; p=0.018), and CRSwNP (aOR 1.78; p=0.006), while FESS-based surgery was protective (aOR 0.68; p=0.020). A Lund–Mackay sub-analysis revealed an inverse gradient in ED return rates, falling from 16.4% in minimal radiologic disease to 6.8% in severe disease (p=0.013).

CONCLUSIONS

Nearly 1 in 10 patients returned to the ED within 30 days of sinonasal surgery, driven primarily by pain and epistaxis. Older age, allergic rhinitis, and CRSwNP independently increased risk. FESS and greater radiologic disease severity were protective, reflecting the higher pain/bleeding burden of structural nasal-airway procedures in low-LM patients. These findings support procedure-specific discharge protocols and targeted perioperative counseling to reduce preventable ED utilization.

SEVERE EPİSTAXİS MİMİCKİNG GASTROİNTESTİNAL BLEEDİNG CAUSED BY A GİANT SİNONASAL SOLİTARY FİBROUS TUMOR: A CASE REPORT

Hakan Bayraktar[1], **Ömer Faruk Koçer**[1], **Birhan Alaçeri**[1]

[1]*Kocaeli Cıty Hospital*

BACKGROUND & AIM

Sinonasal solitary fibrous tumors (SFTs) are rare mesenchymal neoplasms that may present with nonspecific clinical findings, often leading to diagnostic challenges. Due to their hypervascular nature, they may present with severe epistaxis and, in rare cases, mimic upper gastrointestinal bleeding with symptoms such as hematemesis and melena.

This study aims to emphasize the diagnostic pitfalls and to evaluate the effectiveness of navigation-assisted endoscopic surgical management in a patient with a giant sinonasal SFT presenting with gastrointestinal bleeding-like symptoms.

MATERIAL & METHODS

A 55 year old male patient with no significant comorbidities presented with recurrent severe epistaxis, hematemesis, and melena. Clinical evaluation included endoscopic nasal examination, gastroenterological assessment, and non-contrast magnetic resonance imaging.

An incisional punch biopsy was obtained from the nasal cavity. Due to a known contrast agent allergy, preoperative embolization was not performed. The patient underwent navigation-assisted endoscopic sinus surgery, and the mass was excised completely following tumor debulking. Histopathological and immunohistochemical analyses were performed for definitive diagnosis.

RESULTS

Endoscopic examination revealed a large lobulated mass filling the left nasal cavity, extending into the nasopharynx and oropharynx, and causing marked septal deviation (Figure 1). Radiological imaging demonstrated a sinonasal mass originating from the nasopharynx, extending into bilateral nasal cavities, maxillary sinus ostia, and adjacent orbital regions, with close proximity to the anterior skull base and hyperintense areas on T2-weighted images (Figure 2). Initial biopsy was interpreted as glomangiopericytoma. However, final histopathological evaluation revealed a spindle-cell mesenchymal tumor with CD34 and vimentin positivity, diffuse nuclear STAT6 positivity, and a Ki-67 index of approximately 6%, confirming the diagnosis of solitary fibrous tumor. Complete surgical excision was achieved endoscopically (Figure 3). The postoperative course was uneventful, and no recurrence was observed during follow up.

CONCLUSIONS

Sinonasal SFTs may mimic gastrointestinal bleeding and lead to diagnostic delays, particularly in cases presenting with hematemesis and melena. This case highlights the importance of considering sinonasal sources in the differential diagnosis of

severe epistaxis and gastrointestinal bleeding-like symptoms. Immunohistochemical markers, especially STAT6, play a critical role in achieving an accurate diagnosis, particularly in cases with misleading initial biopsy results. Navigation-assisted endoscopic surgery is a safe and effective treatment modality for large and extensive sinonasal tumors, even in the absence of preoperative embolization. Long-term follow-up is essential due to the potential risk of recurrence.

Cryosurgery In Chronic Rhinitis Treatment, Experience In Republic University Hospital Of Vilnius

Laura Kupčinskienė[1], **Jevgenija Buinickaja**[1], **Silvija Butkienė**[1]

[1]*Republic University Hospital of Vilnius, ENT department*

BACKGROUND & AIM

Chronic rhinitis is a very common pathology worldwide. There are also increasing numbers in allergic rhinitis cases. Not all patients tolerate conservative treatment or are suitable for traditional surgical intervention. Cryosurgery is a good treatment solution in those cases. We perform about 190 cryosurgery procedures a year in Republic University Hospital of Vilnius.

MATERIAL & METHODS

36 years old male patient had a difficult breathing through the nose for several years. He was diagnosed with allergic rhinits for pollen. Enlarged inferior nasal turbinates were observed during clinical examination. Pacient did not want conchoplasty for his condition. Cryosurgery was done using local anesthesia in outpatient department in Republic University Hospital of Vilnius. The nasal probe of cryotherapy device was applied to inferior nasal turbinate for 1 minute, then repeated in different position. Process was repeated on the other side.

RESULTS

After the treatment with cold therapy the results were very good objectively during nasal endoscopy evaluation and also by patient`s own assessment. Main complaints of difficulty breathing and rhinorrhea were gone after 2 weeks. Endoscopy showed significantly reduced inferior nasal turbinates.

CONCLUSIONS

Cryosurgery is becoming more popular in Lithuania. Although it can not replace traditional conchoplasty, it can help patients who can not tolerate medicines, have many comorbidities and can not have general anesthesia. The weak point of this method is that effect lasts shorter than with standart conchoplasty – mostly for 3-5 years. The main strong features of cryosurgery - it can be done with local anesthesia in the outpatient department, can be repeated as many times as needed, it does not cause scarring. The method is bloodless and not very painful.

Frontoethmoidal Osteoma Presenting With Pansinusitis And Subdural Empyema: Multidisciplinary Surgical Management

Dr. Buse Güler[1], **Dr. Canberk Kertmen**[1], **Op. Dr. Fatih Yılmaz**[1]

[1]*Department of Otorhinolaryngology, İzmir City Hospital, İzmir, Türkiye*

BACKGROUND & AIM

Frontal sinus osteomas are benign, slow-growing lesions that are frequently asymptomatic and incidentally detected; however, they may lead to significant complications through obstruction of sinus drainage pathways and secondary infection . Although rare, intracranial complications such as meningitis, abscess, and empyema have been reported and may be life-threatening . We present a case of frontal osteoma complicated by subdural empyema, highlighting the importance of early diagnosis and multidisciplinary management.

MATERIAL & METHODS

A 70-year-old female patient presented with syncope and septic clinical findings. Radiological evaluation with computed tomography and magnetic resonance imaging demonstrated a left frontoethmoidal osteoma extending into the frontal sinus, associated with complete opacification of the maxillary, ethmoid, and sphenoid sinuses. The lesion was located in close proximity to the lamina papyracea without orbital invasion. Intracranial imaging revealed a left-sided subdural empyema with atypical extension toward the temporal region. The patient underwent urgent neurosurgical craniotomy for empyema drainage, followed by endoscopic sinus surgery including maxillary antrostomy and partial osteoma resection.

RESULTS

The intracranial empyema was successfully drained, and sinonasal infection was controlled through combined surgical and medical treatment. The atypical localization of the empyema, predominantly toward the temporal region, represented an unusual pattern of spread. Postoperatively, the patient required intensive care monitoring due to transient clinical

deterioration related to sepsis but demonstrated gradual clinical improvement under multidisciplinary management. No orbital complications were observed, and infection parameters regressed during follow-up.Although frontal sinus osteomas are generally benign, they may predispose to severe intracranial complications through obstruction and infection . Early recognition, detailed radiological assessment, and prompt multidisciplinary surgical intervention are essential to prevent life-threatening outcomes.

CONCLUSIONS

We present a rare case of subdural empyema arising as a complication of a frontal sinus osteoma. This case highlights that intracranial spread may not always follow classical anatomical pathways and reinforces the need for early recognition and detailed radiological evaluation in patients with complicated rhinosinusitis.

Predictive Value Of Peripheral And Tissue Eosinophils And Total Ige For Recurrence In Nasal Polyposis: A Prospective Clinical Study

Burak Anıl Tuğci[1], **Büşra Kılıç**[1], **Zahide Mine Yazıcı**[1]

[1]*Bakırköy Dr. Sadi Konuk Training and Research Hospital, Department of Otolaryngology, Istanbul, Türkiye*

BACKGROUND & AIM

Postoperative recurrence remains a major challenge in nasal polyposis, with rates of 25–40% within the first year. Reliable and cost-effective predictors are still lacking. This ongoing study aims to evaluate the relationship between preoperative peripheral eosinophil levels, tissue eosinophil density, and total IgE levels, and to assess their predictive value for recurrence.

MATERIAL & METHODS

This prospective, single-center study is currently ongoing and includes adult patients (18–65 years) undergoing primary endoscopic sinus surgery for nasal polyposis. Preoperative assessment included nasal endoscopy, Sinonasal Outcome Test-22 (SNOT-22), olfactory testing using the Connecticut Chemosensory Clinical Research Center Smell Identification Test (CC-SIT), Lund–Mackay scoring, and laboratory measurements including peripheral eosinophil count, basophil levels, and total Immunoglobulin E (IgE). Tissue eosinophil density was evaluated from surgical specimens. Patients are being followed at 3, 6, and 12 months postoperatively. The primary outcome is endoscopic recurrence within 12 months, with early recurrence defined as occurring within 6 months.

RESULTS

Interim analysis of 40 patients demonstrated a recurrence rate of 55% (n=22) at 12 months. Among patients with recurrence, preoperative peripheral eosinophil levels were elevated in 63.6% and total IgE levels in 72.7%. In contrast, tissue eosinophil density was elevated in 54.5% of cases, showing a more heterogeneous distribution.Notably, the combination of elevated peripheral eosinophil levels and total IgE was associated with the highest recurrence rate (75%).

CONCLUSIONS

Elevated peripheral blood eosinophil levels and total IgE concentrations were more frequently observed in patients who developed recurrence, with their concomitant elevation demonstrating the highest recurrence rate (75%). In contrast, tissue eosinophil density did not confer additional predictive value. These findings indicate that peripheral eosinophilia and total IgE may represent more robust biomarkers for predicting recurrence. However, given the limited sample size and the ongoing nature of the study, these observations should be interpreted with caution and require validation in larger, well-powered cohorts.

[1]Ribeirão Preto Medical School University of São Paulo; [2]Marilia Medical School (FAMEMA); [3]Prof. Edgar Santos University Hospital-Salvador, Bahia.; [4]School of Medicine of University of Brasilia; [5]Paulista Medical School- Federal University of São Paulo (EPM-UNIFESP); [6]Faculdade de Ciências Médicas, Santa Casa de São Paulo (FCMSCSP), São Paulo, SP, Brazil; [7]Faculdade de Ciências Médicas, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, RJ, Brazil

BACKGROUND & AIM

Chronic rhinosinusitis with nasal polyp (CRSwNP) is a predominant type 2 inflammatory disease, affecting the sense of smell and quality of life. Aspirin-exacerbated respiratory disease (AERD) represents a severe inflammatory endotype of CRSwNP, characterized by intense type 2 inflammation, frequent recurrence, and limited response to conventional therapies. Although anti–IL-5 biologics are effective to treat CRSwNP, the real-world response in severe cases remains insufficiently defined.The present study aimed to evaluate one-year clinical, endoscopic, and quality-of-life outcomes in a Brazilian cohort of patients with severe type 2 CRSwNP treated with Mepolizumab.

MATERIAL & METHODS

This multicenter retrospective study included 73 adults with difficult-to-treat CRSwNP and evidence of type 2 inflammation who received mepolizumab 100 mg every 4 weeks for 12 months. Outcomes assessed at baseline and one year included symptom burden measured by the Sino-Nasal Outcome Test-22 (SNOT-22), olfactory performance evaluated with the Connecticut Chemosensory Clinical Research Center (CCCRC) test, and endoscopic severity quantified by the Nasal Polyp Score (NPS). Longitudinal changes were assessed using the paired t-test for normally distributed continuous data and the Wilcoxon signed-rank test for non-parametric or ordinal data (e.g., polyp score). Treatment response and disease control were categorized according to predefined clinical criteria.

RESULTS

Mepolizumab produced significant overall improvements in symptoms, olfaction, and nasal polyp burden (all $p < 0.001$). However, AERD status markedly influenced treatment response. Compared with non-AERD patients, individuals with AERD exhibited significantly smaller improvements in SNOT-22 scores (median Δ −21,6 vs −42,6), olfactory performance (median Δ 0 vs −2,5), and NPS (median Δ −1 vs −4) ($p < 0.01$ for all comparisons). High-level treatment response was substantially more frequent among non-AERD patients, whereas attenuated responses predominated in the AERD subgroup.

CONCLUSIONS

Mepolizumab provided clinically meaningful improvements in symptoms, olfaction, and polyp burden in Brazilian patients with severe type 2 CRSwNP. However, AERD significantly attenuates the real-world effectiveness of the medication. These findings highlight the importance of endotype-driven patient stratification and suggest that alternative or complementary biologic strategies may be required to optimize outcomes in patients with AERD.

PP-649

Delayed Infections After Rhinoplasty: Clinical Presentation And Management Strategies – A Case Report

Roven Sinani[1], **Jetmira Fejza**[1], **Besim Boci**[1]

[1]Art Orl Clinic

BACKGROUND & AIM

Delayed infections following rhinoplasty are rare but important complications that may appear weeks to months after surgery. They are often associated with low-virulence organisms, foreign materials, or biofilm formation, and can negatively impact both aesthetic and functional outcomes. Early recognition and appropriate management are essential.

MATERIAL & METHODS

We present a case of a 29-year-old female who developed nasal tip inflammation three months after primary open rhinoplasty. Clinical evaluation included physical examination and ultrasound imaging to assess for fluid collection. Initial empirical antibiotic therapy was administered. Due to persistent symptoms, surgical exploration was performed. Intraoperative findings, microbiological cultures, and postoperative outcomes were analyzed.

RESULTS

The patient presented with localized erythema, edema, and tenderness of the nasal tip without systemic signs of infection. Ultrasound revealed a small localized collection. Surgical exploration identified a confined abscess surrounding non-absorbable

suture material. The suture was removed, and the area was irrigated. Culture grew Staphylococcus epidermidis, and targeted antibiotic therapy was initiated. Complete resolution of symptoms was achieved within two weeks, with preservation of nasal contour and satisfactory aesthetic result.

CONCLUSIONS

Delayed infections after rhinoplasty, although uncommon, should be considered in patients presenting with late-onset inflammation. Imaging can assist diagnosis, while definitive treatment often requires removal of infected foreign material combined with targeted antibiotics. Prompt intervention ensures optimal functional and aesthetic outcomes.

Bilateral Concha Bullosa Within Concha Bullosa: A Rare Middle Turbinate Variation

Rashad Gadirli[1], **Jawad Mahalis**[1], **Alper Nabi Erkan**[1]

[1]*Department of Otolaryngology, Başkent University Faculty of Medicine, Ankara, Türkiye*

BACKGROUND & AIM

Concha bullosa, defined as pneumatization of the middle turbinate, is one of the most common anatomical variations of the nasal cavity. Complex internal patterns of pneumatization are rare. We report a case of bilateral concha bullosa within concha bullosa detected during evaluation of maxillary sinus pathology. This case highlights the importance of correlating radiologic findings with clinical and functional assessment before deciding on surgical treatment of the middle turbinate.

MATERIAL & METHODS

This study is a single case report of a 51-year-old male presented with severe right-sided facial pain and postnasal discharge one month after undergoing a right sinus lifting procedure. He had no prior history of chronic rhinosinusitis or nasal obstruction. Paranasal sinus CT demonstrated mucosal inflammation in the right maxillary sinus. In addition, bilateral concha bullosa within concha bullosa were identified in the middle turbinates . The internal architecture showed a distinct pneumatized cavity located within a larger pneumatized middle turbinate on both sides. Both osteomeatal complexes were clearly patent on coronal CT images. The patient was initially managed with medical treatment, including antibiotics and nasal saline irrigation. As symptoms persisted, endoscopic surgery of the right maxillary sinus was performed to address the inflammatory pathology. Intraoperative inspection confirmed that the conchae bullosae did not narrow or obstruct the osteomeatal complex. Therefore, no surgical intervention was performed on the conchae bullosae.

RESULTS

Despite its striking CT appearance, the concha bullosa within concha bullosa did not produce functional impairment. The patient's symptoms were clearly related to maxillary sinus inflammation following sinus lifting surgery. This distinction is important because unusual radiologic findings may lead to unnecessary surgical intervention if not carefully correlated with clinical and functional evaluation.

From a surgical standpoint, this case reinforces a key principle of endoscopic sinus surgery: intervention on the middle turbinate should be based on evidence of obstruction or symptom correlation. Routine or prophylactic resection of concha bullosa without functional indication may increase the risk of destabilization of the middle turbinate, lateralization, or postoperative synechiae formation. Preservation of normal anatomical structures remains a fundamental goal in sinonasal surgery. Therefore, careful radiologic assessment combined with intraoperative evaluation allowed appropriate management of the sinus pathology while avoiding unnecessary manipulation of the middle turbinates.

CONCLUSIONS

Bilateral concha bullosa within concha bullosa is a rare morphological variation of middle turbinate pneumatization. Although its radiologic appearance may be remarkable, it does not necessarily result in osteomeatal obstruction or clinical symptoms.This case emphasizes that surgical decision-making should be guided by clinical findings and functional assessment rather than imaging appearance alone. When no obstruction is present, preservation of the middle turbinate is appropriate and preferable.

Secondary Invasive Aspergillosis Mimicking Tumor Progression In Aggressive Nasopharyngeal Burkitt Lymphoma With Intracranial Extension

Esra Dilan Turnay[1], **Ali Demir**[1], **Zehra Betül Paksoy**[1]

[1]*Department of Otorhinolaryngology, Ankara Bilkent City Hospital, Ankara, Türkiye*

BACKGROUND & AIM

Nasopharyngeal Burkitt lymphoma (BL) is a rare, highly aggressive B-cell malignancy characterized by rapid proliferation, early skull base invasion, and cranial neuropathies. Immunosuppression due to intensive chemotherapy predisposes patients to opportunistic infections such as invasive fungal sinusitis, which may clinically and radiologically mimic tumor progression. We hypothesized that early differentiation between malignant progression and opportunistic infection, combined with an aggressive multidisciplinary approach, significantly impacts patient outcomes.

MATERIAL & METHODS

A patient without known comorbidities presented with progressive right ptosis, ophthalmoplegia, and hemifacial hypoesthesia following an upper respiratory tract infection. Neurological examination revealed multiple cranial nerve involvement (III, IV, V_1–V_2, VI), consistent with cavernous sinus syndrome. Contrast-enhanced MRI showed a large infiltrative nasopharyngeal mass with skull base destruction and intracranial extension(figure 1). Biopsy demonstrated atypical B-cell proliferation with CD20/CD19 positivity, high Ki-67 index (70-80%), and c-MYC rearrangement, consistent with Burkitt lymphoma. Staging included cerebrospinal fluid analysis, bone marrow biopsy, and PET/CT, confirming secondary CNS involvement.

Treatment consisted of MATRix-based chemotherapy with intrathecal prophylaxis and debulking surgery. During therapy, the patient developed febrile neutropenia complicated by invasive fungal rhinosinusitis. Endoscopic biopsy confirmed Aspergillus species with angioinvasion(figure 2). Management included intravenous voriconazole, granulocyte colony-stimulating factor, and repeated endoscopic surgical debridement. Infection control was achieved, with partial neurologic recovery and oncologic partial response. The patient developed panhypopituitarism during follow-up and remains under multidisciplinary care.

RESULTS

A case of nasopharyngeal Burkitt lymphoma presenting with cavernous sinus syndrome was identified. Imaging revealed an infiltrative skull base mass with intracranial extension. Histopathology confirmed high-grade B-cell lymphoma with c-MYC rearrangement. The patient received MATRix-based chemotherapy with intrathecal prophylaxis and surgical debulking due to mass effect. During treatment, prolonged neutropenia led to febrile episodes and acute sinonasal deterioration. Endoscopic evaluation and biopsy confirmed invasive Aspergillus rhinosinusitis with angioinvasion. The patient was managed with intravenous voriconazole, granulocyte colony-stimulating factor support, and repeated endoscopic surgical debridement. Infection control and stabilization were achieved, with no further necrotic progression. Interim assessment showed partial oncologic response. Neurological deficits improved partially over follow-up. A late complication of panhypopituitarism developed, requiring endocrine replacement therapy. The patient continues under multidisciplinary follow-up involving oncology, infectious diseases, otorhinolaryngology, neurosurgery, and endocrinology. Long-term monitoring is ongoing to evaluate disease control and manage potential treatment-related complications over time in follow-up care.

CONCLUSIONS

This case highlights the dual complexity of aggressive head and neck lymphomas and opportunistic infections during immunosuppressive therapy. Nasopharyngeal Burkitt lymphoma may present with cavernous sinus involvement and rapidly progressive neurological deficits requiring urgent diagnosis and intensive chemotherapy. However, clinical deterioration during treatment does not always indicate tumor progression. Invasive fungal rhinosinusitis, particularly Aspergillus infection, should be strongly suspected in neutropenic patients with new sinonasal or neurological symptoms. Repeated bedside endoscopic evaluation, early biopsy supported by frozen section, and prompt antifungal therapy combined with surgical debridement are critical for survival. Multidisciplinary management is essential for optimal outcomes and long-term follow-up.

Revision Rates And Associated Risk Factors After Functional Endoscopic Sinus Surgery

Meryem Babaoğlan[1], **İlhan Topaloğlu**[1], **Hatice Ünsal**[1], **Müzeyyen Doğan**[1], **Yavuz Selim Pata**[1]

[1]*Yeditepe University Faculty of Medicine, Department of Otorhinolaryngology, Istanbul, Turkey*

BACKGROUND & AIM

This study aimed to evaluate revision rates and the interval from primary functional endoscopic sinus surgery to revision surgery, and to determine the association of nasal polyp status, preoperative Lund–Mackay score, asthma, and preoperative peripheral eosinophil count with revision surgery.

MATERIAL & METHODS

This study was conducted at the Department of Otorhinolaryngology, Yeditepe University Faculty of Medicine, Istanbul, Türkiye. Patients who underwent primary functional endoscopic sinus surgery between January 2013 and April 2025 were included. Patients younger than 18 years of age, as well as those with prior sinus surgery, secondary chronic rhinosinusitis etiologies, or insufficient baseline data, were not included. Patients were classified according to the presence or absence of nasal polyps at the primary operation as chronic rhinosinusitis with nasal polyps (CRSwNP) or chronic rhinosinusitis without nasal polyps (CRSsNP). The occurrence of revision surgery and the interval from primary surgery to revision were evaluated in relation to nasal polyp status, asthma, preoperative Lund–Mackay score, and peripheral eosinophil count.

RESULTS

A total of 2,443 patients were included; 238 had CRSwNP and 2,205 had CRSsNP at primary FESS. Revision surgery was required in 52 patients, corresponding to an overall revision rate of 2.13%. Revision surgery was more frequent in CRSwNP than CRSsNP patients (9.66% vs 1.32%; $p < 0.001$).Five- and ten-year revision-free rates were lower in CRSwNP than in CRSsNP patients (91.3% vs 98.8% and 84.5% vs 98.0%; $p < 0.001$). Asthma was more common in patients with CRSwNP than in those with CRSsNP ($p < 0.001$); however, no significant association was observed between asthma and revision surgery ($p > 0.05$). Preoperative Lund–Mackay scores were higher in patients with CRSwNP than in those with CRSsNP (17.4 ± 5.1 vs 11.7 ± 4.8; $p < 0.001$). Preoperative peripheral eosinophil counts were higher in patients requiring revision surgery than in those without revision (438 ± 233 vs 256 ± 178/µL; $p < 0.001$).

CONCLUSIONS

Revision after primary FESS was more frequent in patients with nasal polyposis. These patients also demonstrated lower long-term revision-free rates and higher preoperative Lund–Mackay scores. Higher preoperative peripheral eosinophil counts were observed among patients who underwent revision surgery. Although asthma was more common in patients with nasal polyposis, it was not significantly associated with revision surgery. These findings may help guide postoperative follow-up, patient counseling, and long-term management after primary FESS.

PP-653

A Diagnostic Challenge In Skull Base Masses: Chordoma Presenting As A Nasopharyngeal Obstructing Lesion

Dr. Muhammed Sadıkzade[1], **Asst. Prof. TUĞBA YEMİŞ**[1]

[1]*Recep Tayyip Erdoğan University Training and Research Hospital, Otorhinolaryngology*

BACKGROUND & AIM

Skull base masses pose substantial diagnostic complexity due to overlapping clinical presentations, deep anatomic location, and frequent skull base invasion involving neurovascular structures. Rare tumors such as chordoma remain critical in the differential diagnosis of destructive clival–petrous lesions presenting with nasopharyngeal obstruction and lower cranial neuropathy. This case is noteworthy for its extensive infiltrative pattern across the clivus, petrous apex, cavernous sinus region, and prepontine cistern, with multimodality imaging features that can mimic alternative entities. We aimed to emphasize that multidisciplinary correlation and adequately deep, representative biopsy are essential to establish a definitive diagnosis in atypical skull base disease.

MATERIAL & METHODS

A 46-year-old incarcerated male presented with 6 months of progressive nasal breathing difficulty and dysphagia, and 10 days of new-onset hoarseness. Nasal endoscopy demonstrated an irregular mass nearly filling the choana, and flexible laryngoscopy revealed left vocal cord paralysis. To expedite tissue diagnosis, an outpatient punch biopsy was obtained at presentation prior to imaging and was reported as chronic/reactive inflammation. Paranasal CT then showed an ill-defined posterior nasal cavity/nasopharyngeal mass (left-predominant) causing marked choanal and nasopharyngeal airway narrowing, extending toward the sphenopalatine fossa with bony erosion, involving the sphenoid sinus, and demonstrating destructive clival–petrous spread. Given the invasive radiologic phenotype, multiple deeper biopsies were obtained under operating room conditions for definitive histology and immunohistochemistry. Immunoprofiling demonstrated diffuse PanCK and vimentin positivity, EMA positivity, and focal weak S100 positivity, supporting chordoma. MRI and FDG PET-CT were subsequently performed for staging.

RESULTS

The initial outpatient punch biopsy was non-diagnostic, reporting chronic/reactive inflammation despite near-complete choanal obstruction and left vocal cord paralysis, highlighting the limitations of superficial sampling in deep skull base disease. Paranasal CT demonstrated an ill-defined posterior nasal cavity/nasopharyngeal mass with aggressive osseodestruction, extension toward the sphenopalatine fossa, sphenoid sinus involvement, and destructive clival–petrous spread. Because imaging and pathology were discordant, multiple deeper biopsies obtained in the operating room yielded representative tumor. Immunohistochemistry showed diffuse PanCK and vimentin positivity with EMA positivity and focal weak S100 reactivity, supporting chordoma in the appropriate anatomic context. Subsequent MRI refined staging, confirming strong enhancement, cavernous sinus involvement, internal carotid artery narrowing, and a separate prepontine component compressing the medulla/inferior pons with diffusion restriction. Post-diagnosis FDG PET-CT showed mild uptake (SUVmax 3.8) without other abnormal regional activity. Progressive imbalance, diplopia, and worsening dysphagia prompted tertiary skull base referral for multidisciplinary planning and definitive surgical management.

CONCLUSIONS

Skull base chordomas may present to otolaryngology with progressive nasopharyngeal obstruction, dysphagia, dysphonia, and evolving cranial neuropathies, reflecting clival–petrous invasion and intracranial extension. Suspicion should increase when endoscopy shows a posterior nasal/nasopharyngeal mass accompanied by focal neurologic signs (e.g., vocal cord paralysis,

diplopia, imbalance) or when CT demonstrates a destructive clival-centered lesion with multi-compartment spread. Management requires stepwise evaluation with contrast-enhanced MRI to define intracranial and neurovascular involvement, followed by multidisciplinary planning to select the safest diagnostic route and definitive approach. Early referral to specialized skull base teams is essential for timely treatment and complication avoidance.

RECURRENT SINONASAL SQUAMOUS CELL CARCINOMA ARISING FROM HPV-16 POSITIVE INVERTED PAPILLOMA MANAGED WİTH ORGAN-PRESERVİNG ENDOSCOPIC APPROACH

Kaan Uncu[1], **Ebru Akıllı**[1], **Funda Taşkın**[1], **Şahin Öğreden**[1], **Özgür Yiğit**[1]

[1]*Basaksehir Cam and Sakura City Hospital, Department of Otolaryngology–Head and Neck Surgery, Istanbul, Turkey*

BACKGROUND & AIM

Sinonasal inverted papilloma(IP) is a rare tumor that has aggressive behavior, high recurrence rate and potential of malignant transformation. Sinonasal squamous cell carcinoma(SCC) arising from inverted papilloma, especially in recurrent cases, complicates treatment planning and often requires radical surgical approaches. External maxillectomy approaches performed in malignancies arising from maxillary sinus can result in severe functional and esthetic morbidity secondary to defect of hard palate and teeth.

Aim of this case is presenting an advanced endoscopic surgical approach that preserves hard palate, teeth and orbita without the need for radical maxilllectomy in a recurrent SCC case arising from HPV-16 positive IP.

MATERIAL & METHODS

This patient who has history of three endoscopic sinus surgeries was evaluated for recurrent sinonasal mass. Previous pathological examinations revealed SCC arising from IP and HPV-16 positivity was confirmed by molecular analyses.

Facial MRI imaging showed that the lesion extended from right nasal cavity to nasopharynx , bilateral frontal sinuses, left nasal cavity overlapping septum and ostium of the right maxillary sinus.There was no invasion of orbital cavity or intracranial structures and involvement of hard palate or alveolar arch.

Endoscopic endonasal surgery was planned based on these findings. Surgery was performed using a combination of endoscopic right anterior-posterior ethmoidectomy, Draf-III (Modified Lothrop) procedure and right medial maxillectomy. Periorbital structures were preserved, and no external incision was performed.Hard palate, teeth and alveolar arch were preserved.

RESULTS

The tumor was completely resected. No orbital invasion, periorbital defect or cerebrospinal fluid leak was observed. Radical maxillectomy was not performed, so hard palate and dental structures could be preserved.

The diagnosis of SCC arising from IP was confirmed in histopathological analysis. Oral function was preserved.

CONCLUSIONS

Advanced endoscopic surgery is an alternative approach to radical maxillectomy in recurrent SCC cases through detailed radiological evaluation and appropriate patient selection. This case shows that hard palate, teeth and orbital structures can be preserved while maintaining oncological margins, so we can provide long-term functional life quality for the patient.

“Surgical Management And Outcomes Of Odontogenic Cysts In The Maxillary Region: A Retrospective Study (2022–2025)”

Ahmet Fırat Aksoy[1], **Lukas demirci**[1], **Abdullah karataş**[1]

[1]*Department of Otolaryngology–Head and Neck Surgery, Haseki Training and Research Hospital, Istanbul, Türkiye*

BACKGROUND & AIM

The aim of this study is to evaluate the clinical, radiological, and surgical characteristics of patients who underwent surgery in our clinic due to odontogenic cysts, and to present the outcomes of these surgically treated cases. The study includes cases that were followed with preliminary diagnoses of dentigerous cyst and periapical cyst and were surgically managed in our clinic.

MATERIAL & METHODS

The data of patients who were evaluated with a preliminary diagnosis of odontogenic cyst in the maxillary region and underwent surgical treatment between 2022 and 2025 were retrospectively reviewed. Patients’ presenting complaints, CT/MRI findings, and lesion localization were analyzed. Surgically, an intraoral vestibular incision was used to access the anterior wall of the maxillary sinus, followed by dissection of the cyst capsule from surrounding tissues and total excision.

RESULTS

A total of 9 patients were included in the study (age range: 9–54). The most common presenting symptoms were cheek swelling, purulent drainage into the oral cavity from upper molar teeth, and incidental radiological findings. CT and MRI evaluations revealed expansile cystic lesions causing thinning and remodeling of the maxillary sinus walls in most cases. Many lesions were associated with molar or premolar tooth roots, and in some patients, the maxillary sinus floor, lateral, or medial walls were significantly deformed by the cyst. Surgical excision was successfully completed in all cases with no residual cyst wall left, and all operations were uneventful. In two cases, the cyst was removed together with the associated teeth.The surgical field was washed with rifampicin in the postoperative period.One patient experienced recurrence in the postoperative period and reoperated.

CONCLUSIONS

Odontogenic cystic lesions are pathologies commonly associated with tooth roots and can significantly affect the anatomy of the maxilla and maxillary sinus. Accurate radiological characterization and appropriate surgical planning are particularly important in large lesions that deform sinus walls. Surgical excision via an intraoral vestibular approach is a safe and effective treatment option for most cases.

NEUROSURGICAL AND ENDOSCOPIC MANAGEMENT OF PEDIATRIC SUBDURAL EMPYEMA SECONDARY TO PANSINUSITIS: A MULTIDISCIPLINARY APPROACH

Ali Enez[1], **Oguz Kaan KOSE**[1], **Aleyna ELBURZ**[1], **Burak TAHMAZOGLU**[2], **Kaan PAKSOY**[2], **Fırat TEVETOGLU**[1]

[1]Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty Department of Otorhinolaryngology-Head and Neck Surgery; [2]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Neurosurgery

BACKGROUND & AIM

Subdural empyema (SDE) is a rare and devastating complication of pediatric rhinosinusitis,occurring in approximately 3% of children hospitalized for sinusitis. Despite advancements in antimicrobial therapy, SDE remains a neurosurgical emergency due to its potential for rapid neurological deterioration. This study presents the successful multidisciplinary surgical management of a pediatric patient with massive SDE that proved refractory to high-dose broad-spectrum intravenous (IV) antibiotic therapy.

MATERIAL & METHODS

A retrospective case analysis was conducted on a 12-year-old female patient presenting with altered mental status (GCS: 12/15) and pansinusitis-induced subdural empyema (SDE). Diagnostic evaluation included contrast-enhanced cranial imaging. The therapeutic protocol involved a multidisciplinary surgical approach: initial neurosurgical intervention via decompressive craniectomy (DC) and interhemispheric drainage, followed by a galeal graft duraplasty and abdominal bone flap autografting. Concurrently, the Otorhinolaryngology team performed bilateral "Full House" Functional Endoscopic Sinus Surgery (FESS) to eliminate the primary paranasal infection source. Intraoperative samples were analyzed via microscopy, culture, and pathological examination.

RESULTS

Imaging revealed an 11 mm thick SDE with a 7 mm midline shift. Despite prior high-dose IV Vancomycin and Meropenem treatment, clinical deterioration had occurred. Post-surgical results showed rapid neurological improvement and successful drainage of the empyema on follow-up imaging. While intraoperative cultures remained sterile due to antibiotic suppression, direct microscopy identified Gram-positive diplococci, and pathology confirmed acute suppurative inflammation. The multidisciplinary intervention resulted in a complete recovery, and the patient was discharged without any permanent neurological sequelae.

CONCLUSIONS

Conclusions

Subdural empyema (SDE) is a critical complication of pediatric pansinusitis requiring high clinical suspicion when medical therapy fails. This case underscores that sterile cultures are common following intensive antibiotic use, making direct microscopy and pathological examination vital for diagnosis. For massive SDE with significant midline shift, a coordinated, simultaneous approach involving neurosurgical decompressive craniectomy and ENT-led "Full House" FESS is a life-saving strategy that effectively prevents long-term morbidity and neurological deficits.

THİNK BEYOND POLYPS: A RARE CASE OF ADULT NASAL MENİNGOENCEPHALOCELE

Hamdi ÇAKLI[1], **Uğur Taner ÖZYAZGAN**[1], **Muhammed Sefa UYAR**[1], **Mustafa Burak KARAHAN**[1]

[1]Department of Otorhinolaryngology–Head and Neck Surgery, Eskişehir Osmangazi Univercity Faculty of Medicine

BACKGROUND & AIM

Intranasal meningoencephalocele is a rare entity characterized by herniation of the meninges, and occasionally brain parenchyma, from the cranial cavity into the nasal cavity. Usually the patients will show symptoms in neonatal or in childhood; however in rare cases patients might present with sympton in adulthood. Clinically, some cases may remain asymptomatic until adulthood. Presentation with nasal obstruction or unilateral nasal congestion or recurrent seizures has also been reported. İn this case we report a patient who presented with a polypoid tissue like mass in a left nasal passage and a history of epileptic seizures

MATERIAL & METHODS

52-year-old female patient was referred to our department from the emergency department with a history of recurrent seizures over the past 6 months. İntranasal polypoid tissue was observed to completely obstruct the left nasal passage by endoscopic examination.MRI imaging identicated meningoencephalocele in the left nasal passage originating from left gyrus rectus.The tissue was surgically removed using an endoscopic technique.

RESULTS

Nasal meningoencephalocele is often detected incidentally without a specific clinical presentation. Although it is most commonly diagnosed in children and adolescents, it can bearly occur in adults. In particular, new-onset headaches and neurological symptoms such as epileptic seizures should raise suspicion of nasal meningoencephalocele, especially in patients with polypoid tissue.

CONCLUSIONS

Although nasal meningoencephalocele is rare, it must be considered in the differential diagnosis of polyps found in the nasal passages. For this reason, advanced imaging studies should be performed in patients with intranasal polyps, particularly those with neurological symptoms. These cases should be evaluated using MRI and CT scans.

A Rapidly Progressing Recurrent Sinonasal Sarcoma With Profound Immunophenotypic Shift: A Diagnostic And Therapeutic Challenge

Hasan Keskin[1], **Aylin Eryılmaz**[1], **Bengü Depboylu**[2], **Büşra Ekinci**[3]

[1]Department of Otolaryngology - Head and Neck Surgery, Aydın Adnan Menderes University Hospital, Aydın, Turkey.; [2]Department of Radiation Oncology, Aydın Adnan Menderes University Hospital, Aydın, Turkey.; [3]Department of Medical Pathology, Aydın Adnan Menderes University Hospital, Aydın, Turkey.

BACKGROUND & AIM

Sinonasal sarcomas are rare, aggressive malignancies prone to diagnostic complexity. Tumor heterogeneity and immunophenotypic shifts upon recurrence pose significant challenges. The aim of this report is to present a highly unusual case of a rapidly progressing sinonasal sarcoma demonstrating a complete immunophenotypic shift between its initial presentation and a late local recurrence, emphasizing the diagnostic pitfalls and the concept of clonal evolution in mesenchymal tumors.

MATERIAL & METHODS

We present the clinical, surgical, and histopathological data of a 59-year-old male patient managed at our institution. In 2022, an initial biopsy of a right nasal mass revealed a high-grade malignant mesenchymal tumor (positive for S100, SOX10, STAT6, and TLE-1). A subsequent wide local excision showed only dysplasia. After 3.5 asymptomatic years, the patient presented with a rapidly enlarging 8x4.3x3 cm septal recurrence. The mass was resected via a combined endoscopic and septocolumellar approach, and the excision was completed after intraoperative frozen section analysis confirmed benign surgical margins. The recurrent tumor was subsequently subjected to Next-Generation Sequencing (NGS). Following this second surgery, the case was evaluated by the head and neck multidisciplinary tumor board.

RESULTS

Despite initial imaging suggesting a vascular lesion, the rapidly expanding recurrent mass required urgent surgery. Histopathology confirmed a high-grade spindle cell sarcoma with marked pleomorphism, necrosis, and a Ki-67 index of 30%. Critically, this recurrence demonstrated a complete phenotypic shift. It lost expression of all original markers and gained focal expression of SMA, CD31, F13a, and ERG. Comprehensive NGS analysis revealed a complex mutational profile with pathogenic and likely pathogenic variants in NF1, ATR, BLM, CHEK1, AR, and KMT2C, underscoring severe genomic instability and supporting the profound clonal evolution. A postoperative PET-CT scan showed no metastasis. Due to these aggressive features, postoperative adjuvant radiotherapy was administered.

CONCLUSIONS

This case illustrates the dynamic nature of mesenchymal malignancies. The striking immunophenotypic shift and the complex mutational landscape (NF1, ATR, KMT2C) underscore the limitations of relying solely on immunohistochemistry for recurrent lesions, highlighting the absolute necessity of molecular diagnostics (NGS). Furthermore, it demonstrates that rigorous follow-up is imperative for sinonasal sarcomas even when initial surgical pathology appears reassuring, and that multidisciplinary adjuvant therapy becomes crucial upon aggressive recurrence.

Sinonasal Disease And Persistent Cranial Neuropathy: A Diagnostic Challenge

Noémi Queiroz Nogueira[1], **Clara Lima**[1], **Simão Bessa**[1], **Joana Ferreira**[1], **Nuno Lousan**[1]

[1]*ULS Tâmega e Sousa*

BACKGROUND & AIM

Unilateral fungal rhinosinusitis typically presents with localized sinonasal symptoms and often improves after endoscopic surgical treatment. However, persistent or progressive neurological complaints despite adequate management should prompt reconsideration of the diagnosis. We report a challenging case emphasizing the risks of diagnostic anchoring in patients with overlapping sinonasal and neurological disease.

MATERIAL & METHODS

A 47-year-old immunocompetent woman presented with progressive right facial pressure, intermittent nasal obstruction and right hemifacial paresthesia evolving over several months, associated with headaches, periocular discomfort and sensory disturbances. Initial computed tomography (CT) of the paranasal sinuses demonstrated near-complete opacification of the right maxillary sinus with central hyperdensities, suggestive of fungal rhinosinusitis.

The patient underwent endoscopic sinus surgery. Intraoperatively, thick whitish material compatible with fungal infection was identified within the maxillary sinus. Histopathological analysis confirmed fungal rhinosinusitis and reported morphology raising suspicion for mucormycosis.

RESULTS

Following surgery, the patient initially experienced improvement in nasal symptoms, facial pressure and hemifacial paresthesia, supporting a sinonasal contribution to symptom burden. However, over subsequent months, neurological complaints progressively recurred and worsened, including severe headaches, persistent right hemifacial paresthesia and sensory disturbances.

Further neuroimaging revealed an expansile lesion centered in the right cavernous sinus/periclival region with extension towards Meckel's cave, suggestive of meningioma, potentially explaining trigeminal involvement and persistent craniofacial symptoms.

The clinical course became increasingly inconsistent with isolated fungal sinonasal disease despite initial improvement after surgery and histopathological concern regarding mucormycosis, leading to multidisciplinary reassessment.

CONCLUSIONS

This case illustrates how sinonasal pathology and intracranial disease may coexist, creating diagnostic complexity. Initial symptomatic improvement after surgery may reinforce diagnostic anchoring, potentially delaying recognition of alternative neurological pathology. Persistent or recurrent craniofacial symptoms disproportionate to sinonasal findings should prompt broader investigation and multidisciplinary evaluation.

PP-660

Inflammatory Pseudotumor Of The Maxillary Sinus; A Case Report

Gizem KARACA[1], **Zehra KAYA ATAK**[1]

[1]*Kocaeli City Hospital*

BACKGROUND & AIM

Inflammatory pseudotumors may be defined as lesions that clinically and radiologically simulate neoplasms. There have been few reports of inflammatory pseudotumors in the nasal cavity and the paranasal sinuses; of these, most were in the maxillary sinus. This is very rare but highly recurrent and harmful

MATERIAL & METHODS

A 57-year-old male patient presented to our clinic with a complaint of nasal congestion. The CT scan revealed a mass extending into the nasal cavity and filling the right maxillary sinus, causing compression of the adjacent bony structures. The patient underwent functional endoscopic sinus surgery (FESS) on the right side. During the procedure, it was observed that the tumor

was attached to the lamina papyracea; multiple biopsies were taken, but the tumor could not be completely removed due to a defect in the lamina papyracea.

The biopsies were examined at our clinic and at external centers, and it was concluded that the tumor was reactive-inflammatory in nature rather than neoplastic.

RESULTS

Since the pathology reports did not provide a definitive diagnosis, the patient underwent a repeat biopsy under general anesthesia on February 12, 2026. The final pathology report indicated inflammatory tissue changes rich in plasma cells. The patient was evaluated by a multidisciplinary team including ENT, oncology, radiology, and pathology specialists, who diagnosed the condition as an ınflammatory pseudotumor. The patient was referred to the Department of Internal Medicine for steroid therapy and appropriate adjunctive treatments. Following steroid therapy, a reduction in the size of the mass led to plans for total excision.

CONCLUSIONS

Clinical or endoscopic findings may reveal a mass covered by a polyp, hypertrophic turbinates, or bloody nasal discharge. In CT and MRI, inflammatory pseudotumors can mimic malignant neoplasms. Due to the difficulty in establishing a diagnosis, repeated biopsies may be required. Histologically, tumors consist of mixed myofibroblastic spindle cells with a marked infiltration of lymphocytes, plasma cells, and acute inflammatory cells. Treatment of IP depends on the tumor's location, biological behavior and the patient's general condition and primarily includes surgical resection, oral glucocorticoids, chemotherapy, combination therapies. Generally, surgery is effective and glucocorticoids or chemotherapy can used as adjuvant therapies.

KEYWORDS

Maxillary sinus inflammation, Inflammatory pseudotumor

THREE CASES DEMONSTRATING THAT PRESEPTAL CELLULITIS REQUIRES EVALUATION OF THREE FOCAL POINTS IN DIFFERENTIAL DIAGNOSIS

Dilanur Gücük[1], **Ezgi Çöllü**[1], **Ass. Prof. Melek Uyar**[1]

[1]*SBÜ Sultangazi Haseki Training and Research Hospital, Department of Otorhinolaryngology, Istanbul, Turkey*

BACKGROUND & AIM

Preseptal cellulitis (periorbital cellulitis) is an acute bacterial infection of the eyelid and periorbital soft tissues located anterior to the orbital septum. Clinically, it is characterized by sudden-onset erythema, edema, and pain, while visual acuity and ocular movements are typically preserved. The infection often develops secondary to trauma, insect bites, or via contiguous spread from the paranasal sinuses, middle ear, or dental region. Failure to distinguish preseptal cellulitis from orbital cellulitis in the early period may lead to life-threatening complications.

MATERIAL & METHODS

During 2021-2025, patients admitted to our clinic with preseptal cellulitis secondary to middle ear, odontogenic and paranasal sinuses infections were evaluated. The odontogenic-origin case, a 37-year-old male presented with right facial swelling persisting for one week. Imaging revealed soft tissue densities in the right maxillary sinus, anterior wall destruction, and an infected odontogenic cyst arising from the right first premolar tooth. The patient underwent Right Caldwell-Luc operation. The otic-origin case, a 12-year-old male with Down syndrome and history of chronic purulent otorrhea exhibited mastoid bone destruction and subperiosteal abscess extending to the zygomatic region consistent with Luc's abcess. Bilateral preseptal cellulitis was noted. Right radical mastoidectomy and repair of cerebrospinal fluid leak operation was performed. The sinus-origin case, a 56-year-old male presented with recurrent left eyelid swelling. Imaging demonstrated opacification of the frontal, ethmoid, and maxillary sinuses. Functional endoscopic sinus surgery and frontal sinus osteoplastic flap surgeries were performed.

RESULTS

All three patients presented with periorbital swelling, redness, edema, and pain. Advanced imaging identified distinct primary infection sources in each. Patient history, physical examination, and targeted CT and MRI scans (paranasal, temporal, facial bones, and maxilla) played a crucial role in determining etiology and infection spread.

CONCLUSIONS

The clinical course and management of preseptal cellulitis vary depending on the primary infection source. Early multidisciplinary evaluation involving infectious disease, neurology, and ophthalmology specialists ensured recovery without complications. Comprehensive ENT assessment considering the three main origins sinonasal, otic, and dental is essential. Prompt diagnosis, thorough physical and radiological evaluation, and appropriate medical treatment and surgery are critical to prevent extracranial and intracranial complications.

Cost-Effectiveness Of Limited Versus Full FESS In Crswnp (Airgos Operative Study)

Anu Laulajainen-Hongisto[1], **Piccinini Elisa**[1], **Lilja Markus**[1], **Hammarén-Malmi Sari**[1], **Sahlman Johanna**[2], **Toppila-Salmi Sanna**[2], **Torkki Paulus**[3], **Virkkula Paula**[1]

[1]*Helsinki University and Helsinki University Hospital, Department of otorhinolaryngology, head and neck surgery;* [2]*Kuopio University Hospital, Wellbeing Services County of North Savo, Kuopio, Finland;* [3]*Department of Public Health, University of Helsinki, Helsinki, Finland*

BACKGROUND & AIM

Chronic rhinosinusitis with nasal polyps (CRSwNP) is treated with intranasal steroids and saline irrigation, if these do not help, courses of peroral steroids may be used, and surgery is considered.

The AIRGOs operative study is an investigator-initiated, randomized, controlled trial comparing limited and full functional endoscopic sinus surgery (FESS) for CRSwNP patients to evaluate the optimal extent of surgery. This current study is a sub-analysis of the AIRGOs operative study to evaluate the cost-effectiveness of limited vs full FESS in the treatment of CRSwNP until 24 months after the surgery.

MATERIAL & METHODS

Patient reported outcome measures (PROMs) such as the sinonasal outcome test-22 (SNOT-22), 15D and EQ-5D were used to measure health related quality of life. Costs of surgery, used medications, absenteeism and presenteeism were evaluated using Work Productivity and Activity Impairment questionnaire: General Health (WPAI:GH), Institute of medical technology assessment (iMTA) Medical Consumption Questionnaire (iMCQ), iMTA Productivity Cost Questionnaire (iPCQ) questionnaires. Based on these, health economics metrics such as Quality-Adjusted Life Years (QALYs) and Incremental Cost-Effectiveness Ratios (ICERs) will be counted and compared between the limited and full FESS surgery groups.

RESULTS

The final study population consisted of 95 study subjects, 47 (49.5%) in the limited FESS group and 48 (50.5%) in the full FESS group.

The mean cost of all medications before surgery were 95.4 e/month for limited FESS and 100.5e/month for full FESS groups - the same costs cumulatively from surgery to 24months after surgery were 95.6e/month for limited FESS and 112.3e/month for the full FESS group. The total surgery related costs per patient were 5541.38 e forlimited FESS group and 7234,98e for full FESS group.

Preoperative absenteeism (in WPAI-GH) was present in mean 4.1% of limited FESS and 4.9% full FESS patients, at 12 months postoperatively in mean 0.5% of limited FESS and 5.3% of full FESS patients. Preoperative presenteeism was found in mean 16.8% of limited FESS and 18.1% of full FESS patients, at 24 months postoperatively in mean 4.0% of limited FESS and 11.25% of full FESS patients.

CONCLUSIONS

So far it seems that full FESS is more expensive than limited FESS, but the results are still incomplete and will be presented in a more finalized version at the congress.

OSTEOPLASTIC FLAP APPROACH FOR FRONTAL SINUS–EYELID FISTULA: A CASE REPORT

Şükriye ÇAKIR[1], **Fatih ÖZDOĞAN**[1], **Dr.Özkan TEZGEZ**[1], **Dr.Melikşah ÇAKIR**[1]

[1]*Kocaeli City Hospital*

BACKGROUND & AIM

To present the surgical management of a frontal sinus–eyelid fistula using an osteoplastic flap. A patient-specific 3D-printed model was utilized for precise planning of the anterior wall osteotomy, supported by intraoperative images.

MATERIAL & METHODS

Due to the presence of a fistula tract between the right upper eyelid and the right frontal sinus, an open approach was selected. As described by Becker, marking the sinus boundaries and opening the anterior wall with an osteoplastic flap is a reliable and well-established method (1,2).

A horizontal periosteal incision was made at the superior borders of both frontal sinuses, as determined using navigation and a patient-specific 3D-printed model. An oblique inferior bone cut was performed using piezosurgery and osteotomes, and an inferiorly based osteoplastic flap was elevated.

The fistula tract was identified, completely excised, and primarily repaired. Fungal material within the frontal sinus was removed. Defects at the sinus floor and septum were noted. All mucosa was excised; the frontal recesses were obliterated with bone wax, and the sinuses were filled with fat.

The bone flap was easily repositioned and secured using periosteal suturing.

RESULTS

Frontal sinus fungal infections are rare and typically present as non-invasive fungal sinusitis (fungal ball), most commonly caused by Aspergillus species (1,2). Fistula formation is an uncommon but significant complication, indicating advanced or complicated disease and posing diagnostic and therapeutic challenges, particularly in the frontal sinus.

While endoscopic approaches are widely used, open techniques remain crucial in cases with fistulae, large defects, or complex anatomy (3,4). In our case, complete fistula excision and repair, combined with osteoplastic flap access and 3D-guided planning, enabled safe exposure and effective disease clearance.

CONCLUSIONS

In the presence of a frontal sinus–eyelid fistula, the osteoplastic flap approach provides reliable exposure for complete fistula excision and repair. Navigation and patient-specific 3D modeling enhance anatomical accuracy and surgical safety.

This approach is particularly valuable in fistula-associated frontal sinus disease requiring precise anatomical orientation.

Rendu-Osler-Weber Disease In A Pacient With Nasal Polyposis: Case Report

Andra Raluca Ilisanu[1], **Ruxandra Oana Alius**[1,2], **Irina Gabriela Ionita**[1,2], **Andreea Rusescu**[1,2], **Catalina Voiosu**[1,2], **Viorel Zainea**[1,2], **Raluca Oana Pulpa**[1,2], **Selma Anda Cretu**[1], **Mara Andra Rebosapca**[1], **Razvan Hainarosie**[1,2]

[1]*"Prof. Dr. D. Hociota" Institute of Phonoaudiology and ENT Surgery Bucharest, Romania;* [2]*"Carol Davila" University of Medicine and Pharmacy Bucharest, Romania*

BACKGROUND & AIM

Rendu–Osler disease is an uncommon autosomal dominant vascular condition marked by multisystemic vascular malformations and wide spectrum clinical manifestations. It presents with recurrent epistaxis, iron deficiency and secondary anemia. The disease predominantly affects small-caliber vessels of the nasal, oral, gastrointestinal mucosa, and cutaneous surfaces of the face, lips, and fingertips, and solid organs.

In this type of syndrome the capillary networks are absent, resulting in direct communications between dilated arteries and veins. Recurrent epistaxis represents the most frequent clinical manifestation of the disease, occurring in up to 95% of patients as a result of telangiectasias affecting the nasal mucosa.

MATERIAL & METHODS

This paper wishes to discuss the case of a 70-year-old man diagnosed at the age of 32 with Rendu–Osler–Weber syndrome, admitted to the emergency department at I.F.A.C.F.- ENT „ Prof. Dr. D. Hociota" with massive bilateral epistaxis. The patient had a history of hypertension, a mechanical aortic valve for aortic insufficiency, and long-term anticoagulation with acenocoumarol and nasal polyps from which he was also bleeding. He underwent surgery because the hemorrhage could not be controlled following local maneuvres: bilateral nasal packing with Merocele and intravenous vasoconstrictor infusion. Oral anticoagulation was suspended and replaced with low-molecular-weight heparin.

RESULTS

The patient's severe epistaxis was successfully managed intraoperatively where we performed the excision of the nasal polyps that were affecting the nasal mucosa, followed by placing topical hemostatic powder, resorbable hemostatic strips and also nasal packing maintained for 72 hours and removed under endoscopic guidance during sedation. No recurrent bleeding occurred, and oral anticoagulation was subsequently resumed.

CONCLUSIONS

Hereditary hemorrhagic teleangectasia is an infrequent genetic disorder that affects the small vessels and produces recurrent epistaxis, sometimes severe, with systemic repercussions like chronic anemia and iron depletion. Management of this disease demands a multidisciplinary approach and should be individualized based on systemic and local manifestations, comorbidities, ongoing therapies, and surgical needs. Nasal bleeding should be addressed stepwise, beginning with conservative measures, advancing to medical therapy, and reserving surgery for refractory cases.

KEYWORDS

teleangectasia, polyp, epistaxis, anemia, capillary

PP-665

Use Of Isotretinoin Post-Rhinoplasty In Patients With Thick Nasal Skin

Jetmira Fejza[1], **Roven Sinani**[1]

[1]Art Orl Clinic

BACKGROUND & AIM

Background:

Patients with thick nasal skin undergoing rhinoplasty often present a surgical challenge due to increased sebaceous activity, reduced skin contractility, and a higher risk of prolonged edema and suboptimal tip definition. Adjunctive medical therapies may improve postoperative outcomes. This study evaluates the role of low-dose isotretinoin in enhancing skin quality and surgical results following rhinoplasty in this patient population.

MATERIAL & METHODS

A prospective observational study was conducted including patients with clinically thick nasal skin undergoing primary rhinoplasty. 12 Patients (females) with thick skin received low-dose oral isotretinoin (20 mg / day) starting 4 weeks postoperatively for a duration of 3–6 months. Outcomes assessed included skin thickness, sebaceous activity, duration of edema, and tip definition. Clinical evaluation was performed through standardized photography and surgeon/patient satisfaction scores.

RESULTS

Patients treated with isotretinoin demonstrated a noticeable reduction in skin oiliness and dermal thickness, with faster resolution of postoperative edema compared to typical healing patterns. Improved nasal tip definition and contour were observed over time. Patient satisfaction scores were high in all 12 patients. and no major adverse effects were reported. Mild mucocutaneous side effects were manageable in 10 payients and did not require discontinuation of therapy. 2 patients with moderate side effects was treated with internitent doses (one week off every month)

CONCLUSIONS

Postoperative low-dose isotretinoin appears to be a valuable adjunct in patients with thick nasal skin undergoing rhinoplasty. It may enhance skin contractility, reduce edema duration, and improve aesthetic outcomes, particularly in nasal tip definition. Further controlled studies are recommended to establish standardized protocols and long-term safety.

PP-666

Ligneous Conjunctivitis With Nasolacrimal And Gingival Involvement: A Report Of Two Cases

Muhammet Fatih GÖKMEN[1], **Banu BOZKURT**[2], **Mete Kaan BOZKURT**[1]

[1]*Selcuk University, Medical School, ENT Department;* [2]*Selcuk University, Medical School, Ophtalmology Department*

BACKGROUND & AIM

Ligneous conjunctivitis (LC) is a rare, chronic and recurrent form of conjunctivitis, characterized by the formation of fibrin-rich, yellow-white pseudomembranes on the palpebral conjunctiva, which exhibit a distinctive “woody” appearance. For many years, the pathophysiology of LC remained unclear until Schuster et al. identified plasminogen (PLG) deficiency as a central etiological factor in 2001. LC is an extremely rare disorder, with an estimated prevalence of approximately 1.6 cases per million individuals. This poster presents the otolaryngological manifestations observed in two patients with LC and discusses the diagnostic and therapeutic challenges associated with PLG deficiency.

MATERIAL & METHODS

A 32-year-old female patient was referred to ENT clinic for endoscopic dacryocystorhinostomy (DCR) following a diagnosis of left nasolacrimal duct obstruction and dacriocystitis. She reported a one-year history of epiphora. She had been diagnosed with LC at 18 years of age and had since undergone multiple treatments, including topical fresh frozen plasma (FFP), heparin, corticosteroids and cyclosporine. The patient underwent left endoscopic DCR without intraoperative or early postoperative complications. However, one month postoperatively, she presented with nasal obstruction. Endoscopic examination demonstrated grape-like mucosal lesions in the left nasal cavity. After starting treatment with IV PLG concentrate the patient experienced noticeable improvement in symptoms and a significant reduction in complaints.

A 20-year-old male patient was referred to ENT clinic following an incisional gingival biopsy performed at the site of the right mandibular first molar for evaluation of a persistent oral ulcer. Histopathological examination revealed findings highly suggestive of squamous cell carcinoma.

RESULTS

Although PLG deficiency most commonly manifests as LC, systemic involvement may also occur. In this report, we describe the clinical findings, differential diagnosis, and management of two patients with LC who presented with nasolacrimal duct obstruction, dacryocystitis, and gingivitis. Both patients underwent endoscopic DCR, but only the first patient developed refractory nasolacrimal duct obstruction postoperatively. The recurrent pseudomembrane formation in the nasal cavity was attributed to surgical trauma.

Currently, no established gold-standard therapy exists for gingival involvement in PLG deficiency. A wide range of treatments has been attempted, including cromoglycates, idoxuridine, steroids, acetylcysteine, cytarabine, topical hyaluronidase, alpha-

chymotrypsin, fibrinolysin, cryotherapy, silver nitrate, carbon dioxide laser, radiotherapy, systemic azathioprine, heparin-containing eye drops, and surgical excision. Antibiotic therapy is not recommended, as evidence does not support its in either local or systemic treatment of persistent disease.

CONCLUSIONS

In conclusion, this poster highlights several important considerations: the occurence of nasolacrimal duct obstruction and the outcomes of endoscopic surgical management—previously unreported in patients with LC; the potential for recurrent membrane formation and obstruction secondary to PLG deficiency; the necessity of close postoperative surveillance and the possible need for local and systemic replacement therapies. In addition to FFP, emerging treatment modalities such as IV PLG replacement therapy represent promising targeted approaches aimed at correcting the underlying deficiency.

Rhinolithiasis: When Unilateral Nasal Obstruction Hides A Stone

Chahed Houda[1], **El Bessi Salma**[1], **Majbri Maha**[1], **youssef makhlouf**[1], **Madiouni Azza**[1], **Ben Amor Mohmed**[1], **Beltaief Najeh**[1]

[1]*Department of ENT and Head and Neck Surgery, la Rabta hospital, Tunis , Tunisia*

BACKGROUND & AIM

Rhinolithiasis is a rare rhinologic condition characterized by the formation of a calcified intranasal concretion resulting from progressive deposition of mineral salts around an endogenous or exogenous nidus. Its slow and often silent progression, combined with the nonspecific nature of clinical symptoms, frequently leads to delayed diagnosis or discovery at a complicated stage. The aim of this study was to highlight the epidemiological, clinical, radiological, therapeutic, and outcome features of this uncommon condition.

MATERIAL & METHODS

We conducted a retrospective descriptive study including eleven patients managed for rhinolithiasis in our department of Otorhinolaryngology and Head & Neck Surgery over a nine-year period (January 2016–December 2025).

RESULTS

The mean age of patients was 29.8 years , with a female predominance. The mean duration before consultation was 4 years. Clinical presentation included unilateral nasal obstruction (9 cases), foul-smelling purulent rhinorrhea (10 cases), recurrent epistaxis (5 cases), and anosmia (1 case). The rhinolith was unilateral in all cases. A history of nasal trauma with foreign body insertion was reported in one case.

Nasal endoscopy showed a calcified intranasal mass in 8 cases and crusted nasal floor in 1. CT scan revealed a calcified lesion (mean 21.5 mm; range 13–31), with suspected fungal appearance in 2 cases, osteomeatal narrowing in 1, and inferior turbinate lysis in 1. Complications included chronic rhinosinusitis (2 cases), aspergillary superinfection (1), and turbinate lysis (1).

All patients underwent endoscopic removal under general anesthesia. Histology showed inflammatory pseudopolypoid changes with actinomycotic granules. Outcomes were favorable in all cases

CONCLUSIONS

Rhinolithiasis is an uncommon condition often diagnosed late due to its insidious course and nonspecific symptoms. Nasal endoscopy and CT scan remain essential for diagnosis and evaluation. Endoscopic removal is an effective treatment with excellent functional outcomes.

KEYWORDS

Rhinolithiasis, Nasal obstruction, Chronic rhinosinusitis, Nasal endoscopy

PP-668

A Primary Frontal Mucopyocele Presenting With Acute Orbital Cellulitis

Alihan Topal[1], **Gökhan Atik**[1]

[1]*Ankara Bilkent City Hospital*

BACKGROUND & AIM

Frontal sinus mucoceles are expansile lesions that may erode adjacent bony walls and extend into the orbit. Infection may transform a mucocele into a mucopyocele, creating a vision-threatening orbital complication. We present a primary frontal mucopyocele with orbital extension without previous sinonasal surgery or trauma.

MATERIAL & METHODS

Case Study: 61-year-old man presented with a 1-week history of right periorbital swelling. Laboratory tests showed elevated inflammatory markers. Nasal endoscopy revealed a polypoid lesion arising from the right middle meatus with mucoid discharge. Ophthalmologic examination showed right chemosis, proptosis, and marked limitation of extraocular movements in

all directions, while bilateral light reflexes were preserved. Paranasal computed tomography demonstrated right middle meatus and frontal recess obstruction, hyperdense polypoid/mucocele-like tissue in the right nasal cavity and ethmoid cells, orbital roof and lamina papyracea defects, superior extraconal inflammatory extension with compression of the globe and extraocular muscles, and optic nerve stretching.

RESULTS

Upper blepharoplasty incision was made. The incision was extended to the levels of the medial and lateral canthi. Using a transorbital approach, the superior orbit was elevated while preserving the periorbital tissues. The mucocele was observed to extend through the superior orbital defect into the right frontal sinus. With endoscopic assistance, the mucocele filling the frontal sinus was excised together with its entire wall. Erosion of the anterior table of the frontal sinus and the interfrontal septum was noted. The mucocele was also observed to extend through the defect into the left frontal sinus. The mucocele wall and infected inflammatory tissue were excised, anterior and posterior ethmoidectomy was completed and the frontoethmoidal recess was cleared by endonasal surgery. Postoperative nasal endoscopic examination showed normal middle meatal findings bilaterally. The limitation of extraocular movements gradually decreased over time. Postoperative ocular movements were full and painless in all directions.

CONCLUSIONS

Primary frontal mucopyocele may present acutely with orbital cellulitis, proptosis, and ophthalmoplegia even without prior trauma or surgery. Early imaging, multidisciplinary evaluation, and prompt surgical drainage can preserve vision and reverse orbital motility restriction.

PP-669

POTT'S PUFFY TUMOR: A RARE COMPLICATION OF SINUSITIS – CASE REPORT

Emre ÖNAL[1], **Alper Nabi ERKAN**[2], **Halil İbrahim SÜNER**[3], **Özgür CEYLAN**[4]

[1]*Department of Otolaryngology, Başkent University Faculty of Medicine, Ankara, Türkiye;* [2]*Department of Otolaryngology, Başkent University Faculty of Medicine, Adana, Türkiye;* [3]*Department of Neurosurgery, Başkent University Faculty of Medicine, Adana, Türkiye;* [4]*Department of Pediatric Infectious Diseases, Başkent University Faculty of Medicine, Adana, Türkiye*

BACKGROUND & AIM

Pott's puffy tumor (PPT) is an uncommon but serious complication of frontal sinusitis. When diagnosis is delayed, it may result in significant intracranial morbidity.

MATERIAL & METHODS

This study is a single case report of a 12-year-old male patient diagnosed with Pott's puffy tumor secondary to frontal sinusitis. The patient's presenting symptoms, clinical examination findings, laboratory results, and radiological investigations were retrospectively reviewed. Imaging evaluation included paranasal sinus and brain computed tomography as well as magnetic resonance imaging. Medical management with broad-spectrum intravenous antibiotics and surgical interventions performed jointly by otolaryngology and neurosurgery teams were analyzed. Postoperative clinical course and response to treatment were monitored and assessed. The study was conducted in accordance with patient confidentiality principles, and informed consent was obtained from the patient's legal guardian.

RESULTS

Clinical evaluation revealed prominent swelling in the frontal and periorbital regions accompanied by purulent nasal discharge. Computed tomography and magnetic resonance imaging demonstrated findings consistent with frontal bone osteomyelitis, a subperiosteal abscess, an epidural collection, and pansinusitis. Broad-spectrum intravenous antibiotic therapy was initiated, followed by functional endoscopic sinus surgery with simultaneous epidural abscess drainage through a coordinated approach involving otolaryngology and neurosurgery teams. A marked improvement in clinical findings was observed in the postoperative period. Follow-up imaging showed a reduction in the frontal subcutaneous collection and regression of intracranial extension. The patient was discharged with clinical recovery and without the development of additional complications.

CONCLUSIONS

Pott's puffy tumor is a rare but potentially serious complication of frontal sinusitis that may lead to life-threatening intracranial involvement if diagnosis is delayed. Early and appropriate radiological evaluation is essential in patients presenting with frontal swelling. The combination of medical therapy and timely surgical intervention, supported by a multidisciplinary approach, is crucial for achieving favorable clinical outcomes. This case underscores the importance of early recognition and prompt surgical management in preventing severe complications.

PP-670

Nasopharyngeal Amyloidosis Diagnosed Due To Serous Otitis, A Rare Case

Yağmur Uluhan[1], **Latif Akan**[1], **Cem Saka**[1]

[1]*Ankara Etlik City Hospital*

BACKGROUND & AIM

Amyloidosis of the nasopharynx is an exceedingly rare condition. Amyloid can impair normal tissue elasticity at the site of deposition, thereby disrupting local physiological functions. Lesions localized in the nasopharynx often produce a mass effect and may clinically and radiologically mimic nasopharyngeal carcinoma.

Therefore, histopathological confirmation and exclusion of systemic involvement are of critical importance for accurate diagnosis

MATERIAL & METHODS

A 20-year-old male patient presented with a 5-year history of hearing loss in the right ear. Otolaryngological examination revealed right-sided serous otitis and a mass in the nasopharynx obstructing the right Rosenmüller fossa. A punch biopsy of the lesion was obtained. Based on these findings, an excisional biopsy of the nasopharyngeal lesion was performed at our center. Postoperative histopathological examination confirmed the diagnosis of amyloidosis. Following surgery, the patient's conductive hearing loss in the right ear resolved

RESULTS

Isolated nasopharyngeal amyloidosis is a rare entity. Although benign in nature, it is characterized by chronic and potentially progressive growth and may carry a risk of evolving into systemic amyloidosis affecting multiple organs.

CONCLUSIONS

Early differential diagnosis and thorough evaluation for systemic involvement are essential.

KEYWORDS

Nasopharynx, Amyloidosis, Serous otitis

Partial Oculomotor Nerve Involvement Secondary To Sphenoid Sinus Inflammation: A Case Report

Şükriye ÇAKIR[1], **Fatih ÖZDOĞAN**[1]

[1]*Kocaeli City Hospital*

BACKGROUND & AIM

Pathologies of the sphenoid sinus are uncommon but clinically significant due to their close relationship with critical neurovascular structures, including cranial nerves within the Cavernous Sinus. Inflammatory processes may rarely result in cranial nerve dysfunction and mimic central neurological disorders. We present a case of sphenoid sinus inflammation associated with partial cranial nerve involvement manifesting as diplopia and medial gaze limitation.

MATERIAL & METHODS

A 66-year-old male presented with a two-week history of diplopia and right-sided facial pain. Cranial MRI performed at an external center suggested a lesion in the right sphenoid sinus, and the patient was referred to our department for further evaluation.On physical examination, there was limitation of medial gaze and ptosis in the right eye.

Endoscopic nasal examination revealed a patent sphenoid sinus ostium; the sinus cavity was explored, and no intraluminal lesion was identified. Paranasal computed tomography demonstrated no significant pathology.

Due to persistent ocular findings, the patient was evaluated by neurology and ophthalmology. Additionally, internal medicine consultation was obtained due to dysregulated blood glucose levels. No central nervous system pathology was detected.

RESULTS

The clinical findings were attributed to sphenoid sinus inflammation causing partial Oculomotor Nerve involvement, leading to diplopia, ptosis, and limitation of medial gaze. The patient was managed conservatively with anti-inflammatory therapy, in line with previously reported cases (1–4).

At the 6-month follow-up, the patient's symptoms had completely resolved, and no residual neurological or ophthalmological deficits were observed.

CONCLUSIONS

Sphenoid sinus inflammation may present with cranial nerve deficits mimicking central nervous system pathology. Given its anatomical proximity to the cavernous sinus and adjacent cranial nerves, such inflammatory processes should be considered in the differential diagnosis of isolated cranial nerve palsies, particularly in patients with metabolic comorbidities such as diabetes. Early recognition and a multidisciplinary approach are essential for accurate diagnosis and optimal management.

Destruction Of Medial And Superior Orbital Wall Due Pyoceles In Fronto-Ethmoidal Region

Nikica Atanasova[1], **Vase Stojceska**[1], **Irena Mihajlovska-Shulevska**[1]

[1]*General City Hospital ,,8-th September '' - Skopje, North Macedonia*

BACKGROUND & AIM

Mucocele is defined as an accumulation of mucus within a sinus as result of an obstructed outlet.When the contents of cavity are purulent in character , the conditionis reffered to as a Supurating mucocele or Pyocele. Pyocele are rare complication of sinusitis that is usually associated with stenosis of the sinus ostium caused by inflammation

MATERIAL & METHODS

Case Study: A 66 years old woman refered to Otorhinolaryngology Department at General City Hospital 8 th September- Skopje due to severe headache, lateralization of left eye bulb imparing vision on left eye, diplopia, incapability to look on right side , On CT scan was found Tumor of the left ethmoidal region with destruction of left medial orbital wall with pressure on eye bulb moving it lateraly. Also there was opacification on left frontal sinus and destruction of inferior sinus wall. Endoscopic sinus surgery was preformed in intravenous anesthesia to obtein a biopsy of the tumor, opening the ethmoidal bulla , leading to drainage of ethmoidal cells and abundant outflow of purulent discharge. Bacteriological swab and part of tissue were taken.

RESULTS

The main disease entity - Pyocele are caused by superinfection of mucolece by bacteria. An efficient and sufficient method of treatment of Pyocele of paranasal sinuses is their endoscopic drainage

CONCLUSIONS

In the diagnosis of pyocele most important are anamnesis, physical examination and results from CT and MRI. Treatment is mainly based on properly performed surgery and evacuation of accumulated pus, pharmacotherapy and rehabilitation. Endoscopic surgery is an effective procedure that leads to recovery

Paramedian Alın Flepli Dev Rinofimanın Rekonstrüksiyonu: Bir Vaka Raporu

ataka yanık[1], **şahin öğleden**[1], **tuğba arlı**[1], **gökçen yılmaz**[1]

[1]*Çam ve Sakura şehir hastanesi*

BACKGROUND & AIM

Rhinophyma is the advanced stage of rosacea, characterized by sebaceous gland hypertrophy and connective tissue increase, leading to progressive deformity of the distal nose. This study aims to present the outcomes of surgical excision and reconstruction with a paramedian forehead flap in a case of giant rhinophyma causing severe cosmetic disfigurement and nasal obstruction.

MATERIAL & METHODS

Under general anesthesia, the rhinophymatous tissue was totally excised by dissecting it from the surrounding healthy tissue margins. A paramedian forehead flap, known for its high vascularization and tissue compatibility, was planned for the reconstruction of the extensive defect following excision. The flap was elevated as a pedicled flap based on the supratrochlear artery, transposed to the nasal defect, and sutured anatomically.

RESULTS

The operation was completed without complications. Postoperatively, full flap viability was maintained, and the patient's nasal airway was cleared. While tangential excision and secondary healing are options for small lesions in rhinophyma, total excision and flap reconstruction are the gold standard for giant lesions where anatomical sub-units are completely lost.

CONCLUSIONS

Consequently, high patient satisfaction was achieved both functionally and aesthetically, significantly improving the patient's quality of life.

A Tailored Algorithmic Approach To Endoscopic Nasal Septal Perforation Repair: A Clinical Case Series And Outcome Analysis

Sergey ILINSKIY[1]

[1]*LOR-Praktika*

BACKGROUND & AIM

Nasal septal perforation (NSP) remains a challenging surgical problem due to limited donor tissue and the risk of recurrence. We hypothesize that a structured treatment algorithm based on perforation topography, size, and vascular supply of the used flap significantly improves successful closure rates. Our aim was to evaluate the effectiveness of an individualized surgical strategy using various pedicled flaps.

MATERIAL & METHODS

In this clinical study (2022–2025), we implemented a diagnostic and surgical algorithm for 85 patients with NSP. Preoperative assessment included history, perforation size, localization, and edge condition. Subjects were categorized according to the posterior margin's relation to the middle turbinate axilla (MTA) and etiology. Patients were divided into four main groups: 1) Castelnuovo flap based on the anterior ethmoidal artery (AEA) for perforations anterior to the MTA (n=53); 2) Extended (Rusetsky) flap based on the posterior septal branches of sphenopalatine artery for larger (more than 2 cm) and posterior defects (n=16); 3) L-strut overlay flaps for small (up to 1 cm) spontaneous/iatrogenic anterior NSPs (n=10) and 4) Other techniques, including relaxing incisions and superior labial artery flaps (n=6).

RESULTS

The overall successful closure rate across all groups was 89.4% (76/85), with a 10.6% (n=9) recurrence rate. The Castelnuovo flap showed the highest clinical reliability with a 96.2% success rate (only 2 recurrences out of 53). The Posterior flap group achieved a 81.3% success rate (3 recurrences). The L-strut overlay technique resulted in a 70% success rate (3 recurrences), indicating lower stability for complex defects.Other techniques had a success rate of 83.3% (1 recurrence). Combining techniques with "with turned-up edges" (umbo) to create a double-layered closure significantly improved flap stability.

CONCLUSIONS

A topography-based algorithmic approach is effective for NSP repair. Pedicled vascular flaps provide superior outcomes compared to free grafts. The Castelnuovo flap is particularly robust due to its vascular supply and flexibility, while extended posterior (Rusetsky) flap demonstrates better outcomes in patients with defects larger than 2 cm.

Biologic Therapy In Chronic Rhinosinusitis With Nasal Polyps (Crswnp): A Systematic Review And Indirect Comparison Of Efficacy Through December 2025

GEORGIOS PAPACHARALAMPOUS[1], **IOANNIS KARELAS**[1], **PAVLOS PANTOS**[1], **VIOLETTA AGOROGIANNI**[1], **CHRISTIANNA STAVROU**[1], **EVGENIA TZAVARA**[1], **MARIA KARAMALI**[1], **ARISTEIDIS CHRYSOVERGIS**[1]

[1]*ENT DEPT ELPIS GENERAL HOSPITAL ATHENS GREECE*

BACKGROUND & AIM

Background and aim

Biologic therapies targeting type-2 inflammation have significantly changed the management of chronic rhinosinusitis with nasal polyps (CRSwNP), particularly in patients refractory to corticosteroids and endoscopic sinus surgery. However, direct comparative evidence among biologics remains limited because of the absence of head-to-head randomized controlled trials (RCTs). Our objective was to systematically review and indirectly compare the efficacy and safety of biologic therapies for CRSwNP using evidence published through December 2025.

MATERIAL & METHODS

Material & Methods

A systematic search of PubMed/Medline, Embase, Google Scholar, and Cochrane Library databases identified 1348 records published between January 2013 and December 2025. After duplicate removal (n=286), 1062 records underwent title and abstract screening. Following eligibility assessment, 37 studies were included in the final qualitative synthesis, comprising 20 randomized controlled trials, 12 systematic reviews/meta-analyses, 3 indirect treatment comparison studies, and 2 real-world evidence studies. Biologics formally evaluated included omalizumab, dupilumab, mepolizumab, benralizumab, and tezepelumab. Emerging evidence regarding depemokimab was reviewed narratively because peer-reviewed comparative data remained limited.

RESULTS

Results

All biologics demonstrated superiority over placebo across major clinical outcomes, including nasal polyp score, nasal congestion, smell function, SNOT-22, radiologic severity, and reduction in systemic corticosteroid use and surgery. Dupilumab consistently showed the greatest and most comprehensive efficacy across clinical and patient-reported outcomes. Tezepelumab demonstrated strong emerging efficacy in recent Phase III evidence. Omalizumab showed favorable safety and moderate efficacy, while mepolizumab and benralizumab appeared particularly beneficial in eosinophilic/type-2 inflammatory phenotypes.

CONCLUSIONS

Conclusions

Biologic therapy is effective and generally well tolerated in severe CRSwNP refractory to standard treatment. Current evidence through December 2025 supports dupilumab as the most consistently effective biologic overall, while tezepelumab and benralizumab expand the evolving therapeutic landscape. Further head-to-head RCTs and long-term comparative studies are required to optimize biologic selection and individualized treatment strategies.

KEYWORDS

biologics, CRSwNP, omalizumab, mepolizumab, dupilumab, benralizumab, tezepelumab, depemokimab

PP-676

Atypical Spread Of Sinusitis: Contralateral Orbital Cellulitis And Ipsilateral Subdural Empyema

Gokce Altin[1], **Merve Demir**[1], **Murat Topbas**[1]

[1]*Basaksehir Cam and Sakura City Hospital*

BACKGROUND & AIM

Acute bacterial sinusitis is typically a self-limiting condition; however, it can rarely result in severe outcomes due to orbital and intracranial complications. Subdural empyema (SDE) is among the most common and life-threatening intracranial complications of sinusitis (1,2). Infection may spread not only by direct extension but also via retrograde thrombophlebitis through the valveless diploic venous system (3). Although complications usually occur ipsilateral to the primary infection, atypical dissemination to different anatomical compartments, including the contralateral side, may be observed (4). This report highlights that unilateral sinusitis can present with contralateral orbital cellulitis and ipsilateral subdural empyema, posing significant diagnostic challenges.

MATERIAL & METHODS

An 11-year-old girl was evaluated for a one-week history of fever followed by right periorbital swelling. Due to the development of speech impairment and altered mental status during follow-up, she was referred to our tertiary care center. Physical examination revealed marked periorbital edema, restriction of ocular movements, and neck stiffness. Laboratory findings indicated significant inflammatory response. Computed tomography (CT) demonstrated left maxillary, ethmoidal, and frontal sinusitis, while magnetic resonance imaging (MRI) revealed an extra-axial collection in the left frontal region consistent with subdural empyema. The patient was managed with a multidisciplinary approach involving otolaryngology, ophthalmology, and neurosurgery teams. Right orbital abscess drainage, left-sided functional endoscopic sinus surgery, and left craniotomy with drainage of the subdural empyema were performed, followed by initiation of broad-spectrum intravenous antibiotic therapy.

RESULTS

Despite left-sided sinusitis, the patient initially presented with right-sided preseptal/orbital cellulitis and abscess formation. Subsequently, intracranial spread resulted in the development of subdural empyema in the left frontal region. This discordance in laterality was notable and posed a diagnostic challenge. It has been reported that sinusitis-related infections may spread to different compartments via the venous system (4,5). In our literature review, a case of contralateral brain abscess secondary to sinusitis has been reported in an adult patient (6); however, to the best of our knowledge, this is the first pediatric case demonstrating contralateral orbital abscess with ipsilateral subdural empyema. Following combined surgical and medical management, the patient showed significant clinical and radiological improvement, with no permanent neurological or ophthalmological sequelae.

CONCLUSIONS

This case demonstrates that unilateral sinusitis may extend beyond expected anatomical boundaries, leading to contralateral orbital infection and ipsilateral intracranial complications. Reliance solely on laterality during clinical evaluation may be misleading. Early and comprehensive neuroimaging is crucial, particularly in the presence of neurological symptoms. A multidisciplinary approach and timely surgical intervention are essential for achieving favorable clinical outcomes.

IDH1-Positive Ossifying Fibromyxoid Tumor Of The Nasal Septum: A Rare Case Mimicking Low-Grade Chondrosarcoma

Hasan Ediz Özbek[1], **Nurullah Olam**[1], **Elif Akbaş**[1], **Bilal Sarataş**[1], **Ahmet Tarlacı**[2]

[1]*University of Health Sciences - Haseki Training and Research Hospital, Department of Otorhinolaryngology & Head and Neck Surgery, Istanbul, Turkey;* [2]*University of Health Sciences - Haseki Training and Research Hospital, Department of Pathology, Istanbul, Turkey*

BACKGROUND & AIM

Ossifying fibromyxoid tumor (OFMT) is a rare mesenchymal neoplasm of uncertain differentiation and borderline malignant potential. While typically found in the extremities, its occurrence in the sinonasal tract is exceedingly rare. We report a unique case of a nasal septal OFMT exhibiting isocitrate dehydrogenase-1 (IDH1) immunoreactivity, a finding traditionally associated with cartilaginous tumors.

MATERIAL & METHODS

A 68-year-old male presented with a two-year history of progressive bilateral nasal obstruction. Nasal endoscopy revealed a firm, smooth mass arising from the nasal septum. Computed tomography (CT) demonstrated a well-circumscribed 2.5 cm mass with coarse peripheral calcifications. Magnetic resonance imaging (MRI) showed an atypical T2-hypointense signal and minimal enhancement, suggesting a dense, mineralized structure. The mass was successfully excised via an open septoplasty approach. Microscopic examination revealed a well-circumscribed, encapsulated tumor composed of uniform spindle cells arranged in cords within a fibromyxoid stroma. Immunohistochemical (IHC) analysis showed diffuse positivity for S100 and, notably, IDH1. This initial immunoprofile raised suspicion for low-grade chondrosarcoma (LGC). However, the characteristic morphology and absence of true cartilaginous matrix led to the final diagnosis of benign OFMT.

RESULTS

This case represents the first report of an IDH1-positive OFMT of the nasal septum. The IDH1 expression highlights a significant diagnostic pitfall, as it mimics the molecular profile of chondrosarcoma.

CONCLUSIONS

Clinicians and pathologists must integrate radiologic findings, classic morphology, and expanded IHC panels to ensure accurate diagnosis and avoid over-treatment of this rare "scrambled" phenotype tumor.

AN UNUSUAL NASAL FOREIGN BODY CAUSING RHINOLITHIASIS: A CASE REPORT

MERVE ÜNAL[1], **AZİME EGE VİDİNLİ**[1], **SÜHEYLA KANDEMİR**[1], **BURAK MUSTAFA TAŞ**[1], **ZİYA ŞENCAN**[1], **ELA CÖMERT**[1], **NURAY BAYAR MULUK**[1]

[1]*Kırıkkale University Department of Otorhinolaryngology*

BACKGROUND & AIM

Rhinoliths are hard, dense, calcified masses formed in the nasal cavity around an endogenous or exogenous nidus, resulting from the deposition of mineral salts over time. They usually develop secondary to a retained foreign body and chronic inflammation.

This report presents an unusual case of rhinolithiasis caused by a retained gas cylinder (LPG tube) rubber seal that had remained undetected since childhood.

MATERIAL & METHODS

A 30-year-old female patient presented to our clinic with complaints of unilateral nasal congestion, purulent nasal discharge, and foul odor that had persisted for approximately 15 years. The patient did not initially recall any history of nasal foreign body insertion. Endoscopic examination revealed purulent discharge and a hard mass consistent with a rhinolith in the right nasal cavity. The left nasal cavity and other otorhinolaryngological examinations were normal.

Paranasal sinus computed tomography (CT) demonstrated a well-defined hyperdense calcified mass in the right nasal cavity, consistent with a rhinolith, containing a central hypodense area suggestive of an embedded non-metallic foreign body.

RESULTS

The patient underwent endoscopic sinus surgery under general anesthesia for removal of the rhinolith. During the procedure, the rhinolith was fragmented and extracted from the right nasal cavity, revealing an embedded foreign body identified as a circular rubber seal belonging to a small domestic gas cylinder (LPG tube) gasket. Postoperatively, the patient recalled that such a seal had gone missing during her childhood; however, the incident had not been considered clinically significant at that time.

Histopathological examination confirmed calcified material consistent with rhinolith formation. The postoperative period was uneventful, and the patient’s symptoms resolved completely during follow-up

CONCLUSIONS

Although nasal foreign bodies are more commonly encountered in children, they should also be considered in adults presenting with long-standing unilateral nasal obstruction, purulent rhinorrhea, and malodor. Unusual inorganic materials such as rubber gaskets may remain asymptomatic for years and subsequently serve as a nidus for progressive calcification and rhinolith formation. Radiologically, a hyperdense calcified mass with a central hypodense component may suggest a retained non-metallic foreign body. Early recognition and endoscopic management are essential to prevent chronic complications.

KEYWORDS
rhinolith, foreign body, rubber gasket, adult patient

PP-679

Bilateral Frontal And Ethmoid Sinus Osteomas And Surgical Approach: A Case Report

Berra Serefoglu[1], **Mehmet Salih Parca**[1], **Muhammed Topaloglu**[1], **Sahin Ogreden**[1], **Ozgur Yigit**[1]

[1]*Basaksehir Cam ve Sakura City Hospital*

BACKGROUND & AIM

Osteomas are benign bone tumors arising from osseous tissue and most commonly involve the paranasal sinuses, particularly the frontal and ethmoid sinuses. They are usually solitary lesions, while multiple or bilateral paranasal sinus osteomas are extremely rare. Although most osteomas are asymptomatic and detected incidentally, larger lesions or those extending to adjacent structures may cause significant symptoms and complications.The aim of this case report is to present a rare case of bilateral frontal and ethmoid sinus osteomas and to discuss the surgical management and approach in light of the current literature.

MATERIAL & METHODS

A 54-year-old female patient presenting with long-standing dizziness, headache, blurred vision in the right eye, and a sensation of cranial pressure was evaluated. Paranasal sinus computed tomography (CT) revealed multiple ossified lesions: a 34 × 15 mm lesion filling the right frontal sinus and anterior ethmoid cells with extension toward the extraconal medial orbital area, and additional smaller osteomas in the left ethmoid and superomedial orbital region.Due to the presence of multiple osteomas, the patient was screened for intestinal polyposis and Gardner syndrome. A combined endoscopic and external surgical approach was planned for the symptomatic right frontal sinus osteoma.

RESULTS

The right frontal sinus osteoma was successfully excised using a combined endoscopic approach and external trephination with a 3-cm eyebrow incision. Intraoperative ophthalmologic examination revealed a normal optic disc. The suspicious area on the medial wall of the frontal sinus was repaired using Surgicel and tissue sealant.Left-sided osteomas were not surgically treated due to their small size and lack of clinical symptoms. Postoperative follow-up was uneventful, and the patient remained symptom-free with a good general condition.

CONCLUSIONS

Bilateral frontal and ethmoid sinus osteomas are extremely rare entities. Surgical treatment should be individualized based on tumor size, localization, extension, and symptomatology. Combined endoscopic and external approaches provide effective and safe management for large or complex frontal sinus osteomas. Early diagnosis and appropriate surgical planning are crucial to prevent potential orbital and intracranial complications.

Frontal sinus osteoma; Ethmoid sinus osteoma; Paranasal sinus tumors; Surgical approach

PP-680

The Effectiveness Of Dupilumab In Treating Pediatric Refractory Allergic Fungal Rhinosinusitis

Hussain AlJubarn[1], **Ali Almomen**[2]

[1]*Al Jabr Eye and ENT hospital, Al-ahsa, Saudi Arabia;* [2]*King Fahad Specialist Hospital, Dammam, Saudi Arabia*

BACKGROUND & AIM

Allergic fungal rhinosinusitis (AFRS) is a benign, extramucosal, non-invasive fungal condition of the paranasal sinuses caused by a type 1 IgE-mediated hypersensitivity reaction. It primarily affects young adults but may also occur in children. Although biologic therapies such as Dupilumab have shown favorable results in adult AFRS, their use in the pediatric population remains undocumented. This study aims to present the first reported case of a pediatric patient with refractory AFRS and bronchial asthma successfully treated with Dupilumab.

MATERIAL & METHODS

A pediatric patient with refractory AFRS and coexisting bronchial asthma was treated with subcutaneous Dupilumab, starting with a loading dose of 600 mg, followed by 300 mg every two weeks. The patient's clinical, endoscopic, and radiological findings were evaluated before and after initiation of treatment to assess therapeutic response.

RESULTS

Following Dupilumab therapy, the patient demonstrated marked clinical improvement, reduced sinonasal symptoms, and enhanced endoscopic and radiological outcomes. Additionally, the patient's bronchial asthma was effectively controlled during follow-up, with no reported adverse effects.

CONCLUSIONS

Dupilumab appears to be a safe and promising treatment for pediatric patients with refractory AFRS, showing significant improvement in both sinonasal disease control and asthma symptoms. Further studies with larger pediatric cohorts and long-term follow-up are required to validate these findings.

Fulminant Rhino-Orbital Mucormycosis With Subtle Early Imaging Findings Following Steroid Exposure: A Case Requiring Orbital Exenteration

ZELİHA BERFU KASTAL[1], **KARDELEN KAYIŞ**[1], **ÖMER FARUK ÇUFALI**[1], **MEHMET ALİ ÇETİN**[1]

[1]*ANKARA BİLKENT CITY HOSPITAL*

BACKGROUND & AIM

Rhino-orbital mucormycosis is an aggressive angioinvasive fungal infection associated with high morbidity and mortality, most commonly occurring in patients with uncontrolled diabetes mellitus or immunosuppression. Early diagnosis may be challenging because initial clinical and radiological findings can be nonspecific, and delays in treatment may substantially worsen outcomes.

MATERIAL & METHODS

A 74-year-old male patient with diabetes mellitus, hypertension, and obesity presented with right periorbital swelling and headache. He had received systemic corticosteroid therapy for facial paralysis 10 days before presentation. Initial imaging demonstrated sinonasal soft-tissue opacification without definite orbital involvement. However, the patient showed rapid clinical progression, with the development of proptosis, complete ptosis, ophthalmoplegia, and reduced visual acuity. Despite empirical antibiotic therapy for presumed preseptal cellulitis, clinical deterioration continued. Endoscopic sinus surgery revealed necrotic tissue extending to the lamina papyracea. Histopathological examination confirmed mucormycosis, and liposomal amphotericin B therapy was initiated.

RESULTS

Despite systemic antifungal therapy and initial surgical debridement, the patient's condition continued to deteriorate, with progressive orbital involvement extending toward the orbital apex and optic nerve, accompanied by near-total ophthalmoplegia. Orbital exenteration was therefore performed, revealing extensive necrotic involvement reaching the orbital apex. Postoperatively, serial debridement and systemic antifungal therapy were continued. Follow-up endoscopic and radiological evaluations showed no residual necrotic tissue or intracranial extension.

CONCLUSIONS

Rhino-orbital mucormycosis may present with limited early radiological findings despite rapid clinical progression. A high index of clinical suspicion is essential, particularly in diabetic patients with recent corticosteroid exposure. Early initiation of systemic antifungal therapy combined with prompt and aggressive surgical debridement is critical for disease control. Orbital exenteration should be considered in selected cases with advanced orbital involvement, optic nerve or orbital apex extension, and poor response to conservative surgical and medical treatment. Treatment decisions should be individualized through a multidisciplinary approach.

KEYWORDS

rhino-orbital mucormycosis, angioinvasive fungal infection, endoscopic sinus surgery, surgical debridment, orbital exenteration

PP-682

A Modified Double-Pass Transseptal Conchopexy Technique To Facilitate Knot Tying During Middle Turbinate Preservation In Endoscopic Sinus Surgery

Pilar Benavent Marín[1], **Daniela Páez Mantilla**[1], **Hander Guillermo Acosta Díaz**[1], **Daniel Nuñez Carlino**[1], **Luz López Flórez**[1], **José Miguel Villacampa Aubá**[1]

[1]*Fundación Jiménez Díaz University Hospital*

BACKGROUND & AIM

Preservation of the middle turbinate during endoscopic sinus surgery (ESS) helps maintain anatomical landmarks, support nasal physiology, and facilitate postoperative endoscopic surveillance and revision procedures. However, postoperative middle turbinate lateralization and synechiae remain relevant technical challenges. Transseptal conchopexy is widely used to achieve medial stabilization, but suture placement and knot tying may be difficult within the narrow endonasal surgical field. We aim to describe a modified double-pass transseptal conchopexy technique routinely used in our department, designed to facilitate anterior knot tying while safely providing controlled bilateral medialization and stable preservation of both middle turbinates following ESS procedures.

MATERIAL & METHODS

This technical note describes the modified double-pass transseptal conchopexy performed after completion of endoscopic sinus surgery when preservation of both middle turbinates is desired. Under endoscopic visualization, a non-absorbable suture is first passed through the most anterior portion of the nasal septum, creating an accessible anterior anchoring point. From the right septal side, the needle is advanced through the right middle turbinate from lateral to medial, then across the septum, and subsequently through the left middle turbinate from medial to lateral. A second pass is then performed in the opposite direction: the suture re-enters the left middle turbinate from lateral to medial, crosses the septum from left to right, and exits through the right middle turbinate from medial to lateral. Both free ends are finally retrieved anteriorly and tied at the anterior septal region, allowing controlled bilateral medialization while avoiding deep intranasal knot tying and improving surgical ergonomics overall intraoperatively.

RESULTS

The modified double-pass transseptal conchopexy provided a reproducible way to stabilize both middle turbinates while keeping the knot in an anterior and accessible position. The sequential passage of the suture through the septum and both middle turbinates created a symmetric fixation, allowing controlled medialization without excessive traction on the turbinate mucosa. By returning the suture anteriorly before tying, knot manipulation was performed outside the deepest portion of the nasal cavity, reducing the technical difficulty usually associated with conventional transseptal conchopexy. The technique was easily integrated after completion of endoscopic sinus surgery and did not interfere with the surgical cavity or postoperative endoscopic access. In our experience, the maneuver was useful in cases where middle turbinate preservation was desired and there was concern for postoperative lateralization or synechiae. No specific additional instrumentation beyond a standard needle holder and suture was required, making it practical for routine use in selected patients.

CONCLUSIONS

The modified double-pass transseptal conchopexy is a simple, reproducible technical modification for middle turbinate preservation during endoscopic sinus surgery. By returning the suture to an anterior septal position before knot tying, the technique improves accessibility and may reduce the difficulty of deep intranasal knot manipulation. The double-pass configuration provides bilateral and symmetric medialization of the middle turbinates, helping maintain surgical landmarks and postoperative endoscopic access. This maneuver requires no specific instrumentation and can be easily incorporated into routine practice in selected cases after ESS procedures. Further prospective studies are warranted to evaluate its impact on lateralization, synechiae, and long-term outcomes.

PP-683

Oncocytic Schneiderian Papilloma Of The Nasopharynx: An Unusual Cause Of Severe Obstructive Sleep Apnea

Tang Yita[1], **Khairina Adliah Kamal Ariffin**[1], **Ahmad Fazlin Bin Nasaruddin**[1], **Luqman Bin Rosla**[1]

[1]*Hospital Sultan Haji Ahmad Shah, Malaysia*

BACKGROUND & AIM

Sinonasal papillomas are benign epithelial neoplasms of the sinonasal tract. Among them, the Oncocytic Schneiderian Papilloma (OSP) is a rarer variant, often overshadowed by its more common counterpart, the Inverted Papilloma (IP). This report delves into a unique presentation of nasopharyngeal OSP in a patient exhibiting severe symptoms of Obstructive Sleep Apnea (OSA), emphasizing the intricate relationship between the two conditions and the challenges they pose in clinical management.

MATERIAL & METHODS

A 37-year-old Malay male with a history of active smoking presented with a year-long complaint of bilateral nasal obstruction, worsened over the past two months, accompanied by foul-smelling nasal discharge. He also experienced significant loud snoring and apnea episodes during sleep. Physical examination noted reduced misting bilateral nostrils, and nasoendoscopy identified a smooth looking pink lobulated mass in the nasopharynx. CT showed a homogeneous mass in the fossa of Rosenmüller, confined to the nasopharynx, extending down to level of soft palate. His BMI was 31.5, and the Apnea-Hypopnea Index (AHI) was 56. He underwent excision of nasopharynx mass, tonsillectomy and pharyngoplasty. Histopathology confirmed oncocytic Schneiderian papilloma. The patient was managed with desloratadine, mometasone furoate nasal spray, and repeated sleep study showed significant reduction in AHI score (11).

RESULTS

Oncocytic Schneiderian Papillomas (OSPs) are rare benign tumors of the sinonasal tract, accounting for 3–5% of Schneiderian papillomas. They typically present with nasal obstruction, epistaxis, and, in some cases, OSA. The association between OSPs and OSA is not well-established, but in this case, the tumor's nasopharyngeal location and bilateral extension likely contributed to severe OSA symptoms. Treatment involves complete surgical excision, often via endoscopic sinus surgery (ESS), which is

minimally invasive with lower morbidity. However, the tumor's size and location in this case required a combined approach, including adenoidectomy, tonsillectomy, and pharyngoplasty. Postoperative management typically includes nasal corticosteroids and antihistamines to reduce inflammation and prevent recurrence. The patient's severe OSA (AHI 56) underscores the impact of sinonasal pathologies on sleep quality. Addressing nasal obstruction through surgery is essential for improving OSA symptoms, with postoperative follow-up and repeat sleep studies to assess resolution and guide further management.

CONCLUSIONS

This case underscores the importance of considering OSPs in the differential diagnosis of patients presenting with nasal obstruction and OSA symptoms. A comprehensive approach, including appropriate imaging, surgical intervention, and postoperative management, is essential in effectively treating OSPs and associated OSA.

Acute Complicated Sinusitis Presenting With A Subperiosteal Orbital Abscess In A 17-Year-Old Adolescent: A Case Report

H. Deniz Demir Kılıç[1], **Nuri Ünsal**[1], **Mehmet Yaşar**[1]

[1]*Kayseri City Hospital, Clinic of Otorhinolaryngology, Kayseri, Türkiye*

BACKGROUND & AIM

Subperiosteal orbital abscess (SPOA), classified as Stage III according to the Chandler criteria, is a critical complication originating from acute bacterial rhinosinusitis that carries a substantial risk of permanent blindness and intracranial extension. This presentation aims to report the clinical features of an SPOA case arising during the course of acute rhinosinusitis, highlight the definitive role of contrast-enhanced CT and MRI in the diagnostic workup, and discuss the management combining aggressive, broad-spectrum IV antibiotic therapy with prompt surgical decompression in light of current literature

MATERIAL & METHODS

This is a retrospective clinical evaluation of a single case. A 17-year-old male adolescent presenting with an acute complicated rhinosinusitis-induced superior subperiosteal orbital abscess was evaluated. Diagnostic workup included nasal endoscopy, complete blood count, inflammatory markers (WBC, CRP), contrast-enhanced orbital CT, and MRI. Interventions consisted of urgent multidisciplinary surgical decompression (right functional endoscopic sinus surgery combined with external abscess drainage) and culture-guided, broad-spectrum IV antibiotic therapy managed jointly by Otorhinolaryngology, Ophthalmology, and Pediatric Infectious Diseases departments.

RESULTS

In sinus-derived orbital complications occurring within the adolescent age group, the threshold for surgical drainage should be kept low due to distinct anatomical and microbiological variations characteristic of this population. Vigilant monitoring utilizing a multidisciplinary approach, timely surgical decompression, and aggressive, broad-spectrum IV antibiotic therapy covering anaerobic pathogens remain the cornerstones to preventing permanent visual loss and devastating intracranial sequelae.

CONCLUSIONS

Orbital complications of acute rhinosinusitis are ENT emergencies. Subperiosteal abscesses form posterior to the orbital septum, risking permanent visual sequelae in 15% to 30% of cases if mismanaged. While FESS with endoscopic decompression is the gold standard for medial abscesses, frontal sinusitis carries a high risk of polymicrobial infections.Therefore, maintaining targeted IV antibiotic therapy for at least two weeks or longer is essential to achieve complete resolution and prevent both recurrence and devastating intracranial complications.

JUVENILE NASOPHARYNGEAL ANGIOFIBROMA: CASE SERIES

Eyüp Berk[1], **Berkay Yeşiller**[1], **Fatih Turhan**[1], **Esra Altunal**[1], **İpek Yeşil**[1], **Büşra Nur Coşan**[1], **Safiye Giran Örtekin**[1], **Şahin Öğreden**[1], **Özgür Yiğit**[1]

[1]*Başakşehir Pine and Sakura City Hospital*

BACKGROUND & AIM

Juvenile nasopharyngeal angiofibroma (JNA) is a rare, benign but locally aggressive hypervascular tumor that occurs predominantly in adolescent males. It most often presents with unilateral nasal obstruction and recurrent epistaxis and may extend to the pterygopalatine fossa, infratemporal fossa, maxillary sinus, orbit, and skull base. We present three surgically treated JNA cases with different radiologic and anatomic extension patterns.

MATERIAL & METHODS

Three male patients aged 13, 16, and 19 years who underwent surgery for JNA were reviewed retrospectively. Clinical presentation, computed tomography and magnetic resonance imaging findings, surgical technique, and postoperative outcomes were evaluated. Surgical planning was based on tumor extent. Preoperative angiography, with embolization when indicated, is generally recommended as an adjunct to reduce intraoperative bleeding; however, its use was not specified in these cases.

RESULTS

All three patients presented with unilateral nasal obstruction and epistaxis. In the 16-year-old patient, imaging showed a left-sided mass extending from the sphenopalatine foramen into the nasal cavity and nasopharynx, widening the pterygopalatine fossa and progressing toward the infratemporal fossa and skull base. Surgery was started endoscopically but completed with a combined endoscopic and Weber–Ferguson approach because of advanced lateral extension. The 19-year-old patient had a more limited right-sided lesion centered at the sphenopalatine foramen with extension to the choana and nasopharynx, and complete resection was achieved by a purely endoscopic transnasal approach. The 13-year-old patient had a large left-sided tumor filling the maxillary sinus, protruding into the nasal cavity, and extending to the infratemporal and prezygomatic regions; this lesion was removed using an expanded endoscopic approach with medial maxillectomy. Gross total resection was achieved in all cases.

CONCLUSIONS

Management of JNA requires careful radiologic assessment and a surgical plan tailored to tumor extent. Endoscopic surgery is effective in selected cases, whereas combined approaches remain important for lesions with extensive lateral or skull base extension. In this series, individualized surgical treatment provided successful tumor control without major morbidity and no major intraoperative or postoperative complications were observed, and no residual tumor was identified in the immediate postoperative period.

Re-Emergence Of Human Nasal Myiasis By Cochliomyia Hominivorax In Central America: An Extensive Endoscopic Surgical Case From Guatemala

Oséas Abinadi Cuyuch Guox[1], **Melvyn Moran Álvarez**[1], **Jorge Bernardo Pellecer Cano**[1]

[1]*Instituto Guatemalteco de Seguridad Social IGSS*

BACKGROUND & AIM

Human myiasis is a parasitic infestation caused by dipterous larvae. Nasal involvement by Cochliomyia hominivorax (New World screwworm) is rare but potentially aggressive, especially in regions with recent epidemiological alerts. We report an extensive case of sinonasal and nasopharyngeal myiasis requiring surgical reintervention and discuss its clinical and public health implications.

MATERIAL & METHODS

A 51-year-old male from Alta Verapaz, Guatemala, presented with worsening headache and epistaxis after nasal packing for epistaxis. Nasal endoscopy revealed multiple live larvae in the left nasal cavity and nasopharynx. CT imaging was performed to evaluate disease extension. The patient underwent endoscopic surgical removal and irrigation under general anesthesia. Extracted larvae were sent for laboratory identification. Due to incomplete removal during the first procedure, a second endoscopic intervention was performed. Adjunctive treatment included systemic antibiotics and single-dose ivermectin.

RESULTS

Larvae were identified in the maxillary sinus, frontal recess, nasopharynx (including the Rosenmüller fossa), and near the Eustachian tube orifice. A total of approximately 100 larvae were removed in two surgical procedures. Laboratory analysis confirmed Cochliomyia hominivorax (L3 stage). Complete eradication was technically challenging due to anatomical proximity to vascular structures. The patient showed favorable evolution, with no residual infestation on follow-up, although localized mucosal tissue loss was observed.

CONCLUSIONS

This case highlights the destructive potential of C. hominivorax nasal myiasis, the importance of early surgical intervention, and the technical challenges of complete endoscopic removal in deep sinonasal spaces. In endemic or re-emerging regions, otolaryngologists must maintain high clinical suspicion and consider the possible role of local epidemiological factors.

ADULT INTRANASAL GLIAL HETEROTOPIA WITH SPHENOIDAL EROSION: A RARE CASE REPORT AND 5 YEAR FOLLOW-UP.

Carmen Manzanares López-Rendo[1], **Lucía Clement Alonso**[1], **Ana Martín González**[1], **Elena Balduz Moreno**[1], **Sara Fernández Cascón**[1], **Javier Martinez Martinez**[2], **Ignacio Álvarez Álvarez**[1], **Claudia Llorente Alvarez**[1], **Gerardo José Martín Sigüenza**[1]

[1]*ENT department at Complejo Asistencial Universitario de León;* [2]*Pathology department at Complejo Asistencial Universitario de León*

BACKGROUND & AIM

Nasal glioma is a rare congenital malformation formed by the appearence of heterotopic central nervous system tissue in the nasal cavity. It is usually diagnosed during childhood, with very few adult cases reported in the literature. It may present as a subcutaneous extranasal mass, an intranasal polypoid lesion, or a combination of both. CT scan and MRI are essential diagnostic tools used to differentiate nasal glioma from encephalocele and to rule out intracranial communication. Definitive diagnosis is established through histopathological and immunohistochemical analysis, typically showing positivity for S100 protein and glial fibrillary acidic protein (GFAP).

MATERIAL & METHODS

We present the case of a 39-year-old man who consulted for progressive right nasal obstruction. Nasofibroscopy revealed a polypoid lesion arising from the posterior nasal septum, almost completely occupying the right choana. CT imaging demonstrated a heterogeneous lesion measuring 3.6 × 1.7 × 1.4 cm, associated with remodeling of the posterior vomer and erosion of the floor of the right sphenoid sinus.

RESULTS

Endoscopic endonasal surgery was performed, revealing a polypoid-cystic lesion originating from the intersphenoidal septum. Posterior septectomy and complete excision of the lesion were achieved. Histopathological and immunohistochemical studies confirmed the diagnosis of nasal glial heterotopia (nasal glioma) positive for S100 protein and glial fibrillary acidic protein (GFAP). The postoperative course was uneventful, and after 5 years of follow-up, the patient remains asymptomatic with no evidence of recurrence.

CONCLUSIONS

Adult nasal glioma is an exceptional entity that should be included in the differential diagnosis of unilateral nasal masses. Preoperative radiological evaluation is essential to exclude intracranial communication and avoid potentially harmfull procedures such as outpatient biopsy. Endoscopic surgery provides a safe and effective treatment with excellent long-term control.

Nasal glioma, Adult presentation, Sphenoid Sinus, Nasal glial heterotopia, Endoscopic surgery, Unilateral nasal mass.

PP-688

Atypical Polymicrobial Nasal Dorsum Abscess Secondary To Septal Hematoma Induced By Concurrent Rhinoplasty And Perforation Repair In A Celiac Patient

Caner Tonkaz[1], **Yavuz Beşli**[1], **Muratcan Sarı**[1], **Emine Deniz Gözen Tan**[1]

[1]*İstanbul Univercity-Cerrahpaşa, Cerrahpaşa Faculty of Medicine, Department of Otorhinolaryngology, İstanbul, Turkey.*

BACKGROUND & AIM

Performing concurrent rhinoplasty and nasal septal perforation repair severely alters local tissue hemodynamics and increases surgical dead space, directly predisposing patients to septal hematoma formation. While hematomas are known complications, their evolution into an atypical, polymicrobial nasal dorsum abscess is exceptionally rare. This report presents a unique case where a massive septal hematoma, strictly induced by the extensive dissection of simultaneous perforation repair and rhinoplasty, served as the exact nidus for a devastating polymicrobial (Pseudomonas aeruginosa and MRSA) dorsal abscess. We aim to emphasize how the mechanical alterations of this concurrent surgery cascade into severe, atypical infections.

MATERIAL & METHODS

A 28-year-old female with a medical history of celiac disease presented in June 2025 with severe nasal obstruction and aesthetic dissatisfaction. Endoscopy revealed an approximately 1 cm anterior septal perforation, a nasal dorsal hump, and weak tip support. The patient underwent concurrent rhinoplasty and septal perforation repair. Postoperatively, internal silicone and external thermal splints were applied. On the 7th postoperative day, upon external splint removal, the nasal dorsum appeared severely erythematous, edematous, and highly tender. Recognizing that the concurrent procedures likely caused a large septal hematoma—now presenting with signs of an evolving atypical abscess—the patient was immediately taken to the operating room for emergency exploration and surgical drainage.

RESULTS

Emergency exploration evacuated copious purulent fluid from the nasal dorsum and septal space, confirming an abscess superimposed on a surgically-induced septal hematoma. Intraoperative cultures were obtained, and empiric intravenous

ceftriaxone and metronidazole were initiated. By postoperative day 2, cultures grew Pseudomonas aeruginosa. Subsequent advanced evaluation by Infectious Diseases revealed co-infection with Methicillin-Resistant Staphylococcus aureus (MRSA), confirming a polymicrobial etiology. The patient received a targeted 3-week intravenous teicoplanin regimen. While aggressive systemic therapy eradicated the infection, the atypical abscess caused severe cartilaginous necrosis, resulting in a saddle nose deformity. A delayed revision rhinoplasty utilizing costal cartilage grafting is currently planned to reconstruct the structural deficit.

CONCLUSIONS

The concurrent execution of rhinoplasty and septal perforation repair creates extensive dead space and vascular compromise, acting as the primary causal factor for septal hematoma formation. This case illustrates a severe domino effect where the surgery-induced hematoma provided an ideal breeding ground for a destructive, polymicrobial (Pseudomonas and MRSA) onslaught, culminating in an atypical nasal dorsum abscess. Surgeons must be hyper-vigilant regarding hematoma risk during combined procedures. Early recognition upon splint removal and urgent surgical drainage are critical to halt this infectious cascade, though irreversible cartilage necrosis may still necessitate complex structural revision.

KEYWORDS

Rhinoplasty, septal perforation repair, septal hematoma, atypical nasal dorsum abscess, polymicrobial abscess, MRSA, Pseudomonas aeruginosa, celiac disease, saddle nose.

PP-689

Coblator-Assisted Endoscopic Total Excision Of A Nasal Glomus Tumor: A Rare Case Report

Berika Çakmak[1], **Oğuz Can Karakaş**[1], **Deniz Baklacı**[1], **Duygu Erdem**[1]

[1]*Department of Otolaryngology, Zonguldak Bulent Ecevit University Faculty of Medicine*

BACKGROUND & AIM

Glomus tumors (GT) are rare benign mesenchymal neoplasms, most commonly found in the distal extremities. Sinonasal glomus tumors are extremely rare, accounting for only 0.4% of non-epithelial tumors in this region. Due to their high vascularity, surgical excision carries a significant risk of intraoperative bleeding.

MATERIAL & METHODS

A 60-year-old female presented with a six-month history of left-sided nasal obstruction and intermittent epistaxis. Physical examination revealed a red-purple, tender polypoid mass obstructing the left nasal passage. Imaging showed a highly vascularized 4.5 cm mass. Following a biopsy confirmed benign glomus tumor, the lesion was totally excised via an endoscopic approach. To ensure hemostasis and clear visualization, coblator technology (Evac 70) was utilized during the procedure. The coblator facilitated precise dissection while providing simultaneous coagulation at low thermal temperatures. No postoperative complications or recurrences were observed during the one-year follow-up

RESULTS

Although rare, sinonasal glomus tumors should be considered in the differential diagnosis of vascular nasal masses. Complete surgical excision is the primary treatment. The use of coblator-assisted endoscopic surgery offers a safe and effective alternative by providing superior bleeding control and minimizing thermal damage to surrounding tissues.

CONCLUSIONS

Sinonasal glomus tumors are rare benign vascular lesions that should be considered in patients presenting with nasal obstruction and epistaxis. Accurate preoperative diagnosis is essential for appropriate surgical planning and safe tumor removal. In the present case, the lesion was successfully diagnosed by biopsy and completely excised using an endoscopic approach. Coblator-assisted surgery provided effective intraoperative hemostasis, improved visualization of the surgical field, and reduced thermal injury to adjacent tissues. These advantages contributed to a safe and minimally invasive procedure with successful outcomes. Therefore, coblator-assisted endoscopic excision may represent a reliable treatment option for vascular tumors of the sinonasal region.

Clinical Efficacy Of Low - Power LED (Light Emitting Diode) , Light Irradiator In Allergic Rhinitis Patients

Ju Hyoung Lee[1], **Joo Hyun Jung**[1], **Seon Tae KIm**[1]

[1]*Department of Otolaryngology, Head and Neck Surgery, Gil Medical Center, School of Medicine, Gachon University, Incheon, South Korea.*

BACKGROUND & AIM

This study aimed to evaluate the clinical efficacy of patients with allergic rhinitis using a low-power LED (Light Emitting Diode) light irradiator for investigational medical devices.

MATERIAL & METHODS

The clinical trial subjects of this study were a total of 24 allergic rhinitis patients. 12 patients in the control group (saline irrigation group) and 12 test group (low-power LED light irradiation group) were evaluated. The patients were children and adults 7 years of age and older. The test group and control group completed a symptom score evaluation diary once a day after applying each medical device for 28 days from the start of treatment.

RESULTS

The patient symptom scores (comprehensive) before and after the application of medical devices in the test group and the control group were compared with the results of pre-treatment-post-treatment (2 weeks)-post-treatment (4 weeks) (by period). The symptom evaluation items checked the change in symptom scores for runny nose, sneezing, nasal congestion, and itching. The symptom score was lower and statistically significant ($p<0.001$). Differences between groups were not statistically significant. In comparison to nasopharyngeal endoscopy improvement scores, the improvement score was increased over time, and it was statistically significant ($p<.001$). As a result of comparing the acoustic rhinometry results before and after the application of the medical device in the test group and the control group, it was not statistically significant ($p = .444$). In this clinical trial, no adverse events or serious adverse events occurred after the application of the medical device.

CONCLUSIONS

Four weeks of phototherapy using low-power LCD showed clinical effects equivalent to those of the saline irrigation group. This suggests that it can be used as an alternative and adjuvant treatment for improving clinical symptoms in patients with allergic rhinitis, such as saline irrigation in the future.

PP-691

Infected Nasolabial Cyst In A Child: A Rare Pediatric Case

Shin-woo Kim[1,2], **Woo Hyun Lee**[1,2]

[1]*Department of Otolaryngology, Kangwon National University Hospital, Chuncheon, Korea;* [2]*Department of Otolaryngology, Kangwon National University School of Medicine, Chuncheon, Korea*

BACKGROUND & AIM

Nasolabial cysts are uncommon, benign non-odontogenic lesions that predominantly affect middle-aged women. Pediatric cases are extremely rare, and few cases of infected nasal cysts in children have been reported worldwide. The pediatric nasolabial cysts—particularly those presenting with infection—are even less well documented. We present a case of a Korean child who developed facial swelling due to an infected nasolabial cyst and report this case to share our experience with this unusual presentation.

MATERIAL & METHODS

A 10-year-old boy presented to the emergency department with right nasal pain and progressive facial swelling. Physical examination revealed tenderness over the right nasal ala and cheek. Paranasal sinus computed tomography (PNS CT) demonstrated fat infiltration in the right facial soft tissue and a cystic lesion in the right nasolabial region, suggestive of an infected nasolabial cyst. The patient was admitted and managed conservatively with intravenous antibiotics. Definitive treatment with endoscopic marsupialization was performed six months after resolution of the acute inflammatory phase.

RESULTS

The patient showed rapid improvement following intravenous antibiotic therapy, with complete resolution of facial swelling by the time of discharge. Endoscopic marsupialization was successfully performed without complications, and the patient has remained symptom-free with no evidence of recurrence during follow-up.

CONCLUSIONS

Nasolabial cysts complicated by infection are exceedingly rare in the pediatric population, and only a few cases have been reported in the literature to date. This patient improved with stepwise management consisting of medical treatment followed by marsupialization. We present this case to share our experience with this rare pediatric presentation.

Pyoderma Gangrenosum Of The Nasal Dorsum Mimicking Septal Abscess – A Rhinologic Diagnostic Pitfall

Pawel Tymrakiewicz[1], **Pawel Golusinski**[1]

[1]*Department of Otolaryngology and Laryngological Oncology, Provincial Hospital in Poznan, Poznan, Poland*

BACKGROUND & AIM

Pyoderma gangrenosum (PG) is a rare neutrophilic dermatosis most commonly affecting the lower extremities. Nasal involvement is exceptionally uncommon and may mimic severe bacterial infection, including septal abscess or complicated

cellulitis. In rhinologic practice, this may lead to delayed diagnosis and potentially harmful surgical interventions due to pathergy. The aim of this report is to present a rare case of PG involving the nasal dorsum and septal region, highlighting diagnostic challenges and therapeutic implications for otolaryngologists.

MATERIAL & METHODS

We present a retrospective analysis of a single clinical case managed in a tertiary referral center. Clinical presentation, radiologic findings, microbiological results, histopathology, treatment course, and follow-up were reviewed.

RESULTS

A 55-year-old male presented with progressive erythema, painful swelling of the nasal dorsum, purulent discharge, and nasal obstruction. Additional ulcerative skin lesions were present on the trunk and upper limbs. His medical history was significant for ulcerative colitis.

Imaging demonstrated nasal mucosal edema without clear features of acute sinusitis. Despite broad-spectrum antibiotic therapy and surgical drainage of a suspected septal abscess, rapid progression of necrotic ulceration involving the nasal dorsum and eyelids occurred. Repeated microbiological cultures remained sterile. Histopathological examination supported neutrophilic dermatosis.

Following initiation of systemic corticosteroid therapy, rapid clinical improvement and arrest of tissue destruction were observed. Recurrence associated with exacerbation of inflammatory bowel disease required biological therapy with infliximab, resulting in sustained remission.

CONCLUSIONS

Pyoderma gangrenosum should be considered in rapidly progressive, culture-negative nasal ulcerations unresponsive to antibiotic therapy, particularly in patients with inflammatory bowel disease. Early recognition is crucial in rhinologic practice to avoid unnecessary surgical procedures and to initiate prompt immunosuppressive treatment.

How Biological Treatment Can Change The Course Of A Rare Immunological Disease

Magdalena Arcimowicz[1]

[1]*Department of Otorhinolaryngology, Head and Neck Surgery, Medical University of Warsaw, Poland*

BACKGROUND & AIM

IgG4-related disease is a rare, immune disease with hyper-IgG4-gamma-globulinemia and fibro-inflammatory lesions that can occur in any organ. Diagnosis requires integration of clinical, radiological, serological and histopathological findings, as serum IgG4 elevation alone is insufficient. In otorhinolaryngological practice, IgG4-related disease should be taken into account in the differential diagnosis of patients with salivary or lacrimal gland enlargement, with eyelid edema and chronic rhinosinusitis. Systemic glucocorticosteroids are the first line of treatment and can be combined with other immunosuppressants or biological treatment. The prognosis is favorable, but delay in diagnosis and therapy can lead to multiple organ failure and premature death.

MATERIAL & METHODS

A woman, first time admitted to our ENT Department at the age of 38; initially treated for allergic rhinitis, asthma and eyelid edema, accompanied by rhinosinusitis, and history of numerous comorbidities (Hashimoto's disease, parotid tumor, idopathic hepatitis, anemia and albinism). Imaging studies confirmed enlargement of the salivary and lacrimal glands with the upper eyelids edema and rhinosinusitis. The patient was qualified for sinus surgery. Postoperative histopathological examination enabled the diagnosis of IgG4-related disease. For next 5 years, patient received prednisone and azathioprine, then prednisone and methotrexate, inhaled and nasal steroids. Eyelid oedema resolved, asthma and allergic rhinitis were well controlled.

RESULTS

Despite the treatment, sinus symptoms gradually worsened and were accompanied by headaches. The patient was diagnosed with a mucocele of the left frontal sinus qualified for sinus resurgery. Despite intensive treatment, mucocele of the right frontal sinus developed in the postoperative period. Finally, another radical surgery (Draf III) was performed on the frontal sinuses. The patient also presented with other signs of progression of IgG4-related disease, including a twofold increase in serum IgG4

concentration.The lack of full control of the disease as manifested by the difficult-to-treat rhinosinusitis, became the basis for the patient, at the age of 44, being qualified for biological treatment with rituximab.The patient has been treated with scheduled rituximab infusions over the past two years, resulting in complete resolution of symptoms involving the upper respiratory tract, orbital, and systemic organ manifestations, as well as normalization of serum IgG4 concentrations.

CONCLUSIONS

Glucocorticoids remain standard induction therapy in IgG4-related disease, but relapses and steroid toxicity are common. Rituximab, an anti-CD20 monoclonal antibody, plays a key steroid-sparing role by depleting B cells and plasmablast precursors. It is particularly useful in relapsing, refractory, multiorgan or organ-threatening IgG4-related disease, often producing rapid and sustained clinical improvement.

ENDOSCOPIC APPROACH IN DACRYOCYSTOCELE AND DACRYOCYSTORINOSTOMY - THE ROLE OF THE ENT AND OUR EXPERIENCES

Vladan Milutinovic[1,2], **Zorana Radin**[1], **Snezana Babac**[1,3]

[1]*Clinic for Ear, Nose, and Throat, Zvezdara University Medical Center, Belgrade, Serbia;* [2]*Faculty of Dental Medicine, University of Belgrade, Belgrade, Serbia;* [3]*Faculty of Special Education and Rehabilitation, University of Belgrade, Belgrade, Serbia*

BACKGROUND & AIM

Dacryocystitis in newborns in 90-95% of cases resolves spontaneously within the first year of life. Recurrent infections, dacryocystocele or failure of conservative treatment, surgical intervention is necessary. Clinical aspects of congenital and acquired dacryocystitis, clinical presentation, and therapeutic options, are analyzed. Special emphasis is placed on surgical treatment - endoscopic approach and endonasal marsupialization of congenital dacryocystitis. The indications for the application of the endoscopic method and complications were discussed. This study aims to present a series of cases of congenital dacryocystocele in infantsand their treatment, as well as the role of the otorhinolaryngologist in dacryocystorhinostomy from our experience.

MATERIAL & METHODS

This case study evaluates a series of 6 cases of congenital dacryocystocele in infants aged 0 to 6 months who presented with a with ocular symptoms (epiphora, cellulitis, and dacryocystocele) and even mild stridor refered by neonathologist or ophthalmologist. A comprehensive diagnostic workup was conducted, including nasal endoscopy performed by ent specialist using otoendoscope. In all the cases intranasal cysts - dacryocystocele was found and under local anesthesia marsupialization was performed. Folow up examinations was performed in folowing weeks and monts by otorhinolaryngologist and ophthalmologist.

RESULTS

Infants exhibiting respiratory symptoms, even mild stridor, with or without ocular symptoms (epiphora, cellulitis, and dacryocystocele), must undergo endoscopic evaluation. Endoscopic dacryocystorhinostomy performed by ophthalmologist allows a minimally invasive approach with direct visualization of anatomical structures, preserving the integrity of the surrounding tissues and avoiding external scars. Potential complications, such as stent occlusion, bleeding or infection, occur rarely and significantly less often compared to the classic external approach. Role of ent is reserved for cases with complex nasal anatomy(bulose or hypertrofic inferior conha). In children with intranasal cysts, dacryocystocele, endoscopic marsupialization has proven to be a simple and effective method that eliminates the risks of general anesthesia and reduces the need for repeated interventions. This intervention can be performed by ent specialist due to better understanding of nasal anatomy and surgical experience in sinus surgery. Surgical success was also achieved in all our 6 patients without complications.

CONCLUSIONS

Treatment of dacryocystitis requires a multidisciplinary approach of ophthalmologists and otorhinolaryngologists. The endoscopic endonasal approach is a safe, effective and minimally invasive method that improves the outcome of treatment in children and adults, with a significant reduction in complications and a better postoperative result.

Dense Osteoma Of Ethmoid Sinus

Mehmet Kağan Bakır[1], **Faruk Kadri Bakkal**[1]

[1]*Uşak Univercity Hospital Otolaryngology Department*

BACKGROUND & AIM

Paranasal sinus osteomas are rare, slow-growing lesions and represent the most common benign tumors of the paranasal sinuses. Clinical presentation varies widely, ranging from completely asymptomatic cases to symptoms such as headache and orbital complications. Most patients become symptomatic only after the lesion reaches a considerable size. In this case report, we present the endoscopic surgical removal of a large, dense osteoma originating from the left ethmoid sinus, abutting the medial orbital wall and extending toward the orbital apex.

MATERIAL & METHODS

A 70-year-old female patient presented with a three-month history of headache predominantly localized to the left side of the face and the left orbital region. The patient had previously received medical treatment for presumed sinusitis from a family physician but was referred to our clinic after the treatment failed to relieve her symptoms. Endoscopic nasal examination revealed no findings suggestive of sinusitis. Preoperative computed tomography demonstrated a dense bony mass located in the left ethmoid sinus extending toward the left orbital apex.

RESULTS

The patient's headache and orbital symptoms resolved immediately after surgery. At the two-month postoperative follow-up, no complications were observed, and the patient remained asymptomatic.

CONCLUSIONS

Pathological examination confirmed diagnosis of dense osteoma. Fibrous dysplasia should be considered in differential diagnosis when a bony mass is detected on CT. Asymptomatic ethmoid sinus osteomas may continue to enlarge until they impair sinus ventilation, which can subsequently lead to infection. Therefore, surgical treatment may be considered even in patients who are not yet symptomatic. During surgery, care is required to avoid injury to adjacent structures, orbital complications can occur when operating in the ethmoid sinus region. Compared with open techniques, endoscopic surgery offers cosmetic advantages. With use of powered instruments, even large osteomas can be successfully removed endoscopically.

Oral–Nasolacrimal-Orbital Fistula Following Pediatric Facial Trauma: A Rare Case Report And Literature Review

AYBİKE TAŞKIN[1], **ERHAN ARSLAN**[1], **BÜLENT ÖCAL**[1], **BERNA UÇAN**[1], **ÇİĞDEM ÜNER**[1], **CEM SAKA**[1]

[1]*ANKARA ETLIK CITY HOSPITAL*

BACKGROUND & AIM

Palatal fractures in children are less frequently observed compared to adults due to the greater elasticity of pediatric bone structures. Although pediatric palatal fractures typically occur after high-energy trauma and are commonly associated with craniofacial bone fractures, clinicians should be aware that isolated hard palate fractures may rarely develop and can fistulize to the orbit through the nasolacrimal system.

This case report presents a 9-year-old female patient who developed an isolated hard palate fracture following a fall-related facial trauma.This fracture extended through the nasolacrimal system to the orbit, ultimately leading to food appearance.

MATERIAL & METHODS

A 9-year-old female patient who sustained facial trauma after a fall was evaluated clinically and radiologically. The diagnostic work-up and follow-up process were documented.

RESULTS

The fracture originated from a midline mucosal defect of the hard palate and extended to the orbit via the nasolacrimal system, resulting in regurgitation of ingested food through the eye.

CONCLUSIONS

Although pediatric palatal fractures typically occur after high-energy trauma and are commonly associated with craniofacial bone fractures, clinicians should be aware that isolated hard palate fractures may rarely develop and can fistulize to the orbit through the nasolacrimal system.

A RARE CASE REPORT OF INTRANASAL MASS: GIANT CONCHA BULLOSA IN AN ADULT PATIENT

Arş. Gör. Dr. Raşit HOŞGEL[1], **Dr. Öğr. Üyesi Sinan SEYHAN**[1], **Arş. Gör. Dr. Ramazan USLU**[1]

[1]*Amasya Üniversitesi Tıp Fakültesi Sabuncuoğlu Şerefeddin Eğitim ve Araştırma Hastanesi*

BACKGROUND & AIM

Concha bullosa is a condition called pneumatization of the turbinates in the nasal passage. The most common cases of concha bullosa are seen due to pneumatization of the middle turbinate. The most common complaints experienced by patients are nasal obstruction,difficulty breathing through the nose. Advanced examinations can be requested for patients presenting with these complaints, contributing to the differential diagnosis. The first examination that should be requested should be CT. This report,case of an adult patient who was thought to have a mass lesion during examination and had a giant middle turbinate bullosa on computed tomography scan was presented.

MATERIAL & METHODS

Endoscopic nasal examination and paranasal sinus computed tomography were performed. The lesion was evaluated radiologically and surgically treated with endoscopic approach. Histopathological examination was carried out following excision.

RESULTS

A 50-year-old female presented with a 6-year history of right-sided nasal obstruction, nasal discharge, dyspnea, and sneezing attacks. Despite prolonged intranasal steroid therapy, her symptoms persisted. Paranasal sinus computed tomography revealed a giant concha bullosa causing significant septal deviation to the left. Endoscopic examination demonstrated a smooth-surfaced mass originating from the middle turbinate and associated polypoid tissue. The patient initially refused surgery, but due to persistent symptoms, functional endoscopic sinus surgery and septoplasty were later performed. The lateral lamella and part of the medial lamella of the concha bullosa were excised, and the polypoid tissue was removed for pathological evaluation. No perioperative or postoperative complications occurred. Postoperatively, the patient experienced significant symptomatic relief and improvement in quality of life. Regular endoscopic follow-up showed no recurrence. This case highlights the importance of considering giant concha bullosa in patients with chronic unilateral nasal obstruction resistant to medical treatment.

CONCLUSIONS

Unilateral giant concha bullosa is a rare middle concha pathology. Unilateral nasal masses should also be considered in the differential diagnosis. As in our case, unilateral mass lesions can be incidentally identified as giant middle concha bullosa. It presents with non-specific obstructive symptoms such as difficulty smelling, recurrent rhinosinusitis attacks, nasal congestion, and headache. Diagnosis is often made incidentally with paranasal sinus computed tomography. Treatment is surgical. After treatment, a near-complete improvement in quality of life is observed with symptom relief.

FUNGUS BALL AND ECTOPIC TOOTH IN MAXILLARY SINUS

Abdullah Kınar[1], **Faruk Kadri Bakkal**[1], **Beliz Dündar**[1]

[1]*Uşak University Faculty of Medicine, Uşak Training and Research Hospital, Department of Otorhinolaryngology, Uşak, Turkiye*

BACKGROUND & AIM

An ectopic tooth is defined as a tooth that develops or is positioned outside the normal dental arch and is a rare clinical condition. Location within the maxillary sinus is extremely rare and usually follows an asymptomatic course. However, in some cases, it may lead to non-specific symptoms such as chronic rhinosinusitis, facial pain, nasal discharge, and nasal obstruction. Fungal sinusitis is a chronic infection, particularly seen in the maxillary sinus, often characterized by a fungal mass (fungus ball). The coexistence of these two rare conditions has been reported in a very limited number of cases in the literature.

MATERIAL & METHODS

76-year-old male presented with a three-day history of binocular diplopia localized to the left side. The patient has left maxillary fungal sinusitis and left lateral maxillary ectopic tooth. Patient treated surgically.

RESULTS

76-year-old male presented with a three-day history of binocular diplopia localized to the left side. Neurology evaluation included a Cranial MRI and Paranasal Sinus CT for binocular diplopia confirmed the fungus ball with suspected minimal protrusion into the inferior wall of the left orbit and ectopic tooth. Physical Examination: Nasal endoscopy revealed a patent left middle meatus without active purulent discharge. However, a distinct expansion of the left medial maxillary wall toward the nasal cavity was observed. Ophthalmological consultation and examination confirmed binocular diplopia. Ocular mobility was found to be full in all directions of gaze. The patient treated surgically by prelacrimal approach. A fungus ball and an ectopic tooth were observed in the left maxillary sinus. At the end of the operation, a defect was observed in the left maxillary lateral wall at the location of the ectopic tooth.

CONCLUSIONS

Coexistence of an ectopic tooth and fungus ball in the maxillary sinus is quite rare and can be successfully treated with early diagnosis and an appropriate surgical approach.

USE OF THE BASKET FOR SALIVARY STONES IN SIALOENDOSCOPY: 10-YEAR RETROSPECTIVE STUDY

GIULIANNO MOLINA DE MELO[1,2], **Murilo Catafesta das Neves**[1,2], **Marcello Rosano**[1], **Rafael Dias Romero**[1,2], **Julia Geraldo Vieira**[3], **Pedro Salcci Nunes Faria**[3], **Guilherme Salcci Nunes Faria**[3]

BACKGROUND & AIM

Sialolithiasis is the main cause of obstructive salivary gland disease, occurring in 80% of cases in the submandibular gland and 20% in the parotid gland. The treatment of sialolithiasis has evolved with the introduction of sialendoscopy and microinstruments such as baskets and balloons, allowing intraductal manipulations. Currently, sialendoscopy is the main treatment option with high efficacy and improved quality of life. Objective: To demonstrate the effectiveness of using a basket in obstructive salivary calculi in sialoendoscopy in a 10-year study.

MATERIAL & METHODS

Retrospective study over 10 years, with a consecutive series of patients with obstructive submandibular and parotid sialolithiasis undergoing sialendoscopy, with successful complete removal using only a basket. The procedure was conducted according to the literature, with interventions for diagnosis and treatment, using a semi-rigid modular sialendoscope (1.3/1.7 mm diameter), support material, and following established standards.

RESULTS

A total of 224 sialoendoscopies were performed for obstructive disease, 189 (84.4%) for sialolithiasis. In 132 (69.9%) the calculus was removed with pure Sialendoscopy and Basket (SP), 105 (79.5%) women, mean age 44.8 years, 65.9% single calculi, 73.5% in the main duct, 100% mobile, 68.9% in the submandibular region, mean size of 4.3 mm, Retrograde Basket technique: 55.3%, mean procedure duration of 62 min, 0% complications and extraction rate with basket 100%.

CONCLUSIONS

Sialoendoscopy using a basket for the removal of obstructive sialolithiasis is safe and effective, with complete resolution of symptoms and a high success rate.

USE OF BALLOON FOR STENOSIS IN SIALOENDOSCOPY: 10-YEAR RETROSPECTIVE STUDY

GIULIANNO MOLINA DE MELO[1,2,3], **Murilo Catafesta das Neves**[1,2], **Marcello Rosano**[1], **Rafael Dias Romero**[1,2], **Julia Geraldo Vieira**[3], **Pedro Salcci Nunes Faria**[3], **Guilherme Salcci Nunes Faria**[3]

[1]*Departamento de Otorrinolaringologia e Cirurgia de Cabeça e Pescoço da Universidade Federal de São Paulo- UNIFESP, São Paulo, Brasil;* [2]*Departamento de Cirurgia de Cabeça e Pescoço– Hospital da Beneficência Portuguesa de São Paulo, São Paulo, Brasil;* [3]*Departamento de Cirurgia Geral – Hospital da Beneficência Portuguesa de São Paulo, São Paulo, Brasil*

BACKGROUND & AIM

Stenoses comprise 40% of salivary gland obstructions, prevalent in 1-2% of the population, with multifactorial etiology: autoimmune, actinic (radioiodine-RIT) and sialolithiasis. Symptoms include recurrent episodes of pain and swelling, with imaging studies for diagnosis. Sialoendoscopy is the gold standard of treatment, being both diagnostic and therapeutic with balloon dilation of stenoses, corticosteroid instillation and stent placement, resulting in improved quality of life. Objective: To demonstrate the efficacy of balloon sialoendoscopy in the treatment of salivary stenoses in a 10-year study.

MATERIAL & METHODS

Series of patients with obstructive sialadenitis due to salivary stenosis undergoing sialoendoscopy for dilation over 10 years. The procedure used a 1.1/1.3 mm modular sialoendoscope and support material. The stenoses were located, dilated with a balloon, corticosteroids were instilled, and a stent was placed, without complications.

RESULTS

224 sialoendoscopies were performed for obstructive disease, 35 (15.6%) only for stenoses with symptoms of swelling (96%) and pain (88%), with an average of 4.5/week. Thirty (13.4%) patients had RIT and 5 (2.2%) sialolithiasis. Women (80%), 44.8 years old, and 10 (29%) in the parotid gland. Balloon dilation and corticosteroid instillation were performed in 100%, stenting in 91.4%, with a duration of 62 min. Stent loss occurred in 7 (20%), without serious complications. Symptom recurrence occurred in 11 (31.4%) after a period of 3.2 years.

CONCLUSIONS

Balloon sialoendoscopy for stenosis dilation is safe and effective, with complete resolution of symptoms, but has a high recurrence rate over time.

The Role Of Functional Endoscopic Sinus Surgery In Sleep Quality Improvement

Maria Korodima[2], **Konstantinos Patzalis**[3], **Alexandros Chatzakis**[2], **Eugenia Maria Domuta**[1]

[1]*Faculty of Medicine and Pharmacy, University of Oradea,Romania;* [2]*ENT Department, Sismanogleio General Hospital, Athens, Greece;* [3]*2nd Department of Pulmonology, Sismanogleio General Hospital, Athens, Greece*

BACKGROUND & AIM

Introduction: Chronic rhinosinusitis (CRS) is a highly prevalent inflammatory condition of the paranasal sinuses that significantly impairs patients' quality of life. Beyond nasal obstruction, facial pressure, and olfactory dysfunction, sleep disturbance is increasingly recognized as a major comorbidity. Poor sleep quality in CRS patients is multifactorial, involving nasal blockage, inflammatory mediators, and possible interactions with sleep-disordered breathing. Functional Endoscopic Sinus Surgery (FESS) has been established as an effective treatment for medically refractory CRS, primarily improving sinonasal symptoms. However, its impact on sleep quality remains an area of growing scientific interest.

MATERIAL & METHODS

Materials and Methods: A prospective cohort study was conducted including adult patients with medically refractory CRS who underwent FESS. Sleep quality was assessed preoperatively and three months postoperatively using validated questionnaires, including the Pittsburgh Sleep Quality Index (PSQI) , the Epworth Sleepiness Scale (ESS) and the Sinonasal Outcome Test-22 (SNOT-22), focusing on sleep-related items. Statistical analysis compared pre- and postoperative scores and examined correlations between symptom improvement and sleep quality changes.

RESULTS

Results: Postoperative analysis demonstrated a statistically significant improvement in global PSQI scores (mean reduction: 4.1 points, $p<0.001$) and ESS scores (mean reduction: 3.2 points, $p<0.01$). Improvements in sleep quality correlated positively with reductions in SNOT-22 scores. Patients with higher preoperative disease burden showed greater postoperative sleep improvement.

CONCLUSIONS

Conclusions: Patients demonstrated statistically significant improvement in overall PSQI and SNOT-22 sleep-related scores following FESS. Improvements in nasal obstruction and overall inflammatory burden were strongly associated with better sleep outcomes. FESS appears to significantly enhance sleep quality in CRS patients, highlighting the importance of addressing sleep disturbances as part of comprehensive CRS management. Further randomized studies are warranted to confirm long-term outcomes.

Sleep Disorders In Renal Patients: A Comparative Analysis Of Dialysis And Post-Renal Transplant Outcomes

Turki Alharbi[1], **Salman Alahmadi**[1], **Turki Almejaish**[1], **Amer Albaroudi**[1], **Mohammed Alsaif**[1], **Mohammed Albadr**[1], **Ziyad Al-jahdali**[2], **Abdulrahman Altheaby**[3,4,1,2], **Khalid Alharbi**[3,4,1,2], **Hamdan AL-Jahdali**[3,4,1,2]

[1]College of Medicine, King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia; [2]King Abdullah International Medical Research Centre, Riyadh, Saudi Arabia; [3]Department of Medicine, Sleep Disorders Center, Riyadh, Saudi Arabia; [4]King Abdulaziz Medical City, Ministry of National Guard Health Affairs, Riyadh, Saudi Arabia

BACKGROUND & AIM

Sleep disorders are common in patients with end-stage renal disease (ESRD) on dialysis and may persist after renal transplantation. Dialysis-related factors contribute to poor sleep quality, insomnia, obstructive sleep apnea (OSA), and restless legs syndrome (RLS), all associated with increased morbidity and mortality. Although renal transplantation improves several sleep parameters, sleep disorders remain frequent post-transplant, with poor sleep quality and insomnia affecting a substantial proportion of recipients, exceeding rates seen in the general population. We aim to compare the association of sleep disorders between matched cohorts of patients with ESRD on dialysis and renal transplant recipients.

MATERIAL & METHODS

In this cross-sectional study (N = 386; 227 ESRDOD, 159 renal transplant recipients), sleep symptoms and disorders were assessed using validated questionnaires to assess sleep quality (PSQI), risk for sleep apnoea (STOP-BANG, Berlin questionnaires (BQ)), insomnia (ICSD-2), and excessive daytime sleepiness (EDS) using the Epworth sleepiness scale and restless legs syndrom(RLS). Group comparisons used chi-square and t-tests. A multivariate logistic regression model estimated adjusted odds ratios (OR) for poor sleep quality. Variables included demographics, anthropometrics, comorbidities, and sleep-specific indicators.

RESULTS

Poor sleep quality was observed in 57.8% overall, markedly higher in ESRDOD patients versus transplant recipients (68.7% vs 42.1%, P < 0.001). In bivariate analyses, insomnia symptoms (difficulty initiating/maintaining sleep, early awakening), RLS, EDS, high STOP-BANG, and high BQ risk were strongly associated with poor sleep (all P < 0.001). In the adjusted model, renal transplant status was independently protective (OR 0.321, 95% CI 0.193–0.534, P < 0.001). Strong independent risk factors included insomnia (OR 8.44), high STOP-BANG risk (OR 5.68), EDS (OR 5.47), RLS (OR 3.45), and high Berlin risk for OSA (OR 2.17). Age, gender, BMI, HTN, and diabetes were not significant in the multivariate model.

CONCLUSIONS

ESRDOD patients carry a substantially higher burden of poor sleep and insomnia than renal transplant recipients.

“Efficacy Of GLP-1 Receptor Agonists For Obstructive Sleep Apnea: A Systematic Review And Network Meta-Analysis Of Randomized Controlled Trials”

Mohammed Majed Alshenaiber[1]

[1]College of Medicine, King Saud bin University for Health Sciences, Riyadh

BACKGROUND & AIM

Background: Obstructive sleep apnea (OSA) is strongly associated with obesity and cardiometabolic dysfunction. Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) have emerged as effective weight-loss therapies with potential benefits in OSA; however, their comparative efficacy across available agents and against continuous positive airway pressure (CPAP) remains uncertain.

MATERIAL & METHODS

Methods: Following PRISMA 2020 guidelines, we systematically searched PubMed, Scopus, Web of Science, Cochrane Library, and Google Scholar from inception to January 24, 2025. Randomized controlled trials (RCTs) evaluating GLP-1 RAs in adults with confirmed OSA were included. Random-effects pairwise and network meta-analyses were performed. The primary outcome was change in apnea-hypopnea index (AHI). Secondary outcomes included body weight, Epworth Sleepiness Scale (ESS), inflammatory markers, blood pressure, and cardiometabolic parameters.

RESULTS

Results: Ten reports from seven unique RCTs comprising 1,069 participants were included. Compared with placebo, GLP-1 RAs significantly reduced AHI (mean difference [MD]: −14.4 events/hour; 95% confidence interval [CI]: −23.3 to −5.6; P<0.001). Subgroup analysis demonstrated superior efficacy with tirzepatide versus liraglutide (−21.8 vs −6.6 events/hour; P for interaction<0.001). GLP-1 RAs also significantly improved body weight (−13.0%), ESS (MD: −1.95 points), hs-CRP (−38.9%), systolic blood pressure (−4.1 mmHg), HDL-cholesterol (+7.8%), and triglycerides (−19.0%). Network meta-analysis ranked liraglutide plus CPAP highest for AHI reduction (SUCRA 93.9%), followed by tirzepatide (67.9%) and CPAP alone (62.9%). Direct

comparisons showed CPAP remained superior to GLP-1 RAs alone for AHI reduction (MD: 18.6 events/hour favoring CPAP; 95% CI: 13.6–23.6). Treatment duration significantly predicted AHI improvement on meta-regression (β=−0.66 events/hour/week; P<0.001).

CONCLUSIONS

Conclusions: GLP-1 RAs significantly improve OSA severity, sleep-related symptoms, weight, and cardiometabolic outcomes in patients with obesity-related OSA. Tirzepatide demonstrated substantially greater efficacy than liraglutide, while combination therapy with CPAP yielded the greatest overall benefit. Although CPAP remains the most effective standalone therapy for AHI reduction, GLP-1 RAs represent a promising adjunctive or alternative therapeutic strategy, particularly in patients with obesity and cardiometabolic comorbidities.

ANTI-IGLON5 DISEASE PRESENTING WITH RECURRENT VOCAL CORD PARALYSIS & SLEEP APNEA

Claudia Llorente Álvarez[1], **Sara Fernández Cascón**[1], **Gerardo José Martín Sigüenza**[1], **Carmen Manzanares Lopezrendo**[1], **Ana Martín González**[1], **Lucía Clement Alonso**[1], **Elena Balduz Moreno**[1]

[1]*Complejo Asistencial Universitario de León*

BACKGROUND & AIM

Anti-IgLON5 disease is a rare neurological disorder characterized by antibodies against the neuronal cell-surface protein IgLON5, combining autoimmune and neurodegenerative mechanisms. Clinical manifestations are heterogeneous and frequently include sleep disorders, bulbar dysfunction, movement abnormalities, and respiratory compromise, often leading to delayed diagnosis. We present a case initially evaluated as a laryngeal and neuromuscular disorder that ultimately fulfilled diagnostic criteria for anti-IgLON5 disease.

MATERIAL & METHODS

A patient with chronic obstructive pulmonary disease (COPD) and obstructive sleep apnea treated with continuous positive airway pressure (CPAP) was admitted in December 2025 with stridor, dysarthria, dysphagia, excessive daytime sleepiness, confusion, and respiratory symptoms. Family members reported progressive somnolence, nocturnal disorientation, generalized spasm-like movements, and noisy breathing preceding admission. Neurological examination demonstrated severe dysarthria, dysphagia, transient anisocoria, persistent horizontal nystagmus, and symmetric hyperreflexia without focal motor deficits. Brain magnetic resonance imaging and angiography excluded acute ischemia. Chest computed tomography showed bilateral aspiration-related bronchopneumonia, while neck imaging revealed glottic narrowing and laryngeal paralysis. Tracheostomy was performed because of respiratory compromise.

RESULTS

Following tracheostomy, the patient showed marked improvement in respiratory status, somnolence, and neurological manifestations. During hospitalization, fluctuating dysphagia, fatigable dysarthria, intermittent diplopia, and generalized fatigue raised suspicion for myasthenia gravis; however, electromyography including single-fiber studies and fatigability testing were normal. Clinical improvement occurred without specific immunotherapy, and the patient was discharged with outpatient follow-up. In February 2026, recurrent dyspnea and bilateral vocal cord paralysis required repeat tracheostomy. Additional symptoms included nocturnal visual and auditory hallucinations. Serum anti-IgLON5 antibodies tested positive by indirect immunofluorescence with a titer of 1:320, confirming the diagnosis. Persistent sleep-related manifestations and airway symptoms required continued multidisciplinary follow-up.

CONCLUSIONS

Anti-IgLON5 disease should be considered in patients presenting with unexplained stridor, bilateral vocal cord paralysis, dysphagia, sleep disturbances, and fluctuating neurological symptoms. Early recognition is essential because the disorder may mimic neuromuscular junction disease or neurodegenerative conditions, while prompt diagnosis may facilitate earlier immunotherapy and improve outcomes.

Surgical Management Of Palatal Adhesions Using A Fashioned Silastic Sheet Stent: A Case Series.

Marwa Mohamed El-Begermy[1], **Mohamed Abdelazeem El-Begermy**[1], **Abdul Wassa Alaquel**[2]

[1]*Ain Shams University;* [2]*Alaqel Specialised Hospital*

BACKGROUND & AIM

Adhesions of the soft palate and posterior tonsillar pillars to the posterior pharyngeal wall, causing nasopharyngeal stenosis, are uncommon. They lead to nasal obstruction and obstructive sleep apnea, in addition to affecting speech, smell, and taste. In our practice, this condition was encountered in patients with a history of khat consumption, excessive cauterization during adenotonsillectomy, and in the cicatricial stage of rhinoscleroma. Restoration of nasal breathing is challenging due to the high rate of postoperative re-adhesions. In this study we aim to introduce a modified surgical technique and stent designed to prevent re-adhesions and improve nasal breathing.

MATERIAL & METHODS

Ten patients with adhesions between the soft palate, tonsillar pillars, and posterior pharyngeal wall causing nasal obstruction were included in this study. Six patients developed adhesions due to khat consumption, three following excessive cauterizations during a previous adenotonsillectomy and one due to rhinoscleroma. Surgical Technique: Dissection and division of adhesions and excision of scar tissue were performed under general anesthesia (GA). In post-adenotonsillectomy cases, a suture was placed in the posterior pillar and suspended to the pterygomandibular raphe to achieve lateral expansion of the pharynx. A specially tailored stent made of silastic (or plastic) sheet with a quadrangular piece placed between the palate and posterior pharyngeal wall with two long lateral arms placed in both nasal cavities and sutured together outside the nasal cavity anterior to the columella. The stent was removed after 1-2 months to allow healing and new mucosal lining. Postoperative follow-up ranged from 6 to 12 months.

RESULTS

Good postoperative healing with subjective improvement of nasal breathing was observed in all patients. Two cases developed mild lateral palatal adhesions which were easily released under GA without stenting and without recurrence. No cases of nasal regurgitation were observed.

CONCLUSIONS

The use of a specially fashioned silastic sheet stent after surgical dissection of palatal adhesions allows normal mucous membrane healing and prevents recurrence.

OROPHARYNGEAL FLORA IN OBSTRUCTIVE SLEEP APNEA PATIENTS

serhat ekemen[1], **elçin kal çakmaklıoğulları**[1], **hasan casim**[1]

[1]*Karabuk University Faculty of Medicine*

BACKGROUND & AIM

The aim of this study is to investigate whether the oropharyngeal flora changes in patients with Obstructive Sleep Apnea Syndrome (OSAS).

MATERIAL & METHODS

The study included 53 patients diagnosed with OSAS by Standard Polysomnography (PSG) and 65 patients without suspected OSAS. Oropharyngeal cultures were obtained from the patient and control groups included in the study. A fully automated device was used to identify bacteria. The patient group and control group were compared statistically for bacteria and species diversity obtained from culture.

RESULTS

The most common bacteria detected in the patient group and control group were Streptococcus oralis (37.5%) and Streptococcus mitis (37.7%), respectively. When the distribution of microorganisms across the patient and control groups was examined, no significant difference was observed between the two groups in the incidence of each species (P=0.198). When the two groups were compared across various Alpha Diversity measures, which indicate species richness or diversity, 6 of these measures were significantly higher in the OSAS group. Based on this result, species richness is higher in the OSAS group.

CONCLUSIONS

The oropharyngeal flora is significantly higher in terms of species diversity in patients with OSAS.

Nasoseptal Flap Reconstruction For Nasopharyngeal Stenosis: A Two-Case Series

Erdem Ersan Akyürek[1], **Muhammed Çağrı Külekçi**[1]

[1]*Hacettepe University*

BACKGROUND & AIM

Acquired nasopharyngeal stenosis is a rare but challenging condition characterized by partial or complete obstruction of the communication between the nasopharynx and oropharynx, most commonly following adenotonsillectomy or uvulopalatopharyngoplasty. Multiple surgical techniques have been described, including scar excision, laser lysis, stenting, and regional or free flaps; however, restenosis and prolonged stent dependence remain significant concerns. The nasoseptal flap is a well-vascularized pedicled mucosal flap widely used in skull base reconstruction. We hypothesized that nasoseptal flap reconstruction may provide durable patency without routine stenting in refractory nasopharyngeal stenosis.

MATERIAL & METHODS

This prospective observational case series included two patients with severe acquired nasopharyngeal stenosis treated at a tertiary referral center. Both had undergone multiple prior unsuccessful interventions. Surgical management consisted of complete scar release followed by nasoseptal flap reconstruction without routine long-term stenting. Primary outcome was endoscopic patency during follow-up. Secondary outcome was change in Apnea-Hypopnea Index (AHI) in the patient with obstructive sleep apnea. Statistical analysis was not performed due to the small sample size.

RESULTS

Case 1 (16-year-old female) developed total stenosis after adenotonsillectomy and prior pharyngeal flap surgery. Reverse-based nasoseptal flap reconstruction achieved satisfactory patency, maintained at 6-month follow-up without stenting.

Case 2 (69-year-old male) had refractory stenosis after six prior coblation procedures and multiple failed reconstructive attempts. Following nasoseptal flap reconstruction, stable patency was maintained at 8 months. Preoperative AHI was 41.8 events/hour and improved to 6.6 events/hour postoperatively. No restenosis occurred during follow-up. Velopharyngeal insufficiency developed in one patient and was managed with a prosthetic obturator.

CONCLUSIONS

Nasoseptal flap reconstruction may provide effective anatomical restoration in refractory nasopharyngeal stenosis without routine stenting. In selected patients, functional improvement in obstructive sleep apnea may also be observed. Larger studies are required to validate these findings.

PP-709

Office-Based Coblation Soft Palate Reduction For Obstructive Sleep Apnea: A Case Series

Mohammed alwabili[1], **Shaden Alshuaibi**[1], **faris alnosayan**[1]

[1]*King Fahad Specialist Hospital in buraydah*

BACKGROUND & AIM

Retropalatal obstruction is a major contributor to snoring and obstructive sleep apnea (OSA). Conventional surgical management may require general anesthesia, prolonged recovery, and significant postoperative discomfort. Office-based coblation soft palate reduction under local anesthesia may offer a minimally invasive alternative with rapid recovery, minimal morbidity, and favorable patient tolerance.

MATERIAL & METHODS

This case series included patients who underwent office-based coblation soft palate reduction between September 2025 and August 2026 in Qassim, Kingdom of Saudi Arabia. Procedures were performed under local lidocaine anesthesia without sedation. Operative time, patient tolerance, postoperative pain, complications, symptom improvement, Epworth Sleepiness Scale (ESS), apnea-hypopnea index (AHI), oxygen saturation, and follow-up sleep study results were evaluated.

Some patients underwent a second coblation session approximately six months after the initial procedure based on symptom recurrence or residual OSA findings.

RESULTS

32 patients underwent office-based coblation soft palate reduction for snoring and OSA related to retropalatal obstruction. The mean operative time was less than 30 minutes. The procedure was well tolerated in nearly all patients under local anesthesia.

No significant intraoperative or postoperative complications were identified. Patients reported minimal to no postoperative pain, and no major bleeding, airway compromise, dysphagia, velopharyngeal insufficiency, or long-term complications were observed.

Most patients reported significant reduction in snoring and improvement in sleep quality within 1–3 days following the procedure. Follow-up sleep studies demonstrated a reduction in AHI in patients with available postoperative studies.

Clinical improvement was maintained for approximately four months in most patients. A subset of patients underwent a second coblation session after approximately six months, resulting in further symptomatic improvement and superior postoperative sleep study outcomes compared with the first procedure. Early follow-up after the second session demonstrated sustained patient satisfaction without significant complaints.

CONCLUSIONS

Office-based coblation soft palate reduction under local anesthesia appears to be a safe, rapid, and well-tolerated minimally invasive option for selected patients with OSA related to retropalatal obstruction. The procedure demonstrated promising symptomatic and objective sleep improvements with minimal morbidity and high patient satisfaction. Repeat coblation sessions may provide additional benefit and prolonged clinical improvement in selected patients.

LIPOMA-LIKE HIBERNOMA- THE SURPRISING ETHIOLOGY BEHIND THE OBSTRUCTIVE SLEEP APNEA SYNDROME

Răzvan Hainarosie[1], **Cătălina Voiosu**[1], **Viorel Zainea**[1], **Ruxandra Oana Alius**[1], **Irina Gabriela Ioniță**[1], **Andreea Rusescu**[1], **Raluca Oana Pulpa**[1], **Mara-Andra Rebosapca**[1], **Selma Andra Crețu**[1], **Augustina Iurkovski**[1], **Maria-Laura Burlacu**[1], **Carina Russu**[1], **Miruna Andreea Mateescu**[1], **Teofana Andreea Carazanu**[1]

[1]*Institute of Phonoaudiology and Functional Surgery „Prof. Dr. D. Hociotă" Bucharest, Romania*

BACKGROUND & AIM

Hibernomas are benign, lipomatous tumours derived from the brown fat tissue.With less than 200 cases reported in the current literature (<1% of all benign adipocytic tumours), they are considered a rare entity. The lipoma-like variant represents the most uncommon histologic subtype. Rarely discovered in young adults, hibernomas typically arise in regions adjacent to the axial skeleton, corresponding to sites of fetal brown adipose tissue that have persisted into adulthood. Due to its localisation, this cluster of tumours can induce numerous non-distinctive symptoms that may result in delayed diagnosis.

MATERIAL & METHODS

We have analyzed the case of a 40 year old female patient, with no significant medical history, presented with sleep apnea and deglutition difficulties aggravated in supine position. The patient underwent a prior nocturnal polygraphy that revealed a high apnea-hypopnea index (AHI=87,4). The fibroscopy revealed a well-rounded tumoral mass located in the retro-pharyngeal space, bulging anteriorly. The imaging (CT and MRI) were correlated with the clinical data and a biopsy confirmed the presence of a lipoma-like hibernoma.

RESULTS

Endoscopic trans-oral surgery was performed in order to excise the tumor and reestablish the physiological pharyngeal passage.The excised tumoral mass was characterized by a soft consistency, organized in small lobules. No post-operative residual mass was identified imagistically. Furthermore, recurrence was not present during the later monitorization. A significant improvement in deglutition and breathing was reported .

CONCLUSIONS

Lipoma-like hibernomas are exceptionally rare, with a small number of reported cases in the literature. The associated symptomatology can be non-specific, consequently a significant number of cases can pass underdiagnosed. A multidisciplinary approach is necessary in order to diagnose and document this pathology including: imaging, functional tests and an optimal surgical approach to ensure complete resection and full remission of the symptomatology.

Identifying Risk Factors Of Eustachian Tube Dysfunction Among Patients With Obstructive Sleep Apnoea

Yuanzhi Cheah[1,2], **Noor Dina Hashim**[1], **Mawaddah Azman**[1], **Asfa Najmi Mohammad Yusof**[2], **Dayang Suhana Abg. Madzhi**[3]

[1]*Department of Otorhinolaryngology- Head and Neck Surgery, Faculty of Medicine, Hospital Canselor Tuanku Muhriz, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia;* [2]*Department of Otorhinolaryngology - Hospital Umum Sarawak, Sarawak, Malaysia;* [3]*Department of Otorhinolaryngology- Head and Neck Surgery, Faculty of Medicine, Universiti Malaysia Sarawak, Sarawak, Malaysia*

BACKGROUND & AIM

Eustachian tube dysfunction (ETD) affects the function of middle ear to equalize pressure and protect against pathogens. Obstructive sleep apnoea (OSA), characterized by repeated airway obstruction during sleep, has an increased risk of ETD, possibly due to Eustachian tube blockage and delayed nasopharyngeal openings. However, the risk factors of ETD among patients with OSA remains unclear. This study aimed to identify the risk factors of ETD among OSA patients and to determine the ETD proportion in this population. Additionally, to compare the nasoendoscopic characteristics and airway collapse among OSA patients with and without ETD.

MATERIAL & METHODS

A cross-sectional study was conducted involving 101 adult OSA patients. All subjects completed ETDQ-7 and reflux symptom index (RSI) questionnaire, clinical examination including otoscopy, nasoendoscopy, oropharyngeal evaluation followed by audiological assessments. The subjects are divided into ETD and non-ETD groups based on the screening. Endoscopic

assessment of soft palate and lateral pharyngeal wall collapse was performed as part of routine OSA airway evaluation. The Eustachian tube (3ET) score, modified Müller manoeuvre findings, and reflux finding score (RFS) were recorded and compared between groups.

RESULTS

Among the 101 adult OSA patients analyzed, 43 (42.6%) were diagnosed with ETD. Patients with ETD demonstrated a significant higher severity score for the nasoendoscopic parameters compared to non-ETD group. There was no statistically significant difference of severity and pattern of airway collapsibility and among patient with ETD and without ETD. Both RSI-M (p=0.01) and RFS(p=0.009) are statistically significant higher in ETD group than non-ETD group.

CONCLUSIONS

Eustachian tube dysfunction is more common in patients with obstructive sleep apnoea. Tubal tonsil hypertrophy and laryngopharyngeal reflux are significant risk factors, whereas the severity and pattern of airway collapse do not appear to influence ETD occurrence.

PP-712

Syndrome Of Obstructive Sleep Apnea And Snoring In Patients With Vestibular Deficiencies

Mario Milkov[1], **Miroslav Stoykov**[1]

[1]*Medical University "Prof. Dr. Paraskev Stoyanov" - Varna, Bulgaria*

BACKGROUND & AIM

The Syndrome of Obstructive sleep apnea and snoring (SOSAS) is the most widely spread sleep disorder of the present century. Comorbidity, associated with the syndrome, severely diminishes quality of life of patients affected. SOSAS has negative implications on most anatomical systems of the human organism.

MATERIAL & METHODS

30 patients (20 male and 10 female, aged between 55 and 70) were tested on the premises of University medical and dental center, Medical University - Varna in the time period May-October 2025. All patients had their sleep quality and quantity assessed utilizing specialized sleep questionnaires (Berlin, ESS, STOP-BANG) and polygraphic sleep study (HSAT). Vestibular and balance status was studied through static and dynamic computer posturography, vHIT and VNG tests. Specialized vestibular, sleep and general health status questionnaires, and signed written informed consent forms were filled by all participating patients. The study received approval by University's Ethic committee. The study is financed by the European Union-NextGenerationEU, through the National Recovery and Resilience Plan of the Republic of Bulgaria, Project No. BG-RRP-2.004-0009.

RESULTS

Male patients were predominantly affected by moderate and severe forms of SOSAS, compared to female ones. In male patients with SOSAS, expressed symptoms of vestibular deficiencies were more often diagnosed. Female patients coped with vestibular symptoms better than male ones.

CONCLUSIONS

Poor sleep quality and intermittent hypoxia affect vestibular capabilities and balance in patients affected. Treating SOSAS alleviated vestibular symptomatology and improved balance significantly. Vestibular rehabilitation programs should be regularly implemented in the treatment process of SOSAS if symptoms of disbalance are present.

Lingual Tonsil Resection As A Possibility To Improve The Life Quality Of Patients With Severe Obstructive Sleep Apnea (OSA)

Khoroshilova Inessa[1], **Kopylova Yulia**[1], **Yury Talalayko**[1]

[1]*"Medsi group" JSC*

BACKGROUND & AIM

The safest and the most effective treatment for severe OSA is CPAP. However, some patients refuse to use it. Our aim is to improve the life quality by such patients vie surgical treatment.

MATERIAL & METHODS

14 patients were included in our study. The apnea/hypopnea index was between 42 and 61 per hour (average 47.5). There were 9 men and 5 women. The median age was 44.5 years. All patients included in the study underwent drug induced sleep endoscopy (DISE) and CT of the neck. The severity of OSA was detected by cardiorespiratory monitoring or polysomnography.

The inclusion criteria were as follows: severe SOAS (apnea/hypopnea index more than 30 per hour), lingual tonsil enlargement (detected in endoscopy and neck CT scan) and patient's refusal to use CPAP. The patients with body mass index (BMI) greater than 35 and persons without lingual tonsil hypertrophy were excluded. The lingual tonsil resection was performed using a coblation with 70° endoscope visualization. If the intervention was supplemented with pharyngoplasty, it was performed using the standard technique.

RESULTS

Control cardiorespiratory monitoring was performed in 45-60 days after surgery. By all patients apnea/hypopnea index was improved. Medium improvement was 36 score. Most of patients (8) reach light degree of OSA and 6 have recovered completely.

CONCLUSIONS

It can be noted that the lingual tonsil resection is a promising treatment method for patients with severe OSA, who for any reasons refuse to use CPAP therapy.

Prevalence And Factors Associated With Oxygen Desaturation In Patients At A Tertiary Hospital: A Cross-Sectional Study

Damácio Soares Paiva[1], **Rayane Bezerra Freitas**[1], **Daiane de França Falcão Leal**[1], **Kelvin Leite Moura**[2], **Priscila Farias de Oliveira**[3], **Pedro Henrique Breda**[1], **Wendell Dantas Palmeira**[1], **Gabrielle Justiniana Fontes Rocha**[1], **José Diniz Junior**[1], **Maria Luísa Nobre Medeiros e Silva Guimarães**[1]

[1]Department of Surgery, Universidade Federal do Rio Grande do Norte, Hospital Universitário Onofre Lopes, Natal, RN, Brazil; [2]Clínica Otorrinos Santa Clara, Campina Grande, PB, Brazil; [3]Clínica Otossinus, Natal, RN, Brazil

BACKGROUND & AIM

Obstructive Sleep Apnea (OSA) is a respiratory disorder associated with cardiovascular and neurological morbidity. An elevated Oxygen Desaturation Index (ODI) indicates greater OSA severity and is particularly relevant in hospitalized patients, where sleep disorders are often underrecognized. Since standard polysomnography is rarely feasible during hospitalization, screening tools such as the STOP-BANG questionnaire and the Epworth Sleepiness Scale (ESS) may help identify at-risk patients. However, the association between these tools and objective sleep-related parameters in hospitalized patients remains insufficiently explored. This study evaluated the prevalence of elevated ODI in hospitalized patients and its association with comorbidities and validated screening questionnaires.

MATERIAL & METHODS

A cross-sectional study was conducted between 2022 and 2024 at a tertiary hospital in Brazil, including adult hospitalized patients without a previous diagnosis of OSA. STOP-BANG, ESS, sleep quality self-assessment, and overnight pulse oximetry data were obtained. The ODI was considered elevated when ≥ 5 oxygen desaturation events per hour; STOP-BANG scores > 3 indicated OSA risk, and ESS scores > 8 indicated excessive daytime sleepiness. Parametric and nonparametric tests were used, with a significance level of 5%.

RESULTS

Seventy-eight patients were included. The mean age was 54 years, and the mean body mass index was 25.5 kg/m². The mean STOP-BANG score was 3.5 (± 3), indicating intermediate OSA risk, while the mean ESS was 8.59 points (± 4.11). Mean minimum oxygen saturation during sleep was 87%, with a mean saturation of approximately 95%. The mean number of oxygen desaturation events was 31, and the mean ODI was 4.6 events per hour. Time spent with oxygen saturation below 90% and total sleep time with snoring were low on average, with substantial interindividual variability.

CONCLUSIONS

The prevalence of elevated ODI in hospitalized patients highlights the importance of OSA screening, as its association with screening questionnaires may support earlier identification and appropriate clinical management, potentially reducing OSA-related complications.

Risk Factors For Nasal Airway Obstruction And Sleep-Disordered Breathing In Children With Mandibular Deformities

Ravshan Yakubov[2], **Khalida Shaykhova**[1], **Rakhim Yakubov**[1], **Gavkhar Khaydarova**[1]

[1]Tashkent State Medical University; [2]Republican Specialized Scientific and Practical Medical Center of Otorhinolaryngology and Head and Neck Diseases

BACKGROUND & AIM

The study of pathogenesis with consideration of risk factors for combined involvement of ENT organs and internal system diseases in children with mandibular deformities is of significant scientific and practical importance.

Improvement of comprehensive diagnostics of risk factors for nasal and nocturnal breathing disorders caused by ENT pathology and contributing to the persistence of inflammatory and hypoxic conditions in children with mandibular deformities.

MATERIAL & METHODS

Sixty-five children aged 3 to 18 years with mandibular deformities were examined. Health assessments were conducted based on an interdisciplinary approach to the diagnosis of internal organ diseases in children with mandibular deformities. Standard endoscopic methods were used to evaluate the condition of the ENT organs. Radiological diagnostics were performed using multislice computed tomography of the paranasal sinuses, facial bones, and skull with the assistance of the RadiAnt DICOM Viewer program.

RESULTS

The following conditions were identified, which directly or indirectly affect the development of nasal and nocturnal breathing disorders. In 51 patients (78%), radiological and clinical signs of nasal septum deviation were observed, and adenoid vegetations were found in 57 patients (88%). Analysis of structural and functional changes in the maxillofacial region revealed that the children had more pronounced retro-micrognathia, narrowing of the nasopharyngeal airway at the isthmus of the naso- and oropharynx, as well as deformation of the bony and cartilaginous structures of the nasal cavity, leading to impaired breathing. Enlargement of the nasopharyngeal and palatine tonsils, along with narrowing in the area of the nasopharyngeal isthmus and lower jaw, underlies the disruption of nasal breathing. Combined with local structural and functional abnormalities associated with retro-micrognathia, this condition is exacerbated by tissue hypoxia, which increases the risk of systemic inflammation and contributes to the progression of the primary disease.

CONCLUSIONS

ENT disorders (rhinitis, nasal septum deviation, hypertrophy of the nasopharyngeal tonsil) and retro-micrognathia, accompanied by structural and functional abnormalities of the nasal and pharyngeal cavities, increase the risk of respiratory insufficiency and chronic progression of the pathological process. Impaired nasal breathing contributes to changes in blood parameters and autonomic nervous system function, reflects the nature of local microcirculatory disturbances, hypoxia, and acidosis, and leads to the progression of clinical, functional, and metabolic alterations. This underscores the need for the development and implementation of comprehensive diagnostic and therapeutic interventions targeting the ENT organs in children with mandibular deformities.

Obstructive Sleep Apnea .... 2026 Update

Hesham Badr Eldeen Elmashad[1]

[1]*Makkah Institute for Speech and Hearing (MISH)*

BACKGROUND & AIM

To let my colleagues know the newest information on such complicated disese, as OSA is one of the most common sleep disorders. It is one of the most challenging diseases encountered in otolaryngology because its diagnosis and management necessitates cooperation of many specialties. Therefore, the development and progress in this field are great.

MATERIAL & METHODS

This work is devoted to focusing, briefly yet comprehensively, on the most recent trends in definitions, pathophysiology, and management of OSA.

RESULTS

The development in OSA is incredible and tremendous, so following the updates is crucial.

CONCLUSIONS

All physicians must continually follow up on the latest periodicals and research. Therefore, the Ministry of Health must support and provide this information by all means, and these conferences are one of the most important sources for that.

Comparative Value Of Neck Circumference, Body Mass Index, And The Epworth Sleepiness Scale For Identifying Moderate-To-Severe Obstructive Sleep Apnea

Rayane Bezerra Freitas[1], **Daiane de França Falcão Leal**[1], **Ana Cristina Mesquita de Campos**[1], **Thallys Yohanis Benício Fernandes**[1], **Pedro Henrique Breda**[1], **Wendell Dantas Palmeira**[1], **Gabrielle Justiniana Fontes Rocha**[1], **Damácio Soares Paiva**[1], **Yasmim Barros Silveira**[2], **Kelvin Leite Moura**[3], **Priscila Farias de Oliveira**[4], **Maria Luísa Nobre Medeiros e Silva Guimarães**[1]

[1]*Department of Surgery, Universidade Federal do Rio Grande do Norte, Hospital Universitário Onofre Lopes, Natal, RN, Brazil;* [2]*Department of Otorhinolaryngology – Head and Neck Surgery, Universidade Federal de Pernambuco, Hospital das Clínicas, Recife, PE, Brazil;* [3]*Clínica Otorrinos Santa Clara, Campina Grande, PB, Brazil;* [4]*Clínica Otossinus, Natal, RN, Brazil*

BACKGROUND & AIM

Obstructive sleep apnea (OSA) is highly prevalent and linked to cardiovascular morbidity and reduced quality of life, yet remains widely underdiagnosed. Early identification of patients at risk for clinically significant disease is crucial to guide diagnostic testing and treatment. Common screening tools, such as the Epworth Sleepiness Scale (ESS), rely on subjective symptoms and may inadequately detect moderate-to-severe OSA. Objective anthropometric measures, particularly neck circumference, may better represent upper airway structural risk. We hypothesized that neck circumference would demonstrate superior diagnostic accuracy compared with ESS and body mass index (BMI) for identifying moderate-to-severe OSA defined by the apnea–hypopnea index (AHI).

MATERIAL & METHODS

A retrospective observational study included adult patients from a tertiary referral hospital with available AHI data from sleep studies. Clinical, demographic, and anthropometric variables were obtained from a standardized database. Neck circumference, BMI, and ESS were analyzed as independent variables. Moderate-to-severe OSA was defined as AHI ≥15 events/hour. Diagnostic performance was evaluated using receiver operating characteristic (ROC) curve analysis with area under the curve (AUC) estimation and optimal cutoffs determined by the Youden Index. Univariable and multivariable binomial logistic regression models estimated odds ratios (OR) with 95% confidence intervals (CI).

RESULTS

Seventy-seven patients had complete AHI data, of whom 49 had moderate-to-severe OSA. Neck circumference demonstrated the highest discriminative ability (AUC ≈ 0.66), outperforming BMI and the ESS. In logistic regression, neck circumference was significantly associated with moderate-to-severe OSA (OR ≈ 1.14 per cm; $p < 0.05$), while BMI and ESS were not. In the multivariable model, neck circumference remained the only independent predictor, with modest improvement in model fit.

CONCLUSIONS

Neck circumference demonstrated superior performance compared with BMI and the ESS for identifying moderate-to-severe OSA, as defined by the AHI. Although its discriminatory ability was moderate, neck circumference emerged as the most informative independent clinical marker among the variables studied. These findings support the value of simple, objective anthropometric measures in OSA risk stratification and highlight the limitations of subjective sleepiness assessment.

Relationship Between Active Bruxism, Anxiety And Serum Micronutrient Levels: A Controlled Cross-Sectional Study

Yonca ÇOLUK[1], **Esra KOÇ**[1], **Volkan GÜNGÖR**[1], **Serhat YASLIKAYA**[1], **Devrim BEKTAŞ**[1]

[1]*Giresun Training and Research Hospital, Department of Otolaryngology*

BACKGROUND & AIM

Bruxism is a multifactorial parafunctional activity involving clenching and/or grinding of the teeth during sleep or wakefulness. Current evidence indicates that bruxism is a complex neurobehavioral condition associated with psychological stress, autonomic dysregulation, sleep-related factors, and central neuromuscular mechanisms. Micronutrients and trace elements may influence neuromuscular excitability, oxidative stress, neurotransmitter balance, and psychiatric comorbidities. Zinc, magnesium, and vitamin D have been proposed as potential modulators in bruxism pathophysiology, although current evidence remains limited and heterogeneous. This study aimed to evaluate the relationship between active bruxism, anxiety levels, and serum micronutrient profiles.

MATERIAL & METHODS

This controlled cross-sectional study included patients with active bruxism and an age-matched healthy control group. Active bruxism was diagnosed clinically by an experienced oral and maxillofacial surgeon based on clenching/grinding history, dental wear, masseter hypertrophy, and related symptoms. All participants underwent Beck Anxiety Inventory (BAI) assessment and serum micronutrient analysis, including zinc and vitamin D measurements. Groups were demographically comparable. Statistical significance was accepted as $p<0.05$.

RESULTS

Anxiety scores were significantly higher in the active bruxism group compared with controls: BAI score: 18.05 vs 6.96 ($p < 0.001$) Serum zinc levels were significantly lower in the bruxism group: Zinc: 81.75 vs 86.90 ($p = 0.029$) No statistically significant difference was observed in vitamin D levels or other measured micronutrient parameters.

CONCLUSIONS

Active bruxism was significantly associated with increased anxiety levels and reduced serum zinc concentrations. These findings support the concept that bruxism is a multidimensional neurobehavioral disorder involving psychological, neurobiological, and biochemical mechanisms rather than only a mechanical parafunctional activity. The association between anxiety and bruxism highlights the potential role of psychosocial stress, emotional dysregulation, and neurochemical imbalance in disease pathophysiology. Further prospective studies with larger sample sizes are required to clarify the causal relationship between micronutrient alterations and bruxism.

The Role Of Shear Wave Elastography In The Diagnosis And Treatment Monitoring Of Bruxism: A Prospective Clinical Study

Resul Arjin Öksüz[1], **Ahmet S. Yetkin**[1], **Alparslan Gönül**[1], **Evren Üstüner**[1], **Emre Ocak**[1]

[1]*Ankara University*

BACKGROUND & AIM

To assess the diagnostic performance of two-dimensional shear wave elastography (2D-SWE) in detecting bruxism and evaluating treatment response following botulinum toxin injection into the masseter muscle.

MATERIAL & METHODS

This prospective study included 41 female patients with clinically diagnosed bruxism and 20 healthy controls. Bilateral masseter and temporalis muscle stiffness values were measured using 2D-SWE at rest, while masseter stiffness was additionally assessed during contraction. Bruxism patients received 20 U botulinum toxin type A per masseter, and elastography was repeated at three weeks. Diagnostic cut-off values were determined using ROC analysis.

RESULTS

Masseter stiffness during contraction was significantly higher in bruxism patients than controls (right: 54.29±27.32 vs. 34.15±15.49 kPa; left: 54.15±29.44 vs. 32.81±19.98 kPa; $p=0.003$). Post-treatment measurements demonstrated a significant decrease in stiffness ($p=0.001$). ROC analyses identified optimal diagnostic cut-offs of 34.65 kPa (right masseter; sensitivity 75%, specificity 70%) and 59.85 kPa (left masseter; sensitivity 40%, specificity 90%).

CONCLUSIONS

2D-SWE is a reliable, objective, and reproducible tool for diagnosing bruxism and monitoring treatment response following botulinum toxin injection.

Log-Transformed Hypoxic Burden Improves Prediction Of CPAP Utilization

Jarungjit Kraiwattanapong[1]

[1]*Department of Otolaryngology – Head and Neck Surgery, Panyananthaphikkhu Chonprathan Medical Center, Srinakharinwirot University, Thailand*

BACKGROUND & AIM

Obstructive sleep apnea (OSA) is a heterogeneous disorder, and traditional severity metrics such as the apnea–hypopnea index do not fully capture the physiological impact of intermittent hypoxia. Hypoxic burden has emerged as a physiology-based biomarker reflecting cumulative hypoxic exposure. This study aimed to evaluate the association between hypoxic burden proxy and CPAP utilization in OSA and to determine whether log transformation improves predictive performance.

MATERIAL & METHODS

This retrospective observational study included 403 patients who underwent sleep study evaluation for suspected obstructive sleep apnea. Demographic data, comorbidities, and polysomnographic parameters including apnea–hypopnea index, T90, mean oxygen saturation, and nadir oxygen saturation were collected.

A hypoxic burden proxy was calculated from oxygen desaturation parameters. Due to right-skewed distribution, log transformation was applied prior to analysis. CPAP utilization was defined as the clinical outcome.

Statistical analysis included non-parametric comparison, logistic regression modeling, and receiver operating characteristic curve analysis. Cases with missing covariate data were excluded using listwise deletion.

RESULTS

A total of 403 patients were included in the analysis. Hypoxic burden proxy demonstrated a markedly right-skewed distribution, and log transformation improved data distribution and model stability. Patients with higher hypoxic burden were more likely to utilize CPAP therapy.

In logistic regression analysis, log-transformed hypoxic burden was significantly associated with CPAP utilization (OR approximately 1.5 per log unit increase, p<0.001).

Receiver operating characteristic analysis demonstrated modest discrimination. The area under the curve was approximately 0.61 for raw hypoxic burden and improved to approximately 0.63 after log transformation. Predictive performance was comparable to conventional severity metrics including AHI, supporting its potential role in clinical risk stratification.

CONCLUSIONS

Log-transformed hypoxic burden is associated with CPAP utilization and demonstrates modest predictive performance comparable to conventional severity metrics such as AHI. As a physiology-based metric reflecting cumulative hypoxic exposure, hypoxic burden may provide additional information for risk stratification and individualized treatment planning in patients with obstructive sleep apnea.

Periodic Limb Movements, Associated Arousals, And Systemic Arterial Hypertension: Is There A Link?

Cíntia Felicio Adriano Rosa[1,2], **Isabela Moreira Garzedim Santos**[1], **Alessandra Zanatta**[3], **João Guilherme Borgio**[3], **Victor Henrique Dominiak Soares**[3], **Marcela Souza Boldt**[1], **Pedro Henrique Vicari**[4], **Matheus Roberto Schetz Alves**[4], **Enrico Guido Oliveira Minniti**[4], **Gustavo Malucelli Durski**[5]

[1]*Hospital IPO;* [2]*Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, Brazil.;* [3]*Federal University of Paraná, Curitiba, Brazil.;* [4]*Pontificia Universidade Católica do Paraná, Curitiba, Brazil;* [5]*Positivo University, Curitiba, Brazil*

BACKGROUND & AIM

Purpose: This study investigated the prevalence of periodic limb movement during sleep (PLMS), their related clinical and polysomnographic characteristics, and the association between periodic limb movement index (PLMI), periodic limb movement arousal index (PLMAI), and hypertension.

MATERIAL & METHODS

Methods: A total of 1,718 adult patients who underwent polysomnography were analyzed and grouped according to PLMI >15 or ≤15, and PLMAI ≥1 or <1. Age, comorbidities, and medication use were obtained from medical records.

RESULTS

Results: Patients with PLMAI ≥1 (14.2% of the sample) were older, had lower body mass index (BMI), lower apnea-hypopnea (AHI), and higher prevalence of diabetes and use of antidepressants. Patients with PLMI >15 were also older, had lower BMI, and higher prevalence of diabetes, antidepressant use, hypertension, and arrhythmia; however, no significant difference in AHI was observed. In multivariate regression analysis, PLMI >15 was associated with a 1.83-fold increased risk of hypertension (95% CI, 1.26–2.64; p = 0.001), independent of AHI, diabetes, smoking, hypothyroidism, and asthma. However, this association was not independent of age (p = 0.344), suggesting that age may be a confounding factor.

CONCLUSIONS

Conclusion: The prevalence of PLMI >15 (9%) was consistent with the literature (7.6%). We conclude that patients with PLMI >15 have a higher risk of hypertension, independent of AHI, diabetes, smoking, hypothyroidism, and asthma, but not independent of age. PLMAI ≥1, in contrast, was not associated with a higher prevalence of HTN.

Discrepancies In Subjective Sleep Quality Between Home And Hospital Settings: Insights Of Hypnotic Agents Use With Post-Polysomnography Questionnaire

Jing-JieWang[1], **Ming-Feng Wu**[1]

[1]*Taichung Veterans General Hospital, Taiwan*

BACKGROUND & AIM

Polysomnography (PSG) is the gold standard for diagnosing sleep-disordered breathing (SDB). However, in a hospital testing setting, it may produce the first-night effect, viz., prolonged sleep latency, lower sleep efficiency, and uncertain apnea–hypopnea index (AHI). Here, we aim to determine the influences of hypnotic agents and gender.

MATERIAL & METHODS

In this retrospective study, we reviewed the post-PSG questionnaires and electronic medical records of patients aged ≥20 years receiving overnight PSG for the diagnosis of SDB at Taichung Veterans General Hospital in a period between April 2024 and March 2025.

RESULTS

We studied a total of 1053 patients, aged 47.0 ± 14.7 years old. Compared to sleeping at home, 42.2% of patients reported worse perceived sleep quality (PSQ) with hypnotic agents, and 53.0%, without, before PSG testing in the hospital. For those without taking hypnotic agents, men had an odds ratio (OR) of 1.570 (95% CI: 1.127-2.189) for worsening PSQ compared to women ($p = 0.008$). Also, per increasing 1 Epworth Sleepiness Scale (ESS) score, the risk of worsening PSQ was reduced by OR of 0.963 (95% CI: 0.933-0.994) ($p = 0.021$). Once male patients had ESS < 10, as many as 57.3% of them reported the worse PSQ.

CONCLUSIONS

Our study suggests a potentially more patient-centric approach to diagnosing sleep-disordered breathing. In some male patients with ESS scores < 10, short-acting hypnotics might be considered during in-lab PSG to improve subjective comfort, thereby potentially enhancing study reliability. Meanwhile, home sleep apnea testing can serve as a practical initial tool for selected patients-offering convenience, mitigating the first-night effect, and potentially reducing long wait times. However, its use in individuals with comorbid insomnia requires careful clinical judgment to avoid false-negative results, often making in-lab assessment the preferred option in such cases.

KEYWORDS

first-night effect; home sleep apnea testing; perceived sleep quality; polysomnography; sleep-disordered breathing.

Persistent Unilateral Throat Pain Caused By An Elongated Styloid Process: A Case Report

Ivan Delchev[2], **Atanas Tarpov**[2], **Greta Delen**[2], **Maria Charalambous**[2], **Mila Asenova**[1,2], **Asen Asenov**[1,2]

[1]*Medical University of Plovdiv;* [2]*University Hospital of Plovdiv*

BACKGROUND & AIM

Eagle syndrome is a rare but clinically significant condition that is associated with elongation or abnormal angulation of the styloid process or calcification of the styloid ligament complex. Most common symptoms include cervicofacial pain, dysphagia, foreign body sensation and oropharengeal discomfort. This case report aims to present the diagnostic evaluation and surgical management in a young adult patient with persistent unilateral pharyngeal pain following an upper respiratory tract infection.

MATERIAL & METHODS

A 23-year-old patient presented with a two-month history of right-sided pharyngeal pain that developed after an upper respiratory tract infection. The patient described associated foreign body sensation and tenderness near the lower pole of the right tonsil. Clinical examination revealed no inflammatory or structural abnormalities of the tonsils and pharynx. However, manual palpation lateral to the palatoglossal arch identified the styloid process and provoked the patient's characteristic pain. Additional findings such as poor oral hygiene and extensive dental decay were observed. Computer tomography examination demonstrated an elongated right styloid process characterized by pronounced anterior angulation and approximately 0,7 cm greater length than the left side. A transoral surgical approach was chosen. Access was achieved through an incision superior to the palatopharyngeal muscle followed by a blunt dissection through the prestyloid adipose tissue. Approximately 2,5 cm of the elongated styloid process was removed and the operative site was closed with sutures.

RESULTS

Postoperative recovery showed significant clinical improvement with total symptom resolution. Although the sutures were partially compromised due to frequent digital palpation by the patient, complete mucosal healing was observed.

CONCLUSIONS

This case demonstrated the diagnostic value of manual palpation and Computed tomography in identifying symptomatic styloid process elongation. Early recognition and appropriate surgical management can result in complete symptom resolution and favorable postoperative outcomes.

Evaluation Of Clinical, Metabolic, And Hematological Parameters In Patients With Diffuse Idiopathic Skeletal Hyperostosis

Semra Külekçi Öztürk[1], **Zehra Nur Kılıç**[1], **Nurdan Köse Çelebi**[1], **Berkay Güvenir**[1], **Hülya Kartal**[1]

[1]*Fatih Sultan Mehmet Training and Research Hospital*

BACKGROUND & AIM

Diffuse idiopathic skeletal hyperostosis (DISH) is a systemic disease characterized by widespread ossification in the spine and peripheral entheses, associated with metabolic disorders. This study aimed to evaluate the demographic characteristics, presenting complaints, comorbidities, and selected hematological and metabolic parameters of patients diagnosed with DISH.

MATERIAL & METHODS

Nine patients with radiologically diagnosed DISH were retrospectively examined. The patients' ages, presenting complaints, and comorbidities were recorded. In laboratory evaluation, hemoglobin, white blood cell count (WBC), neutrophil/lymphocyte ratio (NLR), triglycerides, fasting glucose, triglyceride-glucose (TyG) index, vitamin B12, and 25-hydroxyvitamin D levels were assessed.

RESULTS

The patients were in the elderly age group, and the most frequent presenting complaints were dysphagia, back and neck pain, and limited mobility. Metabolic comorbidities, particularly glucose and lipid metabolism disorders, were frequently detected. Hemoglobin, WBC, and NLR values were within normal limits in most patients. However, some patients showed elevated triglyceride levels and TyG index. Vitamin D deficiency was common, while vitamin B12 levels varied among patients.

CONCLUSIONS

This small case series supports the idea that DISH is a disease associated with metabolic disorders rather than systemic inflammation. Easily accessible parameters such as triglycerides, glucose, and TyG index may be useful in the clinical evaluation of DISH patients. Keywords: Diffuse idiopathic skeletal hyperostosis, DISH, metabolic syndrome, TyG index

Beyond Dysphagia : ENT Approach To Cervical Tuberculous Spondylitis – A Case Report

Triek Ryma[1], **Mohamed Hachemi**[1], **Samira Medkour**[1], **Mokhtar Hasbellaoui**[1]

[1]*ENT department of Mohamed Lamine Debaghine University Hospital*

BACKGROUND & AIM

Cervical spinal tuberculosis (TB), also known as cervical Pott's disease, is a rare but potentially life-threatening form of osteoarticular tuberculosis. It accounts for only 2–5% of spinal TB cases and may lead to severe neurological complications. Oropharyngeal manifestations revealing cervical tuberculosis remain exceptional.

Our objective is to highlight the diagnostic and therapeutic role of ENT management in an unusual presentation of cervical tuberculous spondylitis.

MATERIAL & METHODS

We report the case of a 32-year-old woman admitted to the ENT department for progressive dysphagia associated with cervical pain and paresthesia of the upper limbs. Clinical examination, including nasofibroscopy, radiological investigations, surgical management, and cytobacteriological analysis were performed.

RESULTS

Nasofibroscopic examination revealed a marked bulging of the posterior oropharyngeal wall causing significant narrowing of the pharyngeal lumen. Given these findings, cervical MRI was performed, demonstrating extensive tuberculous spondylitis extending from C2 to T1, associated with multiple abscess collections, the largest of which measured 118 mm in height and caused marked compression of the pharyngeal lumen; associated multilevel spondylitic and neuritic involvement.

The patient underwent transoral surgical drainage with needle aspiration and incision of the posterior oropharyngeal wall, allowing evacuation of the abscess and collection of samples for cytobacteriological analysis.

Direct smear examination revealed acid-fast bacilli, and mycobacterial culture on Löwenstein–Jensen medium confirmed the diagnosis of tuberculosis.

The patient was referred to the Infectious Diseases Department and was started on antituberculous therapy consisting of 2 months of RHZE followed by 10 months of RH, resulting in favorable clinical improvement.

CONCLUSIONS

Cervical tuberculous spondylitis may present with atypical oropharyngeal symptoms such as dysphagia. ENT evaluation plays a key role in early diagnosis, airway assessment, and surgical management, particularly in cases requiring transoral drainage of compressive collections

Idiopathic Reversible Combined Cranial Nerve X And XII Palsy Following Upper Respiratory Tract Infection: A Rare Case Report

EBRU EĞİNCİ[1], **MELİKŞAH ÇAKIR**[1], **HALİL ERDEM ÖZEL**[1]

[1]*Department of Otolaryngology, Kocaeli City Hospital*

BACKGROUND & AIM

Lower cranial nerve palsies are rare, typically arising from neoplastic, vascular, or traumatic causes. However, post-infectious mechanisms are increasingly recognized, especially following upper respiratory tract infections. While isolated hypoglossal nerve palsy is uncommon—linked to Epstein-Barr virus, COVID-19 vaccination, or tonsillitis—combined involvement of the glossopharyngeal, vagus, and hypoglossal nerves can occur. These idiopathic cases often present with normal neuroimaging and a favorable prognosis, pointing toward post-viral inflammatory neuropathy. Consequently, clinicians should consider post-infectious etiologies in the differential diagnosis for patients presenting with acute dysarthria, dysphagia, and tongue deviation following recent systemic or respiratory infections.

MATERIAL & METHODS

A 52-year-old male presented with acute hoarseness, dysphagia, and slurred speech following an upper respiratory tract infection. Otorhinolaryngological examination revealed leftward tongue deviation with ipsilateral hemiatrophy and dysarthria, indicating left hypoglossal nerve dysfunction. Flexible laryngoscopy confirmed left vocal cord paralysis. While the uvula remained midline, the left soft palate exhibited significant hypotonia; however, bilateral gag reflexes were preserved.

Neuroimaging, including brain MRI, showed only chronic microvascular ischemic changes, with no evidence of malignancy or compression in the neck, temporal bone, or thorax. Laboratory investigations for infectious and vasculitis markers were unremarkable. Given the preceding viral prodrome and negative imaging for structural lesions, a diagnosis of post-infectious inflammatory neuropathy was established. Following multidisciplinary consultation, conservative management was initiated. This case highlights the importance of considering post-viral etiologies in multi-cranial nerve palsies, where unremarkable imaging and a favorable clinical history often suggest a benign, inflammatory process.

RESULTS

At the 1-week follow-up, significant improvement in tongue mobility and partial regression of atrophy were observed. Vocal cord functions returned to normal bilaterally, and soft palate symmetry was restored. The patient reported marked improvement in swallowing functions, though a mild residual difficulty in suction (negative pressure generation) persisted. At the 2-month follow-up, complete resolution of all symptoms was observed.

CONCLUSIONS

Post-infectious lower cranial nerve palsies are rare but clinically significant conditions. While hypoglossal nerve involvement is typically isolated, the literature indicates that adjacent cranial nerves—particularly IX and X—may be affected as part of a broader neuropathic spectrum (3–4).

The absence of structural pathology on imaging and the favorable clinical course support a post-viral or immune-mediated mechanism. Recognizing this condition is crucial to avoid unnecessary invasive diagnostic procedures and to guide appropriate conservative management. Most cases demonstrate spontaneous or treatment-assisted recovery, indicating a generally benign and self-limiting course (1–4).

Superior Thyroid Cornu Syndrome Mimicking Post-Stroke Dysphagia

Fırat Onur[1], **Ethem İlhan**[1]

[1]*Department of Otorhinolaryngology and Head & Neck Surgery, University of Health Sciences Gaziosmanpaşa Training and Research Hospital, Istanbul, Turkey*

BACKGROUND & AIM

Superior thyroid cornu syndrome (STCS) is a rare structural abnormality caused by elongation or medial displacement of the superior thyroid cornu, causing dysphagia and throat discomfort. Because symptoms may overlap with neurologic or gastrointestinal disorders, diagnosis can be delayed. We present a case of STCS initially attributed to neurogenic dysphagia following ischemic stroke.

MATERIAL & METHODS

A 49-year-old male patient presented with persistent dysphagia and right-sided throat sticking sensation following a right lateral medullary ischemic stroke in 2022. The patient also had a history of surgery for mediastinal ectopic parathyroid

adenoma and hemigastrectomy for perforated peptic ulcer disease. Symptoms consisted of persistent, non-progressive solid-food dysphagia localized to the right side of the neck without liquid dysphagia, odynophagia, or weight loss. Upper gastrointestinal endoscopy showed post-hemigastrectomy anatomy and alkaline reflux gastritis without esophageal pathology. Flexible endoscopic examination demonstrated an elongated right superior thyroid cornu causing right lateral hypopharyngeal wall protrusion with intact mucosa. CT and MRI excluded a mass lesion and supported the diagnosis of superior thyroid cornu syndrome. The elongated portion of the right superior thyroid cornu was excised transorally using a CO_2 laser. The mucosa was sutured primarily and reinforced with fibrin glue to achieve a watertight seal.

RESULTS

No postoperative complications occurred. Oral intake was resumed on postoperative day 1 without nasogastric tube placement. At 10-week follow-up, the patient reported marked improvement in dysphagia with complete resolution of the right-sided throat sticking sensation.

CONCLUSIONS

Persistent solid-food dysphagia following stroke should not be attributed solely to neurogenic causes. Although rare, superior thyroid cornu syndrome should be considered in patients with localized mechanical swallowing symptoms and compatible endoscopic and radiologic findings. Surgical excision may provide significant symptomatic improvement in appropriately selected patients.

PERSISTENT DYSPHAGIA AND HYPOPHONIA ASSOCIATED WITH OSMOTIC DEMYELINATION SYNDROME: A CASE REPORT

Diogo Nascimento[1,2], **Pedro Moreira**[3], **Ana Luísa Pires**[3], **Miguel Campos Lopes**[1,4], **Luciana Rodrigues**[1], **Raquel Andrade**[1], **Maria Inês Ribeiro**[1], **Paulo Gonçalves**[1], **Tiago Soares Santos**[1,5]

[1]Department of Otolaryngology, Unidade Local de Saúde de Entre o Douro e Vouga, Santa Maria da Feira, Portugal.; [2]Department of Biomedicine, Experimental Biology Unit, Faculty of Medicine of Porto, University of Porto, Porto, Portugal.; [3]Department of Neurology, Unidade Local de Saúde de Entre o Douro e Vouga, Santa Maria da Feira, Portugal.; [4]Faculty of Medicine of Porto, University of Porto, Porto, Portugal.; [5]Biomedical Research Multidisciplinary Unit, ICBAS, Universidade do Porto, Portugal

BACKGROUND & AIM

Osmotic demyelination syndrome (ODS) is a severe neurological disorder most commonly occurring as a complication of the treatment of profound hyponatremia. Excessively rapid correction of serum sodium leads to an abrupt increase in extracellular tonicity without sufficient time for cerebral osmotic adaptation, promoting water efflux from brain cells and resulting in oligodendrocyte injury and demyelination. The central pons is most frequently affected, accounting for the characteristic clinical manifestations. Patients may present with altered mental status, progressive lethargy, dysarthria, dysphagia, hypophonia, and quadriplegia. Isolated bulbar manifestations without additional neurological deficits are uncommon.

MATERIAL & METHODS

This case report describes a 62-year-old man admitted following cranioencephalic trauma with a 20-day history of dysarthria, productive cough, and asthenia. Laboratory evaluation revealed severe hyponatremia (serum sodium 100 mmol/L), likely related to thiazide use and dehydration, and sodium correction was initiated. Within 24 hours, the patient developed altered mental status requiring invasive mechanical ventilation, raising suspicion of ODS. After extubation on day five, severe dysphagia was observed, necessitating enteral feeding initially via orogastric tube and subsequently by percutaneous endoscopic gastrostomy.

RESULTS

Brain magnetic resonance imaging performed 25 days after admission demonstrated a symmetrical central pontine T2-weighted hyperintense lesion consistent with central pontine myelinolysis. Serial neurological examinations and fiberoptic endoscopic evaluation of swallowing revealed severe dysphagia with gradual improvement, associated with hypophonia. Approximately six months after admission, the patient tolerated a fractionated oral diet with selected consistencies. Hypophonia also progressively improved. No other significant neurological sequelae were identified.

CONCLUSIONS

ODS is associated with considerable morbidity and often results in significant neurological deficits that pose substantial rehabilitation challenges. We describe an atypical presentation in which altered mental status was the primary acute manifestation and persistent deficits were limited to dysphagia and hypophonia. Although uncommon, this clinical pattern should prompt consideration of ODS in the setting of corrected electrolyte disturbances and early magnetic resonance imaging. With appropriate multidisciplinary rehabilitation, patients with ODS-related dysphagia may achieve meaningful recovery.

A Simple Four-Grade Vallecular Jelly Clearance Scale In Video Endoscopic Evaluation Of Swallowing: Reliability And Validity For Diet Selection

Toshiya Kimura[1], **Tomoyuki Haji**[1], **Yuki Kimata**[1], **Tsukasa Takeue**[2]

[1]*Kurashiki Central Hospital;* [2]*Kambara Hospital*

BACKGROUND & AIM

Evaluation of pharyngeal clearance in video-endoscopic evaluation of swallowing (VEES) is valuable not only for diagnosing dysphagia but also for selecting appropriate food textures. Conventional residue rating scales rely on the amount and location of post-swallow residue, which are often complex and require considerable expertise, particularly for assessing pyriform sinus residue. We developed a simple method focusing on the number of swallows required to clear vallecular jelly residue and investigated its reliability and validity.

MATERIAL & METHODS

A 3-g jelly bolus was administered, and vallecular clearance was graded on four levels: 0 = cleared in one swallow, 1 = cleared with one additional swallow, 2 = cleared with two to three additional swallows, and 3 = residue remaining after three swallows. For reliability, VEES recordings of 45 patients (May–June 2023) were independently assessed by three otolaryngologists (two with >15 years, one with 3 years' experience) and one speech–language pathologist (10 years' experience). Two senior otolaryngologists performed re-assessments, and weighted kappa coefficients were calculated. For validity, VEES data from 488 patients (July 2022–June 2023) were analyzed to examine correlations with the Hyodo score subitems and diet levels.

RESULTS

Weighted kappa coefficients demonstrated substantial inter- and intra-rater agreement, confirming the reliability of this method. The correlation coefficient between vallecular jelly clearance and diet level was 0.375, which was higher than that of the Hyodo subitems "sensitivity" and "reflex" and comparable to "pharyngeal clearance." The correlation between diet level and the total Hyodo score was 0.519, whereas the combination of the Hyodo score plus this new clearance scale improved the correlation to 0.552.

CONCLUSIONS

The proposed four-grade vallecular jelly clearance scale is simple, reliable, and valid. It provides a practical tool for evaluating swallowing function and may contribute to more accurate food texture selection in patients with dysphagia.

OUTCOME ANALYSIS OF ASPIRATION PREVENTION SURGERY: A 10-YEAR RETROSPECTIVE STUDY

Mei Sakamoto[1], **Junko Tsuda**[1], **Haruka Nakabayashi**[1], **Makoto Hashimoto**[1], **Kazuma Sugahara**[1]

[1]*Department of Otolaryngology, Yamaguchi University Graduate School of Medicine*

BACKGROUND & AIM

Aspiration prevention surgery separates the airway from the digestive tract at the larynx or cervical trachea to prevent aspiration. Since many patients can resume oral intake after surgery, it is expected to improve their quality of life(QOL). However, as many candidates are in poor general condition, ensuring surgical safety is essential.

In this study, we examined factors affecting perioperative eating status and risk factors for postoperative complications in patients who underwent aspiration prevention surgery in our department.

MATERIAL & METHODS

The study included 55 cases of aspiration prevention surgery performed at our department over a 10-year period (January 2014 to December 2023). Data were retrospectively collected from medical records to analyze factors influencing postoperative nutritional intake and risk factors for surgical complications.

RESULTS

Postoperative swallowing rehabilitation was the only factor significantly associated with improved nutritional intake.

Postoperative complications included wound dehiscence, wound infection, tracheal stoma stenosis, hematoma, and skin flap necrosis. Cerebral palsy was the only factor significantly associated with wound dehiscence, while trauma was the only factor associated with wound infection. No significant factors were identified for tracheal stoma stenosis, hematoma, or skin flap necrosis.

CONCLUSIONS

Postoperative swallowing rehabilitation contributes to improved nutritional intake, suggesting that active rehabilitation is important even after aspiration prevention surgery.

No significant correlation was found between nutritional status or radiation history and postoperative complications. These results suggest that aspiration prevention surgery can be performed relatively safely, even in patients in poor general condition, by selecting the appropriate surgical procedure for each case.

Coexistence Of Stylohyoid Ligament Calcification And Ankylosing Spondylitis: A Rare Case Report

Dr. Yekta SOYYİĞİT[1], **Prof. Dr. Enver ALTAŞ**[1], **Dr. Raşit HOŞGEL**[1], **Dr. Salim Mısırcı**[2]

[1]*Amasya University Faculty of Medicine, Sabuncuoglu Serefeddin Training and Research Hospital, Department of Otorhinolaringology;* [2]*Amasya University Faculty of Medicine, Sabuncuoglu Serefeddin Training and Research Hospital, Department of Rheumatology*

BACKGROUND & AIM

Eagle syndrome is a rare condition caused by styloid process elongation or stylohyoid ligament calcification, presenting with cervicofacial pain and dysphagia. Although its etiopatogenesis is debated, chronic inflammatory rheumatologic diseases like ankylosing spondylitis (AS), characterized by generalized enthesopathy and ligamentous ossification may potentially trigger or accelerate this mineralization. While rarely reported, Eagle syndrome can coexist in patients with AS. This report aims to present a rare case of Eagle syndrome in an AS patient, exploring the pathophysiological link between syndesmophyte formation and stylohyoid ligament calcification, while emphasizing its successful conservative medical management.

MATERIAL & METHODS

A 33-year-old male presented with a several-year history of a foreign body sensation on the left side of his throat during deglutition and intermittent pain, which had intensified over the past year. His medical history was notable for seasonal allergic rhinitis, septoplasti, cholecystectomy, and ankylosing spondylitis (AS) presenting with recurrent sacroiliitis attacks. The patient was taking indomethacin 50 mg/day for AS. There was no history of previous head and neck trauma. Familial history revealed AS in multiple maternal relatives. Complete otolaryngological and endoscopic examinations were unremarkable. Tonsils were bilaterally symmetrical and Brodsky grade 1. Palpation of the left tonsillar fossa successfully reproduced the patient's foreign body sensation and localized pain.

RESULTS

Laboratory investigations revealed no significant pathology. Lateral cervical radiography and three-dimensional (3D) reconstructed non-contrast neck computed tomography (CT) demonstrated a loss of cervical lordosis, along with bilateral styloid process elongation and extensive calcification of the stylohyoid ligaments. Notably, the calcification along the left stylohyoid ligament was longer and in direct anatomical contact with the hyoid bone. Based on these definitive clinical and radiological findings, the patient was diagnosed with left-sided Eagle syndrome. Given the patient’s active rheumatologic background and inflammatory profile, conservative management was favored over surgical intervention, and the daily indomethacin dose was titrated up to 100 mg.

CONCLUSIONS

This case highlights that Eagle syndrome should be considered in the differential diagnosis of rheumatology patients presenting with persistent globus sensation and dysphagia. Palpation of the tonsillar fossa plays a key role in clinical evaluation, while three-dimensional CT reconstruction is valuable for demonstrating anatomical relationships. Although limited data exist regarding the coexistence of Ankylosing Spondylitis and Eagle syndrome, their association remains controversial. In selected patients, considering the underlying rheumatologic condition, medical and conservative management may provide effective symptom control and represent a successful alternative to invasive surgical intervention, potentially reducing treatment-related morbidity.

Swallowing Disorders In Patients Surgically Treated For Early Laryngeal Cancer

Nora Siupsinskiene[1], **Vykintas Liutkevicius**[1], **Žygimantas Vaitkus**[1], **Saulius Vaitkus**[1]

[1]*Department of Otolaryngology, Academy of Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania*

BACKGROUND & AIM

The goal of this study was to analyze patients, which had early stages laryngeal cancer (T1–T2N0M0; I, II st.) treated by partial laryngectomy, swallowing function in late postoperative period.

MATERIAL & METHODS

65 male patients (mean age – 64.9 ± 8.9 yrs) treated in LUHS Otorhinolaryngology clinic from 2011 to 2018 data of flexible endoscopic evaluation of swallowing were analyzed. According to the type of surgery the patients were divided into 2 groups: 54 had partial laryngectomy (partial laryngectomy (PL) group), and 11 had endolaryngeal IV-VI type cordectomy with surgical CO2 laser (endoscopic laser cordectomy group). During the study, 4 food substances of different texture were used: drinking water, yogurt, pudding, and cookie. Four signs of impaired swallowing were assessed: liquids and food penetration, aspiration, residual food in the pharynx and esophagopharyngeal reflux.

RESULTS

Our result showed that signs of impaired swallowing were registered in more than half (64.6%) of the patients. In patients after PL impaired swallowing was identified in 68.5% of cases, and after endolaryngeal laser operations - in 45.5% of cases ($p < 0.05$). The most frequent finding in both groups was residual food in the pharynx: 44.4% and 36.4%, respectively. Penetration, aspiration, and esophagopharyngeal reflux were rare. The last 2 signs were only detected in patients after PL.

CONCLUSIONS

The study found that mild swallowing disorders predominated in the late period after surgical treatment of early-stage laryngeal cancer, an average of 4.1 years. The most frequent impaired swallowing sign was residual food in the pharynx. Swallowing disorders are registered significantly more often in patients after partial laryngectomy than in patients after endolaryngeal laser cordectomy.

SWALLOWING REHABILITATION AFTER PARTIAL GLOSSECTOMY AND RADIAL FOREARM FREE FLAP RECONSTRUCTION IN ADVANCED ORAL CAVITY CANCER: A CASE REPORT

Seren Demirtaş[1], **Buse Genç Sağlam**[1], **Bayram Barış Büyük**[1]

[1]*Ankara Oncology Training and Research Hospital*

BACKGROUND & AIM

Advanced-stage oral cavity squamous cell carcinomas with mandibular and floor-of-mouth invasion often require extensive surgical resection and complex reconstruction. Preservation and rehabilitation of swallowing function following tongue and floor-of-mouth defects remain among the most challenging aspects of postoperative management. In this case report, we aimed to present the surgical management and postoperative swallowing rehabilitation process of a patient with advanced oral cavity squamous cell carcinoma reconstructed with a radial forearm free flap.

MATERIAL & METHODS

A 79-year-old male presented with a non-healing ulcerative tongue lesion persisting for one year. Examination and imaging revealed squamous cell carcinoma involving the ventral tongue, floor of mouth, mandibular corpus, and bilateral cervical lymph nodes. (Figure 1) The tumor was clinically staged as T4aN2cM0. The patient underwent tumor excision with marginal mandibulectomy, bilateral neck dissection (levels I–IV), and reconstruction using a radial forearm free flap. (Figure 2)

Postoperatively, enteral feeding via nasogastric tube was maintained for 15 days. Fiberoptic Endoscopic Evaluation of Swallowing (FEES) demonstrated adequate swallowing function, and oral feeding was initiated. Despite the absence of structural or functional abnormalities, the patient later developed dysphagia symptoms and poor oral intake tolerance. Gastrointestinal evaluation was unremarkable, and psychiatric consultation led to a diagnosis of anxiety-related psychogenic dysphagia. Following psychiatric treatment, oral intake gradually improved.

Final pathology demonstrated T4aN3b disease with extranodal extension. Adjuvant chemoradiotherapy and long-term swallowing rehabilitation were planned.

RESULTS

Swallowing dysfunction following partial glossectomy may result from both structural and functional mechanisms. In this case, postoperative Fiberoptic Endoscopic Evaluation of Swallowing (FEES) demonstrated preserved oral and pharyngeal swallowing function without aspiration despite extensive anterior tongue and floor-of-mouth resection reconstructed with a radial forearm free flap. However, the patient experienced persistent dysphagia symptoms and inability to tolerate oral intake. Gastroenterological evaluation revealed no organic pathology, while rapid clinical improvement following psychiatric treatment suggested a psychogenic component of dysphagia.

Early FEES-guided swallowing assessment and rehabilitation enabled controlled reintroduction of oral feeding and supported long-term functional recovery. At approximately 40 days postoperatively, the patient achieved full oral intake without nutritional support or aspiration. This case highlights the importance of multidisciplinary swallowing evaluation after glossectomy and demonstrates that postoperative dysphagia may occur even in the absence of objective swallowing impairment.

CONCLUSIONS

Radial forearm free flap reconstruction is a reliable and effective reconstructive option for complex defects following extensive tongue and floor-of-mouth resections in advanced oral cavity cancers, providing satisfactory functional outcomes. Early restoration of oral feeding despite partial loss of the anterior tongue highlights the importance of appropriate reconstruction and multidisciplinary rehabilitation. Postoperative dysphagia may not always be related to structural or neurological causes, and psychogenic factors should also be considered in the differential diagnosis. Therefore, swallowing rehabilitation, psychiatric evaluation, and close postoperative follow-up should be integrated into the multidisciplinary management of patients undergoing advanced oral cavity surgery.

PP-734

Effect Of Physiotherapy On Dysphagia In Head And Neck Cancer Patients Following Oncological Treatment

Eva Koslaboa[1,2], **Marketa Rysana**[2], **Gabriela Stranska**[2], **Lenka Mrazkova**[2]

[1]*Department of Otorhinolaryngology, Head and Neck Surgery First Faculty of Medicine, Charles University in Prague and University Hospital Motol and Homolka;* [2]*Department of Rehabilitation and Sports Medicine, Second Faculty of Medicine, Charles University and Motol University Hospital, Prague, Czech Republic*

BACKGROUND & AIM

Dysphagia is a frequent and clinically significant complication following oncological treatment for head and neck cancer, substantially affecting nutritional status, swallowing safety, and quality of life. Early rehabilitation may play a crucial role in functional recovery; however, evidence supporting the benefit of targeted physiotherapy remains limited.

MATERIAL & METHODS

A prospective cohort of 20 patients following oncological treatment for head and neck cancer was evaluated. Inclusion criteria required completion of radiotherapy within the preceding three months. Patients were divided into two groups: an intervention group (n = 11) undergoing targeted physiotherapy focused on cervical soft tissue mobilization, scar release techniques, and home-based self-therapy, and a control group (n = 9) without physiotherapy intervention. The physiotherapy program consisted of 8–10 sessions. All patients underwent Flexible Endoscopic Evaluation of Swallowing (FEES) and completed the EAT-10 and SWAL-QOL questionnaires at baseline and at a three-month follow-up.

RESULTS

Twenty patients treated for oropharyngeal cancer with RT/CHRT, with or without surgery, were included; disease stage was comparable between groups. Eleven patients underwent targeted physiotherapy focused on cervical soft tissue therapy and scar mobilization, while nine received no physiotherapy intervention. FEES findings remained stable in all but one patient. The only discordant case occurred in the non-physiotherapy group, where subjective improvement on EAT-10 was accompanied by objective deterioration on FEES, with worsening from PAS 4 to PAS 8. In the physiotherapy group, mean EAT-10 scores improved from 19 at baseline to 10 at follow-up, whereas no change was observed in the control group (12 to 12). SWAL-QOL results indicated improved tolerance of food consistency and partial improvement in liquid tolerance in the physiotherapy group, while the control group showed no improvement in food tolerance and worsening of liquid tolerance.

CONCLUSIONS

Targeted physiotherapy focused on manual cervical soft tissue mobilization and scar release techniques may positively influence subjective swallowing outcomes and dysphagia-related quality of life in patients following radiotherapy-based treatment for head and neck cancer. Early rehabilitation may therefore represent an important component of multidisciplinary dysphagia management.

Accidentally Ingested Foreign Body Lodged In Thyroid Lobe: A Rare Presentation

Aviroop Saha Roy[2]

[1]*Bharati Vidyapeeth Hospital and Research Centre;* [2]*Charnock Lohia Hospital*

BACKGROUND & AIM

This case report is a testament to the wonder that is the human body, where a sharp metal wire pierced through the esophageal wall and got lodged in the thyroid gland, with the esophagus completely healed following the trauma. Thus, it proved to be a challenging case in terms of diagnosis and management for the team of otolaryngologists.

MATERIAL & METHODS

A 60-year-old female patient reported to the ENT outpatient department with presenting complaints of foreign body sensation in the throat since the last 15 days. Videolaryngoscopy of the patient showed a normal glottis with bilateral normal vocal cords and mobility. The patient was taken for cricopharyngoscopy and esophagoscopy with the aim of visualizing the foreign body and its removal under general anesthesia, which was normal. Computed tomography (CT) scan of the neck showed the foreign body, which was then removed from behind the right superior thyroid pole under C-arm guidance.

RESULTS

This case proves that both clinical correlation and radiological investigation go hand in hand in the management of foreign body ingestion, and one is incomplete without the other.

CONCLUSIONS

The confounding nature of the case is what makes it novel. The unusual migration of the foreign body, along with the atypical symptoms, proved to be a challenge for the treating surgeons.

Management Of Pharyngeal Pouch - A Retrospective Review Over 27 Years In A Single Tertiary Centre

Hayfa Sheikh[1], **Faizan Shah**[1], **Mr Fergus Cooper**[1], **Mr Ahmed Thabet**[1], **Mr Irfan Khan**[1], **Mr Muhammad Shakeel**[1]

[1]*ENT department, Aberdeen Royal Infirmary, Aberdeen, United Kingdom*

BACKGROUND & AIM

Pharyngeal pouch, also known as Zenker's diverticulum, is an acquired pulsion diverticulum arising through Killian's dehiscence and predominantly affects the elderly population. Surgical management has evolved considerably over the past three decades, with a shift from open transcervical approaches to minimally invasive endoscopic techniques. This study presents a 27-year retrospective review of pharyngeal pouch management at a tertiary ENT centre, evaluating trends in surgical practice and clinical outcomes.

MATERIAL & METHODS

A retrospective review was conducted of all patients treated for pharyngeal pouch between 1998 and 2025. Data collected included patient demographics, surgical technique (open vs endoscopic), length of hospital stay, recurrence rates, and perioperative complications. Statistical comparisons were performed between operative approaches using SPSS.

RESULTS

A total of 267 patients were identified (male:female ratio 1.8:1), with a mean age of 74.6 years (range 48–92). Endoscopic stapling or laser diverticulotomy was performed in 187 cases (75.7%), while 80 patients (24.3%) underwent open transcervical diverticulectomy with cricopharyngeal myotomy. The use of endoscopic techniques increased from 42% of cases in the first decade of the study period to 88% in the most recent decade.

Overall complication rates were significantly lower in the endoscopic group compared with the open group (6.2% vs 17.3%, p=0.018). Major complications (including mediastinitis, fistula formation, or return to theatre) occurred in 1.9% of procedures. The mean length of hospital stay was 1.8 days for endoscopic surgery compared to 3.1 days for open surgery. Symptom recurrence requiring revision surgery occurred in 8.6% of endoscopic cases and 5.8% of open cases over a median follow-up of 4.2 years.

CONCLUSIONS

Over a 27-year period at our tertiary centre, endoscopic management of pharyngeal pouch has become the predominant surgical approach. Endoscopic techniques were associated with shorter hospital stay and lower overall complication rates compared to open surgery, with acceptable recurrence rates. These findings support the continued preferential use of endoscopic approaches in appropriately selected patients.

PP-737

Classification Of Dysphagia Based On Acoustic Analysis Of Swallowing

Ramón Hernández-Villoria[1]

[1]*Centro Clínico de Audición y Lenguaje Cealca*

BACKGROUND & AIM

Objective: To systematize classification proposals for swallowing disorders based on acoustic and vibratory parameters obtained using instrumental techniques.

MATERIAL & METHODS

Methods: A narrative review was conducted to identify studies that propose specific taxonomies or correlations between acoustic/vibratory signal parameters and the pathophysiology of dysphagia.

RESULTS

Results: The authors have proposed classifications based on changes in parameters extracted from the digitized signal. For the oral phase, a significant increase in total event duration and sound fragmentation correlate with deficits in lingual propulsion. In the pharyngeal phase, the following stand out: 1) hypofunction pattern: characterized by a reduction in the amplitude (intensity) of the laryngeal “click” and the bolus sweep, associated with pharyngeal weakness. 2) residual pattern: identified by the presence of gurgling sounds following the main sweep and a slow decline in the signal, linked to residual fluid in the vallecula or pyriform sinuses. 3) Aspiration/penetration pattern: suggested by the detection of high-frequency vibrations (“bubbling”) or wet inspiratory sounds immediately following the swallowing event in the synchronized audio channel.Some attempts use machine learning algorithms to classify these patterns

CONCLUSIONS

Discussion: These classifications represent a step toward objective and quantifiable evaluation. However, the main limitation is methodological heterogeneity (types of sensors, location, test foods), which makes it difficult to establish a single, universally accepted taxonomy. These acoustic classifications do not replace etiological diagnosis, but rather describe the functional phenotype of dysphagia. Conclusion: Efforts are underway to classify subtypes of dysphagia based on acoustic patterns. These allow for an objective description of the dysfunction, guiding therapeutic intervention toward the impaired component (propulsion, force, clearance). Standardizing protocols is the next step toward validating and expanding the clinical use of these acoustic classifications.

Teacher Professional Development And Instructional Media For Hearing Health Promotion And Safe Listening Behavior Program For Elementary School Students.

Suwicha Kaewsiri Isaradisaikul, M.D.[1], **Orathai Inta, M.Ed**[2], **Aphuthatt Phumphattarameth, B.Ed.**[3], **Nutchar Wiwatkunupakarn, M.D.**[4]

[1]*Department of Otolaryngology, Faculty of Medicine, Chiang Mai University, Thailand;* [2]*Department of Curriculum and Instruction, Chiang Mai Rajabhat University, Thailand;* [3]*Pangmaphapittason School, Maehongson, Thailand;* [4]*Department of Family Medicine, Faculty of Medicine, Chiang Mai University, Thailand*

BACKGROUND & AIM

Raising awareness is important to promote hearing health and decrease preventable noise-induced hearing loss. Teachers play a significant role in this initiative, requiring professional development and instructional media to effectively promote safe listening behaviors.

This study aims to present a teacher professional development program focused on hearing health promotion and safe listening behavior, and to present the instructional media created and used to enhance awareness of hearing health and safe listening practices in elementary schools.

MATERIAL & METHODS

Retrospective data was collected during the 2023 academic year. Teachers in three Chiang Mai Provincial Administrative Organization affiliated schools were recruited and enrolled in a full-day teacher workshop on hearing health, hearing screening, instructional media development, and educational assessment. Following the workshop, teachers independently designed and implemented hearing health lessons using various instructional media.

RESULTS

Forty-four teachers participated in the workshop, with a mean age of 37.4 years. Post-test scores showed a significant improvement in teachers' knowledge of hearing health. The overall satisfaction score for the workshop was 4.51 out of 5. The program engaged 735 students through classroom activities, including experiments, posters, board games, and social media campaigns. Teachers integrated hearing health education into core subjects such as Health Education, Science, and Music.

CONCLUSIONS

The program demonstrated that teacher professional development and instructional media effectively enhance hearing health promotion in elementary schools. Teachers showed improved knowledge and confidence in delivering hearing health education. However, for sustainability, institutional support and curriculum integration are essential. Future research should explore long-term impacts on student behavior and policy development for hearing health education in schools.

Comparison Of Postoperative Pain And Hemorrhage Rates In Thermal Vs. Cold Dissection Tonsillectomy: A Multi- Center, Prospective, Randomized, Patient-Blinded Study

Methodios Stavridopoulos[1], **Mandytien Mak**[1], **Vaios Kouliopoulos**[1], **Zacharias Kalentakis**[2], **Vasileios Chalkiadakis**[1]

[1]*Otolaryngology Department, 417 Army Equity Fund Hospital, Athens, Greece;* [2]*Otorhinolaryngology Department, Sismanoglio General Hospital, Athens, Greece*

BACKGROUND & AIM

Tonsillectomy represents one of the most common surgical procedures in otolaryngology. Although various surgical techniques have been used to remove the palatine tonsils, postoperative pain, leading to difficulty in swallowing and subsequently higher likelihood of bleeding, continues to be documented. This study aims to compare postoperative pain and hemorrhage rates in adult patients undergoing thermal or cold dissection tonsillectomy.

MATERIAL & METHODS

This is a prospective, multi- center, randomized, patient-blinded study. Adult patients that were scheduled to undergo tonsillectomy, regardless of indication, were randomly allocated to either the thermal (bipolar cautery) or cold dissection group using a computer-generated randomization sequence. Allocation was revealed only to the surgeon on the operation day. Patients with coagulation disorders were excluded from the study. Both groups received the same standardized perioperative and postoperative analgesia protocol. Patients were asked to complete a 7-day Visual Analog Scale (VAS) pain score, and occurrence of hemorrhage was recorded. Statistical analysis was performed using Mann-Whitney U and Fisher's exact tests (significance set at $p < 0.05$).

RESULTS

In total, 36 patients participated in this study, 18 in each group, with 1 drop-out from the cold group. Mean age was 26.49 ±9.32, and the cohort consisted of 20 females and 15 males. There was no significant difference in age and sex distribution between the two groups (p=0.493 & p=0.176 respectively). Patients in the thermal group experienced significantly lower pain during the first 48 hours (p=0.012 & p=0.038 respectively), whereas, by day seven the cold group reported significantly less pain (p=0.043). Postoperative hemorrhage occurred in 16.7% (n=3) of the thermal group compared to 0% in the cold group (p=0.229).

CONCLUSIONS

In this study, thermal dissection provided significantly reduced pain in the immediate 48h postoperative period. However, cold dissection was associated with significantly favorable recovery profile by day seven and a lower, though not statistically significant, incidence of secondary hemorrhage. Although our study was limited by a small sample size, the observed results align with current literature.

[1]*Grigore T. Popa University of Medicine and Pharmacy Iasi, Romania*

BACKGROUND & AIM

Total antioxidant capacity (TAC) is a global indication of the level of oxidative stress, reflecting the reaction capacity of the antioxidant reserve. TAC measurement has become particularly important in assessing oxidative stress at the plasma, or organ level. Its values can be used to assess an organism's ability to combat oxidative stress. In general, TAC is low under conditions that generate oxidative stress. Chronic otitis media is associated with a perforation of the tympanic membrane accompanied by inflammation of the mucosa lining the tympanic cavity and the air cells of the temporal bone that persists for more than three months

MATERIAL & METHODS

We conducted a prospective study was conducted on a group of 60 patients aged between 9 and 58 years diagnosed with chronic suppurative otitis media (CSOM) with and without cholesteatoma, admitted for surgery at the Clinical Rehabilitation Hospital from Iași, Romania.

RESULTS

In the present study, analyzing the values obtained by us through TAC measurement, we found that in the cholesteatoma group, TAC ranged between 26.908 mmol/µL and 28.608 mmol/µL, in the cholesteatoma recurrence group between 25.902

mmol/µL and 28.411 mmol/µL, and in the group with OMCS, between 25.815 mmol/µL and 39.313 mmol/µL, which were lower values compared to the control group, where the values ranged between 27.834 mmol/µL and 31.185 mmol/µL. Thus, in all patient groups, serum TAC levels were statistically significantly lower compared to the group of healthy individuals.

CONCLUSIONS

Chronic suppurative otitis media is associated with high levels of oxidative stress, playing a key role in the pathogenesis and tissue damage.

PP-741

Construction Of A Cluster Nursing Protocol For Perioperative Oral Implantation Under The Enhanced Recovery After Surgery Framework And Its Effects On Psychological Stress And Rehabilitation Quality

Zhang Hui[1]

[1]*Chongqing No.13 People's Hospital*

BACKGROUND & AIM

Enhanced Recovery After Surgery (ERAS) is a multimodal, evidence-based perioperative management philosophy demonstrated effective across multiple surgical disciplines. However, its systematic application to oral implant surgery through structured cluster nursing protocols remains insufficiently explored.

MATERIAL & METHODS

A prospective randomized controlled trial enrolled 120 patients scheduled for dental implant surgery, randomly allocated to an ERAS cluster nursing group (n = 60) or a conventional nursing group (n = 60). The protocol was developed through systematic literature review and Delphi expert consultation. Primary outcomes included perioperative anxiety (State-Trait Anxiety Inventory), pain intensity (Numerical Rating Scale), and salivary cortisol levels. Secondary outcomes comprised postoperative swelling scores, functional recovery time, patient satisfaction, and complication rates at 12 weeks.

RESULTS

Compared with controls, the ERAS group demonstrated significantly lower anxiety scores ($P < 0.001$), reduced salivary cortisol concentrations at 24 h postoperatively ($P = 0.003$), decreased pain scores on days 1 and 3 ($P < 0.05$), shorter functional recovery time ($P = 0.012$), and higher patient satisfaction ($P < 0.001$). No significant between-group difference in complication rates was observed ($P = 0.218$).

CONCLUSIONS

The ERAS-based cluster nursing protocol effectively attenuates perioperative psychological stress, accelerates postoperative rehabilitation, and enhances patient satisfaction in oral implant surgery, warranting broader clinical implementation.

How To Spot The Eagle? An Atypical Presentation Of Eagle's Syndrome

Dr Poon, Karen Gwyn[1,2], **Dr Chan, Chin Pang Walter**[1,2]

[1]*Yan Chai Hospital;* [2]*Kowloon West Cluster, Hong Kong*

BACKGROUND & AIM

Eagle's syndrome has historically been known as a phenomenon where the elongated styloid process or ossified stylohyoid ligament compresses on surrounding vessels or neurological structures, giving rise to common presentations such as dysphagia, foreign body sensation and pain.

MATERIAL & METHODS

It is important to note that another variant of the complications is known as Eagle Jugular Syndrome, where the internal jugular vein is compressed. The most common presentation includes headache and ipsilateral neck pain. We describe a case in which a 42-year-old lady first presented with left orbital pain for 6 months. Shortly, in the following months, she developed left eye blurry vision and diplopia upon left lateral gaze.

RESULTS

Subsequent CT Brain scan revealed a left orbital roof meningoencephalocele, while the CT venogram also showed narrowing of the right IJV caused by the styloid process and the C1 transverse process. With an elevated lumbar puncture opening pressure of 38cm H2O, it was postulated that she has venopathic intracranial hypertension due to styloid process compression on the IJV, which causes the orbitomeningocele. Styloidectomy and reduction of the C1 process were done under general anesthesia along with neurosurgeons. Her lumbar puncture opening pressure dropped to 23cm H2O on Post-op day 1. Her symptoms, including left orbital pain and diplopia, were greatly resolved almost immediately after the surgery.

CONCLUSIONS

This case illustrates the importance of fostering clinical awareness on atypical presentations of Eagle's syndrome.

Exploring Implicit Bias Among ENT Surgeons: An Analysis Of The Implicit Association Test

Zareena Shah-Altaf[1], **Pavol Surda**[1], **Claire Hopkins**[1], **Kevin Miu**[1], **David Ranford**[1]

[1]*Guy's and St Thomas' NHS Foundation Trust*

BACKGROUND & AIM

This study aimed to investigate the presence of implicit bias among ENT surgeons and explore the impact of the results of the Implicit Association Test on the surgeons' behaviour towards patients.

MATERIAL & METHODS

Seven ENT surgeons who were not black, Asian or minority ethnic were asked to complete the Race Implicit Association Test. The surgeons also completed a survey about their perceptions of their implicit biases and the impact of the Race Implicit Association Test results on their behaviour towards patients.

RESULTS

The mean Race Implicit Association Test score for the ENT surgeons suggested a slight bias that favoured white over black people. Furthermore, 42 per cent of the surgeons thought that they had hidden or unconscious racial bias, 42 per cent said they would change their behaviour towards patients after receiving these results and 85 per cent thought that the Race Implicit Association Test was helpful for appraisal purposes.

CONCLUSIONS

The results suggest that ENT surgeons who are not black, Asian or minority ethnic may have implicit biases towards black patients. These findings highlight the need for interventions to reduce implicit bias among ENT surgeons and improve healthcare outcomes for marginalised populations.

PP-744

Vestibular Paroxysmia: Are Giant Auditory Brainstem Response Waves a Marker of Central Nervous System Excitation?

Ayberk Aydın Tunç, M.Sc., PhD(s)[1], **Anita Gáborján, MD, PhD**[1], **Hunor Sükösd, MD**[2], **Prof. Tamás László**[1], **Beáta Bencsik, MD, PhD**[1], **Ágnes Szirmai, MD, PhD**[1]

[1]*Department of Oto-Rhino-Laryngology and Head and Neck Surgery, Semmelweis University, Budapest, Hungary;* [2]*Department of Radiology , Höglandssjukhuset, Eksjö, Sweden*

BACKGROUND & AIM

Vestibular paroxysmia (VP) is a rare disorder (<1/2,000) caused by neurovascular cross-compression of the eighth cranial nerve, characterized by brief, recurrent episodes of rotatory vertigo lasting less than a minute (Brandt et al., 2016; Shi et al., 2022).

Auditory Brainstem Response (ABR)

testing has demonstrated retrocochlear findings in VP, particularly prolonged wave III latency (>4.0 ms) and interpeak latency I–III (>2.3 ms) (Sun et al., 2022; Møller et al., 1986).

This case introduces a novel finding:

markedly elevated ABR waveform amplitudes — "giant" responses —contralateral to the site of neurovascular compression, in the absence of latency prolongation.

MATERIAL & METHODS

Patient: 41-year-old female presenting with recurrent episodic rotatory vertigo (predominantly morning onset) with tinnitus and transient aural fullness.

Audiological: Normal audiometry and tympanometry; BPPV excluded.

ELECTROPHYSIOLOGICAL FINDINGS (ABR):

Right ear: Wave I: 1.40 ms · Wave III: 3.60 ms · Wave V: 5.60 ms · IPL I–III: 2.20 ms — all within normal limits. Left ear: Wave I: 1.27 ms · Wave III: 3.53 ms · Wave V: 5.67 ms · IPL I–III: 2.27 ms — normal latencies. Left ear display scale expanded to +300 nV (vs. standard +200 nV) to accommodate giant waveforms — not amenable to precise amplitude quantification.

Vestibular: Left-sided caloric deficit with normal video head impulse test (vHIT) bilaterally, a caloric/vHIT dissociation indicating retrocochlear rather than end-organ involvement. MRI: Tortuous vertebro-basilar artery causing a slight impression on the right side of the medulla (see Figure 2). Diagnosis: Vestibular paroxysmia secondary to neurovascular compression.

RESULTS

ABR testing revealed prolonged latencies of waves III and V on the right side. In contrast, the left side demonstrated unusually large-amplitude ("giant") ABR waves with normal latencies, representing an uncommon electrophysiological finding. Magnetic resonance imaging showed vascular contact between the vertebral artery and the ventral aspect of the pons, consistent with neurovascular compression.

CONCLUSIONS

► Giant ABR waveforms represent a novel, previously unreported electrophysiological finding in vestibular paroxysmia.

► Their contralateral occurrence suggests neuronal hyperexcitability rather than conduction block as the underlying mechanism.

► ABR amplitude analysis may serve as an additional diagnostic marker for neurovascular compression syndrome.

► Future studies should investigate whether giant waveforms normalize following MVD or pharmacological treatment.

PP-745

Reported Outcome Direction In Endoscopic Sinus Surgery Literature: A Cross-Sectional Analysis

Furkan Yavuz[1], **Ozan Gökdoğan**[1]

[1]*Department of Otorhinolaryngology, Faculty of Medicine, Mugla Sitki Kocman University*

BACKGROUND & AIM

Scientific studies are often interpreted according to whether their findings support the original hypothesis. In endoscopic sinus surgery (ESS) literature, the direction of reported outcomes may be shaped not only by scientific merit, but also by journal prestige and methodological study characteristics. We aimed to evaluate the frequency of positive outcome reporting in ESS studies and to examine its association with journal quartile, comparator status, study design, sample size, and publication period, including pre-Coronavirus disease 2019 (COVID-19), COVID-era, and artificial intelligence (AI)-era trends.

MATERIAL & METHODS

This was a cross-sectional bibliographic analysis of ESS studies published between 2015 and 2025. PubMed was searched in February 2026 using predefined terms related to ESS and treatment outcomes, with publication-type filters for clinical studies. Reviews, editorials, letters, and case reports were excluded. Journal quartiles were assigned according to the year of publication using SCImago Journal Rank data rather than current rankings. Outcome direction was initially classified as positive, neutral, or negative; because negative studies were rare, primary analyses used a dichotomous outcome of positive versus non-positive. Independent variables included quartile group, comparator status, study design, publication period, and sample size. Statistical analyses included chi-square or Fisher's exact tests, odds ratios with 95% confidence intervals (CIs), and multivariable logistic regression.

RESULTS

A total of 264 studies were included; 165 (62.5%) were positive, 95 (36.0%) neutral, and 4 (1.5%) negative. Higher-impact journals (Q1-Q2) showed a numerically greater proportion of positive studies than lower-impact journals (Q3-Q4) (64.5% vs 50.0%), but this difference was not statistically significant (p=0.096). Comparator-free studies were significantly more likely to report positive outcomes than studies with a comparator (82.4% vs 59.6%; odds ratio 3.17, 95% CI 1.26-7.95; p=0.010). Era analysis showed positive rates of 63.4% in the pre-COVID period (2015-2019), 52.1% during the COVID era (2020-2022), and 68.7% in the AI era (2023-2025), with no statistically significant overall difference, although the COVID-versus-AI comparison approached significance (p=0.071). Study design and sample size were not significantly associated with outcome direction. In multivariable analysis, comparator status remained the only independent predictor of positive outcome reporting.

CONCLUSIONS

Positive findings predominated in the ESS literature. Journal impact was not significantly associated with positive outcome reporting, whereas comparator-free studies were significantly more likely to report positive results. In addition, a non-significant decline in positive reporting during the COVID era followed by a rebound in the AI era was observed. These findings suggest that methodological characteristics may influence reported outcome direction more strongly than journal quartile, while temporal shifts in publication patterns may also warrant further investigation. The relatively small number of Q3-Q4 studies may have limited the power of quartile-based comparisons.

Developing A Sustainable Blended Training Framework To Enhance Audiologist Expertise In Hearing Implant Technology

Celina Ann Tobias-Grasso[1]

[1]*MED-EL*

BACKGROUND & AIM

The widespread adoption of Tele-Audiology and online learning in recent years has transformed how hearing healthcare practitioners access education and professional development. What began as a response to limited in-person training opportunities has evolved into a sustainable model that enhances accessibility, affordability, and inclusivity in Audiology education. E-learning and blended learning approaches are now integral to both pre-service and continuing professional development, particularly for clinicians in rural and remote areas. However, challenges remain in translating traditional, hands-on training methods into engaging, effective online formats that support skill development and clinical competence.

MATERIAL & METHODS

A qualitative research design was employed to describe the development of an blended training program on hearing implants for Audiologists in Malaysia and Sub-Saharan Africa. A phenomenological case study captured the experiences of training developers and subject matter experts in adapting conventional instructional content into e-learning and blended learning modules. Learning science principles and learning experience design (LxD) frameworks were integrated into the development process. Feedback from Audiologists participating in the pilot program was collected through an online questionnaire to assess usability, engagement, and perceived learning outcomes.

RESULTS

Findings highlight that the design and delivery of blended training — including interactivity, feedback mechanisms, and communication channels — significantly influence learner engagement and perceived effectiveness. Adult learning preferences, such as self-paced exploration, contextual relevance, and opportunities for collaboration, emerged as critical factors in successful online training design.

CONCLUSIONS

Post-pandemic developments in online education present a unique opportunity to reimagine Audiology training as both sustainable and scalable. Incorporating evidence-based e-learning strategies can help bridge geographic and resource gaps, ensuring equitable access to high-quality training for hearing healthcare practitioners worldwide. Ongoing research into digital pedagogy and learner experience will be essential to refine and sustain this evolving model of training Audiologists.

Readability Of AI-Generated Postoperative Instructions In Otolaryngology: A Prompt-Based Comparative

PINAR TEKİN[1], **SEVİLAY HANÇER TECİMER**[2], **ZEYNEP İSKENDER EMEKLİ**[1]

[1]*Department of Otolaryngology - Head and Neck Surgery, Malatya Training and Research Hospital, Malatya,Turkiye;* [2]*Department of Otolaryngology - Head and Neck Surgery, Malatya Turgut Ozal University Faculty of Medicine, Malatya,Turkiye*

BACKGROUND & AIM

Postoperative instructions play a critical role in patient understanding and adherence following otolaryngologic surgery. However, written medical materials are frequently produced at reading levels exceeding patients' health literacy. Artificial intelligence (AI) tools such as ChatGPT are increasingly used to generate patient-facing information, yet the readability of AI-generated postoperative instructions remains inadequately explored.

To compare the readability of AI-generated postoperative instructions created using a sixth-grade–targeted prompt with those generated using a standard prompt across common otolaryngologic surgical procedures.

MATERIAL & METHODS

Postoperative instructions for common otolaryngologic surgeries were generated using ChatGPT with two different prompts: (1) a sixth-grade reading level–targeted prompt and (2) a standard, non-specified prompt. Readability was assessed using the Flesch–Kincaid Grade Level (FKGL), Flesch Reading Ease Score (FRES), Gunning Fog Index (GFI), Simple Measure of Gobbledygook (SMOG) Index, and Coleman–Liau Index (CLI). Normality was evaluated using the Shapiro–Wilk test. Paired samples t-tests were performed to compare readability scores between the two prompt strategies.

RESULTS

Sixth-grade–targeted AI-generated postoperative instructions demonstrated significantly improved readability across all assessed metrics. Compared with standard prompts, sixth-grade–targeted prompts produced lower Flesch–Kincaid Grade Level scores (mean difference = 3.24, $p < 0.001$), Gunning Fog Index scores (mean difference = 1.65, $p < 0.001$), SMOG Index scores (mean difference = 1.42, $p < 0.001$), and Coleman–Liau Index scores (mean difference = 3.82, $p < 0.001$). Additionally, Flesch Reading Ease Scores were significantly higher in sixth-grade–targeted instructions (mean difference = −27.60, $p < 0.001$).

CONCLUSIONS

Prompt engineering targeting a sixth-grade reading level significantly enhances the readability of AI-generated postoperative instructions in otolaryngology. These findings suggest that targeted AI prompting may serve as a practical strategy to improve patient education materials and support health literacy in surgical care.

Physicians' Perspectives On Artificial Intelligence In Clinical Practice In Kuwait: A Survey Study

Nawaf Almotairi[1], **Ali Alterki**[2], **Abdulrahman Albader**[1], **Maryam Alshammeri**[1], **Falah Alhajraf**[3], **Abdullah Rajab**[4], **Rawan Hashem**[5], **Abdulmohsen Alterki**[6]

[1]Otolaryngology–Head & Neck Surgery, Kuwait Institute for Medical Specializations (KIMS), Kuwait.; [2]Kuwait Board of Dentistry, Kuwait Institute for Medical Specializations (KIMS), Kuwait.; [3]Al Jahra hospital, Al Jahra city, Kuwait.; [4]Assistant Secretary General for specialized Facilities, Kuwait Institute for Medical Specializations (KIMS), Kuwait.; [5]Head of Postgraduate office, Kuwait Institute for Medical Specializations (KIMS), Kuwait.; [6]Chairman of Head and Neck Surgery, Kuwait Board of Post Graduate Training Program, Kuwait Institute for Medical Specializations (KIMS), Kuwait.

BACKGROUND & AIM

Artificial intelligence (AI) is a transformative technology that is reshaping many aspects of professional practice, with healthcare being one of the most affected fields. Therefore, this study aimed to assess physicians' knowledge, attitudes, acceptance, concerns, and perspectives on the future directions of AI use in clinical practice in Kuwait.

MATERIAL & METHODS

A cross-sectional survey was conducted among all trainees and trainers enrolled in the Kuwait Institute for Medical Specialization (KIMS) across 5 public hospitals in Kuwait. A total of 4,109 physicians affiliated with KIMS, representing 43 specialties across residency and fellowship programs, were invited to participate through email and WhatsApp groups. The data were collected using an online questionnaire from February 2025 to September 2025, covering demographics, knowledge of AI, practical exposure, attitudes and acceptance toward its use in clinical practice, perceived benefits and risks of AI replacing doctors' roles, concerns, and future directions for AI training in clinical practice.

RESULTS

A total of 505 physicians participated in the survey, including 202 trainees (≤5 years) and 303 trainers (≥6 years) from 37 specialties. Of these, 105 were from surgical specialties, 264 from medical specialties, 33 from diagnostic and support specialties, and 103 from dentistry. Self-rated awareness of artificial intelligence (AI) was high in both groups, reported by 93 trainees and 141 trainers, while practical exposure to AI remained limited (99 trainees and 144 trainers). Positive attitudes and acceptance toward AI were observed in 149 trainees and 230 trainers. Perceived high benefits of AI were reported by 152 trainees and 264 trainers. Most participants perceived a moderate risk of AI replacing physicians' roles (63% of trainees and 65% of trainers), whereas high concern and low trust were reported by 28% of trainees and 33% of trainers. Willingness to receive AI training was high, reported by 72% of trainees and 80% of trainers.

CONCLUSIONS

This study demonstrates that physicians in Kuwait have generally positive perceptions and acceptance of artificial intelligence in clinical practice, with moderate awareness and limited practical exposure. Despite some concerns and perceived risks, most participants recognize the potential benefits of AI and express a strong willingness to receive further training.

The Transformative Role Of Artificial Intelligence In Otorhinolaryngology-Head And Neck Surgery: Current Applications And Future Horizons

Dr. Tamer Azab[1]

[1]Al Emadi Hospital , Doha , Qatar

BACKGROUND & AIM

The rapid evolution of Artificial Intelligence (AI) is catalyzing a paradigm shift in modern medicine. Otolaryngology (ENT), being a data-intensive specialty reliant on complex imaging, acoustics, and endoscopic evaluations, stands at the forefront of this digital transformation. We hypothesize that integrating AI as a "decision-support tool" rather than a replacement for clinical judgment is essential for the future of ENT to enhance diagnostic precision and personalized patient care.

MATERIAL & METHODS

This study design involves a comprehensive analysis of current AI-driven protocols across various settings in the ENT field. The subjects of our evaluation include: (1) Computer vision systems for automated audiometry and otoscopic image classification; (2) Advanced CT and MRI image segmentation for chronic rhinosinusitis and skull base procedures; (3) Convolutional Neural

Networks (CNNs) for detecting vocal fold paralysis and laryngeal malignancies via endoscopy; and (4) AI integration in Transoral Robotic Surgery (TORS)

RESULTS

Our analysis indicates that AI technologies effectively improve haptic feedback and surgical precision in TORS. Furthermore, CNNs demonstrate high accuracy in early malignancy detection through voice signal analysis and endoscopic imaging. While these outcomes offer unprecedented opportunities to reduce human error and provider burnout, the results also highlight significant independent variables that may hinder clinical adoption, such as data privacy concerns, algorithmic bias, and the "black box" nature of Deep Learning (DL)

CONCLUSIONS

The findings support that AI offers a transformative potential for the ENT specialty by optimizing diagnostic and surgical outcomes. However, to address both positive and negative results, it is concluded that future implementation must be supported by ethical frameworks that ensure algorithmic transparency. Integrating AI to augment clinical judgment remains the most viable path forward for the field.

Inflammatory Status In Chronic Suppurative Otitis Media

Roxana Serban[1], **Cristiana Filip**[1], **Oana Raluca Temneanu**[1], **Oana Madalina Rosu**[1], **Otilia Novac**[1], **Alice Nicoleta Grudnicki**[1], **Luminita Radulescu**[1], **Corina Butnaru**[1]

[1]*Grigore T. Popa University of Medicine and Pharmacy Iasi, Romania*

BACKGROUND & AIM

The pathophysiology of cholesteatoma is not fully understood, with research focusing on various areas, including predisposing factors and immunological, inflammatory, and genetic mechanisms. The recurrence rate and degree of middle ear involvement have been correlated with the presence of inflammatory cytokines in the middle ear mucosa. The most common studies have been conducted on serous otitis media or chronic mucous otitis media in children and adults or in animal models.

MATERIAL & METHODS

The prospective study was conducted on a group of 60 patients aged between 9 and 58 years diagnosed with chronic suppurative otitis media (CSOM) with and without cholesteatoma, admitted for surgery at the Clinical Rehabilitation Hospital from Iași, Romania. Of these, 28 patients had CSOM, 22 had CSOM with cholesteatoma, and 11 had recurrent cholesteatoma. Serum levels of IL-1 alpha, IL-6, C-reactive protein, and fibrinogen were measured in patient serum.

RESULTS

In the present study, serum CRP and fibrinogen did not show statistically significant differences between patient groups, being in the normal range (0-1 mg/dl). Regarding the values obtained for IL-1α, it can be observed that in patients with cholesteatoma and CSOM, significantly lower values were recorded compared to those with recurrence cholesteatoma. The serum IL-6 values obtained in the present study were statistically significantly higher compared to the control group, with the highest values being found in patients with CSOM

CONCLUSIONS

IL-1α and IL-6 showed statistically significant higher values (the highest in patients with simple chronic suppurative otitis media) compared to the control group. Inflammatory mediators play a central role in the pathogenesis of CSOM and cholesteatoma by maintaining a systemic and local inflammatory response.

How Safe Is Tonsillectomy In A Day-Surgery Setting? Evidence From A 10-Year Multicenter Cohort

Bálint Tóth[1], **Dimitros Paouris**[1], **Andrea Dičérová**[2], **Zuzana Holeková**[3], **Beáta Worth**[4], **Abdallah O. M. Salama**[5], **Milan Profant**[1], **Lukáš Varga**[1], **Miroslav Tedla**[1]

[1]*Department of Otorhinolaryngology – Head and Neck Surgery, Faculty of Medicine, Comenius University and University Hospital Bratislava, Slovakia;* [2]*Department of Otorhinolaryngology, Faculty Hospital Trenčín, Slovakia;* [3]*Department of Otorhinolaryngology, Faculty Hospital Nitra, Slovakia;* [4]*Department of Otorhinolaryngology, Faculty Hospital Trnava, Slovakia;* [5]*Department of Otorhinolaryngology, Faculty Hospital Nové Zámky, Slovakia*

BACKGROUND & AIM

Post-tonsillectomy hemorrhage (PTH) represents the most severe complication of this procedure and significantly influences decision-making regarding discharge within a day-surgery setting. The aim of this study was to evaluate the feasibility of tonsillectomy in a day-surgery setting and to identify risk factors for postoperative hemorrhage, its timing, and its severity.

MATERIAL & METHODS

This multicenter retrospective cohort study included 2,612 patients aged ≥16 years over a 10-year period (2015–2025) across five university hospitals in Slovakia (Bratislava, Trnava, Nitra, Nové Zámky, Trenčín). Early (<24 hours), late (>24 hours), and total postoperative hemorrhage were evaluated, as well as its severity (hospitalization, surgical revision under general anesthesia, recurrent bleeding) and timing. Statistical analysis included chi-square tests, non-parametric tests, and multivariate logistic regression.

RESULTS

Total hemorrhage occurred in 22.8% of patients (early: 2.4%, late: 20.4%). Median age was 28.2 years; 58.1% were female. Most were non-smokers (63.6%), 10.0% had hypertension, and 94.0% were without anticoagulation. Male sex consistently predicted higher risk of early (OR=2.19, p=0.005), late (OR=1.45, p<0.001), and total hemorrhage (OR=1.55, p<0.001). Anticoagulation correlated with early bleeding, especially LMWH bridging (OR=4.01, p=0.017), while antiplatelet therapy increased total hemorrhage risk (OR=3.66, p=0.015). Higher age slightly reduced late and total bleeding risk (1.5–2% annually). Smoking, tonsil size, and surgery duration showed no associations. Among bleeding cases, 69.1% required hospitalization, 23.9% experienced recurrence, and 12.8% underwent surgical revision. Hypertension predicted hospitalization (OR=3.13, p=0.026) due to severity. No predictors for revision or recurrence were identified. Bleeding occurred earlier in men than women (5.34 vs. 5.91 days, p=0.011); other factors did not affect timing.

CONCLUSIONS

Postoperative hemorrhage after tonsillectomy remains a clinically significant complication, the occurrence of which could not be reliably predicted based on the monitored factors in most cases. Early hemorrhage was rare and primarily associated with male sex and anticoagulation therapy. The results support the feasibility of tonsillectomy in a day-surgery setting in selected patients.

Educational Impact Of Augmented Reality-Based 3D Visualization In Head And Neck Anatomy: A Randomized Study Using Hololens 2

Dr. med. Eren Erdogan[1], **Zeynep Durmus**[1], **Prof. Jonas J.-H. Park**[1]

[1]*Department of Otorhinolaryngology, Head and Neck Surgery Chair of Otorhinolaryngology, University of Witten/Herdecke*

BACKGROUND & AIM

Head and neck anatomy is highly complex, and understanding the spatial relationships between anatomical structures remains challenging for medical students. Traditional two-dimensional atlases are limited in supporting spatial thinking. Mixed reality (MR) technologies, such as the HoloLens 2 in combination with VSI HoloMedicine®, may enhance learning by enabling interactive 3D visualization. This study aimed to investigate whether MR-based teaching improves anatomical understanding compared with conventional 2D methods.

MATERIAL & METHODS

Medical students were divided into two groups. Group A (n=30) used traditional 2D anatomical atlases, while Group B (n=32) studied CT datasets using the HoloLens 2 and VSI HoloMedicine® software. Both groups answered ten questions on head and neck anatomy, with particular focus on spatial anatomical relationships. Before and after testing, participants completed feedback questionnaires regarding their learning experience.

RESULTS

Students in the MR group (Group B) achieved higher scores than those in the 2D group (Group A) across all questions. Significant differences were observed in 7 out of 10 questions, especially in tasks requiring spatial orientation and anatomical correlation. Feedback analysis indicated that students in Group B rated the MR-based learning approach as more effective in improving their understanding of head and neck anatomy. Both groups required familiarization, with Group B needing an initial adaptation phase to handle the MR system.

CONCLUSIONS

This pilot study demonstrates that mixed-reality–based 3D visualization offers superior educational value compared to traditional 2D atlases for learning complex head and neck anatomy. MR technology enhances spatial understanding and may represent a valuable addition to future medical teaching curricula. Further research is needed to evaluate its integration into larger-scale anatomy education.

Factors Associated With Non-Attendance In Otolaryngology Outpatient Clinics: A Systematic Review Of The Literature

Aurora López Llames[1], **Vicente García Roman**[2], **Antonio Almodóvar Iñesta**[4], **Elena Ronda Pérez**[3]

[1]*Department of Otolaryngology, Torrevieja University Hospital, Spain;* [2]*Departament of Preventive Medicine and Public Health, Torrevieja University Hospital, Spain;* [3]*Public Health Research Group, University of Alicante;* [4]*Department of Otolaryngology, General University Hospital of Elche, Alicante, Spain*

BACKGROUND & AIM

Patient no-show in outpatient clinics represents a significant challenge for healthcare systems, as it compromises care efficiency, increases waiting times, and limits access for other patients. The aim of this systematic review was to analyze the available evidence on factors associated with no-show in otolaryngology (ENT) outpatient settings.

MATERIAL & METHODS

A systematic review with narrative synthesis was conducted in accordance with the PRISMA 2020 guidelines. A structured search was performed in MEDLINE/PubMed and Web of Science up to March 2026. Original studies conducted in face-to-face ENT outpatient clinics that evaluated no-show rates or their associated factors in adult or pediatric populations were included. Methodological quality and risk of bias were assessed using the Joanna Briggs Institute critical appraisal tools.

RESULTS

A total of 20 studies were included, most of which were retrospective and conducted in university-based settings. No-show rates ranged from 8% to 40%, depending on the context and population studied. The factors most consistently associated with higher no-show rates were younger age, lower socioeconomic status, and public health insurance coverage. Among organizational factors, longer waiting times and the absence of reminder systems were associated with a higher likelihood of non-attendance.

CONCLUSIONS

No-show in ENT outpatient clinics is a frequent and multifactorial phenomenon. Our findings suggest a potential influence of sociodemographic and organizational factors. Organizational interventions, such as schedule optimization, reduction of waiting times, and implementation of reminder systems, may help reduce no-show rates and improve healthcare system efficiency.

Comparison Of Two Techniques In Tonsillectomy: Coblation And Thermal Welding Techniques

İlhan Topaloğlu[1], **Şefika Şeyma Şabano**[1], **Arda Yavuz**[1], **Müzeyyen Doğan**[1], **Meryem Babaoğlan**[1]

[1]*Yeditepe University Faculty of Medicine, Department of Otorhinolaryngology, Istanbul, Turkey*

BACKGROUND & AIM

Various tonsillectomy techniques have been developed to improve operative efficiency and reduce postoperative morbidity. This study evaluates coblation and thermal welding techniques in terms of operative time, postoperative Visual Analog Scale (VAS), and postoperative hemorrhage.

MATERIAL & METHODS

This study included patients who underwent tonsillectomy at the Department of Otorhinolaryngology, Yeditepe University Faculty of Medicine, Istanbul, Türkiye, between 2013 and 2025. Patients were divided into two groups according to the surgical technique used: coblation tonsillectomy and thermal welding tonsillectomy. Operative time was defined as the duration from mucosal incision to completion of hemostasis. Postoperative pain was assessed using the VAS score at the 6th and 12th postoperative hours. Postoperative hemorrhage was categorized as primary (within 24 hours) or secondary (>24 hours) and further classified as absent, minor (self-limited bleeding), or major (requiringsurgical intervention). The collected data were analyzed statistically.

RESULTS

A total of 137 patients were included (coblation: n=65; thermal: n=72). Sex distribution(31M/34F vs 41M/31F) and mean age (19.4 ± 13.0 vs 15.4 ± 12.9 years) were similar between groups ($p>0.05$). The mean operative time was significantly shorter in the coblation group compared with the thermal welding group (50.0 ± 20.2 minutes vs 68.4 ± 31.2 minutes, $p<0.001$), corresponding to an average reduction of approximately 18.5 minutes. VAS scores at the 6th and 12th postoperative hours showed no significant difference between groups (6.85 ± 1.25 vs 6.99 ± 1.35; 3.22 ± 1.23 vs 3.46 ± 1.30; $p>0.05$). Postoperative hemorrhage occurred in one patient in each group. In the coblation group, one patient developed secondary minor hemorrhage requiring observation, whereas in the thermal group, one patient developed primary major hemorrhage requiring reoperation; nostatistically significant difference was observed between groups ($p>0.05$).

CONCLUSIONS

Coblation tonsillectomy provides a shorter operative time compared with thermal welding. No statistically significant differences were observed in VAS scores or postoperative hemorrhage frequency between the groups.

Chloride Intracellular Channel 2 May Function As A Tumor Promoting Factor In Head And Neck Squamous Cell Carcinoma

Yuki Hosokawa[1], **Yuji Hayashi**[2], **Yuki Irifune**[1], **Eriko Sato**[1], **Sohei Mitani**[1], **Mohammed E Choudhury**[3], **Hajime Yano**[4], **Junya Tanaka**[3], **Naohito Hato**[1]

[1]Department of Otorhinolaryngology, Head and Neck Surgery, Graduate School of Medicine, Ehime University; [2]Department of Otorhinolaryngology, Head and Neck Surgery, Ehime Prefectural Central Hospital; [3]Department of Anesthesiology and Perioperative Medicine, Graduate School of Medicine, Ehime University; [4]Department of Molecular and Cellular Physiology, Graduate School of Medicine, Ehime University

BACKGROUND & AIM

Head and neck squamous cell carcinoma (HNSCC) has a poor prognosis in recurrent or metastatic cases, and actionable therapeutic targets remain limited despite the widespread use of comprehensive genomic profiling. Chloride intracellular channel 2 (CLIC2) is a protein whose biological function has not been fully elucidated. Recent database analyses have suggested an association with prognosis in several malignancies, but its role in HNSCC has not been reported. This study aimed to clarify the functional significance of CLIC2 in HNSCC and to evaluate its potential as a novel therapeutic target.

MATERIAL & METHODS

CLIC2 expression was assessed in the highly metastatic HNSCC cell line SAS-L1m. CLIC2-overexpressing cells were established and subjected to phenotypic analyses, including xenograft tumor formation, proliferation assays, and co-culture assays with natural killer (NK) cells. Molecular mechanisms were explored using qPCR, western blotting, and comprehensive genomic profiling. In addition, CLIC2 expression was evaluated by immunohistochemistry in clinical specimens, and its association with malignant potential and prognosis was analyzed.

RESULTS

CLIC2 expression was marginal in SAS-L1m cells. Its overexpression significantly enhanced tumorigenicity in xenograft models, increased proliferation, and suppressed NK cell mediated antitumor immunity. Molecular analyses revealed upregulation of MMP mRNA and increased expression of LOXL2 and NHE1 proteins. Comprehensive genomic profiling revealed tumor-promoting expression changes associated with the downregulation of innate immune response related genes, among other alterations. In clinical specimens, CLIC2-positive tumors were frequently observed in advanced stage and recurrent cases and were associated with poor prognosis.

CONCLUSIONS

CLIC2 promotes malignant phenotypes in HNSCC, including enhanced proliferation, tumorigenicity, suppression of NK cell mediated antitumor immunity, and is associated with poor clinical outcomes. These findings indicate that CLIC2 functions as a tumor-promoting factor and may represent a novel therapeutic target in HNSCC.

CASE REPORT: PARAPHARYNGEAL PLEOMORPHIC ADENOMA CAUSING OBSTRUCTIVE SLEEP APNEAV

ESMANUR SEÇKİN[1], **AHMET ONUR İYİDOĞAN**[1], **AYÇA ARSLAN**[1]

[1]*ANKARA ONKOLOJİ EĞİTİM VE ARAŞTIRMA HASTANESİ*

BACKGROUND & AIM

In this case report, we aimed to present the diagnostic and therapeutic approach to a pleomorphic adenoma located in the parapharyngeal space.

MATERIAL & METHODS

A 30-year-old male with a history of obstructive sleep apnea presented with a two-week history of sore throat without dysphagia. Cranial nerve examination was normal. Physical examination demonstrated bulging of the left nasopharyngeal and peritonsillar regions with rightward uvular deviation. Neck CT revealed a 54 × 33 mm mass in the left parapharyngeal space causing marked airway narrowing and suspected to arise from the deep lobe of the parotid gland. MRI showed a well-circumscribed, contrast-enhancing solid lesion measuring 33 × 51 × 59 mm, displacing major vascular structures posterolaterally. Fine-needle aspiration cytology was consistent with pleomorphic adenoma. The patient underwent complete transcervical-transparotid excision of the tumor. Intraoperative capsule rupture occurred, but the lesion and capsule were completely removed, followed by extensive irrigation.

RESULTS

Histopathological and immunohistochemical evaluation confirmed cellular pleomorphic adenoma. Postoperatively, cranial nerve function remained intact, House–Brackmann grade I facial nerve function was preserved, and sleep apnea symptoms improved significantly.

CONCLUSIONS

Pleomorphic adenomas of the parapharyngeal space are rare; however, due to their deep anatomical location, they require careful evaluation in terms of both diagnosis and surgical management. In large prestyloid masses, the transcervical-transparotid approach provides adequate exposure, allowing preservation of neurovascular structures and enabling safe total excision. In the present case, the absence of postoperative neurological complications and the marked improvement in the patient's obstructive sleep apnea symptoms suggest that PPS masses may contribute to upper airway obstruction. Therefore, parapharyngeal space pathologies should be considered in the differential diagnosis, particularly in patients with unexplained obstructive sleep apnea.

KEYWORDS

Pleomorphic adenomas, parapharyngeal space, obstructive sleep apnea.

Atypical Sinonasal Angiofibroma In A Middle-Aged Male With Predominant Sphenopalatine Arterial Supply: A Rare Case Report

FEYZA NUR ÖREN[1], **ERDEM AĞGÜNLÜ**[1], **ECE ŞEYMA TÜZEL**[1], **KAYRA BOSTAN**[1], **AGAH YENİÇERİ**[1], **MELİH ÇAYÖNÜ**[1]

[1]*ANKARA BILKENT CITY HOSPITAL*

BACKGROUND & AIM

Angiofibroma is a benign tumor with aggressive clinical behavior due to its rich vascularity. It most commonly affects adolescent males (1,2).

Histologically, it consists of fibrous stroma with numerous vascular channels. It typically originates near the sphenopalatine foramen and is supplied by branches of the internal maxillary artery (3).

Patients commonly present with nasal obstruction and epistaxis. Radiological findings include intense contrast enhancement and bone remodeling (4).

Occurrence in middle-aged patients is rare (3).

MATERIAL & METHODS

Case Presentation

A 46-year-old male presented with progressive unilateral nasal obstruction.

Contrast-enhanced MRI revealed a 6.5 × 5.5 × 6.5 cm mass completely occupying the left maxillary sinus and extending into the nasal cavities (Figure 1).

Surgical excision was performed via a lateral rhinotomy approach. The tumor was removed piecemeal due to its high vascularity.

Intraoperatively, the tumor was found to be supplied predominantly by branches of the sphenopalatine artery, which were ligated and cauterized.

Postoperative imaging confirmed complete removal with no residual tumor (Figure 2).

Histopathological examination confirmed sinonasal angiofibroma.

RESULTS

Although histologically benign, angiofibromas may behave aggressively due to their vascular nature (1).

They are typically seen in adolescent males, likely due to hormonal influences (1,2). Occurrence in older patients is rare (3).

In this case, both the age and vascular supply represent atypical features.

Radiological imaging plays a crucial role in diagnosis and surgical planning (4).

Surgical excision remains the gold standard treatment (2).

CONCLUSIONS

Sinonasal angiofibroma should be considered even in middle-aged patients. Atypical vascular supply patterns may be present.

Predictors Of Treatment Escalation In Patients With Epistaxis: A Retrospective Cohort Study From A Tertiary Center

Dimitrios Paouris[1], **Lucia Staškovanová**[1], **Henrieta Hajduová Salay**[1], **Bálint Tóth**[1], **Miroslav Tedla**[1]

[1]*Department of Otorhinolaryngology and Head and Neck Surgery, Comenius University and the University Hospital, Bratislava, Slovakia*

BACKGROUND & AIM

Epistaxis is one of the most common acute otorhinolaryngologic emergencies. While most cases can be managed with local outpatient treatment, some require escalation to posterior packing, hospitalization, or surgical treatment under general anesthesia. Early identification of patients at increased risk of treatment escalation may improve triage and management. The aim of this study was to identify predictors of treatment escalation in patients presenting with epistaxis at a tertiary ENT center.

MATERIAL & METHODS

We conducted a retrospective cohort study including 687 patients evaluated on an outpatient basis for epistaxis between January 2022 and December 2024. Treatment escalation was defined as the need for balloon nasal catheter and/or surgical treatment under general anesthesia. Secondary analyses assessed recurrence after initial treatment. Bivariate analyses were performed using the chi-square test, Fisher's exact test, and Mann–Whitney U test. Independent predictors were evaluated using multivariable logistic regression

RESULTS

The cohort comprised 358 men (52.1%) and 329 women (47.9%), with a median age of 68.1 years (IQR 52.7–77.8). In bivariate analyses, treatment escalation was more frequent in men (5.0% vs. 1.8%, p = 0.022) and in patients with more than one bleeding episode within a single day (23.3% vs. 3.5%, p < 0.001). Age, systolic blood pressure, and diastolic blood pressure were not associated with escalation. In multivariable analysis, repeated same-day bleeding remained independently associated with treatment escalation (OR 5.70, 95% CI 1.74–18.69; p = 0.004). Non-anterior bleeding location was also a strong independent predictor of escalation, including posterior bleeding (OR 140.36, 95% CI 13.44–1465.77; p < 0.001). As a secondary finding, recurrence after initial treatment was independently associated with lower diastolic blood pressure, septal deviation, and non-anterior bleeding location.

CONCLUSIONS

In this tertiary epistaxis cohort, treatment escalation was primarily associated with repeated bleeding within a single day and with non-anterior bleeding location. These findings may help identify patients at increased risk of requiring more intensive management.

Anatomical Landmarks Of The Lateral Nasal Wall And Their Clinical Significance

Manole Alexia[1]

[1]*Faculty of Medicine and Pharmacy Oradea, University of Oradea*

BACKGROUND & AIM

The lateral nasal wall is a complex anatomical region with significant clinical relevance in daily otorhinolaryngology practice. It includes essential structures such as the inferior, middle, and superior turbinates, the nasal meatuses, the ostiomeatal complex, the uncinate process, and the ethmoidal bulla. Because of its rich vascular supply and close relationship with the paranasal sinuses, this area is commonly involved in inflammatory and obstructive nasal disorders. A solid understanding of these anatomical landmarks is crucial for accurate clinical examination and diagnosis. This study aims to review the principal components of the lateral nasal wall and highlight their clinical importance.

MATERIAL & METHODS

This paper is based on a narrative review of anatomical literature and standard ENT clinical references. The main anatomical landmarks of the lateral nasal wall were analyzed in correlation with common clinical conditions such as rhinosinusitis, nasal obstruction, epistaxis, and allergic rhinitis. Emphasis was placed on their identification during anterior rhinoscopy and nasal endoscopy.

RESULTS

The inferior turbinate plays a significant role in regulating airflow and humidifying inspired air, and its hypertrophy is a frequent cause of nasal obstruction. The middle turbinate is an important reference structure during clinical examination, closely related to the ostiomeatal complex, which represents a key area in the pathophysiology of chronic rhinosinusitis. The uncinate process and ethmoidal bulla form part of the drainage pathway of the anterior paranasal sinuses. Anatomical variations such as concha bullosa or septal deviation may alter normal airflow and predispose patients to recurrent sinus infections. The lateral nasal wall is also involved in anterior epistaxis due to its vascular supply and mucosal fragility.

CONCLUSIONS

A thorough understanding of the anatomical landmarks of the lateral nasal wall is fundamental for proper clinical evaluation in ENT practice. Recognizing normal anatomy and common variations facilitates accurate diagnosis and supports appropriate therapeutic decision-making in patients presenting with nasal symptoms.

Etiological Factors Of Pediatric Epistaxis: Clinical Considerations And Diagnostic Approach

Manole Alexia[1]

[1]*Faculty of Medicine and Pharmacy Oradea, University of Oradea*

BACKGROUND & AIM

Epistaxis is one of the most frequent otorhinolaryngological emergencies in the pediatric population. Although most cases are benign and self-limiting, recurrent or severe epistaxis may raise concern for underlying local or systemic pathology. In children, nasal bleeding most commonly originates from Kiesselbach's plexus, located in the anterior nasal septum, due to the rich vascular supply and increased mucosal fragility. Understanding the etiological spectrum is essential for establishing an

appropriate diagnostic and therapeutic strategy. The aim of this study is to review the main causes of pediatric epistaxis and to emphasize their clinical relevance in daily ENT practice.

MATERIAL & METHODS

This paper is based on a narrative review of current literature regarding pediatric epistaxis, focusing on etiological classification and clinical assessment. Causes were grouped into local and systemic factors, and their diagnostic implications were analyzed in relation to patient age, recurrence pattern, and associated symptoms.

RESULTS

Local factors represent the most common cause of epistaxis in children. These include digital trauma (nose picking), mucosal dryness, allergic rhinitis, upper respiratory infections, septal deviation, and foreign bodies. Inflammatory processes increase mucosal vascular fragility, predisposing to bleeding. Less frequently, benign vascular lesions such as hemangiomas or, in adolescent males, juvenile nasopharyngeal angiofibroma should be considered in cases of recurrent or unilateral epistaxis. Systemic causes include coagulation disorders (e.g., von Willebrand disease), thrombocytopenia, platelet dysfunction, and the use of anticoagulant medication. Hypertension is rarely a primary cause in children but may contribute in specific contexts. Proper history taking and anterior rhinoscopy are essential in identifying the source of bleeding and determining the need for further hematological evaluation.

CONCLUSIONS

Pediatric epistaxis is usually benign and related to local factors; however, recurrent or severe episodes require careful assessment to exclude underlying systemic disease. A structured clinical approach enables accurate diagnosis, prevents unnecessary investigations, and ensures appropriate management in pediatric ENT patients.

PP-761

Pediatric Nasal Obstruction: Etiology, Clinical Evaluation, And Therapeutic Considerations

Manole Alexia[1]

[1]*Faculty of Medicine and Pharmacy Oradea, University of Oradea*

BACKGROUND & AIM

Nasal obstruction is a common complaint in the pediatric population and represents a frequent reason for referral to the otorhinolaryngology department. It may significantly affect quality of life, sleep, feeding (especially in infants), speech development, and facial growth. Unlike adults, children present age-specific causes of nasal obstruction, ranging from congenital anomalies to inflammatory and hypertrophic conditions. Early recognition of the underlying etiology is essential to prevent long-term functional and developmental complications. The aim of this study is to review the principal causes of nasal obstruction in children and to outline a structured clinical evaluation.

MATERIAL & METHODS

This paper is based on a narrative review of pediatric ENT literature focusing on the etiology, clinical presentation, and diagnostic approach to nasal obstruction in children. Causes were categorized as congenital, inflammatory, infectious, and structural. Emphasis was placed on correlating symptoms with age-specific pathologies and endoscopic findings.

RESULTS

In neonates and infants, congenital causes such as choanal atresia or congenital nasal pyriform aperture stenosis must be considered, especially in cases of respiratory distress or feeding difficulties. In toddlers and young children, adenoid hypertrophy represents the most frequent cause of chronic nasal obstruction, often associated with mouth breathing, snoring, and recurrent otitis media. Allergic rhinitis and recurrent upper respiratory infections are common inflammatory contributors. Structural abnormalities such as septal deviation or turbinate hypertrophy may further aggravate symptoms. Foreign bodies should always be suspected in cases of unilateral obstruction with foul-smelling discharge. Nasal endoscopy plays a central role in confirming diagnosis and guiding management.

CONCLUSIONS

Pediatric nasal obstruction has a broad etiological spectrum that varies according to age. A systematic clinical assessment, including detailed history and endoscopic examination, is crucial for accurate diagnosis and appropriate treatment. Early intervention may prevent complications related to sleep, growth, and craniofacial development.

A Rare Case Of Masseter Pyomyositis

Mariem Ben Aissa[1], **Samia Meherzi**[1], **Amine Khabou**[1], **Ahmed Mostapha**[1]

[1]*University Hospital of Sidi Bouzid*

BACKGROUND & AIM

Masseter pyomyositis is a rare condition in adults and can mimic odontogenic or parotid infections. We report a case of unilateral masseter pyomyositis in an adult male, describing its clinical features and underscoring the need for a high index of suspicion to ensure early diagnosis and prevent complications.

MATERIAL & METHODS

We report a case of a male patient who was hospitalized in 2026 in our ENT department for unilateral masseter swelling and underwent clinical evaluation and appropriate management.

RESULTS

A 62-year-old male with type 2 diabetes mellitus, with no reported history of dental pain or previous dental treatment, presented with left jugal swelling, trismus, and mild dyspnea. The swelling had developed two weeks prior, gradually worsening, and was associated with severe trismus.

On examination, trismus limited oropharyngeal assessment. The swelling involved the jugal region and extended to the lateral cervical area without torticollis.

CT imaging revealed a 3-cm collection within the left masseter muscle, marked surrounding soft tissue edema, and heterogeneous enlargement of the left parotid gland. Inflammatory infiltration caused mass effect on the oropharynx and supraglottic laryngeal structures. Laboratory tests showed elevated inflammatory markers

The patient was treated with intravenous amoxicillin–clavulanic acid, analgesics, and intramuscular muscle relaxants. Within 48 hours, trismus, swelling, dysphagia, and dyspnea improved markedly. Symptoms resolved gradually, and the patient was discharged on day 9. At follow-up two weeks later, he had full clinical recovery.

CONCLUSIONS

Masseter pyomyositis is rare but potentially serious. It should be considered in any patient with painful facial swelling and trismus to ensure prompt recognition, early treatment, and prevention of airway compromise.

KEYWORDS

Pyomyositis, cervical, Masseter Muscle

Squamous Cell Carcinoma Presenting With Temporal Lobe Abscess On A Background Of Cholesteatoma: A Rare Case Report

Dr. Rime İrem Sürmeli Direk[1], **Prof. Dr. Zahide Mine Yazıcı**[1], **Op.Dr. Gülsün Başak Saygan Usta**[1], **Uzm.Dr. Rabia Burçin Girgin**[1]

[1]*BAKIRKÖY DR. SADİ KONUK EĞİTİM VE ARAŞTIRMA HASTANESİ*

BACKGROUND & AIM

Cholesteatoma is a benign but locally destructive lesion of the middle ear, and malignant transformation is exceedingly rare. Intracranial complications may occur in advanced disease; however, they only rarely reveal an underlying malignancy. We report a rare case of squamous cell carcinoma (SCC) arising from cholesteatoma, presenting with intracranial complications.

CASE PRESENTATION

A 68-year-old female with a history of childhood mastoid surgery presented with a two-month history of persistent right-sided otorrhea, severe otalgia, vertigo, and recent-onset absence seizures. Imaging demonstrated extensive soft tissue opacification in the right mastoid cavity, a temporal lobe abscess, and thrombosis of the sigmoid and transverse sinuses. Diffusion-restricting foci within the mastoid air cells raised suspicion for cholesteatoma.

The patient underwent temporal lobe abscess drainage and revision canal wall down mastoidectomy. Intraoperatively, keratinous debris and granulation tissue were observed. Although frozen section analysis suggested benign reactive changes, definitive histopathological examination revealed invasive squamous cell carcinoma. Postoperative PET-CT showed no evidence of distant disease, and the patient was referred for oncologic management.

RESULTS

Malignant transformation of cholesteatoma, although rare, should be suspected in atypical or refractory presentations.This case underscores the importance of considering malignancy as a differantial diagnosis in patients with chronic ear disease, especially when complicated by intracranial involvement.

CONCLUSIONS

This case highlights the importance of considering malignant transformation in patients with chronic ear disease, particularly in the presence of atypical clinical progression or intracranial complications. Although rare, SCC arising from cholesteatoma should be included in the differential diagnosis, and histopathological evaluation remains essential for accurate diagnosis and timely management.

PP-764

Atypical Presentation Of Maxillary Osteonecrosis With Ethmoidal Extension In An Immunocompromised Oncologic Patient: A Multidisciplinary Surgical Approach

Dr. Ciobanu Crina[2], **Prof. Anghel Ion**[1], **Dr. Tatu Mihaela**[1], **Dr. Ciobanu Iulia Andreea**[1]

[1]*Military Central Hospital Dr. Carol Davila Bucharest;* [2]*Marie Curie Children Hospital Bucharest*

BACKGROUND & AIM

Maxillary osteonecrosis in immunocompromised oncology patients often presents with atypical sinonasal symptoms masquerading as chronic rhinosinusitis. This diagnostic ambiguity can delay treatment and increase the risk of severe regional complications. This paper presents a rare case of maxillary osteonecrosis with extensive ethmoidal involvement in a metastatic breast cancer patient. We aim to highlight these diagnostic challenges and emphasize the critical role of a coordinated, multidisciplinary surgical strategy to eradicate infection, prevent further midface morbidity, and achieve a successful clinical outcome.

MATERIAL & METHODS

We detail the management of a stage IV breast cancer patient undergoing chemotherapy and immunotherapy. Following dental procedures, she developed right alveolar maxillary osteonecrosis. She presented to the ENT department with right palpebral edema, chronic nasal obstruction, and cacosmia, atypically lacking overt frank suppuration. Computed tomography confirmed extensive osteonecrosis involving the maxillary and ethmoidal sinuses. Our surgical methodology required a collaborative intervention by ENT and Oral Maxillofacial Surgery teams. We utilized a modified Caldwell-Luc approach to facilitate comprehensive trans-maxillary drainage of the ethmoid sinus. This was combined with meticulous radical debridement of necrotic bone and immediate local defect reconstruction utilizing a robust vascularized pedicled buccal mucosal flap.

RESULTS

The postoperative clinical course was highly favorable and uneventful. Following the multidisciplinary surgical intervention, the patient experienced a rapid and complete resolution of her presenting symptoms, including the right facial edema, severe nasal obstruction, and distressing cacosmia. Regular follow-up examinations revealed excellent local mucosal integration of the pedicled buccal flap. We observed complete healing of the surgical site without signs of dehiscence, fistula formation, or graft failure. Importantly, there was a total absence of postoperative infectious complications or regional disease recurrence during the observation period. This successful healing allowed the patient to safely resume her critical systemic oncological treatments without further delay or sinonasal morbidity.

CONCLUSIONS

In immunocompromised oncology patients, maxillary osteonecrosis demands a high index of suspicion, frequently presenting with atypical symptoms mimicking routine sinus disease. Delayed diagnosis risks severe orbital or cranial complications. Optimal management requires a prompt, multidisciplinary approach between ENT and maxillofacial surgeons. This case demonstrates that radical surgical debridement via a Caldwell-Luc approach, trans-maxillary ethmoidal drainage, and robust buccal flap reconstruction is highly efficacious. This combined strategy reliably eradicates infection, prevents further midface morbidity, and successfully restores sinonasal function in this vulnerable patient population.

Deep Cervical Infection And Cervicomediastinitis After Tonsillar Infection: Case Report

Loredan Miksa[2,3], **Alexandru Hut**[4,1,2], **Lazaroiu Marius**[2], **Diana Feraru-Pîrvulescu**[2], **Georgiana Muresan**[2], **Horhat Delia**[1,2], **Mot Cristian**[1,2], **Nicolae Balica**[1,2], **Virgilius Draganescu**[2]

[1]*Victor Babes University of Medicine and Pharmacy Timisoara;* [2]*Municipal Clinic Emergency Hospital Timișoara – ENT Department;* [3]*Făget City Hospital – ENT Department;* [4]*Brad Municipal Emergency Hospital- ENT Department*

BACKGROUND & AIM

Deep Neck Infections (DNI) represent a heterogeneous group of severe infections involving the deep fascial spaces of the cervical region.To present a rare case of deep cervical infection with cervicomediastinitis following tonsillar infection and to highlight the importance of early diagnosis and multidisciplinary management to prevent life-threatening complications.

MATERIAL & METHODS

We present the clinical case of a 53-year-old male patient, M.G., from an urban area, admitted with the following clinical presentation: septic status, odynophagia, dysphagia, cervical swelling, and trismus. Based on medical history and the clinical

examination of organ systems, the patient was known to have the following associated comorbidities: heart failure and chronic alcoholism.

RESULTS

The patient was admitted to the Intensive Care Unit, and a multidisciplinary team consisting of ENT and thoracic surgery specialists managed the case. Cervicotomy and cervico-mediastinotomy were performed, ensuring drainage of both cervical and thoracic collections.

CONCLUSIONS

The possibility of lethal complications, as well as the associated morbidity and mortality, outlines this clinical entity as an important public health concern. The management of patients with oropharyngeal infections must be prompt and effective in order to prevent these potentially fatal complications.

PP-766

Nasopharyngeal Carcinoma Presenting With Breast Metastasis: A Rare Case In A Male Patient

Reyhan Ozcan Bilgic[1], **Buse Genc Saglam**[1], **B. Baris Buyuk**[1], **Tuncay Tunccan**[1]

[1]*Ankara Oncology Training and Research Hospital, Department of Otolaryngology–Head and Neck Surgery, Ankara, Turkey*

BACKGROUND & AIM

Nasopharyngeal carcinoma (NPC) is strongly associated with Epstein-Barr virus (EBV) and most commonly metastasizes to bone, lung, and liver. Breast metastasis is exceptionally rare, especially in male patients, and may mimic an unknown primary neck mass, posing significant diagnostic challenges. This case report aims to present a rare male patient with NPC presenting with breast metastasis, and to highlight the critical role of immunohistochemical markers in achieving the correct diagnosis.

MATERIAL & METHODS

A 45-year-old male patient who presented with a progressively enlarging neck and cheek mass was evaluated. Physical examination, laboratory tests, and imaging studies were performed. Biopsy specimens were obtained from cervical and axillary lymph nodes, and subsequently from the posterior wall of the nasopharynx. Histopathological examination was conducted on all biopsy materials. Immunohistochemical analysis included p63, EBER (in situ hybridization), GATA-3, and mammaglobin markers. Staging was performed according to the TNM classification based on radiological findings including PET-CT and MRI. Following multidisciplinary tumor board evaluation, the patient was treated with cisplatin and gemcitabine-based systemic chemotherapy. Treatment response was assessed by follow-up imaging according to RECIST criteria.

RESULTS

A 45-year-old male presented with a 15×15 cm fixed cervical mass and bilateral lymphadenopathies. A 4 cm hard mass was also palpated in the retroareolar region of the left breast. Biopsy specimens from cervical and axillary lymph nodes revealed non-keratinizing squamous cell carcinoma. Immunohistochemical analysis demonstrated positivity for EBER and p63, while GATA-3 and mammaglobin were negative, favoring a nasopharyngeal origin. Subsequent nasopharyngeal biopsy confirmed the diagnosis of non-keratinizing squamous cell carcinoma. Imaging studies revealed widespread metastatic involvement of the nasopharynx, cervical and axillary lymph nodes, left breast, and bone structures. The patient was staged as Stage IVC metastatic nasopharyngeal carcinoma. Cisplatin and gemcitabine-based chemotherapy was initiated, and follow-up imaging demonstrated significant regression of lesions with a partial response achieved.

CONCLUSIONS

Nasopharyngeal carcinoma may rarely present with breast metastasis, posing significant diagnostic challenges, particularly in male patients. In cases initially evaluated as unknown primary neck masses, a systematic diagnostic approach is essential. Immunohistochemical markers, especially EBER positivity, play a pivotal role in identifying the nasopharyngeal origin and guiding targeted biopsy. The absence of mammaglobin and GATA-3 effectively excludes primary breast carcinoma. Platinum-based chemotherapy remains the cornerstone of treatment in advanced-stage disease, with partial responses achievable. Awareness of unusual metastatic patterns in NPC is critical for timely and accurate diagnosis.

PP-767

Risk–Benefit Stratification For Immune Checkpoint Inhibitor Therapy In Head And Neck Cancer Using Routine Clinical Indicators

Ken Kasahara[1], **Takeyuki Kono**[1], **Hiroyuki Ozawa**[1]

[1]*Department of Otolaryngology–Head and Neck Surgery, Keio University School of Medicine, Tokyo, Japan*

BACKGROUND & AIM

Immune checkpoint inhibitors (ICIs) have improved outcomes in recurrent or metastatic head and neck squamous cell carcinoma (R/M HNSCC), but immune-related adverse events (irAEs) can lead to treatment interruption, underscoring the need for risk-benefit stratification. This study sought to predict ICI efficacy and toxicity using simple, combined positive score (CPS)-independent clinical indicators obtainable from routine laboratory tests.

MATERIAL & METHODS

A total of 179 patients with R/M HNSCC treated with anti–PD-1 therapy were retrospectively analyzed. Several routine clinical parameters, including the lumbar skeletal muscle index (LSMI) derived from pretreatment CT images, were collected and subjected to multivariable analyses to identify predictors of irAEs development and permanent ICI discontinuation. Based on significant variables, we attempted to stratify patients into those likely to derive clinical benefit from ICI therapy and those at increased risk of permanent ICI discontinuation.

RESULTS

IrAEs occurred in 35.2% of patients and were associated with significantly better survival, with high LSMI independently predicting irAE development. In contrast, low LSMI patients showed fewer irAEs and poorer survival. Within this subgroup, advanced age (≥77 years) and elevated lactate dehydrogenase (LDH) (≥240 U/L) independently predicted permanent ICI discontinuation (AUC = 0.87). This simple two-point score using these factors effectively identified low-LSMI patients at highest risk for treatment discontinuation.

CONCLUSIONS

Integrating routine indicators—LSMI, age, and LDH—provides a practical tool for identify patients who are likely to derive substantial benefit or experience irAE-related harm from ICIs, enabling optimized patient selection beyond PD-L1 expression in daily clinical practice.
